# Online Policy Learning and Inference by Matrix Completion 

Congyuan Duan ${ }^{1}$, Jingyang Li and Dong Xia ${ }^{1}$<br>Department of Mathematics, Hong Kong University of Science and Technology

(April 29, 2024)

#### Abstract

Making online decisions can be challenging when features are sparse and orthogonal to historical ones, especially when the optimal policy is learned through collaborative filtering. We formulate the problem as a matrix completion bandit (MCB), where the expected reward under each arm is characterized by an unknown low-rank matrix. The $\varepsilon$-greedy bandit and the online gradient descent algorithm are explored. Policy learning and regret performance are studied under a specific schedule for exploration probabilities and step sizes. A faster decaying exploration probability yields smaller regret but learns the optimal policy less accurately. We investigate an online debiasing method based on inverse propensity weighting (IPW) and a general framework for online policy inference. The IPW-based estimators are asymptotically normal under mild arm-optimality conditions. Numerical simulations corroborate our theoretical findings. Our methods are applied to the San Francisco parking pricing project data, revealing intriguing discoveries and outperforming the benchmark policy.

## 1 Introduction

Recent decades have seen a rapidly growing demand for personalized policy design, with applications across a wide range of domains, including clinical trials and healthcare services Murphy, 2003, Kim et al., 2011, Bertsimas et al., 2017, online advertising and marketing Bottou et al., 2013, He et al., 2012, Bertsimas and Kallus, 2020], revenue management [Chen et al., 2022b], and online news recommendation Li et al., 2010, Ban and Rudin, 2019. Personalized policies incorporate covariate heterogeneity into decision-making by exploiting individual-level characteristics, such as assigning medicine dosages according to patients' lab test results Murphy, 2003 and recommending news

[^0]based on users' profiles Li et al. 2010. Policy learning is often challenging due to its inherent online learning nature, where data or requests arrive sequentially. An online learning algorithm endeavors to make informed decisions to achieve larger rewards and to refine the estimated policy, that is, the decision rules.

The contextual bandit (CB, Langford and Zhang 2007) model provides a convenient framework for examining online policy learning algorithms and studying their statistical limitations. A decision maker is equipped with a finite set $\mathcal{A}$ of available actions (called arms). At every time $t$, a request (e.g., a patient) with context $x_{t}$ arrives, and the decision maker must choose an action $a_{t} \in \mathcal{A}$ which returns a reward $r_{t}$ with expectation $\mathbb{E} r_{t}=f_{a_{t}}\left(x_{t}\right)$. If the reward functions $f_{a}(x)$, for each $a \in \mathcal{A}$, are known, the optimal policy that maximizes the reward is simply to take action $a_{t}:=\arg \max _{a \in \mathcal{A}} f_{a}\left(x_{t}\right)$ at time $t$. Oftentimes, the reward functions are unknown and need to be learned from history. The decision maker may endeavor to achieve several goals separately or simultaneously, such as maximizing the overall reward Bastani and Bayati, 2020, Li et al., 2010, Zhang et al., 2021, learning the optimal policy Agarwal et al., 2014, Perchet and Rigollet, 2013, Bastani et al., 2021, Gur et al., 2022, May et al., 2012, and making inferences regarding the optimal policy Hadad et al., 2021, Chen et al. 2022a, 2021, Zhang et al., 2021. Once a decision $a_{t}$ is made, the counterfactual outcomes $\left\{f_{a}\left(x_{t}\right): a \in \mathcal{A}, a \neq a_{t}\right\}$ cannot be observed. To achieve the aforementioned goals, the decision maker should accumulate sufficient data (exploration) for each arm to accurately learn the reward functions and make greedy decisions (exploitation) whenever appropriate to maximize cumulative rewards under uncertainty. This balance is known as the exploration-exploitation dilemma Lattimore and Szepesvári, 2020.

The special case of CB where the reward functions are linear (subject to stochastic noise) is known as the linear contextual bandit ( LCB Li et al. 2010]). The linearity assumption simplifies the estimation of reward functions, allowing the decision maker to focus on balancing exploration and exploitation to minimize regret - the expected difference between the rewards received and the maximum possible rewards. The success of LCB has been empirically observed in a variety of applications, including news recommendation Li et al. 2010 and online advertising Bottou et al., 2013, Miao and Chao, 2022. Popular LCB algorithms include the Linear Upper Confidence Bound (LinUCB, Chu et al. 2011]), Thompson Sampling Agrawal and Goyal, 2013, and the $\varepsilon$-greedy approach Lattimore and Szepesvári, 2020. A regret lower bound of $\Omega\left((T d)^{1 / 2}\right)$ was established for LCB Chu et al. 2011, where $T$ is the time horizon and $d$ represents the dimension of covariate $x_{t}$ 's. It was shown there that LinUCB achieves a regret upper bound of $O\left((T d)^{1 / 2} \log ^{3 / 2}(T \log (T))\right)$. These rates demonstrate that the optimal regret in LCB grows on the order of $O\left(d^{1 / 2}\right)$ with respect
to the covariate dimension. This growth makes the aforementioned algorithms particularly vulnerable in high-dimensional problems Zhang et al., 2017, Zhou et al., 2018. In fact, the covariate dimension can sometimes be much larger than the time horizon in certain applications. This situation is especially common in personalized medicine or treatment scenarios where a patient's medical history and genetic profile are commonly used as covariates Bayati et al., 2014, Ozer et al., 2020. Similarly, most e-commerce and streaming platforms base their recommendations on users' click and browse history from past months. This observation motivates the study of structured highdimensional LCB. Even though the covariate space may have a high ambient dimension, it is often the case that only a few features are relevant, indicating that the reward functions are sparse Wang et al., 2018, Kim and Paik, 2019, Bastani and Bayati, 2020, Hao et al., 2020, Oh et al., 2021, Ren and Zhou, 2023. By integrating the classical LASSO estimator with an $\varepsilon$-greedy bandit algorithm, Kim and Paik 2019 proposed a doubly-robust method that achieves a regret of $O\left(s T^{1 / 2} \log (d T)\right)$, where $s$ denotes the sparsity of the reward functions. Under an extra gap condition - that is, the difference in rewards between the optimal and sub-optimal arm - and a forced sampling scheme, Bastani and Bayati 2020 and Wang et al. 2018 showed that UCB-type algorithms can achieve a regret of $O\left(s^{2}(\log T+\log d)^{2}\right)$. Recently, LCB with high-dimensional matrix-valued covariates has been investigated by Johnson et al. 2016], Jun et al. 2019, Lu et al. 2021, Han et al. 2022, Li et al. 2022. Assuming that the reward functions are parameterized by a $d_{1} \times d_{2}$ matrix with a small rank $r$, Johnson et al. 2016 and Lu et al. 2021 studied UCB-type bandit algorithms, achieving regret upper bounds of $O\left(\left(d_{1}+d_{2}\right)(r T)^{1 / 2}\right)$ and $O\left(\left(d_{1}+d_{2}\right)^{3 / 2}(r T)^{1 / 2}\right)$, respectively. The explore-then-commit algorithm was explored in Jun et al. 2019, and Li et al. 2022, achieving regret upper bounds of $O\left(\left(d_{1}+d_{2}\right)^{3 / 2}(r T)^{1 / 2}\right)$ and $O\left(r^{1 / 3} T^{2 / 3} \log \left(d_{1}+d_{2}\right)\right)$, respectively, with the latter imposing an additional restricted eigenvalue condition.

Policy inference, such as that regarding reward functions or maximum cumulative reward, has drawn tremendous attention in recent years. This area is technically challenging due to the noni.i.d. nature of data generated by adaptive bandit algorithms. Most existing works focus on low-dimensional LCB Bibaut et al., 2021, Chen et al., 2021, Shen et al., 2021, Zhan et al., 2021, Zhang et al., 2021, Chen et al., 2022a, where explicit forms of parametric estimators are accessible, providing analytical convenience for distributional studies. For example, Chen et al. 2021 ] and Chen et al. 2022a explored the $\varepsilon$-greedy algorithm and investigated the asymptotic normality of the least squares estimator (LSE) and averaged stochastic gradient descent (SGD) estimator, respectively. These estimators can achieve $\sqrt{T}$-consistency and asymptotic normality if the tuning parameter $\varepsilon$ is kept constant, which, however, results in a trivial $O(T)$ regret upper bound.

Conversely, if $\varepsilon$ decreases at a certain rate, one can achieve non-trivial regret; but the resulting estimators, while being asymptotically normal, are not $\sqrt{T}$-consistent, as described in Chen et al. 2021]. This is because a diminishing $\varepsilon$ significantly increases the variance of the estimator. Policy inference becomes even more challenging in high-dimensional LCB, where estimators typically are biased and lack an explicit representation formula. Inverse probability weighting (IPW) is a common technique to correct for the different sampling probabilities in non-i.i.d. data and to reduce estimator bias. However, IPW may inflate estimator variance. One notable example is Han et al. [2022], which introduced an online debiased estimator for the low-rank matrix regression bandit using the $\varepsilon$-greedy algorithm. Under an isotropic Gaussian design, their estimator is asymptotically normal, albeit not $\sqrt{T}$-consistent.

Most existing LCB frameworks and methods share a fundamental assumption: the feature vector $x_{t}$ representing the request at time $t$ is dense and typically correlated with historical features. This suggests that the features cannot be sparse or $\left\langle x_{s}, x_{t}\right\rangle \neq 0$ with high probability for all $s<t$. This assumption is supported by several conditions in the literature, such as the compatibility condition Bastani and Bayati, 2020, Kim and Paik, 2019, the restricted eigenvalue condition Oh et al., 2021, Li et al., 2022, the diverse covariate condition Ren and Zhou, 2023, Han et al., 2020, and the (sub-) Gaussian sampling distribution Lu et al., 2021, Han et al., 2022. This inherent correlation provides a link between current requests and historical ones, which is one of the primary reasons why past actions and feedback can inform and enhance current predictions.

The aforementioned approaches encounter difficulties when the features are sparse and sampled from an orthonormal basis, such that the currently observed feature may be orthogonal to all historical ones with high probability. Let us consider a scenario in which we compare two marketing strategies for recommending $d_{2}$ products to $d_{1}$ users on an online shopping platform. Let $M_{0}$ and $M_{1}$ be two $d_{1} \times d_{2}$ unknown matrices representing the expected amount of money users will spend on products under each of the two marketing strategies. At each time $t$, a user $i_{t} \in\left[d_{1}\right]$ arrives intending to buy an item $j_{t} \in\left[d_{2}\right]$ (e.g., based on her search keyword on Amazon); the platform must then choose one of the marketing strategies (e.g., low-price first or high-ratings first). The preferred strategy, which maximizes the expected revenue, is determined by the ( $i_{t}, j_{t}$ )-th entries of $M_{0}$ and $M_{1}$, respectively. This problem can be conveniently formulated as an LCB with reward functions parameterized by $M_{0}$ and $M_{1}$, and a matrix-valued covariate $X_{t}$ sampled randomly from an orthonormal basis $\mathcal{X}:=\left\{e_{j_{1}} e_{j_{2}}^{\top}: j_{1} \in\left[d_{1}\right], j_{2} \in\left[d_{2}\right]\right\}$, where $e_{j}$ denotes the $j$-th canonical basis vector (whose actual dimension may vary in different appearances). Here, $[d]:=\{1, \ldots, d\}$. More
precisely, if the strategy (action) $a_{t} \in\{0,1\}$ is chosen, the observed reward $r_{t}$ satisfies

$$
\begin{equation*}
\mathbb{E} r_{t}=f_{a_{t}}\left(X_{t}\right):=\left\langle M_{a_{t}}, X_{t}\right\rangle . \tag{1}
\end{equation*}
$$

Basically, at each time, the decision maker can only observe one noisy entry from either $M_{0}$ or $M_{1}$. Two additional examples are as follows:

Parking pricing (SFpark, SFMTA [2013]). The San Francisco government plans to implement dynamic pricing for parking lots across $d_{1}$ blocks during $d_{2}$ different time periods (hourly, each week). For simplicity, suppose the government has two pricing options: high and low. High prices are intended to discourage parking in overcrowded blocks, while low prices aim to attract more drivers to under-occupied blocks. The goal is to achieve moderate occupancy rates across more blocks throughout the majority of time periods. Let $M_{1}$ and $M_{0}$ represent two $d_{1} \times d_{2}$ unknown matrices that express the deviation (in absolute value) from the target occupancy rate under high and low pricing strategies, respectively. The optimal policy is then determined by comparing the corresponding entries of $M_{0}$ and $M_{1}$. If $M_{1}(i, j)<M_{0}(i, j)$, a high price should be set for block $i$ at time period $j$, and vice versa. Learning the optimal policy involves estimating these two underlying matrices. To mitigate the impact of sudden changes on drivers' experiences, an adaptive experiment with sequential observations has been designed. At each time step, a block and a time period are randomly selected, a high or low pricing decision is made, and the subsequent occupancy rate is observed. The authorities aim to learn the optimal policy from as few pricing experiments as possible, while minimizing the cumulative regret during these experiments and quantifying the uncertainty of the learned policy.

Supermarket discount (Walmart sales, Kaggle (2020]). A supermarket manager aims to decide whether to offer discounts on $d_{1}$ products during $d_{2}$ different time periods (weekly, throughout the year). Offering discounts might reduce per-unit profits but could potentially increase overall revenue, depending on seasonal demand. The objective is to devise a policy that determines the optimal times and products for discounting in order to maximize annual total profits. Let $M_{1}$ and $M_{0}$ represent two $d_{1} \times d_{2}$ unknown matrices that indicate sales profits with and without discounts, respectively. The optimal policy is characterized by comparing the entries of $M_{0}$ and $M_{1}$. If $M_{1}(i, j)>M_{0}(i, j)$, a discount should be offered for product $i$ during time period $j$, and vice versa. Therefore, it is necessary to estimate these two underlying matrices. An adaptive experiment could be implemented over the course of one or more years. At each time, a random product is chosen, the manager decides whether to apply a discount, and the resulting sales profit is recorded. Similarly, the manager's goal is to rapidly learn the optimal policy, maximize total profit during
the experimental phase, and assess the uncertainty of the policy outcomes.
These problems are, in essence, covariate free, as the observed covariates do not capture the similarity between the current request and historical ones. Instead, a more appropriate measure of similarity can be derived from the observed rewards. When determining which marketing strategy to apply to user $i_{t}$ for product $j_{t}$, the platform can identify numerous users with potentially similar preferences to user $i_{t}$ and base the decision on historical rewards. This approach is known as collaborative filtering [Su and Khoshgoftaar, 2009, a widely-used technique in recommender systems. The fundamental assumption is that both matrices $M_{0}$ and $M_{1}$ are low-rank, indicating that users and products can be represented by low-dimensional latent features. Consequently, we refer to the policy that exploits this assumption as the collaborative filtering policy, or the covariate-free policy (CF-policy). From a technical standpoint, the problem can be conceptualized as a matrix completion bandit (MCB).

Learning and inference for CF-policy are challenging for several reasons. First, most of the existing matrix completion literature has focused on independent and offline observations, whereas the observations in MCB arrive sequentially and depend on historical data. Second, regret analysis for MCB hinges on developing sharp upper bounds for the entrywise error of low-rank estimators, which are technically challenging, even for offline i.i.d. observations. Lastly, the adaptively collected data also pose significant challenges for the statistical inference, where the tradeoff between bias and variance must be carefully managed.

### 1.1 Main contributions

We study the problem of online decision-making when features are sparse and orthogonal to historical ones, and we propose learning the optimal policy through collaborative filtering. We formulate the problem as a matrix completion bandit. Our contributions are summarized as follows.

General convergence of $\varepsilon$-greedy bandit and online gradient descent algorithms. The optimal policy under MCB is characterized by low-rank matrices. We propose an online gradient descent algorithm with an $\varepsilon$-greedy bandit strategy to learn the MCB parameters. The convergence performance of the algorithm is established under general conditions on the schedule of step sizes and exploration probabilities. One of our key contributions is that we have derived a sharp entry-wise error rate of the estimated MCB parameters, showing that error is delocalized over all the matrix entries. By setting a constant exploration probability and step size (assuming a known horizon $T$ ), and under the classical conditions of offline matrix completion, the algorithm delivers estimators
that are statistically optimal (up to logarithmic factors) in both the matrix Frobenius norm and the sup-norm. The sup-norm error rates play a crucial role in regret analysis and policy inference. We achieve these sharp error rates by sophisticated spectral analysis and martingale techniques.

Tradeoff between policy learning and regret performance. A constant exploration probability yields trivial regret performance. We study an exploration-then-commit (ETC) style schedule for exploration probabilities, which decay geometrically fast in the later stages of the algorithm. A trade-off is observed between policy learning and regret performance. For instance, if the exploration probabilities decay as $\varepsilon_{t} \asymp t^{-\gamma}$ for some $\gamma \in[0,1)$, the algorithm achieves a regret upper bound $O\left(T^{1-\gamma}+d_{1}^{1 / 2} T^{(1+\gamma) / 2}\right)$, and the final estimators attain an error rate $\widetilde{O}_{p}\left(r d_{1} / T^{1-\gamma}\right)$ in the sup-norm. The parameter $\gamma$ also affects the horizon and signal strength conditions. A non-trivial regret requires $\gamma>0$. The minimal regret achievable by the algorithm is $\widetilde{O}\left(T^{2 / 3} d_{1}^{1 / 3}\right)$. The $O\left(T^{2 / 3}\right)$ regret performance has been widely observed in online high-dimensional bandit algorithms Hao et al., 2020, Ma et al. 2023b.

Online inference framework by IPW-based debiasing. We introduce a general framework for the online statistical inference of the optimal policy. The estimators produced by gradient descent algorithms are usually biased due to implicit regularizations. The IPW-based online debiasing method was initially proposed by Han et al. 2022 for the low-rank matrix regression bandit and investigated under a schedule of constant exploration probability. We extend the IPW-based debiasing method to MCB , allowing the exploration probability to diminish over time. Asymptotic normality is established for the studentized IPW-based estimator, based on which valid confidence intervals are constructed.

Real data analysis. We evaluate the managerial merit of MCB using the SFpark dataset, which has been widely studied in the transportation and operations management literature. This dataset presents a pricing decision problem aimed at implementing dynamic pricing for various parking lots during different time periods to reduce the rates of over-occupancy and under-occupancy. We apply our algorithm to learn the optimal parking prices for each block at every time period and make inferences to evaluate the effectiveness of the learned policy. Our method outperforms the benchmark policy used in practice, resulting in a higher percentage of blocks and time periods that achieve the target occupancy rate.

### 1.2 Related works

Our work intersects with multiple disciplines, including statistics, machine learning, and operations research.

Policy evaluation and inference with adaptively collected data. A closely related area is policy evaluation with adaptively collected data. The problem is challenging because estimators constructed from such data typically suffer from potential bias and inflated variance. These issues are addressed by some general approaches in the existing literature, all sharing the common idea of de-biasing and reweighting. For instance, Bottou et al. 2013, Wang et al. 2017, Su et al. 2020 use importance sampling to explore the trade-off between bias and variance, while Luedtke and Van Der Laan 2016, Hadad et al. 2021, Zhan et al. 2021 design specific weights and apply them to IPW-based unbiased estimator to stabilize the variance. Policy inference and regret performance are not simultaneously studied in these works. Most of the aforementioned works focused on the scenarios with low-dimensional and dense contexts.

Matrix completion and inference. The literature on matrix completion is extensive. The seminal work by Candes and Plan 2010 laid the foundation for exact matrix completion through convex programming. Keshavan et al. 2010 proposed a computationally efficient non-convex method based on matrix factorization, which delivers a statistically optimal estimator when entries are observed with sub-Gaussian noise. In the past decade, numerous methods, including computationally efficient optimization algorithms and their statistical performance, have been investigated. See, for example, Koltchinskii et al. 2011a, Hastie et al. 2015, Ge et al. 2016, Ma et al. 2018], and the references therein. Online matrix completion and regret analysis have been explored by Jin et al. 2016] and Cai et al. 2023. The statistical inference for noisy matrix completion is technically challenging and has been recently investigated by Chen et al. 2019], Xia and Yuan 2021, Yan et al. [2021], Chernozhukov et al. [2023]. The methods introduced by Chen et al. 2019] and Yan et al. 2021] are based on the sophisticated leave-one-out analysis framework and can provide entry-wise inference, while Xia and Yuan 2021 utilized double-sample debiasing and low-rank projection, offering a general framework for the statistical inference of linear forms. More recently, Ma et al. 2023a developed a method based on symmetric data aggregation to control the false discovery rate for multiple tests in noisy matrix completion. The aforementioned works mostly assume that observations are mutually independent. In this paper, we develop inferential methods for matrix completion that can handle adaptively collected data.

Causal inference by matrix completion. Our work is partially inspired by the matrix completion
methods for estimating average treatment effect in the causal inference literature Athey et al. 2021, Bai and Ng, 2021, Xiong and Pelger, 2023, Choi and Yuan, 2023. The $d_{1} \times d_{2}$ matrices $M_{1}$ and $M_{0}$ represent the potential outcomes with/without treatments of $d_{1}$ patients during a period of $d_{2}$ time intervals. However, these causal inference studies are usually offline and the entries are missing not at random.

## 2 Collaborative Filtering Policy and Matrix Completion Bandits

We begin by introducing some notations that will be used throughout this paper. Let $\|\cdot\|$ denote the $\ell_{2}$-norm for vectors and the spectral norm for matrices. The matrix Frobenius norm is denoted by $\|\cdot\|_{\text {F }}$. We use $\|\cdot\|_{\max }$ to represent the sup-norm for matrices or vectors, which is defined as the maximum absolute value of their entries. The 2 -max norm of a matrix is defined by $\|A\|_{2, \max }:=$ $\max _{j}\left\|e_{j}^{\top} A\right\|$, representing the maximum row-wise $\ell_{2}$-norm. Let $\mathbb{O}^{d \times r}:=\left\{U \in \mathbb{R}^{d \times r}: U^{\top} U=I_{r}\right\}$, where $I_{r}$ is the identity matrix of size $r$. For a matrix $U \in \mathbb{O}^{d \times r}$, we denote by $U_{\perp} \in \mathbb{O}^{d \times(d-r)}$ its orthogonal complement, such that the concatenation $\left(U, U_{\perp}\right)$ forms a $d \times d$ orthogonal matrix.

The collaborative filtering (CF) policy can be viewed as a strategy for making decisions with missing values. Let us assume there are $d_{1} d_{2}$ distinct possible requests (states) organized in a $d_{1} \times d_{2}$ grid, indexed by $\left(j_{1}, j_{2}\right)$, where $j_{1} \in\left[d_{1}\right]$ and $j_{2} \in\left[d_{2}\right]$ for simplicity. There are $K$ arms (actions), and each is associated with a reward function represented by a $d_{1} \times d_{2}$ matrix $M_{k}$, where $k \in[K]$. Given the $\left(j_{1}, j_{2}\right)$-th request, selecting the $k$-th action yields an expected reward denoted by $\left[M_{k}\right]_{j_{1} j_{2}}$. The optimal CF policy, which achieves the maximum expected reward, is given by

$$
\begin{equation*}
a^{*}\left(j_{1}, j_{2}\right):=\underset{k \in[K]}{\arg \max }\left[M_{k}\right]_{j_{1} j_{2}}, \quad \forall j_{1} \in\left[d_{1}\right], j_{2} \in\left[d_{2}\right] \tag{2}
\end{equation*}
$$

The matrices $M_{k}$ are unknown and must be estimated to learn the optimal policy. Requests arrive in sequence, and only a single (noisy) entry from one of the $M_{k}$ matrices can be observed each time after a decision is made. A fundamental assumption of collaborative filtering is that the matrices $M_{k}$ are low-rank, implying the existence of a low-dimensional embedding of their row and column spaces. In the SFpark parking pricing example, the rows and columns of $M_{k}$ represent distinct city blocks and weekly time periods, respectively. It is not uncommon to see that a city block can be mainly characterized by a few features such as location and neighborhood style, and weekly time periods can be primarily summarized by day/night and weekday/weekend distinctions.

We formulate the problem as a matrix completion bandit (MCB) under the trace regression model Koltchinskii et al. 2011b. Without loss of generality, we focus on the two-arm setting where
$K=2$. Let $\left\{\left(X_{t}, a_{t}, r_{t}\right): t \in[T]\right\}$ denote a sequence of observations where the $d_{1} \times d_{2}$ matrices $X_{t}$ 's are independently sampled uniformly from the orthonormal basis $\mathcal{X}=\left\{e_{j_{1}} e_{j_{2}}^{\top}: j_{1} \in\left[d_{1}\right], j_{2} \in\left[d_{2}\right]\right\}$. The action $a_{t} \in\{0,1\}$, and the observed reward satisfies

$$
\begin{equation*}
r_{t}=\left\langle M_{a_{t}}, X_{t}\right\rangle+\xi_{t}, \tag{3}
\end{equation*}
$$

where the noise $\xi_{t}$ is assumed sub-Gaussian and independent of $X_{t}$. The noise may have unequal variances under different arms. We assume that, conditioned on $a_{t}=1$, the noise $\xi_{t}$ has mean zero, variance $\sigma_{1}^{2}$, and a variance proxy $O\left(\sigma_{1}^{2}\right)$; if the action $a_{t}=0$ is taken, the noise has variance $\sigma_{0}^{2}$ and a variance proxy $O\left(\sigma_{0}^{2}\right)$. Denote $\mathcal{F}_{t}:=\mathfrak{S}\left(\left\{\left(X_{\tau}, a_{\tau}, r_{\tau}\right): \tau \in[t]\right\}\right)$ the sigma-algebra that contains all information available up to time $t$, which defines the filtration $\mathcal{F}_{0} \subset \mathcal{F}_{1} \subset \cdots \subset \mathcal{F}_{T}$ with $\mathcal{F}_{0}=\emptyset$. Since the action $a_{t}$ is usually made based on $\mathcal{F}_{t-1}$, the observed data is thus adaptively collected, i.e., $\left(X_{t}, a_{t}, r_{t}\right), t \in[T]$ are neither independent nor identically distributed. Without loss of generality, we assume $d_{1} \geq d_{2}$, and that $M_{1}$ and $M_{0}$ have a common rank $r \ll d_{2}$.

Let $\widehat{M}_{1, t-1}$ and $\widehat{M}_{0, t-1}$ denote the estimated MCB parameters after time $t-1$. Given the new request $X_{t} \in \mathcal{X}$ at time $t$, a greedy decision rule is to choose the action $a_{t} \in\{0,1\}$ such that $\left\langle\widehat{M}_{a_{t}, t-1}, X_{t}\right\rangle$ is larger than $\left\langle\widehat{M}_{\left|a_{t}-1\right|, t-1}, X_{t}\right\rangle$. If the estimates $\widehat{M}_{0, t-1}$ and $\widehat{M}_{1, t-1}$ are sufficiently accurate, the greedy approach can maximize the expected cumulative reward. However, the greedy approach may yield a sub-optimal total reward if the uncertainties in the estimated MCB parameters are significant. Therefore, a prudent strategy is to introduce a certain amount of randomness (exploration) into decision-making, ensuring that each arm is pulled with a non-zero probability, allowing the MCB parameters to be estimated more accurately over time. A well-known example is the $\varepsilon$-greedy algorithm Lattimore and Szepesvári, 2020, Sutton and Barto, 2018]. Let $\varepsilon_{t}, t \in[T]$ be a sequence of small positive numbers representing the exploration probabilities. At each time $t$, the $\varepsilon$-greedy algorithm makes a decision by randomly sampling an arm according to the Bernoulli distribution:

$$
a_{t} \sim \operatorname{Bernoulli}\left(\pi_{t}\right),
$$

where $\pi_{t}:=\mathbb{P}\left(a_{t}=1 \mid X_{t}, \mathcal{F}_{t-1}\right)=\left(1-\varepsilon_{t}\right) \mathbf{1}\left(\left\langle\widehat{M}_{1, t-1}-\widehat{M}_{0, t-1}, X_{t}\right\rangle>0\right)+\varepsilon_{t} / 2$. Essentially, the algorithm will choose the greedy decision with probability $1-\varepsilon_{t} / 2$ (exploitation) and the less preferable decision with probability $\varepsilon_{t} / 2$. The sequence $\varepsilon_{t}, t=1, \cdots, T$ is usually non-increasing, suggesting that the algorithm tends to make more greedy decisions as time progresses. The rationale is that as more data is accumulated, the estimated MCB parameters become more accurate, meaning that the greedy action is more likely to be the optimal one. Consequently, the decision maker will increase the probability of exploitation and decrease the likelihood of exploration.

Most existing LCB methods estimate the bandit parameters in an offline nature, i.e., the parameters are re-estimated using all the observed data at each time step. Offline learning brings technical convenience to regret analysis but faces challenges in finite-sample error analysis and inferential studies, since the data are not mutually independent. Bastani and Bayati 2020 and Kim and Paik 2019] explored the forced-sampling scheme to mitigate the dependence issue, but its efficacy in providing valid inferential results remains unclear. Offline learning is computationally intensive since it requires frequently re-solving optimization programs with increasing problem sizes. Meanwhile, Chen et al. 2022a and Ma et al. 2023b investigated online gradient descent algorithms for learning bandit parameters. Online learning enables the application of martingale techniques for finite-sample error analysis and inferential studies. However, Hao et al. 2020 noted that online learning may result in sub-optimal regrets due to "data scarcity". For technical convenience and inferential purposes, we employ online methods Jin et al., 2016, Han et al., 2022, Cai et al., 2023 to estimate the MCB parameters $M_{0}$ and $M_{1}$.

## 3 Policy Learning by Online Gradient Descent

We begin by introducing some useful notations and common assumptions. For each $i=0,1$, denote by $M_{i}=L_{i} \Lambda_{i} R_{i}^{\top}$ the singular value decomposition (SVD), where $L_{i} \in \mathbb{O}^{d_{1} \times r}$ and $R_{i} \in \mathbb{O}^{d_{2} \times r}$ contain the left and right singular vectors, respectively. The diagonal matrix $\Lambda_{i}=\operatorname{diag}\left(\lambda_{i, 1}, \cdots, \lambda_{i, r}\right)$ represents the singular values of $M_{i}$, arranged in non-increasing order. The signal strength is defined by $\lambda_{\min }:=\min \left\{\lambda_{0, r}, \lambda_{1, r}\right\}$. Denote by $\lambda_{\max }:=\max \left\{\lambda_{0,1}, \lambda_{1,1}\right\}$ the largest singular value among two matrices. We define the condition number of the two matrices as $\kappa:=\lambda_{\max } / \lambda_{\min }$. The balanced decomposition of $M_{i}$ is written as $M_{i}=U_{i} V_{i}^{\top}$, where $U_{i}^{\top} U_{i}=V_{i}^{\top} V_{i}=\Lambda_{i}$. This is attainable by setting $U_{i}=L_{i} \Lambda_{i}^{1 / 2}$ and $V_{i}=R_{i} \Lambda_{i}^{1 / 2}$. Matrix completion becomes an ill-posed problem if the underlying matrix is spikied, meaning that one or a few entries significantly dominate the others. The incoherence parameter [Candes and Recht, 2012] of $M_{i}$ is defined by

$$
\mu\left(M_{i}\right):=\max \left\{\sqrt{\frac{d_{1}}{r}}\left\|L_{i}\right\|_{2, \max }, \sqrt{\frac{d_{2}}{r}}\left\|R_{i}\right\|_{2, \max }\right\} .
$$

We assume that $\max \left\{\mu\left(M_{0}\right), \mu\left(M_{1}\right)\right\} \leq \mu_{0}$. For cleanness of presentation, we treat $\mu_{0}$ and $\kappa$ as bounded constants in the main theories, meaning that majority entries of $M_{0}$ ( $M_{1}$, similarly) have comparable magnitudes and $M_{0}, M_{1}$ are well-conditioned. Nevertheless, the explicit dependence of our theoretical results on $\mu_{0}$ and $\kappa$ can be found in the proofs.

At time $t$, a classical offline matrix completion method Keshavan et al, 2009 is to estimate
$M_{1}$ by minimizing the sum of squares $\overline{\mathscr{L}}_{1, t}(U, V):=\sum_{\tau=1}^{t} \ell_{1, \tau}(U, V):=\sum_{\tau=1}^{t} \mathbb{1}\left(\left\{a_{\tau}=1\right\}\right)\left(r_{\tau}-\right.$ $\left.\left\langle X_{\tau}, U V^{\top}\right\rangle\right)^{2}$ subject to $U \in \mathbb{R}^{d_{1} \times r}$ and $V \in \mathbb{R}^{d_{2} \times r}$. This is a non-convex program and can be locally optimized by gradient descent algorithms with guaranteed convergence and statistical performance [Burer and Monteiro, 2003, Zheng and Lafferty, 2016] if the observations are i.i.d. However, since data are adaptively collected under MCB, the probabilities $\pi_{\tau}=\mathbb{P}\left(a_{\tau}=1\right)$ are unequal. The impact to this can be easily seen in the conditional expected loss $\mathbb{E}\left[\ell_{1, t}(U, V) \mid\left\{\mathcal{F}_{t-1}, X_{t}, r_{t}\right\}\right]=$ $\pi_{t}\left(r_{t}-\left\langle X_{t}, U V^{\top}\right\rangle\right)^{2}$, which likely places more significant weight on the entries where $M_{1}$ is larger than $M_{0}$. To mitigate the bias issue, we consider using the weighted sum of squares

$$
\begin{equation*}
\min _{U, V} \mathscr{L}_{1, t}^{\pi}(U, V)=\sum_{\tau=1}^{t} \frac{\mathbb{1}\left(a_{\tau}=1\right)}{\pi_{\tau}} \cdot\left(r_{\tau}-\left\langle X_{\tau}, U V^{\top}\right\rangle\right)^{2} \quad \text { s.t. } \quad U^{\top} U=V^{\top} V, \tag{4}
\end{equation*}
$$

where the last constraint enforces a balanced factorization and is for algorithmic stability Jin et al., 2016. When estimating $M_{0}$, we define the loss $\mathscr{L}_{0, t}^{\pi}$ as in (4), but replace the weight $\mathbb{1}\left(a_{\tau}=1\right) / \pi_{\tau}$ with $\mathbb{1}\left(a_{\tau}=0\right) /\left(1-\pi_{\tau}\right)$. One possible approach is to re-solve the program (4) each time a new observation arrives, which is computationally costly. For computational efficiency and inferential purposes, we apply online gradient descent to update the estimated MCB parameters when only one new observation becomes available.

Let $\widehat{M}_{1, t-1}=\widehat{U}_{1, t-1} \widehat{V}_{1, t-1}^{\top}$ be the estimate of $M_{1}$ before time $t$. Suppose that a new observation $X_{t}$ arrives and the $\varepsilon$-greedy algorithm selects an action $a_{t}=1$, which yields a reward $r_{t}$. The online gradient descent algorithm updates the estimates via $\widetilde{U}_{1, t}:=\widehat{U}_{1, t-1}-\eta_{t} \cdot \nabla_{U} \ell_{1, t}^{\pi}\left(\widehat{U}_{1, t-1}, \widehat{V}_{1, t-1}\right)$ and $\widetilde{V}_{1, t}:=\widehat{V}_{1, t-1}-\eta_{t} \cdot \nabla_{V} \ell_{1, t}^{\pi}\left(\widehat{U}_{1, t-1}, \widehat{V}_{1, t-1}\right)$, where $\eta_{t}$ is the step size and the one-point loss is defined by $\ell_{1, t}^{\pi}(U, V):=\mathbb{1}\left(a_{t}=1\right) \pi_{t}^{-1}\left(r_{t}-\left\langle X_{t}, U V^{\top}\right\rangle\right)^{2}$. The updated estimate of $M_{1}$ is thus $\widehat{M}_{1, t}:=\widetilde{U}_{1, t} \widetilde{V}_{1, t}^{\top}$, and its balanced factorization can be written as $\widehat{M}_{1, t}=\widehat{U}_{1, t} \widehat{V}_{1, t}^{\top}$. The detailed implementations of $\varepsilon$-greedy bandit and online gradient decent can be found in Algorithm 1. The general convergence and statistical performance of Algorithm 1 are guaranteed by Theorem 1 .

Theorem 1. Suppose that the horizon $T \leq d_{1}^{100}$ and the initializations are incoherent, satisfying $\left\|\widehat{M}_{0,0}-M_{0}\right\|_{\mathrm{F}}+\left\|\widehat{M}_{1,0}-M_{1}\right\|_{\mathrm{F}} \leq c_{0} \lambda_{\text {min }}$ for some small constant $c_{0}>0$. Let $\widehat{M}_{0, t}, \widehat{M}_{1, t}, t \in[T]$ denote the output of Algorithm 1. There exist absolute constants $C_{1}, C_{2}, C_{3}, C_{4}>0$ such that if, for any $t \in[T]$,

$$
\begin{equation*}
\min \left\{\frac{\lambda_{\min }^{2}}{\sigma_{0}^{2}+\sigma_{1}^{2}}, d_{1} d_{2} \log d_{1}\right\} \geq C_{1} \sum_{\tau=1}^{t} \frac{\left(\eta_{\tau} \lambda_{\max }\right)^{2}}{\varepsilon_{\tau}} \cdot \frac{r \log ^{2} d_{1}}{d_{2}} \quad \text { and } \quad \max _{\tau \in[t]} \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}} \leq C_{2} \sum_{\tau=1}^{t} \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}} \tag{5}
\end{equation*}
$$

```
Algorithm 1 -greedy two-arm MCB with online gradient descent

end for
```

then with probability at least $1-8 t d^{-200}$,

$$
\begin{aligned}
& \left\|\widehat{M}_{i, t}-M_{i}\right\|_{\mathrm{F}}^{2} \leq C_{3}\left\|\widehat{M}_{i, 0}-M\right\|_{\mathrm{F}}^{2} \cdot \prod_{\tau=1}^{t}\left(1-\frac{\eta_{\tau} \lambda_{\min }}{4 d_{1} d_{2}}\right)+C_{4} \sigma_{i}^{2} \frac{r \log ^{2} d_{1}}{d_{2}} \cdot \sum_{\tau=1}^{t} \frac{\left(\eta_{\tau} \lambda_{\max }\right)^{2}}{\varepsilon_{\tau}} \\
& \left\|\widehat{M}_{i, t}-M_{i}\right\|_{\max }^{2} \leq C_{3} \frac{\lambda_{\min }^{2} r^{3}}{d_{1} d_{2}} \prod_{\tau=1}^{t}\left(1-\frac{\eta_{\tau} \lambda_{\min }}{4 d_{1} d_{2}}\right)+C_{4} \sigma_{i}^{2} \frac{r^{3} \log ^{2} d_{1}}{d_{1} d_{2}^{2}} \cdot \sum_{\tau=1}^{t} \frac{\left(\eta_{\tau} \lambda_{\max }\right)^{2}}{\varepsilon_{\tau}}
\end{aligned}
$$

for $i=0,1$.
The upper bounds in both Frobenius and sup-norms are characterized by two terms: the first concerns the computational convergence of Algorithm 1, which contracts over time; the second is the cumulative statistical error due to stochastic noise and random sampling. The first term depends only on the step sizes: a larger $\eta_{\tau}$ facilitates a more aggressive gradient descent learning rate, allowing Algorithm 1 to reach a local minimum faster. The second error term depends on both the step sizes and exploration probabilities. A more aggressive learning rate enlarges the stochastic noise, and a smaller exploration probability increases the variance. The condition (5) implies that the exploration probabilities cannot decrease too fast compared with the learning rates. Selecting appropriate learning rates and exploration probabilities is crucial to attaining statistically optimal estimators for MCB parameters.

The general performance guaranteed by Theorem 1 can be greatly simplified by considering specific schedules for learning rates and exploration probabilities. Suppose that the horizon $T$ is known beforehand, e.g., based on the schedule of a parking pricing experiment or the promotion periods of supermarket discounts. More precisely, we divide the entire learning process into two phases. In the first phase, we fix a constant step size and exploration probability to attain reasonably accurate estimators. However, a constant exploration probability will result in trivial regret performance. Therefore, the first phase should be relatively short compared to the full horizon. In the second phase, we choose a geometrically decaying schedule for learning rates and exploration probabilities. Since the estimated MCB parameters from phase one are sufficiently accurate, they will guarantee non-trivial regret in the second phase. The whole learning procedure bears resemblance to the "Explore-Then-Commit" (ETC) algorithm Garivier et al., 2016, Lattimore and Szepesvári, 2020, Perchet et al. 2016. Typical ETC algorithms usually make the greedy decision during the second phase, i.e., by setting a zero exploration probability. In sharp contrast, our proposed method still performs exploration during the second phase.

Corollary 1. Suppose that the horizon $T \leq d_{1}^{100}$ and the initializations are incoherent satisfying $\left\|\widehat{M}_{0,0}-M_{0}\right\|_{\mathrm{F}}+\left\|\widehat{M}_{1,0}-M_{1}\right\|_{\mathrm{F}} \leq c_{0} \lambda_{\min }$ for some small constant $c_{0}>0$. Fix some $\gamma \in[0,1)$,
$\varepsilon \in(0,1 / 2)$, and set $T_{0}:=C_{0} T^{1-\gamma} \log \left[\lambda_{\min } /\left(\sigma_{0} \wedge \sigma_{1}\right)\right]$ for a large constant $C_{0}>0$ depending on $\varepsilon$. When $t \leq T_{0}$, set $\varepsilon_{t} \equiv \varepsilon$ and $\eta_{t} \equiv \eta:=c_{1} d_{1} d_{2} /\left(T^{1-\gamma} \lambda_{\max }\right)$; when $T_{0}<t \leq T$, set $\varepsilon_{t}=c_{2} t^{-\gamma}$ and $\eta_{t}=\varepsilon_{t} \eta$, where $c_{1}, c_{2}>0$ are numerical constants. Suppose that the horizon and signal-to-noise ratio (SNR) satisfy

$$
T \geq C_{1} r^{3} d_{1}^{1 /(1-\gamma)} \log ^{2} d_{1} \quad \text { and } \quad \frac{\lambda_{\min }^{2}}{\sigma_{0}^{2}+\sigma_{1}^{2}} \geq C_{2} \frac{r d_{1}^{2} d_{2} \log ^{2} d_{1}}{T^{1-\gamma}}
$$

for some large constants $C_{1}, C_{2}>0$ depending on $C_{0}, c_{0}, c_{1}, c_{2}$ only. There exists a numerical constant $C_{3}>0$ such that, with probability at least $1-8 T d^{-200}$, the output $\widehat{M}_{0, T}$ and $\widehat{M}_{1, T}$ by Algorithm 1 satisfy

$$
\begin{aligned}
& \left\|\widehat{M}_{i, T}-M_{i}\right\|_{\mathrm{F}}^{2} \leq C_{3} \sigma_{i}^{2} \frac{r d_{1}^{2} d_{2} \log ^{4} d_{1}}{T^{1-\gamma}} \\
& \left\|\widehat{M}_{i, T}-M_{i}\right\|_{\max }^{2} \leq C_{3} \sigma_{i}^{2} \frac{r d_{1} \log ^{4} d_{1}}{T^{1-\gamma}}
\end{aligned}
$$

for $i=0,1$.

The value $\gamma$ controls the length of phase one, which has a constant exploration probability. If the primary goal is to estimate MCB parameters (i.e., to learn the optimal policy), the value $\gamma$ can be set as small as near zero. In this case, the horizon and signal strength conditions reduce to the classic ones found in the existing literature on matrix completion Candes and Recht, 2012, Keshavan et al., 2010. In fact, the constant exploration probability ensures that $O(T)$ observations are available for estimating each of $M_{0}$ and $M_{1}$. Moreover, the final estimators $\widehat{M}_{0, T}$ and $\widehat{M}_{1, T}$ are statistically optimal up to logarithmic factors Koltchinskii et al., 2011b, Ma et al., 2018, Cai et al., 2023. However, if maximizing the expected cumulative reward is the primary goal, the value $\gamma$ should not be too close to zero. The reason is that a constant exploration probability implies a constant risk of making sub-optimal decisions during phase one.

## 4 Regret Analysis

One of the decision maker's goals is to maximize the expected cumulative reward during the policy learning process. The maximum expected cumulative reward $\mathbb{E}\left[\sum_{t \in[T]} \max _{i \in\{0,1\}}\left\langle M_{i}, X_{t}\right\rangle\right]$ is attainable from making decisions using the optimal policy $a^{*}$ defined in (2). Let $a_{t}, t \in[T]$ be the sequence of actions taken according to Algorithm 1, which results in an expected cumulative reward $\mathbb{E}\left[\sum_{t \in[T]}\left\langle M_{a_{t}}, X_{t}\right\rangle\right]$. Here, the expectation is taken with respect to $\mathcal{F}_{T}$. The difference between the
achieved expected cumulative reward and the maximum one is referred to as the regret, formally defined by

$$
R_{T}:=\mathbb{E}\left[\sum_{t=1}^{T} \max _{i \in\{0,1\}}\left\langle M_{i}, X_{t}\right\rangle-\left\langle M_{a_{t}}, X_{t}\right\rangle\right] .
$$

Under mild conditions, it is easy to show that the regret is bounded mainly by two terms:

$$
R_{T} \lesssim\left\|M_{1}-M_{0}\right\|_{\max } \cdot \sum_{t=1}^{T} \varepsilon_{t}+\sum_{t=1}^{T} \max _{i \in\{0,1\}}\left\|\widehat{U}_{i, t} \widehat{V}_{i, t}^{\top}-M_{i}\right\|_{\max } .
$$

The first term originates from exploration, which is present even if both MCB parameters are perfectly estimated. The second term concerns the incorrect decisions made due to the uncertainties in estimated MCB parameters. Since each request is related to one entry of two matrices, the regret is characterized by the entry-wise error rates.

Let us consider the ETC-style schedule for exploration probabilities as in Section 3 and illustrate the trade-off between policy learning and regret performance.

Theorem 2. Suppose that the conditions in Corollary 1 hold, and denote by $\bar{m}:=\left\|M_{0}\right\|_{\max }+$ $\left\|M_{1}\right\|_{\max }$ and $\bar{\sigma}:=\max \left\{\sigma_{0}, \sigma_{1}\right\}$. Then there exists a numerical constant $C_{5}>0$ such that the regret is upper bounded by

$$
R_{T} \leq C_{5}\left[\bar{m} r \cdot T^{1-\gamma}+\bar{\sigma} \cdot T^{(1+\gamma) / 2} \sqrt{r d_{1}} \log ^{2} d_{1}\right]
$$

Assuming $r=O(1)$, Theorem 2 shows that the ETC-style MCB algorithm achieves the regret $R_{T}=\widetilde{O}\left(\bar{m} \cdot T^{1-\gamma}+\bar{\sigma} \cdot T^{(1+\gamma) / 2} d_{1}^{1 / 2}\right)$, where logarithmic factors are hidden in $\widetilde{O}(\cdot)$. As discussed after Corollary 1, the MCB algorithm can learn the optimal policy more accurately if the value $\gamma$ is closer to 0 . However, setting $\gamma=0$ will lead to a trivial regret upper bound of $O(T)$. By choosing a value $\gamma>0$ so that $T^{1-3 \gamma}=(\bar{\sigma} / \bar{m})^{2} d_{1}$, we end up with the regret upper bound $R_{T}=\widetilde{O}\left(\left(\bar{m} \bar{\sigma}^{2}\right)^{1 / 3} d_{1}^{1 / 3} T^{2 / 3}\right)$. The $O\left(T^{2 / 3}\right)$ regret performance has been observed in online highdimensional bandit algorithms especially, when the horizon $T$ is not too large. See, e.g., Hao et al. 2020, Ma et al. 2023b, and references therein. In the extreme case where $\bar{m} \ll \bar{\sigma}$, such that the second term dominates, the regret upper bound $O\left(T^{(1+\gamma) / 2}\right)$ becomes smaller as $\gamma$ approaches zero.

It is worth noting that a classical ETC bandit algorithm may achieve a similar policy learning accuracy and regret performance. The classical ETC algorithm will make greedy decisions in the second phase without exploration. By setting $\varepsilon_{t}=\eta_{t}=0$ for $T_{0}<t \leq T$, the estimated MCB parameters will not be further updated after phase one. The decisions made during phase two are
only determined by the entry-wise difference between $\widehat{M}_{0, T_{0}}$ and $\widehat{M}_{1, T_{0}}$. It is easy to check that the error rates achieved by $\widehat{M}_{0, T_{0}}$ and $\widehat{M}_{1, T_{0}}$ are comparable to those stated in Corollary 1 , up to constant factors. Although no exploration is made during phase two, its regret performance is comparable to that in Theorem 2. We choose the proposed exploration probability schedule as in Corollary 1 for the purpose of policy inference. If no exploration is made during phase two, the inferential methods in Section 5 will be invalid because the debiasing procedure does not yield an unbiased estimator.

## 5 Policy Inference by Inverse Propensity Weighting

One of our major contributions is a novel debiasing method and general framework for the statistical inference of CF policy. Suppose that the platform manager wants to decide on a marketing strategy to recommend a specific collection of products to a particular group of users. Then, there exists a $d_{1} \times d_{2}$ matrix $Q$ such that the expected rewards under strategies one and two may be written as $\left\langle M_{0}, Q\right\rangle$ and $\left\langle M_{1}, Q\right\rangle$, respectively. For instance, $Q=2 e_{1} e_{1}^{\top}+e_{2} e_{3}^{\top}$ corresponds to the case that user 1 plans to purchase two units of product 1 and user 2 plans to purchase one unit of product 3 . Oftentimes, the manager desires not just a decision but also a confidence level in the correctness of the chosen decision. The decision-making process can be conveniently formulated as a hypothesis testing problem:

$$
\begin{equation*}
H_{0}:\left\langle M_{1}-M_{0}, Q\right\rangle=0 \quad \text { v.s. } \quad H_{1}:\left\langle M_{1}-M_{0}, Q\right\rangle>0 . \tag{6}
\end{equation*}
$$

Rejecting the null hypothesis means that strategy two is preferred for this specific marketing task.

### 5.1 Debiasing

Constructing a good estimator is the first step in testing hypotheses (6). The plug-in estimator $\left\langle\widehat{M}_{1, T}-\widehat{M}_{0, T}, Q\right\rangle$ suffers from potential bias caused by the implicit regularization of gradient descent, and $\widehat{M}_{0, T}, \widehat{M}_{1, T}$ may not be unbiased estimators. Proper debiasing treatment is crucial for valid inference. The commonly used debiasing method Chen et al., 2019, Xia and Yuan, 2021 in offline matrix completion considers

$$
\widehat{M}_{1}^{\mathrm{u} \text {-off }}:=\widehat{M}_{1, T}+\frac{d_{1} d_{2}}{\left|\left\{t \in[T]: a_{t}=1\right\}\right|} \sum_{t=1}^{T} \mathbb{1}\left(a_{t}=1\right) \cdot\left(r_{t}-\left\langle\widehat{M}_{1, T}, X_{t}\right\rangle\right) X_{t} .
$$

This method may not work for MCB because data are adaptively collected, and $\widehat{M}_{1}^{\mathrm{u} \text {-off }}$ may still be a biased estimator of $M_{1}$. Moreover, the estimator $\widehat{M}_{1}^{\text {-off }}$ requires access to historical data to compute $\left\langle\widehat{M}_{1, T}, X_{t}\right\rangle X_{t}$.

An online debiasing method was recently proposed by Han et al. 2022 for the low-rank matrix regression bandit, which provides an unbiased estimator even if data are adaptively collected. The crucial ingredient is to include the inverse propensity weight (IPW), and we modify it into matrix completion setting:

$$
\begin{equation*}
\widehat{M}_{1}^{\mathrm{PPW}}:=\frac{1}{T} \sum_{t=1}^{T} \widehat{M}_{1, t-1}+\frac{d_{1} d_{2}}{T} \sum_{t=1}^{T} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}}\left(r_{t}-\left\langle\widehat{M}_{1, t-1}, X_{t}\right\rangle\right) X_{t} . \tag{7}
\end{equation*}
$$

The estimator $\widehat{M}_{0}^{\mathrm{IPW}}$ is similarly defined using $\left(1-\pi_{t}\right)^{-1}$ as the IPW. The unbiasedness of $\widehat{M}_{0}^{\mathrm{IPW}}$ and $\widehat{M}_{1}^{\mathrm{IPW}}$ can be easily verified by noticing the the independence between $\widehat{M}_{1, t-1}$ and $\left(X_{t}, r_{t}, a_{t}\right)$, conditioned on $\mathcal{F}_{t-1}$. The debiasing procedure (7) is online in nature, since it does not require saving historical data. The method only needs the incremental updating of the two summands in (7) over time. Nevertheless, the debiasing procedure (7) accumulates all past estimates, but estimates from the early stage may not be sufficiently accurate, which can potentially inflates the variance. This issue can be resolved by assuming that the initializations are already accurate enough Han et al., 2022 . As shown by the proof of Corollary 1, the estimates $\widehat{M}_{1, T_{0}}$ and $\widehat{M}_{0, T_{0}}$ attained at the end of phase one are sufficiently accurate in the sense $\left\|\widehat{M}_{1, T_{0}}-M_{1}\right\|_{\max }+\left\|\widehat{M}_{0, T_{0}}-M_{0}\right\|_{\max }=O\left(\sigma_{0}+\sigma_{1}\right)$ under the horizon condition stated there. Therefore, our IPW debiasing approach only uses the estimates from the second phase. Since the length of phase one is relatively small, we still have $O(T)$ data points for constructing the debiased estimator. Define

$$
\begin{align*}
& \widehat{M}_{0}^{\mathrm{PW}}:=\frac{1}{T-T_{0}} \sum_{t=T_{0}+1}^{T} \widehat{M}_{0, t-1}+\frac{d_{1} d_{2}}{T-T_{0}} \sum_{t=T_{0}+1}^{T} \frac{\mathbb{1}\left(a_{t}=0\right)}{1-\pi_{t}}\left(r_{t}-\left\langle\widehat{M}_{0, t-1}, X_{t}\right\rangle\right) X_{t} \\
& \widehat{M}_{1}^{\mathrm{PW}}:=\frac{1}{T-T_{0}} \sum_{t=T_{0}+1}^{T} \widehat{M}_{1, t-1}+\frac{d_{1} d_{2}}{T-T_{0}} \sum_{t=T_{0}+1}^{T} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}}\left(r_{t}-\left\langle\widehat{M}_{1, t-1}, X_{t}\right\rangle\right) X_{t} . \tag{8}
\end{align*}
$$

Finally, given the low-rank assumption of MCB parameters, our final estimators are defined by the best rank- $r$ approximation of $\widehat{M}_{1}^{\mathrm{IPW}}$ and $\widehat{M}_{0}^{\mathrm{PWW}}$, denoted by $\widehat{M}_{1}$ and $\widehat{M}_{0}$, respectively. More precisely, $\widehat{M}_{1}=\widehat{L}_{1} \widehat{L}_{1}^{\top} \widehat{M}_{1}^{\mathrm{PW}} \widehat{R}_{1} \widehat{R}_{1}^{\top}$, where $\widehat{L}_{1}$ and $\widehat{R}_{1}$ consist of the left and right top- $r$ singular vectors of $\widehat{M}_{1}^{\mathrm{PW}}$, respectively. As explained in Xia and Yuan 2021, spectral projection further reduces the variance at the cost of introducing a negligible bias. Using the plug-in method, we propose $\left\langle\widehat{M}_{1}-\widehat{M}_{0}, Q\right\rangle$ as the point estimator for the linear form $\left\langle M_{1}-M_{0}, Q\right\rangle$.

### 5.2 Asymptotic normality

We now investigate the variances of $\left\langle\widehat{M}_{1}, Q\right\rangle$ and $\left\langle\widehat{M}_{0}, Q\right\rangle$, respectively, and prove that these test statistics are asymptotically normal under mild conditions. Two factors play key roles in determining the variance of $\left\langle\widehat{M}_{1}, Q\right\rangle$ : the properness of linear form $Q$ and the source of variances in estimating $\widehat{M}_{1}$. Xia and Yuan 2021 and Ma et al. 2023a show that the variance of $\left\langle\widehat{M}_{1}, Q\right\rangle$ is characterized by the alignment between $Q$ and $M_{1}$. More precisely, the quantity $\left\|\mathcal{P}_{M_{1}}(Q)\right\|_{\mathrm{F}}$ determines the size the variance, where

$$
\mathcal{P}_{M_{1}}(Q):=Q-L_{1 \perp} L_{1 \perp}^{\top} Q R_{1 \perp} R_{1 \perp}^{\top}
$$

with $L_{1 \perp}$ and $R_{1 \perp}$ such that $\left(L_{1}, L_{1 \perp}\right)$ and $\left(R_{1}, R_{1 \perp}\right)$ are $d_{1} \times d_{1}$ and $d_{2} \times d_{2}$ orthogonal matrices. If $Q$ is orthogonal to $M_{1}$ in the sense that $L_{1}^{\top} Q=0$ and $Q R_{1}=0$, the statistical inference for $\left\langle M_{1}, Q\right\rangle$ becomes an ill-posed problem.

There are two sources of variance when constructing the de-biased estimator $\widehat{M}_{1}$ : the effective sample size and the variance inflation cased by IPW. The former concerns how likely arm 1 will be pulled over time, and the latter is mainly determined by the occasions when arm 1 is pulled for exploration. We characterize these variances by the following arm optimality conditions. For any $\delta>0$, define $\Omega_{1}(\delta):=\left\{X \in \mathcal{X}:\left\langle M_{1}-M_{0}, X\right\rangle>\delta\right\}, \Omega_{0}(\delta):=\left\{X \in \mathcal{X}:\left\langle M_{0}-M_{1}, X\right\rangle<\delta\right\}$, and $\Omega_{\emptyset}(\delta):=\left(\Omega_{1}(\delta) \cup \Omega_{0}(\delta)\right)^{c}$. Essentially, $\Omega_{1}(\delta)$ represents the instances where arm 1 is the optimal one, with an expected regret that is strictly larger than that of the other arm. The parameter $\delta$ is often referred to as the reward gap between the optimal and sub-optimal arms. For notational cleanness, we simply write $\Omega_{0}, \Omega_{1}$, and $\Omega_{\emptyset}$ to omit their dependence on $\delta$. The two sets $\Omega_{1}$ and $\Omega_{0}$ make distinct contributions to the variance of $\widehat{M}_{1}$. Suppose that $\widehat{M}_{0}$ and $\widehat{M}_{1}$ are sufficiently accurate so that $\Omega_{1}$ and $\Omega_{0}$ are already identifiable from historical data. For a future observation, if the request $X_{t} \in \Omega_{1}$, it is utilized in constructing $\widehat{M}_{1}$ with a probability approaching to one as $t \rightarrow \infty$. On the other hand, if the request $X_{t} \in \Omega_{0}$, this probability approaches zero as $t \rightarrow \infty$. The effective sample size is determined by $\Omega_{1}$, and variance inflation due to IPW is mainly caused by $\Omega_{0}$. Let $\mathcal{P}_{\Omega_{1}}(M)$ denote the operator which zeros out the entries of $M$ except those in the set $\Omega_{1}$.

Assumption 1. (Arm Optimality) There exists a gap $\delta>0$ such that the sets $\Omega_{0}, \Omega_{1}$, and $\Omega_{\emptyset}$ ensure $\left\|\mathcal{P}_{\Omega_{\emptyset}} \mathcal{P}_{M_{i}}(Q)\right\|_{\mathrm{F}}^{2} / \min \left\{\left\|\mathcal{P}_{\Omega_{1}} \mathcal{P}_{M_{i}}(Q)\right\|_{\mathrm{F}}^{2},\left\|\mathcal{P}_{\Omega_{0}} \mathcal{P}_{M_{i}}(Q)\right\|_{\mathrm{F}}^{2}\right\}=o(1)$ as $d_{1}, d_{2} \rightarrow \infty$ for $i=0,1$.

It is worth noting that the gap specified in Assumption 1 is allowed to diminish as $d_{1}, d_{2} \rightarrow \infty$, which is much weaker than the existing literature that requires a constant gap. See, e.g., Bastani
and Bayati 2020. Note that observations with requests sampled from the set $\Omega_{\emptyset}$ also contribute to the variances of $\widehat{M}_{0}$ and $\widehat{M}_{1}$. However, it is difficult to identify the optimal arm if the request $X_{t} \in \Omega_{\emptyset}$, especially when the gap $\delta$ diminishes asymptotically. This poses significant challenges in precisely characterizing the variance contributed by the set $\Omega_{\emptyset}$. For technical convenience, we assume that the variance contributed by $\Omega_{\emptyset}$ is negligible compared with those from $\Omega_{0}$ and $\Omega_{1}$.

The following theorem instates the central limit theorem for $\left\langle\widehat{M}_{1}, Q\right\rangle$ and $\left\langle\widehat{M}_{0}, Q\right\rangle$. Here $\|Q\|_{\ell_{1}}$ denotes the vectorized $\ell_{1}$-norm, i.e., $\|Q\|_{\ell_{1}}=\sum_{X \in \mathcal{X}}|\langle Q, X\rangle|$.

Theorem 3. Suppose that the conditions in Corollary 1 hold and Assumption 1 holds with $\delta^{2}:=$ $\delta_{T}^{2}:=C_{1}\left(\sigma_{0}^{2}+\sigma_{1}^{2}\right)\left(r d_{1} / T^{1-\gamma}\right) \log ^{4} d_{1}$ for some large constant $C_{1}>0$. Define $S_{1}^{2}=T^{-\gamma}\left\|\mathcal{P}_{\Omega_{1}} \mathcal{P}_{M_{1}}(Q)\right\|_{\mathrm{F}}^{2}+$ $C_{\gamma}\left\|\mathcal{P}_{\Omega_{0}} \mathcal{P}_{M_{1}}(Q)\right\|_{\mathrm{F}}^{2}$ and $S_{0}^{2}=T^{-\gamma}\left\|\mathcal{P}_{\Omega_{0}} \mathcal{P}_{M_{0}}(Q)\right\|_{\mathrm{F}}^{2}+C_{\gamma}\left\|\mathcal{P}_{\Omega_{1}} \mathcal{P}_{M_{0}}(Q)\right\|_{\mathrm{F}}^{2}$, where $C_{\gamma}=2 /\left(c_{2}(1+\gamma)\right)$ and $c_{2}$ is defined in Corollary 1. Assume that for each $i=0,1$,

$$
\begin{equation*}
\frac{r^{2} d_{1} \log ^{5} d_{1}}{T^{1-\gamma}}+\frac{\sigma_{i}}{\lambda_{\min }} \sqrt{\frac{r d_{1}^{2} \log d_{1}}{T^{1-\gamma}}} \frac{\|Q\|_{\ell_{1}}}{S_{i}} \rightarrow 0 \tag{9}
\end{equation*}
$$

as $d_{1}, d_{2}, T \rightarrow \infty$. Then,

$$
\begin{equation*}
\frac{\left\langle\widehat{M}_{0}, Q\right\rangle-\left\langle M_{0}, Q\right\rangle}{\sigma_{0} S_{0} \sqrt{d_{1} d_{2} / T^{1-\gamma}}} \rightarrow N(0,1) \quad \text { and } \quad \frac{\left\langle\widehat{M}_{1}, Q\right\rangle-\left\langle M_{1}, Q\right\rangle}{\sigma_{1} S_{1} \sqrt{d_{1} d_{2} / T^{1-\gamma}}} \rightarrow N(0,1), \tag{10}
\end{equation*}
$$

as $d_{1}, d_{2}, T \rightarrow \infty$.
Theorem 3 shows that the variance of $\left\langle\widehat{M}_{1}, Q\right\rangle$ is characterized by two terms:

$$
\begin{equation*}
\frac{\sigma_{1}^{2} d_{1} d_{2}}{T}\left\|\mathcal{P}_{\Omega_{1}} \mathcal{P}_{M_{1}}(Q)\right\|_{\mathrm{F}}^{2}+\frac{2 \sigma_{1}^{2} d_{1} d_{2}}{c_{2}(1+\gamma) T^{1-\gamma}}\left\|\mathcal{P}_{\Omega_{0}} \mathcal{P}_{M_{1}}(Q)\right\|_{\mathrm{F}}^{2} \tag{11}
\end{equation*}
$$

where the former term arises from exploitation with an effective sample size $\asymp T$, and the latter derives from exploration with an effective sample size $\asymp T^{1-\gamma}$. The additional $O\left(T^{\gamma}\right)$ factor in the latter term can also be interpreted as the variance inflation induced by IPW. If the arm optimality sets are balanced, such that $\left\|\mathcal{P}_{\Omega_{1}} \mathcal{P}_{M_{1}}(Q)\right\|_{\mathrm{F}}$ and $\left\|\mathcal{P}_{\Omega_{0}} \mathcal{P}_{M_{1}}(Q)\right\|_{\mathrm{F}}$ are comparable, the variance is primarily determined by the second term, implying that the error rate of $\left\langle\widehat{M}_{1}, Q\right\rangle$ decays at the order $O\left(T^{-(1-\gamma) / 2}\right)$. Moreover, observations with requests from $\Omega_{0}$ play the predominant role in characterizing the variance of $\left\langle\widehat{M}_{1}, Q\right\rangle$. One particularly interesting case occurs when the first term in (11) dominates, so that the sup-norm error rate of de-biased estimator $\left\|\widehat{M}_{1}-M_{1}\right\|_{\max }$ converges at the order $O\left(T^{-1 / 2}\right)$, suggesting that IPW may improve the estimation accuracy of the estimator produced by bandit Algorithm 1 .

### 5.3 Policy inference

The asymptotic normality established in Theorem 3 depends on some unknown quantities such as $\sigma_{0}, \sigma_{1},\left\|\mathcal{P}_{\Omega_{1}} \mathcal{P}_{M_{0}}(Q)\right\|_{\mathrm{F}},\left\|\mathcal{P}_{\Omega_{0}} \mathcal{P}_{M_{0}}(Q)\right\|_{\mathrm{F}},\left\|\mathcal{P}_{\Omega_{1}} \mathcal{P}_{M_{1}}(Q)\right\|_{\mathrm{F}}$, and $\left\|\mathcal{P}_{\Omega_{0}} \mathcal{P}_{M_{1}}(Q)\right\|_{\mathrm{F}}$. These quantities must be estimated for the purposes of constructing confidence intervals and testing hypothesis (6). Towards that end, we propose the following estimators:

$$
\begin{aligned}
& \widehat{\sigma}_{0}^{2}:=\frac{1}{T-T_{0}} \sum_{t=T_{0}+1}^{T} \frac{\mathbb{1}\left(a_{t}=0\right)}{1-\pi_{t}}\left(r_{t}-\left\langle\widehat{M}_{0, t-1}, X_{t}\right\rangle\right)^{2} \\
& \widehat{\sigma}_{1}^{2}:=\frac{1}{T-T_{0}} \sum_{t=T_{0}+1}^{T} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}}\left(r_{t}-\left\langle\widehat{M}_{0, t-1}, X_{t}\right\rangle\right)^{2} \\
& \widehat{S}_{0}^{2}=\left(1 / T^{\gamma}\left\|\mathcal{P}_{\widehat{\Omega}_{0, T}} \mathcal{P}_{\widehat{M}_{0}}(Q)\right\|_{\mathrm{F}}^{2}+C_{\gamma}\left\|\mathcal{P}_{\widehat{\Omega}_{1, T}} \mathcal{P}_{\widehat{M}_{0}}(Q)\right\|_{\mathrm{F}}^{2}\right) b_{T} \\
& \widehat{S}_{1}^{2}=\left(1 / T^{\gamma}\left\|\mathcal{P}_{\widehat{\Omega}_{1, T}} \mathcal{P}_{\widehat{M}_{1}}(Q)\right\|_{\mathrm{F}}^{2}+C_{\gamma}\left\|\mathcal{P}_{\widehat{\Omega}_{1, T}} \mathcal{P}_{\widehat{M}_{1}}(Q)\right\|_{\mathrm{F}}^{2}\right) b_{T} .
\end{aligned}
$$

where $\widehat{\Omega}_{i, T}=\left\{X \in \mathcal{X}:\left\langle\widehat{M}_{i, T}-\widehat{M}_{1-i, T}, X\right\rangle>0\right\}$ for $i=0,1$ and $b_{T}=T /\left(T-T_{0}\right)$. In the supplementary materials, we show that all these estimators are consistent, and the asymptotic normality still holds when replacing the standard deviations by its data-driven estimates.

Theorem 4. Suppose that the conditions in Theorem 3 hold. Then,

$$
\frac{\left\langle\widehat{M}_{0}, Q\right\rangle-\left\langle M_{0}, Q\right\rangle}{\widehat{\sigma}_{0} \widehat{S}_{0} \sqrt{d_{1} d_{2} / T^{1-\gamma}}} \rightarrow N(0,1) \quad \text { and } \quad \frac{\left\langle\widehat{M}_{1}, Q\right\rangle-\left\langle M_{1}, Q\right\rangle}{\widehat{\sigma}_{1} \widehat{S}_{1} \sqrt{d_{1} d_{2} / T^{1-\gamma}}} \rightarrow N(0,1),
$$

as $d_{1}, d_{2}, T \rightarrow \infty$.
Finally, we need to study the distribution of the point estimator $\left\langle\widehat{M}_{1}-\widehat{M}_{0}, Q\right\rangle=\left\langle\widehat{M}_{1}, Q\right\rangle-$ $\left\langle\widehat{M}_{0}, Q\right\rangle$ and its studentized version to test between the two hypotheses in (6). A simple fact is that $\left\langle\widehat{M}_{1}, Q\right\rangle$ and $\left\langle\widehat{M}_{0}, Q\right\rangle$ are uncorrelated, and the following asymptotic normality holds. This immediately enables the classic Z-test and the construction of valid confidence intervals.

Corollary 2. Suppose that the conditions in Theorem 3 hold. Then,

$$
\frac{\left\langle\widehat{M}_{1}-\widehat{M}_{0}, Q\right\rangle-\left\langle M_{1}-M_{0}, Q\right\rangle}{\sqrt{\left(\widehat{\sigma}_{0}^{2} \widehat{S}_{0}^{2}+\widehat{\sigma}_{1}^{2} \widehat{S}_{1}^{2}\right) d_{1} d_{2} / T^{1-\gamma}}} \longrightarrow N(0,1),
$$

as $d_{1}, d_{2}, T \rightarrow \infty$.

## 6 Numerical Experiments

In this section, we present several numerical studies to evaluate the practical performance of matrix completion bandit.

### 6.1 Statistical Inference

First, we show the performance of online inference. The dimension of the true matrices $M_{1}$ and $M_{0}$ are $d_{1}=d_{2}=300$, with a rank $r=2$. We generate $M_{1}$ by applying SVD to a random matrix with entries independently drawn from $U(-100,100) . M_{0}$ is obtained by first adding a perturbation matrix with entries drawn from $U(-2,2)$ to the aforementioned matrix, and then applying SVD to obtain a low-rank matrix using the same procedure. This construction ensures that the gap between corresponding entries in the two matrices is relatively small. $\lambda_{\max }$ is approximately 1981.3 and $\lambda_{\text {min }}$ is about 1950.5. The noise level is set to be $\sigma_{1}=\sigma_{0}=1$. The initial estimates $\widehat{M}_{1,0}$ and $\widehat{M}_{0,0}$ are obtained by randomly collecting some offline data and then applying the SOFT-IMPUTE algorithm proposed in Mazumder et al. 2010.

We propose the inference procedure on several scenarios: (1) $\left\langle M_{1}, e_{1} e_{5}^{\top}\right\rangle$, (2) $\left\langle M_{0}, e_{1} e_{5}^{\top}\right\rangle,(3)\left\langle M_{0}-\right.$ $\left.M_{1}, e_{1} e_{5}^{\top}\right\rangle$ and (4) $\left\langle M_{0}, e_{1} e_{5}^{\top}-e_{2} e_{2}^{\top}\right\rangle$. For each scenario, we conduct 1000 independent runs under two different settings: $\gamma=\frac{1}{3}$ and $\gamma=\frac{1}{4}$. For both settings, the sample size is set to be $T=60000$ and $T_{0}=20000$. The exploration parameter is set to be $\varepsilon=0.6$ for phase $I$, while $\varepsilon_{t}=10 t^{-\gamma}$ for phase $I I$. The stepsize is $\eta=0.025 \frac{d_{1} d_{2} \log d_{1}}{T^{1-\gamma} \lambda_{\max }}$ for phase $I$ and $\eta_{t}=\varepsilon_{t} \eta$ for phase $I I$.

In Figure 1 , we present the density histogram of $\left(\left\langle\widehat{M}_{i}, Q\right\rangle-\left\langle M_{i}, Q\right\rangle\right) / \widehat{\sigma}_{i} \widehat{S}_{i} \sqrt{d_{1} d_{2} / T^{1-\gamma}}$ (scenario (1), (2),(4)) or $\left(\left(\left\langle\widehat{M}_{0}, Q\right\rangle-\left\langle\widehat{M}_{1}, Q\right\rangle\right)-\left(\left\langle M_{0}, Q\right\rangle-\left\langle M_{1}, Q\right\rangle\right)\right) / \sqrt{\left(\widehat{\sigma}_{1}^{2} \widehat{S}_{1}^{2}+\widehat{\sigma}_{0}^{2} \widehat{S}_{0}^{2}\right) d_{1} d_{2} / T^{1-\gamma}}$ (scenario (3)) for each scenario under $\gamma=\frac{1}{3}$. The empirical distributions are very close to the standard normal distribution represented by the red curve. Figure 2 displays the results under $\gamma=\frac{1}{4}$, which also align with the theoretical findings.

### 6.2 Regret Analysis

Next, we proceed to the verify the regret of the matrix completion bandit algorithm under the same settings. For $\gamma=\frac{1}{3}$, the time $T$ vary from 40,000 to 80,000 in increments of 5,000 , while setting $T_{0}=13.5 T^{1-\gamma}$ for each $T$. Similarly, for $\gamma=\frac{1}{4}$, we vary $T$ from 20,000 to 60,000 , also in increments of 5,000 , and $T_{0}$ is set to be $4.5 T^{1-\gamma}$ for each $T$. We conduct 100 simulation trials and plot the average cumulative regret against $T^{2 / 3}$ when $\gamma=\frac{1}{3}$ and $T^{3 / 4}$ when $\gamma=\frac{1}{4}$. Figure 3 clearly demonstrates a linear scaling, indicating that the cumulative regret follows an $O\left(T^{2 / 3}\right)$ trend when $\gamma=\frac{1}{3}$, and an $O\left(T^{3 / 4}\right)$ trend when $\gamma=\frac{1}{4}$, which aligns with our theoretical result in Theorem 2 .

Figure 1: Empirical distribution of $\left(\left\langle\widehat{M_{i}}, Q\right\rangle-\left\langle M_{i}, Q\right\rangle\right) / \widehat{\sigma}_{i} \widehat{S}_{i} \sqrt{d_{1} d_{2} / T^{1-\gamma}}$ or $\left(\left(\left\langle\widehat{M}_{0}, Q\right\rangle-\left\langle\widehat{M}_{1}, Q\right\rangle\right)-\right.$ $\left.\left(\left\langle M_{0}, Q\right\rangle-\left\langle M_{1}, Q\right\rangle\right)\right) / \sqrt{\left(\widehat{\sigma}_{1}^{2} \widehat{S}_{1}^{2}+\widehat{\sigma}_{0}^{2} \widehat{S}_{0}^{2}\right) d_{1} d_{2} / T^{1-\gamma}}$ based on 1000 independent trails under $\gamma=\frac{1}{3}$, and the red curve represents the p.d.f. of standard normal distributions. Top left: scenario (1); top right: scenario (2). Bottom left: scenario (3); bottom right: scenario (4).

## 7 Real Data Analysis: SFpark Parking Pricing Project

Starting in April 2011, San Francisco Municipal Transportation Agency (SFMTA) adopted the SFpark pilot project, which marked the largest pricing reform for on-street parking in San Francisco. The objective of this project was to effectively manage parking towards availability targets. Prior to that, parking meters in San Francisco charged a single hourly price regardless of the time of day or location within a zone. Consequently, certain blocks experienced severe overcrowding especially during peak hours, while others remained underutilized. Recognizing this issue, extensive literature has identified the on-street parking pricing as the dominant factor that determines parking behavior

Figure 2: Empirical distribution of $\left(\left\langle\widehat{M_{i}}, Q\right\rangle-\left\langle M_{i}, Q\right\rangle\right) / \widehat{\sigma}_{i} \widehat{S}_{i} \sqrt{d_{1} d_{2} / T^{1-\gamma}}$ or $\left(\left(\left\langle\widehat{M}_{0}, Q\right\rangle-\left\langle\widehat{M}_{1}, Q\right\rangle\right)-\right.$ $\left.\left(\left\langle M_{0}, Q\right\rangle-\left\langle M_{1}, Q\right\rangle\right)\right) / \sqrt{\left(\widehat{\sigma}_{1}^{2} \widehat{S}_{1}^{2}+\widehat{\sigma}_{0}^{2} \widehat{S}_{0}^{2}\right) d_{1} d_{2} / T^{1-\gamma}}$ based on 1000 independent trails under $\gamma=\frac{1}{4}$, and the red curve represents the p.d.f. of standard normal distributions. Top left: scenario (1); top right: scenario (2). Bottom left: scenario (3); bottom right: scenario (4).
(Aljohani et al. 2021]). In general, higher prices encourage a few drivers to move away from the most crowded blocks, while lower prices attract the drivers to the underoccupied blocks.

SFpark thus allocates parking spaces more efficiently than uniform prices can by adjusting the price varied by time of day, day of week and from block to block. The occupancy rate of a block of a given hour is defined to be divided by 3600 seconds multiplied by the number of spaces in the block. SFMTA established the desired target occupancy rate for every block at each hour at between $60 \%$ and $80 \%$. Numerous previous studies have evaluated the effectiveness of SFpark (Pierce and Shoup 2013], Millard-Ball et al. [2014]). We would like to apply our matrix completion bandit algorithm on SFpark data, and determine the optimal parking prices for each block in a specific hour, with

Figure 3: Average empirical cumulative regret against $T^{2 / 3}$ for $\gamma=\frac{1}{3}$ (left) and $T^{3 / 4}$ for $\gamma=\frac{1}{4}$ (right) under 100 trails.
the aim of achieving the target occupancy rates for a greater number of blocks and time periods.
We collected the data from https://www.sfmta.com/getting-around/drive-park/demand-responsive-pri sfpark-evaluation. The dataset includes the hourly occupancy rate and price for each block at every hour, covering seven pilot zones and two control zones, across each day throughout the study period from April 2011 to July 2013. The pilot zones implemented a new pricing policy and involved significant data collection, while the control zones had no new policy but still underwent substantial data collection. During the study period, SFMTA executed ten demand-responsive parking price adjustments in the pilot zones, where price for each block at every hour was adjusted gradually and periodically according to the following rules: if the average occupancy rate after last adjustment was between $60 \%$ and $80 \%$, the hourly price would remain unchanged; if the average occupancy rate was larger than $80 \%$, the hourly price would be raised; if the occupancy rate was less than $60 \%$, the hourly price would be lowered. In the following analysis, we will focus on the data from Downtown, which is one of the designated pilot zones, covering the time period from April 1st, 2011, to March 27th, 2012, as an illustrative example. We choose to include only one year of data because the occupancy rate after 2012 can be influenced by confounding factors such as changes in garage policies and overall city traffic developments. During the selected time period, a total of four pricing adjustments occurred on the following dates: August 1st, 2011; October 11th, 2011; December 13th, 2011; and February 14th, 2012. These adjustments allow us to divide the entire time period into five distinct periods for further analysis.

Most parking meters in Downtown are operational from 7 am to 6 pm , and the traffic conditions differ between weekdays and weekends. To capture this variation, we define $d_{2}=22$, representing each hour from 7 am to 6 pm on both weekdays and weekends. Here the action 1 corresponds to a high-price policy, where the hourly price is larger than or equal to $\$ 3.5$. Conversely, action 0
represents a low-price policy, with an hourly price below $\$ 3.5$. We identified $d_{1}=34$ blocks that had at least one hour for both actions during the entire time period. The underlying matrices $M_{1}$ and $M_{0}$ represent the expected deviation of the real occupancy rate from the target range $[0.6,0.8]$ across different blocks and hours, under high price and low price, respectively. For instance, when making a decision for block $j_{1} \in\left[d_{1}\right]$ at hour $j_{2} \in\left[d_{1}\right]$, the contextual matrix can be represented as $X_{t}=e_{j_{1}} e_{j_{2}}^{\top}$. If we further choose $a_{t}=1$ for the high price and observe an occupancy rate of 0.7 , the reward $r_{t}$ would be calculated as $r_{t}=0$; if the actual occupancy rate is 0.5 or 0.9 , then $r_{t}=-0.1$. To simulate the online data collection procedure, we evaluate each observation by comparing the decision made by our algorithm with the actual observed action. If they align, we retain the sample to fit the model and update the online estimators. Otherwise, we discard it and proceed to the next sample. Each hour for every block on each day throughout the entire time period is treated as an observation, resulting in a time horizon $T=105,825$. Given that we have a nearly equal amount of data for each block and hour, we can consider the context $X_{t}$ to be uniformly distributed, meeting our requirements. We set the low rank $r=5$ since $\sum_{k=1}^{5} \lambda_{1, k} / \sum_{k=1}^{22} \lambda_{1, k}=0.843$ and $\sum_{k=1}^{5} \lambda_{0, k} / \sum_{k=1}^{22} \lambda_{0, k}=0.840$, where $\lambda_{1, k}$ and $\lambda_{0, k}$ denote the $k$-th singular values of the roughly estimated $M_{1}$ and $M_{0}$.

We select two representative blocks and conduct statistical inference for their corresponding entries. The first one is the weekday of block 02ND ST 200, and the other is the weekend of block BATTERY ST 400. The average hourly occupancy rates for these blocks across different periods are shown in Figure 4. Clearly, 02ND ST 200 is a crowded block in period 1, with an occupancy rate consistently exceeding $80 \%$, particularly after 12 pm . Throughout all five periods, the SFpark policy maintained high prices for all hours on weekdays for 02ND ST 200, resulting in a noticeable decrease in the occupancy rate due to the sustained high pricing. However, it's important to note from Figure 4 that the occupancy rate usually did not reach $60 \%$ during the early morning hours. The prolonged high prices during these hours further pushed the occupancy rate away from the target range. Conversely, our learned policy suggests implementing low prices before 11 am , which facilitates optimal utilization of parking spaces during these hours. Table 1 indicates that action 0 demonstrates statistical significance at the $95 \%$ confidence level before 12 pm , while action 1 shows statistical significance most of the time after 12 pm . On the other hand, BATTERY ST 400 represents an underutilized block, with an occupancy rate consistently below $60 \%$ on weekends. The SFpark policy began implementing low prices for BATTERY ST 400 starting from period 2, resulting in an increasing trend in the occupancy rate from period 2 to 5 . Our analysis in Table 2 also demonstrates that action 0 exhibits statistical significance for most of the hours during

Figure 4: Average Occupancy Rate of 5 periods in different time of day of Left: Weekday of 02ND ST 200; Right: Weekend of BATTERY ST 400.
weekends, indicating the effectiveness of the price adjustments.

| Time | 7 | 8 | 9 | 10 | 11 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | p-value | 0.282 | 0.016 | 0.009 | 0.002 | 0.304 |
|  |  |  |  |  |  |  |
| Time | 12 | 13 | 14 | 15 | 16 | 17 |
| p-value | $<0.001$ | $<0.001$ | $<0.001$ | 0.773 | $<0.001$ | 0.999 |

Table 1: Top : the p-values of $H_{0}:\left\langle M_{0}-M_{1}, e_{j_{1}} e_{j_{2}}^{\top}\right\rangle \leq 0$ vs $H_{1}:\left\langle M_{0}-M_{1}, e_{j_{1}} e_{j_{2}}^{\top}\right\rangle>0$, where $j_{1}$ denotes block 02ND ST 200 and $j_{2}$ denotes weekday 7 am to 11am; Bottom : the p-values of $H_{0}:\left\langle M_{1}-M_{0}, e_{j_{1}} e_{j_{2}}^{\top}\right\rangle \leq 0$ vs $H_{1}:\left\langle M_{1}-M_{0}, e_{j_{1}} e_{j_{2}}^{\top}\right\rangle>0$, where $j_{1}$ denotes block 02ND ST 200 and $j_{2}$ denotes weekday 12 pm to 17 pm .

Finally, we evaluate the overall performance of matrix completion bandit in comparison to the originally SFpark policy. This time, to generate the online data, we follow the same method as described earlier, keeping the samples where our decision coincides with the actual action. However, in cases where the actual action contradicts our decision, we utilize the occupancy rate of the current block and time with the matching action from the nearest date to fit the model, instead of simply dropping the sample. We only discard a sample when no other samples are available for the same actions at the given block and time.

Figure 5 displays the percentage of all the selected time and blocks that achieved the target occupancy rate in each period under both SFpark policy and matrix completion bandit. Across

| Time | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| p-value | 0.002 | 0.019 | 0.024 | 0.272 | 0.038 | $<0.001$ | 0.010 | 0.002 | 0.003 | $<0.001$ | 0.003 |

Table 2: The p-values of $H_{0}:\left\langle M_{0}-M_{1}, e_{j_{1}} e_{j_{2}}^{\top}\right\rangle \leq 0 \quad$ vs $\quad H_{1}:\left\langle M_{0}-M_{1}, e_{j_{1}} e_{j_{2}}^{\top}\right\rangle>0$, where $j_{1}$ denotes block BATTERY ST 400 and $j_{2}$ denotes weekend 7 am to 17 pm .

Figure 5: Comparison of percentage of blocks and times achieve target occupancy rate over periods under Matrix Completion Bandit and SFpark policy
all time periods, there was an overall improvement in achieving the target occupancy rate. The matrix completion bandit consistently outperformed the original policy, particularly in the first three periods. This is because the original SFpark policy explored too much and may adopt sub-optimal policies in the beginning, sometimes maintaining unsuitable prices for more than one period. In contrast, the matrix completion bandit could adjust the price as soon as it detected that the current policy was not optimal enough.

## Supplement to "Online Policy Learning and Inference by Matrix Completion"

## A Proofs of Main Results

## A. 1 Proof of Theorem 1

Proof. Define event

$$
\begin{aligned}
\mathcal{E}_{t}=\{\forall i \in\{0,1\}, \forall \tau<t & :\left\|\widehat{M}_{i, \tau}-M_{i}\right\|_{\mathrm{F}}^{2} \lesssim \prod_{k=1}^{\tau}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)\left\|\widehat{M}_{i, 0}-M\right\|_{\mathrm{F}}^{2}+\sum_{k=1}^{\tau} \frac{\eta_{k}^{2} r \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}}, \\
\left\|\widehat{M}_{i, \tau}-M_{i}\right\|_{\max }^{2} & \lesssim \prod_{k=1}^{\tau}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\operatorname{poly}(\mu, r, \kappa) \lambda_{\min }^{2}}{d_{1} d_{2}}+\sum_{k=1}^{\tau} \frac{\eta_{k}^{2} \operatorname{poly}(\mu, r, \kappa) \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{1} d_{2}^{2}}, \\
& \left.\left\|e_{l}^{\top} \widehat{U}_{i, \tau} \widehat{V}_{i, \tau}^{\top}\right\|^{2} \leq \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{1}},\left\|e_{j}^{\top} \widehat{V}_{i, \tau} \widehat{U}_{i, \tau}^{\top}\right\|^{2} \leq \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}}, \quad \forall l \in\left[d_{1}\right], j \in\left[d_{2}\right]\right\},
\end{aligned}
$$

where $f\left(\eta_{k}\right)=\frac{\eta_{k} \lambda_{\min }}{d_{1} d_{2}}$ and $\mu_{0}=100 \mu$.
Recall in Algorithm 1, at each step, we update $\widetilde{U}_{i, t}$ and $\widetilde{V}_{i, t}$ by

$$
\begin{aligned}
& \widetilde{U}_{i, t}=\widehat{U}_{i, t-1}-\frac{\mathbb{1}\left(a_{t}=i\right)}{i \pi_{t}+(1-i)\left(1-\pi_{t}\right)} \eta_{t}\left(\left\langle\widehat{U}_{i, t-1} \widehat{V}_{i, t-1}^{\top}, X_{t}\right\rangle-r_{t}\right) X_{t} \widehat{V}_{i, t-1}, \\
& \widetilde{V}_{i, t}=\widehat{V}_{i, t-1}-\frac{\mathbb{1}\left(a_{t}=i\right)}{i \pi_{t}+(1-i)\left(1-\pi_{t}\right)} \eta_{t}\left(\left\langle\widehat{U}_{i, t-1} \widehat{V}_{i, t-1}^{\top}, X_{t}\right\rangle-r_{t}\right) X_{t}^{\top} \widehat{U}_{i, t-1} .
\end{aligned}
$$

Then

$$
\begin{aligned}
\widehat{U}_{i, t} \widehat{V}_{i, t}^{\top}= & \widetilde{U}_{i, t} \widetilde{V}_{i, t}^{\top}=\widehat{U}_{i, t-1} \widehat{V}_{i, t-1}^{\top}-\frac{\mathbb{1}\left(a_{t}=i\right)}{i \pi_{t}+(1-i)\left(1-\pi_{t}\right)} \eta_{t}\left(\left\langle U_{i, t-1} V_{i, t-1}^{\top}, X_{t}\right\rangle-y_{t}\right) X_{t} \widehat{V}_{i, t-1} \widehat{V}_{i, t-1}^{\top} \\
& -\frac{\mathbb{1}\left(a_{t}=i\right)}{i \pi_{t}+(1-i)\left(1-\pi_{t}\right)} \eta_{t}\left(\left\langle\widehat{U}_{i, t-1} \widehat{V}_{i, t-1}^{\top}, X_{t}\right\rangle-r_{t}\right) \widehat{U}_{i, t-1} \widehat{U}_{i, t-1}^{\top} X_{t} \\
& +\frac{\mathbb{1}\left(a_{t}=i\right)}{i \pi_{t}^{2}+(1-i)\left(1-\pi_{t}\right)^{2}} \eta_{t}^{2}\left(\left\langle\widehat{U}_{i, t-1} \widehat{V}_{i, t-1}^{\top}, X_{t}\right\rangle-r_{t}\right)^{2} X_{t} \widehat{V}_{i, t-1} \widehat{U}_{i, t-1}^{\top} X_{t} .
\end{aligned}
$$

Without loss of generality, in the rest of the proof, we only consider $i=1$ and omit the subscript $i$, then $i=0$ case can be proved similarly. Let

$$
\begin{aligned}
\Delta_{t}= & \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}} \eta_{t}\left(\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M, X_{t}\right\rangle-\xi_{t}\right) X_{t} \widehat{V}_{t-1} \widehat{V}_{t-1}^{\top} \\
& +\frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}} \eta_{t}\left(\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M, X_{t}\right\rangle-\xi_{t}\right) \widehat{U}_{t-1} \widehat{U}_{t-1}^{\top} X_{t} \\
& -\frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}^{2}} \eta_{t}^{2}\left(\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M, X_{t}\right\rangle-\xi_{t}\right)^{2} X_{t} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} X_{t},
\end{aligned}
$$

where $\pi_{t}=\mathbb{P}\left(a_{t}=1 \mid X_{t}, \mathcal{F}_{t-1}\right)$. In the following steps, we prove that if event $\mathcal{E}_{t-1}$ happens, event $\mathcal{E}_{t}$ will happen with high probability.
step 1: bounding $\left\|\widehat{U}_{t} \widehat{V}_{t}^{\top}-M\right\|_{F}^{2}$
We have $\widehat{U}_{t} \widehat{V}_{t}=\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-\Delta_{t}$ and

$$
\mathbb{E}\left[\left\|\widehat{U}_{t} \widehat{V}_{t}^{\top}-M\right\|_{\mathrm{F}}^{2} \mid \mathcal{F}_{t-1}\right]=\left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\|_{\mathrm{F}}^{2}-2\left\langle\mathbb{E}\left[\Delta_{t} \mid \mathcal{F}_{t-1}\right], \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\rangle+\mathbb{E}\left[\left\|\Delta_{t}\right\|_{\mathrm{F}}^{2} \mid \mathcal{F}_{t-1}\right] .
$$

We first compute $2\left\langle\mathbb{E}\left[\Delta_{t} \mid \mathcal{F}_{t-1}\right], \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\rangle$,

$$
\begin{aligned}
& 2\left\langle\mathbb{E}\left[\Delta_{t} \mid \mathcal{F}_{t-1}\right], \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\rangle=\frac{2 \eta_{t}}{d_{1} d_{2}}\left(\left\|\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right) \widehat{V}_{t-1}\right\|_{\mathrm{F}}^{2}+\left\|\widehat{U}_{t-1}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)\right\|_{\mathrm{F}}^{2}\right) \\
& \quad-2 \eta_{t}^{2} \mathbb{E}\left[\frac { \mathbb { 1 } ( a _ { t } = 1 ) } { \pi _ { t } ^ { 2 } } \left(\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M, X_{t}\right\rangle^{2}\left\langle X_{t} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} X_{t}, \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\rangle\right.\right. \\
& \left.\left.\quad+\xi_{t}^{2}\left\langle X_{t} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} X_{t}, \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\rangle\right) \mid \mathcal{F}_{t-1}\right] \\
& \geq \frac{\eta_{t} \lambda_{\min }}{d_{1} d_{2}}\left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\|_{\mathrm{F}}^{2} \\
& \quad-\frac{4 \eta_{t}^{2}}{\varepsilon_{t}}\left\|\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top}\right\|_{\max }\left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\|_{\max }\left(\frac{1}{d_{1} d_{2}}\left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\|_{\mathrm{F}}^{2}+\sigma^{2}\right)
\end{aligned}
$$

It is clear to see that $\left\|\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right) \widehat{V}_{t-1}\right\|_{\mathrm{F}}^{2}+\left\|\widehat{U}_{t-1}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)\right\|_{\mathrm{F}}^{2} \geq \frac{\lambda_{\text {min }}}{2}\left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\|_{\mathrm{F}}^{2}$, and we apply $\frac{1}{\pi_{t}} \leq \frac{2}{\varepsilon_{t}}$ in the latter term. Applying the incoherence property of $\widehat{U}_{t-1}, \widehat{V}_{t-1}, U$ and $V$ and Cauchy Schwarz inequality, $\left\|\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top}\right\|_{\max }=O\left(\frac{\mu_{0} r \lambda_{\max }}{\sqrt{d_{1} d_{2}}}\right)$ and $\left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\|_{\max } \leq \frac{2 \mu_{0} r \lambda_{\max }}{\sqrt{d_{1} d_{2}}}$ under event $\mathcal{E}_{t-1}$. Therefore,

$$
\begin{aligned}
2\left\langle\mathbb{E}\left[\Delta_{t} \mid \mathcal{F}_{t-1}\right], \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\rangle \geq & \frac{\eta_{t} \lambda_{\min }}{d_{1} d_{2}}\left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\|_{\mathrm{F}}^{2} \\
& -\frac{8 \eta_{t}^{2}}{\varepsilon_{t}} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{1} d_{2}}\left(\frac{1}{d_{1} d_{2}}\left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\|_{\mathrm{F}}^{2}+\sigma^{2}\right)
\end{aligned}
$$

Then we compute $\mathbb{E}\left[\left\|\Delta_{t}\right\|_{\mathrm{F}}^{2} \mid \mathcal{F}_{t-1}\right]$. Since $(a+b+c)^{2} \leq 3\left(a^{2}+b^{2}+c^{2}\right)$,

$$
\begin{aligned}
& \mathbb{E}\left[\left\|\Delta_{t}\right\|_{\mathrm{F}}^{2} \mid \mathcal{F}_{t-1}\right] \leq 3 \mathbb{E}\left[\left.\frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}^{2}} \eta_{t}^{2}\left(\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M, X_{t}\right\rangle-\xi_{t}\right)^{2}\left\|X_{t} \widehat{V}_{t-1} \widehat{V}_{t-1}^{\top}\right\|_{\mathrm{F}}^{2} \right\rvert\, \mathcal{F}_{t-1}\right] \\
& \quad+3 \mathbb{E}\left[\left.\frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}^{2}} \eta_{t}^{2}\left(\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M, X_{t}\right\rangle-\xi_{t}\right)^{2}\left\|\widehat{U}_{t-1} \widehat{U}_{t-1}^{\top} X_{t}\right\|_{\mathrm{F}}^{2} \right\rvert\, \mathcal{F}_{t-1}\right] \\
& \quad+3 \mathbb{E}\left[\left.\frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}^{4}} \eta_{t}^{4}\left(\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M, X_{t}\right\rangle-\xi_{t}\right)^{4}\left\|X_{t} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} X_{t}\right\|_{\mathrm{F}}^{2} \right\rvert\, \mathcal{F}_{t-1}\right] .
\end{aligned}
$$

For the first expectation, we have

$$
\begin{aligned}
& \mathbb{E}\left[\left.\frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}^{2}} \eta_{t}^{2}\left(\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M, X_{t}\right\rangle-\xi_{t}\right)^{2}\left\|X_{t} \widehat{V}_{t-1} \widehat{V}_{t-1}^{\top}\right\|_{\mathrm{F}}^{2} \right\rvert\, \mathcal{F}_{t-1}\right] \\
\leq & \frac{2 \eta_{t}^{2}}{\varepsilon_{t}}\left(\mathbb{E}\left[\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M, X_{t}\right\rangle^{2} \mid \mathcal{F}_{t-1}\right]\left\|\widehat{V}_{t-1} \widehat{V}_{t-1}^{\top}\right\|_{2, \text { max }}^{2}+\mathbb{E}\left[\xi_{t}^{2}\right] \mathbb{E}\left[\left\|X_{t} \widehat{V}_{t-1} \widehat{V}_{t-1}^{\top}\right\|_{\mathrm{F}}^{2} \mid \mathcal{F}_{t-1}\right]\right) \\
\leq & \frac{2 \eta_{t}^{2}}{\varepsilon_{t}}\left(\frac{1}{d_{1} d_{2}}\left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\|_{\mathrm{F}}^{2} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}}+\sigma^{2} \frac{1}{d_{2}}\left\|\widehat{V}_{t-1} \widehat{V}_{t-1}^{\top}\right\|_{\mathrm{F}}^{2}\right) \\
\leq & \frac{2 \eta_{t}^{2}}{\varepsilon_{t} d_{1} d_{2}}\left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\|_{\mathrm{F}}^{2} \frac{\mu_{0} r \lambda_{\text {max }}^{2}}{d_{2}}+\frac{2 \eta_{t}^{2} r \sigma^{2}}{\varepsilon_{t} d_{2}} O\left(\lambda_{\text {max }}^{2}\right) .
\end{aligned}
$$

The last inequality holds since $\left\|\widehat{V}_{t-1} \widehat{V}_{t-1}^{\top}\right\|_{\mathrm{F}}^{2} \leq r\left\|\widehat{V}_{t-1} \widehat{V}_{t-1}^{\top}\right\|^{2}$ and $\left\|\widehat{V}_{t-1} \widehat{V}_{t-1}^{\top}\right\|^{2}=O\left(\lambda_{\max }^{2}\right)$. By symmetry, $\mathbb{E}\left[\left.\frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}^{2}} \eta_{t}^{2}\left(\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M, X_{t}\right\rangle-\xi_{t}\right)^{2}\left\|\widehat{U}_{t-1} \widehat{U}_{t-1}^{\top} X_{t}\right\|_{\mathrm{F}}^{2} \right\rvert\, \mathcal{F}_{t-1}\right] \leq \frac{2 \eta_{t}^{2}}{\varepsilon_{t} d_{1} d_{2}} \| \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-$ $M \|_{\mathrm{F}}^{2} \frac{\mu_{0} r \lambda_{\text {max }}^{2}}{d_{1}}+\frac{2 \eta_{\eta}^{2} r \sigma^{2}}{\varepsilon_{t} d_{1}} O\left(\lambda_{\text {max }}^{2}\right)$. Similarly, the last expectation can be written as

$$
\begin{aligned}
& \mathbb{E}\left[\left.\frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}^{4}} \eta_{t}^{4}\left(\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M, X_{t}\right\rangle-\xi_{t}\right)^{4}\left\|X_{t} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} X_{t}\right\|_{\mathrm{F}}^{2} \right\rvert\, \mathcal{F}_{t-1}\right] \\
\leq & \frac{8 \eta_{t}^{4}}{\varepsilon_{t}^{3}}\left(\mathbb{E}\left[\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M, X_{t}\right\rangle^{4} \mid \mathcal{F}_{t-1}\right]\left\|\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top}\right\|_{\max }^{2}+\mathbb{E}\left(\xi_{t}^{4}\right)\left\|\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top}\right\|_{\max }^{2}\right) \\
\lesssim & \frac{\eta_{t}^{4}}{\varepsilon_{t}^{3}}\left(\frac{1}{d_{1} d_{2}}\left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\|_{\max }^{2} \sum\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)_{i j}^{2}\right) \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{1} d_{2}}+\frac{\eta_{t}^{4} \sigma^{4}}{\varepsilon_{t}^{3}} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{1} d_{2}} \\
\lesssim & \frac{\eta_{t}^{4}}{\varepsilon_{t}^{3}} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{4}}{d_{1}^{3} d_{2}^{3}}\left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\|_{\mathrm{F}}^{2}+\frac{\eta_{t}^{4} \sigma^{4}}{\varepsilon_{t}^{3}} \frac{\mu_{0}^{2} r^{2} \lambda_{\text {max }}^{2}}{d_{1} d_{2}} .
\end{aligned}
$$

As long as $\eta_{t} \lesssim \frac{\varepsilon_{t} d_{1} d_{2}^{1 / 2}}{\sqrt{\mu_{0} r \lambda_{\text {max }}}}$ and $\frac{\lambda_{\text {min }}^{2}}{\sigma^{2}} \gg \frac{\eta_{t}^{2}}{\varepsilon_{t}^{2}} \frac{\lambda_{\text {max }}^{2}}{d_{1} r \kappa^{2}}$, the second order terms of $\eta_{t}$ above will dominate the fourth order terms. Above all, for some positive constants $c_{1}$ and $c_{2}$,

$$
\begin{aligned}
& -2 \mathbb{E}\left(\left\langle\Delta_{t}, \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\rangle \mid \mathcal{F}_{t-1}\right)+\mathbb{E}\left(\left\|\Delta_{t}\right\|_{\mathrm{F}}^{2} \mid \mathcal{F}_{t-1}\right) \\
\leq & \left(-\frac{\eta_{t} \lambda_{\min }}{d_{1} d_{2}}+\frac{c_{1} \eta_{t}^{2} \mu_{0} r \lambda_{\max }^{2}}{\varepsilon_{t} d_{1} d_{2}^{2}}\right)\left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\|_{\mathrm{F}}^{2}+\frac{c_{2} \eta_{t}^{2} r \lambda_{\max }^{2} \sigma^{2}}{\varepsilon_{t} d_{2}} \\
\leq & -f\left(\eta_{t}\right)\left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\|_{\mathrm{F}}^{2}+\frac{c_{2} \eta_{t}^{2} r \lambda_{\max }^{2} \sigma^{2}}{\varepsilon_{t} d_{2}},
\end{aligned}
$$

where $f\left(\eta_{t}\right)=\frac{\eta_{t} \lambda_{\text {min }}}{2 d_{1} d_{2}}$. The second order term $\frac{c_{1} \eta_{t_{2}}^{2} \mu_{0} r \lambda_{\text {max }}^{2}}{\varepsilon_{t} d_{1} d_{2}^{2}}$ is dominated as long as $\eta_{t} \lesssim \frac{\varepsilon_{t} d_{2}}{\mu_{0} r \kappa \lambda_{\text {max }}}$. Next, we use telescoping to derive the relationship between $\left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\|_{\mathrm{F}}^{2}$ and $\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}$.

Notice that,

$$
\begin{aligned}
\left\|\widehat{U}_{t} \widehat{V}_{t}^{\top}-M\right\|_{\mathrm{F}}^{2}= & \left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-\Delta_{t}-M\right\|_{\mathrm{F}}^{2}=\left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\|_{\mathrm{F}}^{2}-2\left\langle\Delta_{t}, \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\rangle+\left\|\Delta_{t}\right\|_{\mathrm{F}}^{2} \\
= & \left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\|_{\mathrm{F}}^{2}-2\left(\left\langle\Delta_{t}, \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\rangle-\mathbb{E}\left(\left\langle\Delta_{t}, \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\rangle \mid \mathcal{F}_{t-1}\right)\right) \\
& +\left(\left\|\Delta_{t}\right\|_{\mathrm{F}}^{2}-\mathbb{E}\left(\left\|\Delta_{t}\right\|_{\mathrm{F}}^{2} \mid \mathcal{F}_{t-1}\right)\right)-2 \mathbb{E}\left(\left\langle\Delta_{t}, \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\rangle \mid \mathcal{F}_{t-1}\right)+\mathbb{E}\left(\left\|\Delta_{t}\right\|_{\mathrm{F}}^{2} \mid \mathcal{F}_{t-1}\right) \\
\leq & \left(1-f\left(\eta_{t}\right)\right)\left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\|_{\mathrm{F}}^{2}+\frac{c_{2} \eta_{t}^{2} r \lambda_{\max }^{2} \sigma^{2}}{\varepsilon_{t} d_{2}} \\
& +\underbrace{2\left(\mathbb{E}\left(\left\langle\Delta_{t}, \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\rangle \mid \mathcal{F}_{t-1}\right)-\left\langle\Delta_{t}, \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\rangle\right)}_{A_{t}}+\underbrace{\left(\left\|\Delta_{t}\right\|_{\mathrm{F}}^{2}-\mathbb{E}\left(\left\|\Delta_{t}\right\|_{\mathrm{F}}^{2} \mid \mathcal{F}_{t-1}\right)\right)}_{B_{t}} \\
= & \left(1-f\left(\eta_{t}\right)\right)\left(1-f\left(\eta_{t-1}\right)\right)\left\|\widehat{U}_{t-2} \widehat{V}_{t-2}^{\top}-M\right\|_{\mathrm{F}}^{2}+\frac{c_{2} \eta_{t}^{2} r \lambda_{\max }^{2} \sigma^{2}}{\varepsilon_{t} d_{2}}+\left(1-f\left(\eta_{t}\right)\right) \frac{c_{2} \eta_{t-1}^{2} r \lambda_{\max }^{2} \sigma^{2}}{\varepsilon_{t-1} d_{2}} \\
& +\left(1-f\left(\eta_{t}\right)\right)\left(A_{t-1}+B_{t-1}\right)+\left(A_{t}+B_{t}\right) \\
= & \prod_{k=1}^{t}\left(1-f\left(\eta_{k}\right)\right)\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}+\sum_{\tau=1}^{t-1} \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) \frac{c_{2} \eta_{\tau}^{2} r \lambda_{\max }^{2} \sigma^{2}}{\varepsilon_{\tau} d_{2}}+\frac{c_{2} \eta_{t}^{2} r \lambda_{\max }^{2} \sigma^{2}}{\varepsilon_{t} d_{2}} \\
& +\sum_{\tau=1}^{t-1} \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) A_{\tau}+\sum_{\tau=1}^{t} \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) B_{\tau}+A_{t}+B_{t} \\
\leq & \prod_{k=1}^{t}\left(1-f\left(\eta_{k}\right)\right)\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}+\sum_{k=1}^{t} \frac{c_{2} \eta_{k}^{2} r \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}} \\
& +\sum_{\tau=1}^{t-1} \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) A_{\tau}+\sum_{\tau=1}^{t-1} \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) B_{\tau}+A_{t}+B_{t} .
\end{aligned}
$$

In Lemma 1. we show $\sum_{\tau=1}^{t-1} \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) A_{\tau}+A_{t}$ and $\sum_{\tau=1}^{t} \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) B_{\tau}+B_{t}$ will be dominated.

Lemma 1. For any $1 \leq t \leq T$, under the conditions in Theorem 1 and event $\mathcal{E}_{t-1}$, with probability at least $1-t d_{1}^{-200}$,

$$
\begin{aligned}
& \sum_{\tau=1}^{t-1} \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) A_{\tau}+A_{t} \lesssim \gamma \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}+\gamma \sum_{k=1}^{t} \frac{\eta_{k}^{2} r \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}} \\
& \sum_{\tau=1}^{t-1} \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) B_{\tau}+B_{t} \lesssim \gamma \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}+\gamma \sum_{k=1}^{t} \frac{\eta_{k}^{2} r \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}}
\end{aligned}
$$

Combine with the union bound, with probability at least $1-t d_{1}^{-200}$,

$$
\left\|U_{t} V_{t}^{\top}-M\right\|_{\mathrm{F}}^{2} \lesssim \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)\left\|U_{0} V_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} r \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}}
$$

## step2: Incoherence

In Lemma 2, we prove the incoherence property holds true for every $U_{t}$ and $V_{t}$.
Lemma 2. For any $1 \leq t \leq T$, under the conditions in Theorem 1 and event $\mathcal{E}_{t-1}$, with probability at least $1-t d_{1}^{-200}$,

$$
\left\|e_{l}^{\top} \widehat{U}_{i, \tau} \widehat{V}_{i, \tau}^{\top}\right\|^{2} \leq \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{1}} \quad\left\|e_{j}^{\top} \widehat{V}_{i, \tau} \widehat{U}_{i, \tau}^{\top}\right\|^{2} \leq \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}}, \quad \forall l \in\left[d_{1}\right], j \in\left[d_{2}\right]
$$

where $\mu_{0}=100 \mu$.
step3: Bounding $\left\|\widehat{U}_{t} \widehat{V}_{t}^{\top}-M\right\|_{\max }^{2}$
In order to bound $\left\|\widehat{U}_{t} \widehat{V}_{t}^{\top}-M\right\|_{\text {max }}^{2}$, we need to bound $\left\|e_{l}^{\top}\left(\widehat{U}_{t} \widehat{V}_{t}^{\top}-M\right)\right\|^{2}$ and $\left\|e_{j}^{\top}\left(\widehat{V}_{t} \widehat{U}_{t}^{\top}-M^{\top}\right)\right\|^{2}$ for any $l \in\left[d_{1}\right], j \in\left[d_{2}\right]$ first.

Lemma 3. For any $1 \leq t \leq T$, under the conditions in Theorem 1 and event $\mathcal{E}_{t-1}$, with probability at least $1-d_{1}^{-200}$,

$$
\begin{aligned}
& \left\|e_{l}^{\top}\left(\widehat{U}_{t} \widehat{V}_{t}^{\top}-M\right)\right\|^{2} \lesssim \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{p o l y(\mu, r, \kappa) \lambda_{\min }^{2}}{d_{1}}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} p o l y(\kappa, \mu, r) \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{1} d_{2}}, \\
& \left\|e_{j}^{\top}\left(\widehat{V}_{t} \widehat{U}_{t}^{\top}-M^{\top}\right)\right\|^{2} \lesssim \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{p o l y(\mu, r, \kappa) \lambda_{\min }^{2}}{d_{2}}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} p o l y(\kappa, \mu, r) \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}^{2}}
\end{aligned}
$$

for $\forall l \in\left[d_{1}\right], j \in\left[d_{2}\right]$.
Now we are ready to prove the upper bound for $\left\|\widehat{U}_{t} \widehat{V}_{t}^{\top}-M\right\|_{\text {max }}^{2}$. For simplicity, denote $\widehat{M}_{t}=\widehat{U}_{t} \widehat{V}_{t}^{\top}$ .The SVD of $\widehat{M}_{t}$ and $M$ are $M_{t}=\widehat{L}_{t} \widehat{\Lambda}_{t} \widehat{R}_{t}$ and $M=L \Lambda R$, respectively. Then, $\widehat{M}_{t}-M$ can be written as

$$
\begin{aligned}
\widehat{M}_{t}-M & =\widehat{L}_{t} \widehat{L}_{t}^{\top} \widehat{M}_{t} \widehat{R}_{t} \widehat{R}_{t}^{\top}-L L^{\top} M R R^{\top} \\
& =\widehat{L}_{t} \widehat{L}_{t}^{\top}\left(\widehat{M}_{t}-M\right) \widehat{R}_{t} \widehat{R}_{t}^{\top}+\left(\widehat{L}_{t} \widehat{L}_{t}^{\top}-L L^{\top}\right) M \widehat{R}_{t} \widehat{R}_{t}^{\top}+L L^{\top} M\left(\widehat{R}_{t} \widehat{R}_{t}^{\top}-R R^{\top}\right)
\end{aligned}
$$

As a result, for any $l \in\left[d_{1}\right], j \in\left[d_{2}\right], e_{l}^{\top}\left(M_{t}-M\right) e_{j}$ can be decomposed as

$$
\begin{aligned}
\left\|e_{l}^{\top}\left(\widehat{M}_{t}-M\right) e_{j}\right\|^{2} \lesssim & \underbrace{\left\|e_{l}^{\top} \widehat{L}_{t} \widehat{L}_{t}^{\top}\left(\widehat{M}_{t}-M\right) \widehat{R}_{t} \widehat{R}_{t}^{\top} e_{j}\right\|^{2}}_{I}+\underbrace{\left\|e_{l}^{\top}\left(\widehat{L}_{t} \widehat{L}_{t}^{\top}-L L^{\top}\right) M \widehat{R}_{t} \widehat{R}_{t}^{\top} e_{j}\right\|^{2}}_{I I} \\
& +\underbrace{\left\|e_{l}^{\top} L L^{\top} M\left(\widehat{R}_{t} \widehat{R}_{t}^{\top}-R R^{\top}\right) e_{j}\right\|^{2}}_{I I I} .
\end{aligned}
$$

Term $I$ can be bounded in the following way,

$$
\begin{aligned}
I & \leq\left\|e_{l}^{\top} \widehat{L}_{t} \widehat{L}_{t}^{\top}\right\|^{2}\left\|M_{t}-M\right\|_{\mathrm{F}}^{2}\left\|\widehat{R}_{t} \widehat{R}_{t}^{\top} e_{j}\right\|^{2} \\
& \lesssim \frac{\mu_{0} r}{d_{1}}\left(\prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)\left\|\widehat{M}_{0}-M\right\|_{\mathrm{F}}^{2}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} r \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}}\right) \frac{\mu_{0} r}{d_{2}} \\
& \lesssim \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\mu_{0}^{2} r^{2}\left\|\widehat{M}_{0}-M\right\|_{\mathrm{F}}^{2}}{d_{1} d_{2}}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} \mu_{0}^{2} r^{3} \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{1} d_{2}^{2}} \\
& \lesssim \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\mu_{0}^{2} r^{2} \lambda_{\min }^{2}}{d_{1} d_{2}}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} \mu_{0}^{2} r^{3} \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{1} d_{2}^{2}} .
\end{aligned}
$$

The last inequality holds since $\left\|\widehat{M}_{0}-M\right\|_{\mathrm{F}}^{2} \lesssim \lambda_{\text {min }}^{2}$. Next, we look at Term II. Let $O_{\widehat{L}_{t}}=$ $\arg \min _{O \in \mathbb{O}_{r}}\left\|\widehat{L}_{t}-L O\right\|$, where $\mathbb{O}_{r}$ denotes the set of all $r \times r$ real matrices with orthonormal columns, then

$$
I I \lesssim\left\|e_{l}^{\top}\left(\widehat{L}_{t}-L O_{\widehat{L}_{t}}\right) \widehat{L}_{t}^{\top} M \widehat{R}_{t} \widehat{R}_{t}^{\top} e_{j}\right\|^{2}+\left\|e_{l}^{\top} L O_{\widehat{L}_{t}}\left(\widehat{L}_{t}^{\top}-O_{\widehat{L}_{t}}^{\top} L^{\top}\right) M \widehat{R}_{t} \widehat{R}_{t}^{\top} e_{j}\right\|^{2} .
$$

The second part can be bounded by,

$$
\begin{aligned}
\left\|e_{l}^{\top} L O_{\widehat{L}_{t}}\left(\widehat{L}_{t}^{\top}-O_{\widehat{L}_{t}}^{\top} L^{\top}\right) M \widehat{R}_{t} \widehat{R}_{t}^{\top} e_{j}\right\|^{2} & \leq\left\|e_{l}^{\top} L O_{\widehat{L_{t}}}\right\|^{2}\left\|\widehat{L}_{t}^{\top}-O_{\widehat{L}_{t}}^{\top} L^{\top}\right\|^{2}\left\|M \widehat{R}_{t} \widehat{R}_{t}^{\top} e_{j}\right\|^{2} \\
& \leq \frac{\mu r}{d_{1}}\left\|\widehat{L}_{t}^{\top}-O_{\widehat{L}_{t}}^{\top} L^{\top}\right\|^{2} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}},
\end{aligned}
$$

where we use the incoherence property and the consistency of matrix norm and vector norm. By Wedin's $\sin \Theta$ Theorem (Davis and Kahan 1970, Wedin 1972),

$$
\begin{aligned}
\left\|\widehat{L}_{t}^{\top}-O_{\widehat{L}_{t}}^{\top} L^{\top}\right\|^{2} & \leq \frac{4\left\|\widehat{M}_{t}-M\right\|_{\mathrm{F}}^{2}}{\lambda_{\min }^{2}} \\
& \lesssim \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\left\|\widehat{M}_{0}-M\right\|_{\mathrm{F}}^{2}}{\lambda_{\min }^{2}}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} r \kappa^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}} \\
& \lesssim \gamma \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)+\gamma \sum_{k=1}^{t} \frac{\eta_{k}^{2} r \kappa^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}}
\end{aligned}
$$

The first part can be bounded by the upper bound of $\left\|e_{l}^{\top}\left(\widehat{U}_{t} \widehat{V}_{t}^{\top}-M\right)\right\|^{2}$ we have obtained in Lemma 3 .

$$
\begin{aligned}
\left\|e_{l}^{\top}\left(\widehat{L}_{t}-L O_{\widehat{L}_{t}}\right) L_{t}^{\top} M \widehat{R}_{t} \widehat{R}_{t}^{\top} e_{j}\right\|^{2} & \leq\left\|e_{i}^{\top}\left(\widehat{L}_{t}-L O_{\widehat{L}_{t}}\right)\right\|^{2}\left\|\widehat{L}_{t}^{\top} M\right\|^{2}\left\|\widehat{R}_{t} \widehat{R}_{t}^{\top} e_{j}\right\|^{2} \\
& \leq\left\|e_{i}^{\top}\left(\widehat{L}_{t}-L O_{\widehat{L}_{t}}\right)\right\|^{2} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}} .
\end{aligned}
$$

By Theorem3.7 in Cape et al. 2019 and Wedin's $\sin \Theta$ Theorem again,

$$
\begin{aligned}
\left\|e_{l}^{\top}\left(\widehat{L}_{t}-L O_{\widehat{L}_{t}}\right)\right\| & \leq 4 \frac{\left\|\left(I-L L^{\top}\right)\left(\widehat{M}_{t}-M\right)\right\|_{2, \max }}{\lambda_{\min }}+\left\|\sin \Theta\left(\widehat{L}_{t}, L\right)\right\|^{2}\|L\|_{2, \max } \\
& \leq 4 \frac{\left\|\widehat{M}_{t}-M\right\|_{2, \max }+\left\|L L^{\top}\right\|\left\|\widehat{M}_{t}-M\right\|_{2, \max }}{\lambda_{\min }}+\left\|\sin \Theta\left(\widehat{L}_{t}, L\right)\right\|^{2} \sqrt{\frac{\mu r}{d_{1}}} \\
& \leq 8 \frac{\left\|\widehat{M}_{t}-M\right\|_{2, \max }}{\lambda_{\min }}+2 \frac{\left\|\widehat{M}_{t}-M\right\|_{\mathrm{F}}}{\lambda_{\min }} \sqrt{\frac{\mu r}{d_{1}}}
\end{aligned}
$$

Then

$$
\begin{aligned}
\left\|e_{i}^{\top}\left(\widehat{L}_{t}-L O_{\widehat{L}_{t}}\right)\right\|^{2} & \lesssim \frac{\left\|\widehat{M}_{t}-M\right\|_{2, \max }^{2}}{\lambda_{\min }^{2}}+\frac{\left\|\widehat{M}_{t}-M\right\|_{\mathrm{F}}^{2}}{\lambda_{\min }^{2}} \frac{\mu r}{d_{1}} \\
& \lesssim \prod_{k=t}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\operatorname{poly}(\mu, r, \kappa)}{d_{1}}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} \sigma^{2} \log ^{2} d_{1} \operatorname{poly}(\mu, r, \kappa)}{\varepsilon_{k} d_{1} d_{2}}
\end{aligned}
$$

Above all,

$$
I I \lesssim \prod_{k=t}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\operatorname{poly}(\mu, r, \kappa) \lambda_{\min }^{2}}{d_{1} d_{2}}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1} \operatorname{poly}(\mu, r, \kappa)}{\varepsilon_{k} d_{1} d_{2}^{2}}
$$

By symmetry, following the same arguments, III will also have the same upper bound.
Combine the above three terms together as well as the union bound, we can conclude that with probability at least $1-8 t d_{1}^{-200}$,

$$
\left\|\widehat{M}_{t}-M\right\|_{\max }^{2} \lesssim \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\operatorname{poly}(\mu, r, \kappa) \lambda_{\min }^{2}}{d_{1} d_{2}}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} \operatorname{poly}(\mu, r, \kappa) \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{1} d_{2}^{2}}
$$

## A. 2 Proof of Corollary 1

Here we prove the upper bound of $\left\|\widehat{M}_{i, t}-M_{i}\right\|_{\mathrm{F}}^{2}$ for all $1 \leq t \leq T$, and the entrywise error bound can be derived following the same arguments. According to the result in Theorem 1, when $1 \leq t \leq T_{0}=C_{0} T^{1-\gamma}, \eta_{t}=\eta=\frac{c_{1} d_{1} d_{2} \log d_{1}}{T^{1-\gamma} \lambda_{\max }^{2}}$ and $\varepsilon_{t}=\varepsilon$. Then

$$
\begin{aligned}
\left\|\widehat{M}_{i, t}-M_{i}\right\|_{\mathrm{F}}^{2} & \lesssim\left\|\widehat{M}_{i, 0}-M_{i}\right\|_{\mathrm{F}}^{2} \prod_{\tau=1}^{t}\left(1-\frac{c_{1} \log d_{1}}{4 \kappa T^{1-\gamma}}\right)+\sigma_{i}^{2} \frac{r \log ^{2} d_{1}}{d_{2}} \frac{t c_{1}^{2} d_{1}^{2} d_{2}^{2} \log ^{2} d_{1}}{T^{2(1-\gamma) \varepsilon}} \\
& \lesssim\left\|\widehat{M}_{i, 0}-M_{i}\right\|_{\mathrm{F}}^{2}\left(1-\frac{c_{1} \log d_{1}}{\left.4 \kappa T^{1-\gamma}\right)^{t}+\frac{t r d_{1}^{2} d_{2} \log ^{4} d_{1}}{T^{2(1-\gamma)}}} .\right.
\end{aligned}
$$

When $T_{0}+1 \leq t \leq T, \varepsilon_{t}=c_{2} t^{-\gamma}$ and $\eta_{t}=\varepsilon_{t} \eta$. Note that the contraction term becomes $\left(1-\frac{c_{1} \log d_{1}}{4 \kappa T^{1-\gamma}}\right)^{T_{0}} \prod_{\tau=T_{0}+1}^{t}\left(1-\frac{c_{1} c_{2} \varepsilon t \log d_{1}}{4 \kappa T^{1-\gamma}}\right) \leq\left(1-\frac{c_{1} \log d_{1}}{4 \kappa T^{1-\gamma}}\right)^{C_{0} T^{1-\gamma}}=O\left(d_{1}^{-C_{0} c_{1} / 5 \kappa}\right)$. Since $C_{0}$ can be
sufficiently large, $O\left(d_{1}^{-C_{0} c_{1} / 4 \kappa}\right)$ can be small enough to make the first computational error term dominated by the second statistical error term. Therefore,

$$
\begin{equation*}
\left\|\widehat{M}_{i, t}-M_{i}\right\|_{\mathrm{F}}^{2} \lesssim \sigma_{i}^{2} r d_{1}^{2} d_{2} \log ^{4} d_{1} \frac{T^{1-\gamma}+\sum_{\tau=T_{0}+1}^{t} \tau^{-\gamma}}{T^{2(1-\gamma)}} \lesssim \frac{\sigma_{i}^{2} r d_{1}^{2} d_{2} \log ^{4} d_{1}}{T^{1-\gamma}} \tag{12}
\end{equation*}
$$

where the second inequality comes from the fact that $\sum_{\tau=T_{0}+1}^{t} \tau^{-\gamma} \leq \sum_{\tau=1}^{t} \tau^{-\gamma}=O\left(t^{1-\gamma}\right) \leq$ $O\left(T^{1-\gamma}\right)$.

## A. 3 Proof of Theorem 2

Proof. Without loss of generality, assume at time $t$, arm 1 is optimal, i.e., $\left\langle M_{1}-M_{0}, X_{t}\right\rangle>0$, then the expected regret is

$$
\begin{aligned}
r_{t}= & \mathbb{E}\left[\left\langle M_{1}-M_{0}, X_{t}\right\rangle \mathbb{1}(\text { choose arm } 0)\right] \\
= & \mathbb{E}\left[\left\langle M_{1}-M_{0}, X_{t}\right\rangle \mathbb{1}\left(\text { choose arm } 0,\left\langle\widehat{M}_{1, t-1}-\widehat{M}_{0, t-1}, X_{t}\right\rangle \geq 0\right)\right] \\
& +\mathbb{E}\left[\left\langle M_{1}-M_{0}, X_{t}\right\rangle \mathbb{1}\left(\text { choose arm } 0,\left\langle\widehat{M}_{0, t-1}-\widehat{M}_{1, t-1}, X_{t}\right\rangle>0\right)\right] \\
\leq & \frac{\varepsilon t}{2}\left\|M_{1}-M_{0}\right\|_{\max }+\underbrace{\mathbb{E}\left[\left\langle M_{1}-M_{0}, X_{t}\right\rangle \mathbb{1}\left(\left\langle\widehat{M}_{0, t-1}-\widehat{M}_{1, t-1}, X_{t}\right\rangle>0\right)\right]}_{(2)} .
\end{aligned}
$$

Define $\delta_{t}^{2}$ the entrywise bound in the proof of Corollary 1 such that $\left\|U_{i, t} V_{i, t}^{\top}-M\right\|_{\max }^{2} \leq \delta_{t}^{2}$ with probability at least $1-8 t d_{1}^{-200}$, and event $B_{t}=\left\{\left\langle M_{1}-M_{0}, X_{t}\right\rangle>2 \delta_{t}\right\}$, then the latter expectation can be written as

$$
\begin{aligned}
(2) \leq & \mathbb{E}\left[\left\langle M_{1}-M_{0}, X_{t}\right\rangle \mathbb{1}\left(\left\langle\widehat{M}_{0, t-1}-\widehat{M}_{1, t-1}, X_{t}\right\rangle>0 \cap B_{t}\right)\right] \\
& +\mathbb{E}\left[\left\langle M_{1}-M_{0}, X_{t}\right\rangle \mathbb{1}\left(\left\langle\widehat{M}_{0, t-1}-\widehat{M}_{1, t-1}, X_{t}\right\rangle>0 \cap B_{t}^{c}\right)\right] \\
\leq & \left\|M_{1}-M_{0}\right\|_{\max } \mathbb{E}\left[\mathbb{1}\left(\left\langle\widehat{M}_{0, t-1}-\widehat{M}_{1, t-1}, X_{t}\right\rangle>0 \cap B_{t}\right)\right]+2 \delta_{t} \mathbb{E}\left[\mathbb{1}\left(B_{t}^{c}\right)\right] .
\end{aligned}
$$

Under event $B_{t}$ and $\left\langle\widehat{M}_{0, t-1}-\widehat{M}_{1, t-1}, X_{t}\right\rangle>0$,

$$
\begin{aligned}
0>\left\langle\widehat{M}_{1, t-1}-\widehat{M}_{0, t-1}, X_{t}\right\rangle & =\left\langle\widehat{M}_{1, t-1}-M_{1}, X_{t}\right\rangle+\left\langle M_{0}-\widehat{M}_{0, t-1}, X_{t}\right\rangle+\left\langle M_{1}-M_{0}, X_{t}\right\rangle \\
& >\left\langle\widehat{M}_{1, t-1}-M_{1}, X_{t}\right\rangle+\left\langle M_{0}-\widehat{M}_{0, t-1}, X_{t}\right\rangle+2 \delta_{t} .
\end{aligned}
$$

This means either $\left\langle\widehat{M}_{1, t-1}-M_{1}, X_{t}\right\rangle<-\delta_{t}$ or $\left\langle M_{0}-\widehat{M}_{0, t-1}, X_{t}\right\rangle<-\delta_{t}$, which further implies either $\left\|\widehat{M}_{1, t-1}-M_{1}\right\|_{\max }$ or $\left\|M_{0}-\widehat{M}_{0, t-1}\right\|_{\max }$ should be larger than $\delta_{t}$. Therefore,

$$
\begin{aligned}
\mathbb{E}\left(\mathbb{1}\left(\left\langle M_{0, t-1}-M_{1, t-1}, X_{t}\right\rangle>0\right) \cap B_{t}\right) & =\mathbb{P}\left(\left\langle M_{0, t-1}-M_{1, t-1}, X_{t}\right\rangle>0 \cap B_{t}\right) \\
& \leq \mathbb{P}\left(\left\|M_{1, t-1}-M_{1}\right\|_{\max }>\delta_{t}\right)+\mathbb{P}\left(\left\|M_{0, t-1}-M_{0}\right\|_{\max }>\delta_{t}\right) \\
& \leq \frac{16(t-1)}{d^{200}},
\end{aligned}
$$

For the other term, since $\mathbb{E}\left[\mathbb{1}\left(B_{t}^{c}\right)\right]=\mathbb{P}\left(\left\langle M_{1}-M_{0}, X_{t}\right\rangle<2 \delta_{t}\right) \leq 1$, then

$$
r_{t} \leq \varepsilon_{t}\left\|M_{1}-M_{0}\right\|_{\max }+\frac{16(t-1)}{d^{200}}\left\|M_{1}-M_{0}\right\|_{\max }+2 \delta_{t} .
$$

The total regret up to time $T$ is

$$
R_{T}=\sum_{t=1}^{T} r_{t} \leq \sum_{t=1}^{T} \varepsilon_{t}\left\|M_{1}-M_{0}\right\|_{\max }+\frac{8 T(T-1)}{d_{1}^{200}}\left\|M_{1}-M_{0}\right\|_{\max }+2 \sum_{t=1}^{T} \delta_{t}
$$

In the proof of Corollary 1, we have shown that $\delta_{t}^{2}=C_{3} \frac{\lambda_{\text {min }}^{2} r^{3}}{d_{1} d_{2}} \prod_{\tau=1}^{t}\left(1-\frac{c_{1} \log d_{1}}{4 \kappa T^{1-\gamma}}\right)+C_{4} \frac{t \cdot r d_{1} \log ^{4} d_{1} \sigma_{i}^{2}}{T^{2(1-\gamma)}}$ when $1 \leq t \leq T_{0}$ and $\delta_{t}^{2}=C_{5} \frac{r d_{1} \log ^{4} d_{1} \bar{\sigma}^{2}}{T^{1-\gamma}}$ when $T_{0}+1 \leq t \leq T$, for some constants $C_{3}, C_{4}$ and $C_{5}$. Therefore,

$$
\begin{aligned}
R_{T} \lesssim & \sum_{t=1}^{T_{0}} \varepsilon\left\|M_{1}-M_{0}\right\|_{\max }+\sum_{t=T_{0}+1}^{T} \frac{1}{t^{\gamma}}\left\|M_{1}-M_{0}\right\|_{\max }+\frac{\left\|M_{1}-M_{0}\right\|_{\max } T^{2}}{d_{1}^{200}} \\
& +\sum_{t=1}^{T_{0}} \sqrt{\frac{\lambda_{\min }^{2} r^{3}}{d_{1} d_{2}} \prod_{\tau=1}^{t}\left(1-\frac{c_{1} \log d_{1}}{4 \kappa T^{1-\gamma}}\right)}+\sum_{t=1}^{T_{0}} \sqrt{\frac{t \cdot r d_{1} \log ^{4} d_{1} \bar{\sigma}^{2}}{T^{2(1-\gamma)}}}+\sum_{t=T_{0}+1}^{T} \sqrt{\frac{r d_{1} \log ^{4} d_{1} \bar{\sigma}^{2}}{T^{1-\gamma}}} .
\end{aligned}
$$

Since $T \ll d_{1}^{50}$, the third term is negligible. As a result, from the fact that $\sum_{t=1}^{T} t^{-\gamma} \lesssim T^{1-\gamma}$,

$$
\begin{aligned}
R_{T} & \lesssim T^{1-\gamma}\left\|M_{1}-M_{0}\right\|_{\max }+T^{1-\gamma} \frac{\lambda_{\min } r^{3 / 2}}{\sqrt{d_{1} d_{2}}}+T^{(1+\gamma) / 2} \sqrt{r d_{1} \log ^{4} d_{1} \bar{\sigma}^{2}} \\
& \lesssim T^{1-\gamma}\left(\left\|M_{1}\right\|_{\max }+\left\|M_{0}\right\|_{\max }\right)+T^{(1+\gamma) / 2} \sqrt{r d_{1} \log ^{4} d_{1} \bar{\sigma}^{2}}
\end{aligned}
$$

## A. 4 Proof of Theorem 3

Proof. Without loss of generality, we only consider the proof for $i=1$, and omit all the subscript. We follow the arguments in Xia and Yuan 2021 to decompose $\widehat{m}_{Q}-m_{Q}$. Notice that

$$
\widehat{m}_{Q}-m_{Q}=\left\langle\widehat{L} \widehat{L}^{\top} \widehat{Z} \widehat{R} \widehat{R}^{\top}, Q\right\rangle+\left\langle\widehat{L} \hat{L}^{\top} M \widehat{R} \widehat{R}^{\top}-M, Q\right\rangle .
$$

Let $b=\frac{T}{T-T_{0}}$, notice that $b=O(1)$ and will converge to 1 as $T \rightarrow \infty$. We can write $\widehat{M}^{\mathrm{PW}}$ in (8) into

$$
\begin{aligned}
\widehat{M}^{\mathrm{IPW}} & =\frac{b}{T} \sum_{t=T_{0}+1}^{T} \widehat{M}_{t-1}+\frac{b}{T} \sum_{t=T_{0}+1}^{T} \frac{d_{1} d_{2} \mathbb{1}\left(a_{t}=1\right)}{\pi_{t}}\left(y_{t}-\left\langle M_{t-1}, X_{t}\right\rangle\right) X_{t} \\
& =M_{1}+\underbrace{\frac{b}{T} \sum_{t=T_{0}+1}^{T} \frac{d_{1} d_{2} \mathbb{1}\left(a_{t}=1\right)}{\pi_{t}} \xi_{t} X_{t}}_{=: \widehat{Z}_{1}}+\underbrace{\frac{b}{T} \sum_{t=T_{0}+1}^{T}\left(\frac{d_{1} d_{2} \mathbb{1}\left(a_{t}=1\right)}{\pi_{t}}\left\langle\widehat{\Delta}_{t-1}, X_{t}\right\rangle X_{t}-\widehat{\Delta}_{t-1}\right)}_{=: \widehat{Z}_{2}} .
\end{aligned}
$$

Moreover, recall that $\widehat{L}$ and $\widehat{R}$ are the top- $r$ left and right singular vectors of $\widehat{M}^{\mathrm{IPW}}$. Define $\left(d_{1}+d_{2}\right) \times(2 r)$ matrices

$$
\Theta=\left(\begin{array}{ll}
L & 0 \\
0 & R
\end{array}\right) \quad \widehat{\Theta}=\left(\begin{array}{ll}
\widehat{L} & 0 \\
0 & \widehat{R}
\end{array}\right) \quad A=\left(\begin{array}{cc}
0 & M \\
M^{\top} & 0
\end{array}\right) .
$$

Then, we can write

$$
\widehat{\Theta} \widehat{\Theta}^{\top} A \widehat{\Theta} \widehat{\Theta}^{\top}-\Theta \Theta^{\top} A \Theta \Theta^{\top}=\left(\begin{array}{cc}
0 & \widehat{L} \widehat{L}^{\top} M \widehat{R} \widehat{R}^{\top}-M \\
\left(\widehat{L} \hat{L}^{\top} M \widehat{R} \widehat{R}^{\top}-M\right)^{\top} & 0
\end{array}\right) .
$$

We further define

$$
\widetilde{Q}=\left(\begin{array}{cc}
0 & Q \\
0 & 0
\end{array}\right) \quad \text { and } \quad \widehat{E}=\left(\begin{array}{cc}
0 & \widehat{Z} \\
\widehat{Z}^{\top} & 0
\end{array}\right)
$$

where $\widehat{Z}=\widehat{Z}_{1}+\widehat{Z}_{2}$. Therefore, we have

$$
\left\langle\widehat{L} \widehat{L}^{\top} M \widehat{R} \widehat{R}^{\top}-M, Q\right\rangle=\left\langle\widehat{\Theta} \widehat{\Theta}^{\top} A \widehat{\Theta} \widehat{\Theta}^{\top}-\Theta \Theta^{\top} A \Theta \Theta^{\top}, \widetilde{Q}\right\rangle .
$$

Define

$$
\mathfrak{P}^{-s}=\left\{\begin{array}{cc}
\left(\begin{array}{cc}
L \Lambda^{-s} L^{\top} & 0 \\
0 & R \Lambda^{-s} R^{\top}
\end{array}\right) & \text { if } s \text { is even } \\
\left(\begin{array}{cc}
0 & L \Lambda^{-s} R^{\top} \\
R \Lambda^{-s} L^{\top} & 0
\end{array}\right) & \text { if } s \text { is odd }
\end{array}\right.
$$

and

$$
\mathfrak{P}^{0}=\mathfrak{P}^{\perp}=\left(\begin{array}{cc}
L_{\perp} L_{\perp}^{\top} & 0 \\
0 & R_{\perp} R_{\perp}^{\top}
\end{array}\right) .
$$

By Theorem 1 in Xia 2021, $\widehat{\Theta} \widehat{\Theta}^{\top}-\Theta \Theta^{\top}$ has explicit representation formula of empirical spectral projector, in the form of

$$
\begin{aligned}
& \widehat{\Theta} \widehat{\Theta}^{\top}-\Theta \Theta^{\top}=\sum_{k=1}^{\infty} \mathcal{S}_{A, k}(\widehat{E}) \\
& \mathcal{S}_{A, k}(\widehat{E})=\sum_{s_{1}+\cdots+s_{k+1}=k}^{k}(-1)^{1+\tau(s)} \mathfrak{P}^{-s_{1}} \widehat{E} \mathfrak{P}^{-s_{2}} \ldots \mathfrak{P}^{-s_{k}} \widehat{E}_{\mathfrak{P}_{-s_{k+1}}}
\end{aligned}
$$

where $s_{1}, \cdots, s_{k+1} \geq 0$ are integers, $\tau(\mathbf{s})=\sum_{i=1}^{k+1} \mathbb{1}\left(s_{i}>0\right)$.
As a result,

$$
\begin{aligned}
\widehat{\Theta} \widehat{\Theta}^{\top} A \widehat{\Theta} \widehat{\Theta}^{\top}-\Theta \Theta^{\top} A \Theta \Theta^{\top}= & \left(\mathcal{S}_{A, 1}(\widehat{E}) A \Theta \Theta^{\top}+\Theta \Theta^{\top} A \mathcal{S}_{A, 1}(\widehat{E})\right)+\sum_{k=2}^{\infty}\left(\mathcal{S}_{A, k}(\widehat{E}) A \Theta \Theta^{\top}+\Theta \Theta^{\top} A \mathcal{S}_{A, k}(\widehat{E})\right) \\
& +\left(\widehat{\Theta} \widehat{\Theta}^{\top}-\Theta \Theta^{\top}\right) A\left(\widehat{\Theta} \widehat{\Theta}^{\top}-\Theta \Theta^{\top}\right)
\end{aligned}
$$

By definition of $\mathcal{S}_{A, 1}(\widehat{E})$,

$$
\begin{aligned}
& \left\langle\mathcal{S}_{A, 1}(\widehat{E}) A \Theta \Theta^{\top}+\Theta \Theta^{\top} A \mathcal{S}_{A, 1}(\widehat{E}), \widetilde{Q}\right\rangle=\left\langle L L^{\top} \widehat{Z} R_{\perp} R_{\perp}^{\top}, Q\right\rangle+\left\langle L_{\perp} L_{\perp}^{\top} \widehat{Z} R R^{\top}, Q\right\rangle \\
& \quad=\left\langle L L^{\top} \widehat{Z}_{1} R_{\perp} R_{\perp}^{\top}, Q\right\rangle+\left\langle L_{\perp} L_{\perp}^{\top} \widehat{Z}_{1} R R^{\top}, Q\right\rangle+\left\langle L L^{\top} \widehat{Z}_{2} R_{\perp} R_{\perp}^{\top}, Q\right\rangle+\left\langle L_{\perp} L_{\perp}^{\top} \widehat{Z}_{2} R R^{\top}, Q\right\rangle .
\end{aligned}
$$

Combine all the terms above, $\widehat{m}_{Q}-m_{Q}$ can be decomposed into

$$
\begin{align*}
\widehat{m}_{Q}-m_{Q}= & \left\langle L L^{\top} \widehat{Z}_{1} R_{\perp} R_{\perp}^{\top}, Q\right\rangle+\left\langle L_{\perp} L_{\perp}^{\top} \widehat{Z}_{1} R R^{\top}, Q\right\rangle+\left\langle L L^{\top} \widehat{Z}_{1} R R^{\top}, Q\right\rangle  \tag{13}\\
& +\left\langle L L^{\top} \widehat{Z}_{2} R_{\perp} R_{\perp}^{\top}, Q\right\rangle+\left\langle L_{\perp} L_{\perp}^{\top} \widehat{Z}_{2} R R^{\top}, Q\right\rangle+\left\langle L L^{\top} \widehat{Z}_{2} R R^{\top}, Q\right\rangle  \tag{14}\\
& +\left\langle\widehat{L} \widehat{L}^{\top} \widehat{Z} \widehat{R} \widehat{R}^{\top}, Q\right\rangle-\left\langle L L^{\top} \widehat{Z}^{\top} R R^{\top}, Q\right\rangle  \tag{15}\\
& +\left\langle\sum_{k=2}^{\infty}\left(\mathcal{S}_{A, k}(\widehat{E}) A \Theta \Theta^{\top}+\Theta \Theta^{\top} A \mathcal{S}_{A, k}(\widehat{E})\right), \widetilde{Q}\right\rangle+\left\langle\left(\widehat{\Theta} \widehat{\Theta}^{\top}-\Theta \Theta^{\top}\right) A\left(\widehat{\Theta} \widehat{\Theta}^{\top}-\Theta \Theta^{\top}\right), \widetilde{Q}\right\rangle \tag{16}
\end{align*}
$$

In Lemma4, we aim to show equation (13) is the main term which is asymptotic normal. In Lemma 5. Lemma 6 and Lemma 7 , we show equation (14), (15) and (16) are negligible higher order terms, respectively.

Lemma 4. Under the conditions in Theorem 3 ,

$$
\frac{\left(\left\langle L L^{\top} \widehat{Z}_{1} R_{\perp} R_{\perp}^{\top}, Q\right\rangle+\left\langle L_{\perp} L_{\perp}^{\top} \widehat{Z}_{1} R R^{\top}, Q\right\rangle+\left\langle L L^{\top} \widehat{Z}_{1} R R^{\top}, Q\right\rangle\right)}{\sigma S \sqrt{d_{1} d_{2} / T^{1-\gamma}}} \rightarrow N(0,1)
$$

where $S^{2}=1 / T^{\gamma}\left\|\mathcal{P}_{\Omega_{1}} \mathcal{P}_{M}(Q)\right\|_{\mathrm{F}}^{2}+C_{\gamma}\left\|\mathcal{P}_{\Omega_{0}} \mathcal{P}_{M}(Q)\right\|_{\mathrm{F}}^{2}$.
Lemma 5. Under the conditions in Theorem 3.

$$
\frac{\left|\left\langle L L^{\top} \widehat{Z}_{2} R_{\perp} R_{\perp}^{\top}, Q\right\rangle+\left\langle L_{\perp} L_{\perp}^{\top} \widehat{Z}_{2} R R^{\top}, Q\right\rangle+\left\langle L L^{\top} \widehat{Z}_{2} R R^{\top}, Q\right\rangle\right|}{\sigma S \sqrt{d_{1} d_{2} / T^{1-\gamma}}} \xrightarrow{p} 0 .
$$

Lemma 6. Under the conditions in Theorem 3.

$$
\frac{\left|\left\langle\widehat{L} \widehat{L}^{\top} \widehat{Z} \widehat{R} \hat{R}^{\top}, Q\right\rangle-\left\langle L L^{\top} \widehat{Z} R R^{\top}, Q\right\rangle\right|}{\sigma S \sqrt{d_{1} d_{2} / T^{1-\gamma}}} 0 .
$$

Lemma 7. Under the conditions in Theorem 3,

$$
\begin{aligned}
& \frac{\left|\sum_{k=2}^{\infty}\left\langle\left(\mathcal{S}_{A, k}(\widehat{E}) A \Theta \Theta^{\top}+\Theta \Theta^{\top} A \mathcal{S}_{A, k}(\widehat{E})\right), \widetilde{Q}\right\rangle\right|}{\sigma S \sqrt{d_{1} d_{1} / T^{1-\gamma}}} \stackrel{p}{\rightarrow} 0, \\
& \frac{\left|\left\langle\left(\widehat{\Theta} \widehat{\Theta}^{\top}-\Theta \Theta^{\top}\right) A\left(\widehat{\Theta} \widehat{\Theta}^{\top}-\Theta \Theta^{\top}\right), \widetilde{Q}\right\rangle\right|}{\sigma S \sqrt{d_{1} d_{1} / T^{1-\gamma}}} 0 .
\end{aligned}
$$

Combine Lemma 4 4 , we can conclude that

$$
\frac{\widehat{m}_{Q}-m_{Q}}{\sigma S \sqrt{d_{1} d_{2} / T^{1-\gamma}}} \rightarrow N(0,1) .
$$

## A. 5 Proof of Theorem (4)

Proof. Without loss of generality, we only prove the $i=1$ case. As long as we show $\widehat{\sigma}^{2} \xrightarrow{p} \sigma^{2}$ and $\widehat{S}^{2} \xrightarrow{p} S^{2}$, then by Slutsky's Theorem, we can obtain the desired result.
$\widehat{\sigma}^{2} \xrightarrow{\mathrm{p}} \sigma^{2}$ Notice that, $\widehat{\sigma}^{2}$ can be written as

$$
\begin{aligned}
\widehat{\sigma}^{2}= & \underbrace{\frac{b}{T} \sum_{t=T_{0}+1}^{T} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}}\left\langle M-\widehat{M}_{t-1}, X_{t}\right\rangle^{2}}_{I}+\underbrace{\frac{2 b}{T} \sum_{t=T_{0}+1}^{T} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}}\left\langle M-\widehat{M}_{t-1}, X_{t}\right\rangle \xi_{t}}_{I I} \\
& +\underbrace{\frac{b}{T} \sum_{t=T_{0}+1}^{T} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}} \xi_{t}^{2}}_{I I I} .
\end{aligned}
$$

For term I,

$$
\left|\frac{b}{T} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}}\left\langle M-\widehat{M}_{t-1}, X_{t}\right\rangle^{2}\right| \lesssim \frac{t^{\gamma}}{T}\left\|\widehat{\Delta}_{t-1}\right\|_{\max }^{2} \lesssim \frac{1}{T^{1-\gamma}} \sigma^{2}
$$

and

$$
\begin{aligned}
\mathbb{E}\left[\left.\frac{b^{2}}{T^{2}} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}^{2}}\left\langle M-\widehat{M}_{t-1}, X_{t}\right\rangle^{4} \right\rvert\, \mathcal{F}_{t-1}\right] & \leq \frac{b^{2}}{T^{2}} \frac{2}{\varepsilon_{t}}\left\|\widehat{\Delta}_{t-1}\right\|_{\max }^{2} \frac{1}{d_{1} d_{2}}\left\|\widehat{\Delta}_{t-1}\right\|_{\mathrm{F}}^{2} \\
& \lesssim \frac{t^{\gamma}}{T^{2}} \sigma^{4} .
\end{aligned}
$$

By martingale Bernstein inequality, with probability at least $1-d_{1}^{-2}$,

$$
\begin{aligned}
I & \lesssim\left|\frac{b}{T} \sum_{t=T_{0}+1}^{T} \mathbb{E}\left[\left.\frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}}\left\langle M-\widehat{M}_{t-1}, X_{t}\right\rangle^{2} \right\rvert\, \mathcal{F}_{t-1}\right]\right|+\sqrt{\frac{\log d_{1}}{T^{1-\gamma}}} \sigma^{2} \\
& \lesssim \frac{d_{1} r \sigma^{2} \log ^{4} d_{1} \operatorname{poly}(\mu, r, \kappa)}{T^{1-\gamma}}+\sqrt{\frac{\log d_{1}}{T^{1-\gamma}}} \sigma^{2},
\end{aligned}
$$

which indicates $I \xrightarrow{p} 0$ when $\frac{d_{1} \log ^{4} d_{1}}{T^{1-\gamma}} \rightarrow 0$.
Similarly, for term $I I$, note that $\left|\xi_{t}\right|$ is bounded with $\sigma \log ^{1 / 2} d_{1}$ with high probability,

$$
\left|\frac{2 b}{T} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}}\left\langle M-\widehat{M}_{t-1}, X_{t}\right\rangle \xi_{t}\right| \leq \frac{2 b}{T} \frac{2}{\varepsilon_{t}}\left\|\widehat{\Delta}_{t-1}\right\|_{\max } \sigma \log ^{1 / 2} d_{1} \lesssim \frac{\sigma^{2} \log ^{1 / 2} d_{1}}{T^{1-\gamma}},
$$

and

$$
\mathbb{E}\left[\left.\frac{4 b^{2}}{T^{2}} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}^{2}}\left\langle M-\widehat{M}_{t-1}, X_{t}\right\rangle^{2} \xi_{t}^{2} \right\rvert\, \mathcal{F}_{t-1}\right] \lesssim \frac{t^{\gamma} \sigma^{2}}{T^{2}}\left\|\widehat{\Delta}_{t-1}\right\|_{\max }^{2} \lesssim \frac{t^{\gamma} \sigma^{4}}{T^{2}}
$$

By martingale Bernstein inequality, with probability at least $1-d_{1}^{-2}$,

$$
\left|I I-\frac{2 b}{T} \sum_{t=T_{0}+1}^{T} \mathbb{E}\left[\left.\frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}}\left\langle M-\widehat{M}_{t-1}, X_{t}\right\rangle \xi_{t} \right\rvert\, \mathcal{F}_{t-1}\right]\right| \lesssim \sqrt{\frac{\log d_{1}}{T^{1-\gamma}}} \sigma^{2},
$$

which indicates $I I \xrightarrow{p} 0$ as long as $\frac{\log d_{1}}{T^{I-\gamma}} \rightarrow 0$.
Lastly, for term III,

$$
\left\|\frac{b}{T} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}} \xi_{t}^{2}\right\|_{\psi_{1}} \lesssim \frac{t^{\gamma} \sigma^{2}}{T},
$$

and

$$
\mathbb{E}\left[\left.\frac{b^{2}}{T^{2}} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}^{2}} \xi_{t}^{4} \right\rvert\, \mathcal{F}_{t-1}\right] \lesssim \frac{t^{\gamma} \sigma^{4}}{T} .
$$

By martingale Bernstein inequality, with probability at least $1-d_{1}^{-2}$,

$$
\left|I I I-\frac{b}{T} \sum_{t=T_{0}+1}^{T} \mathbb{E}\left[\left.\frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}} \xi_{t}^{2} \right\rvert\, \mathcal{F}_{t-1}\right]\right| \lesssim \sqrt{\frac{\log d_{1}}{T^{1-\gamma}}} \sigma^{2}
$$

which indicates $I I I \xrightarrow{p} \sigma^{2}$ as long as $\frac{\log d_{1}}{T^{1-\gamma}} \rightarrow 0$.
Showing $\widehat{S}^{2} \xrightarrow{p} S^{2}$. Notice that

$$
\begin{aligned}
\left|\left\|\mathcal{P}_{M}(Q)\right\|_{\mathrm{F}}^{2}-\left\|\mathcal{P}_{\widehat{M}}(Q)\right\|_{\mathrm{F}}^{2}\right| & =\left|\left\|L^{\top} Q\right\|_{\mathrm{F}}^{2}+\left\|L_{\perp}^{\top} Q R\right\|_{\mathrm{F}}^{2}-\left\|\widehat{L}^{\top} Q\right\|_{\mathrm{F}}^{2}-\left\|\widehat{L}_{\perp}^{\top} Q \widehat{R}\right\|_{\mathrm{F}}^{2}\right| \\
& \leq\left|\left\|L^{\top} Q\right\|_{\mathrm{F}}^{2}-\left\|\widehat{L}^{\top} Q\right\|_{\mathrm{F}}^{2}\right|+\left|\left\|L_{\perp}^{\top} Q R\right\|_{\mathrm{F}}^{2}-\left\|\widehat{L}_{\perp}^{\top} Q \widehat{R}\right\|_{\mathrm{F}}^{2}\right| .
\end{aligned}
$$

Observing that $L$ and $\widehat{L}$ both have orthonormal columns, then

$$
\begin{aligned}
\left|\left\|L^{\top} Q\right\|_{\mathrm{F}}^{2}-\left\|\widehat{L}^{\top} Q\right\|_{\mathrm{F}}^{2}\right| & =\left|\left\|L L^{\top} Q\right\|_{\mathrm{F}}^{2}-\left\|\widehat{L} \hat{L}^{\top} Q\right\|_{\mathrm{F}}^{2}\right| \\
& \leq\left\|\left(L L^{\top}-\widehat{L} \widehat{L}^{\top}\right) Q\right\|_{\mathrm{F}}^{2}+2\left|\left\langle\left(L L^{\top}-\widehat{L} \widehat{L}^{\top}\right) Q, L L^{\top} Q\right\rangle\right| .
\end{aligned}
$$

In the following we shall consider the upper bound under the event $\mathcal{E}$ defined in the proof of Lemma 10. The probability of the following event

$$
\begin{gathered}
\left\|\left(L L^{\top}-\widehat{L} \widehat{L}^{\top}\right) Q\right\|_{\mathrm{F}}^{2} \leq\left(\sum_{j_{1}, j_{2}} \mid Q\left(j_{1}, j_{2}\right)\| \|\left(L L^{\top}-\widehat{L} \widehat{L}^{\top}\right) e_{j_{1}} \|\right)^{2} \\
\leq\|Q\|_{\ell_{1}}^{2}\left\|L L^{\top}-\widehat{L} \widehat{L}^{\top}\right\|_{2, \max }^{2} \lesssim\|Q\|_{\ell_{1}}^{2} \frac{\sigma^{2}}{\lambda_{\min }^{2}} \frac{\mu r d_{1} d_{2} \log d_{1}}{T^{1-\gamma}} .
\end{gathered}
$$

approaches 1 as $\|Q\|_{\ell_{1}}^{2} \frac{\sigma^{2}}{\lambda_{\text {min }}^{2}} \frac{d_{1} d_{2} \log d_{1}}{T^{1-\gamma}} \rightarrow 0$, which can be easily satisfied under the conditions in Theorem 3.

Similarly,

$$
\begin{aligned}
& \left|\left\langle\left(L L^{\top}-\widehat{L} \widehat{L}^{\top}\right) Q, L L^{\top} Q\right\rangle\right| \leq\left\|L^{\top} Q\right\|_{F}\left\|L^{\top}\left(L L^{\top}-\widehat{L} \widehat{L}^{\top}\right) Q\right\|_{\mathrm{F}} \\
& \quad \leq\left\|L^{\top} Q\right\|_{F}\|Q\|_{\ell_{1}}\| \| L L^{\top}-\widehat{L} \widehat{L}^{\top}\left\|_{2, \max } \lesssim\right\| Q\left\|_{\mathrm{F}}\right\| Q \|_{\ell_{1}} \frac{\sigma}{\lambda_{\min }} \sqrt{\frac{\mu r d_{1} d_{2} \log d_{1}}{T^{1-\gamma}}} .
\end{aligned}
$$

Therefore, as long as $\|Q\|_{\mathrm{F}}\|Q\|_{\ell_{1}} \frac{\sigma}{\lambda_{\text {min }}} \sqrt{\frac{\mu r d_{1} d_{2} \log d_{1}}{T^{1-\gamma}}} \rightarrow 0$, the above term converges to 0 in probability.
Next we bound $\left|\left\|L_{\perp}^{\top} Q R\right\|_{\mathrm{F}}^{2}-\left\|\widehat{L}_{\perp}^{\top} Q \widehat{R}\right\|_{\mathrm{F}}^{2}\right|$. It can be decomposed into

$$
\left|\left\|L_{\perp}^{\top} Q R\right\|_{\mathrm{F}}^{2}-\left\|\widehat{L}_{\perp}^{\top} Q \widehat{R}\right\|_{\mathrm{F}}^{2}\right| \leq\left|\left\|L_{\perp}^{\top} Q R\right\|_{\mathrm{F}}^{2}-\left\|L_{\perp}^{\top} Q \widehat{R}\right\|_{\mathrm{F}}^{2}\right|+\left|\left\|L_{\perp}^{\top} Q \widehat{R}\right\|_{\mathrm{F}}^{2}-\left\|\widehat{L}_{\perp}^{\top} Q \widehat{R}\right\|_{\mathrm{F}}^{2}\right| .
$$

It follows that

$$
\begin{aligned}
& \left|\left\|L_{\perp}^{\top} Q R\right\|_{\mathrm{F}}^{2}-\left\|L_{\perp}^{\top} Q \widehat{R}\right\|_{\mathrm{F}}^{2}\right| \leq\left\|L_{\perp}^{\top} Q\left(R R^{\top}-\widehat{R} \widehat{R}^{\top}\right)\right\|_{\mathrm{F}}^{2}+2\left|\left\langle L_{\perp}^{\top} Q\left(R R^{\top}-\widehat{R} \widehat{R}^{\top}\right), L_{\perp}^{\top} Q R\right\rangle\right| \\
& \quad \lesssim\|Q\|_{\ell_{1}}^{2} \frac{\sigma^{2}}{\lambda_{\text {min }}^{2}} \frac{\mu r d_{1}^{2} \log d_{1}}{T}+\left\|L_{\perp}^{\top} Q R\right\|_{\mathrm{F}}\|Q\|_{\ell_{1}} \frac{\sigma}{\lambda_{\text {min }}} \sqrt{\frac{\mu r d_{1}^{2} \log d_{1}}{T^{1-\gamma}}},
\end{aligned}
$$

and

$$
\begin{aligned}
& \left|\left\|L_{\perp}^{\top} Q \widehat{R}\right\|_{\mathrm{F}}^{2}-\left\|\widehat{L}_{\perp}^{\top} Q \widehat{R}\right\|_{\mathrm{F}}^{2}\right| \leq\left\|\left(\widehat{L} \hat{L}^{\top}-L L^{\top}\right) Q \widehat{R} \widehat{R}^{\top}\right\|_{\mathrm{F}}^{2}+2\left|\left\langle L_{\perp}^{\top} Q\left(R R^{\top}-\widehat{R} \widehat{R}^{\top}\right), L_{\perp}^{\top} Q \widehat{R}\right\rangle\right| \\
\lesssim & \|Q\|_{\ell_{1}}^{2} \frac{\sigma^{2}}{\lambda_{\min }^{2}} \frac{\mu r d_{1} d_{2} \log d_{1}}{T^{1-\gamma}}+\left(\left\|L_{\perp}^{\top} Q R\right\|_{\mathrm{F}}+\left\|L_{\perp}^{\top} Q\left(R R^{\top}-\widehat{R} \widehat{R}^{\top}\right)\right\|_{\mathrm{F}}\right)\|Q\|_{\ell_{1}} \frac{\sigma}{\lambda_{\min }} \sqrt{\frac{\mu r d_{1}^{2} \log d_{1}}{T^{1-\gamma}}} \\
\lesssim & \|Q\|_{\ell_{1}}^{2} \frac{\sigma^{2}}{\lambda_{\min }^{2}} \frac{\mu r d_{1} d_{2} \log d_{1}}{T^{1-\gamma}}+\left\|L_{\perp}^{\top} Q R\right\|_{\mathrm{F}}\|Q\|_{\ell_{1}} \frac{\sigma}{\lambda_{\min }} \sqrt{\frac{\mu r d_{1}^{2} \log d_{1}}{T^{1-\gamma}}}+\|Q\|_{\ell_{1}}^{2} \frac{\sigma^{2}}{\lambda_{\min }^{2}} \frac{\mu r d_{1}^{2} \log d_{1}}{T^{1-\gamma}} .
\end{aligned}
$$

We can show $\left|\left\|L_{\perp}^{\top} Q \widehat{R}\right\|_{\mathrm{F}}^{2}-\left\|\widehat{L}_{\perp}^{\top} Q \widehat{R}\right\|_{\mathrm{F}}^{2}\right|$ converges to 0 in probability as long as $\|Q\|_{\ell_{1}}^{2} \frac{\sigma^{2}}{\lambda_{\min }^{2}} \frac{d_{1}^{2} \log d_{1}}{T^{1-\gamma}} \rightarrow$ 0 . As a result, $\left\|\mathcal{P}_{\widehat{M}}(Q)\right\|_{\mathrm{F}}^{2} \xrightarrow{p}\left\|\mathcal{P}_{M}(Q)\right\|_{\mathrm{F}}^{2}$. By Lemma 8 , it directly follows $\left\|\mathcal{P}_{\widehat{\Omega}_{i, T}} \mathcal{P}_{\widehat{M}}(Q)\right\|_{\mathrm{F}}^{2} \xrightarrow{p}$ $\left\|\mathcal{P}_{\Omega_{i}} \mathcal{P}_{M}(Q)\right\|_{\mathrm{F}}^{2}$ for $i=0,1$. Moreover, $b_{T} \rightarrow 1$ when $T \rightarrow \infty$. Then by Slutsky's Theorem, $\widehat{S}^{2} \xrightarrow{p} S^{2}$.

## A. 6 Proof of Corollary 2

Proof. Note that

$$
\left(\widehat{m}_{Q}^{(1)}-\widehat{m}_{Q}^{(0)}\right)-\left(m_{Q}^{(1)}-m_{Q}^{(0)}\right)=\left(\widehat{m}_{Q}^{(1)}-m_{Q}^{(1)}\right)-\left(\widehat{m}_{Q}^{(1)}-m_{Q}^{(1)}\right),
$$

then $\widehat{m}_{Q}^{(1)}-m_{Q}^{(1)}$ and $\widehat{m}_{Q}^{(1)}-m_{Q}^{(1)}$ can be decomposed into main term and negligible terms in the same way as Theorem 3. The upper bound of all the negligible terms for both $i=0$ and 1 still follow the Lemma $5 \cdot-7$. The main CLT term is

$$
\frac{b}{T} \sum_{t_{1}=T_{0}+1}^{T} \frac{d_{1} d_{2} \mathbb{1}\left(a_{t_{1}}=1\right)}{\pi_{t_{1}}} \xi_{t_{1}}\left\langle X_{t_{1}}, \mathcal{P}_{M_{1}}(Q)\right\rangle-\frac{b}{T} \sum_{t_{2}=T_{0}+1}^{T} \frac{d_{1} d_{2} \mathbb{1}\left(a_{t_{2}}=0\right)}{1-\pi_{t_{2}}} \xi_{t_{2}}\left\langle X_{t_{2}}, \mathcal{P}_{M_{0}}(Q)\right\rangle
$$

As long as we show $\sum_{t_{1}=T_{0}+1}^{T} \frac{d_{1} d_{2} \mathbb{M}\left(a_{t_{1}}=1\right)}{\pi_{t_{1}}} \xi_{t_{1}} X_{t_{1}}$ is uncorrelated with $\sum_{t_{2}=T_{0}+1}^{T} \frac{d_{1} d_{2} \mathbb{}\left(a_{2}=0\right)}{1-\pi_{t_{2}}} \xi_{t_{2}} X_{t_{2}}$, then the asymptotic variance is the sum of their individual variance, i.e., $\sigma_{1}^{2} S_{1}^{2}+\sigma_{0}^{2} S_{0}^{2}$. Notice that,

$$
\begin{aligned}
& \frac{b^{2}}{T^{2}} \sum_{t_{1}=T_{0}+1}^{T} \frac{d_{1} d_{2} \mathbb{1}\left(a_{t_{1}}=1\right)}{\pi_{t_{1}}} \xi_{t_{1}} X_{t_{1}} \sum_{t_{2}=T_{0}+1}^{T} \frac{d_{1} d_{2} \mathbb{1}\left(a_{t_{2}}=0\right)}{1-\pi_{t_{2}}} \xi_{t_{2}} X_{t_{2}} \\
= & \frac{b^{2} d_{1}^{2} d_{2}^{2}}{T^{2}} \sum_{t_{1}=T_{0}+1}^{T} \sum_{t_{2}=T_{0}+1}^{T} \frac{\mathbb{1}\left(a_{t_{1}}=1\right) \mathbb{1}\left(a_{t_{2}}=0\right)}{\pi_{t_{1}}\left(1-\pi_{t_{2}}\right)} \xi_{t_{1}} \xi_{t_{2}} X_{t_{1}} X_{t_{2}} .
\end{aligned}
$$

When $t_{1}=t_{2}, \mathbb{1}\left(a_{t_{1}}=1\right) \mathbb{1}\left(a_{t_{2}}=0\right)=0$. When $t_{1} \neq t_{2}, \mathbb{E}\left[\frac{\mathbb{1}\left(a_{t_{1}}=1\right) \mathbb{1}\left(a t_{2}=0\right)}{\pi t_{1}\left(1-\pi t_{2}\right)} \xi_{t_{1}} \xi_{t_{2}} X_{t_{1}} X_{t_{2}}\right]=0$ due to the i.i.d. distributed $\xi_{t}$. As a result, the two terms are uncorrelated.
Together with Lemma $5 \sqrt{7}$, all the negligible terms converge to 0 when divided by $\sqrt{\left(\sigma_{1}^{2} S_{1}^{2}+\sigma_{0}^{2} S_{0}^{2}\right) d_{1} d_{2} / T^{1-\gamma}}$. Then similar as Theorem 4, we can replace $\sigma_{1}^{2} S_{1}^{2}+\sigma_{0}^{2} S_{0}^{2}$ with $\widehat{\sigma}_{1}^{2} \widehat{S}_{1}^{2}+\widehat{\sigma}_{0}^{2} \widehat{S}_{0}^{2}$ and conclude the proof.

## B Proofs of Technical Lemmas

## B. 1 Proof of Lemma 1

Proof. step 1: Uniform bound for $\prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) A_{\tau}$ and $\prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) B_{\tau}$
For $\forall 1 \leq \tau \leq t-1$, under $\mathcal{E}_{\tau-1}$, by inequality $(a+b+c)^{2} \leq 3\left(a^{2}+b^{2}+c^{3}\right)$,

$$
\begin{aligned}
\left\|\Delta_{\tau}\right\|_{\mathrm{F}}^{2} & \leq \frac{24}{\varepsilon_{\tau}^{2}} \eta_{\tau}^{2}\left(\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{t}\right)^{2} \max \left(\left\|\widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|_{2, \max }^{2},\left\|\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right\|_{2, \max }^{2}\right) \\
& +\frac{48}{\varepsilon_{t}^{4}} \eta_{\tau}^{4}\left(\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right)^{4}\left\|\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right\|_{\max }^{2} .
\end{aligned}
$$

Since $\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\text {max }}^{2} \lesssim \frac{\mu_{0} r \kappa^{2}}{d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}}^{2} \lesssim \mu_{0} r \kappa^{2} \prod_{k=1}^{\tau-1}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\left\|\widehat{U}_{0} \hat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}}{d_{2}}+$ $\sum_{k=1}^{\tau-1} \frac{\mu_{0} \kappa^{2} \eta_{k}^{2} r^{2} \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}^{2}}$. And by the property of subGaussian random variable, $\max \left|\xi_{\tau}\right|<$
$C \sigma \log ^{1 / 2} d_{1}$ for some constant $C$. Therefore,

$$
\begin{aligned}
& \left\|\Delta_{\tau}\right\|_{\mathrm{F}}^{2} \lesssim \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}}\left(\mu_{0} r \kappa^{2} \prod_{k=1}^{\tau-1}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}}{d_{2}}+\sum_{k=1}^{\tau-1} \frac{\mu_{0} \kappa^{2} \eta_{k}^{2} r^{2} \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}^{2}}+\sigma^{2} \log d_{1}\right) \\
& \quad+\frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{4}} \frac{\mu_{0}^{3} r^{3} \kappa^{2} \lambda_{\max }^{2}}{d_{1} d_{2}}\left(\frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{1} d_{2}}\left(\prod_{k=1}^{\tau-1}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}}{d_{2}}+\sum_{k=1}^{\tau-1} \frac{\eta_{k}^{2} r \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}^{2}}\right)+\sigma^{4} \log ^{2} d_{1}\right)
\end{aligned}
$$

where we use $\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{4}=\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{2}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{2} \lesssim \frac{2 \mu_{0}^{3} r^{3} \kappa^{2} \lambda_{\max }^{2}}{d_{1} d_{2}}\left(\prod_{k=1}^{\tau-1}(1-\right.$ $\left.\left.\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}}{d_{2}}+\sum_{k=1}^{\tau-1} \frac{\eta_{k}^{2} r \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}^{2}}\right)$ in the second line. The fourth order terms will be dominated as long as $\eta_{\tau} \lesssim \frac{\varepsilon_{\tau} d_{1} d_{2}^{1 / 2}}{\mu_{0} r \lambda_{\max }}$ and $\frac{\lambda_{\min }^{2}}{\sigma^{2}} \gg \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}} \frac{\mu_{0} r \lambda_{\max }^{2} \log d_{1}}{d_{1} \kappa^{2}}$. So $\left\|\Delta_{\tau}\right\|_{\mathrm{F}}^{2} \lesssim \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}}\left(\mu_{0} r \kappa^{2} \prod_{k=1}^{\tau-1}(1-\right.$ $\left.\left.\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\left\|U_{0} V_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}}{d_{2}}+\sum_{k=1}^{\tau-1} \frac{\mu_{0} \kappa^{2} \eta_{k}^{2} r^{2} \lambda_{\text {max }}^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}^{2}}+\sigma^{2} \log d_{1}\right)$.
Similarly,

$$
\begin{aligned}
\left|\left\langle\Delta_{\tau}, \widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\rangle\right| \leq & \left|\frac{\mathbb{1}\left(a_{\tau}=1\right)}{\pi_{\tau}} \eta_{\tau}\left(\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right)\left\langle X_{\tau},\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right) \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\rangle\right| \\
& +\left|\frac{\mathbb{1}\left(a_{\tau}=1\right)}{\pi_{\tau}} \eta_{t}\left(\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right)\left\langle X_{\tau}, \widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right)\right\rangle\right| \\
& +\left|\frac{\mathbb{1}\left(a_{\tau}=1\right)}{\pi_{\tau}^{2}} \eta_{\tau}^{2}\left(\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right)^{2}\left\langle X_{\tau} \widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top} X_{\tau}, \widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\rangle\right| .
\end{aligned}
$$

For term $\left\langle X_{\tau},\left(U_{\tau-1} V_{\tau-1}^{\top}-M\right) \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\rangle$, we have

$$
\begin{aligned}
& \left\langle X_{\tau},\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right) \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\rangle=\left\langle X_{\tau} \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}, \widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\rangle \\
& \quad \leq\left\|\widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|_{2, \max }\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}} \leq \sqrt{\frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}}
\end{aligned}
$$

By symmetry, $\left\langle X_{\tau}, \widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right)\right\rangle \leq \sqrt{\frac{\mu_{0} r \lambda_{\max }^{2}}{d_{1}}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}}$. In addition,
$\left\langle X_{\tau} \widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top} X_{\tau}, \widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\rangle \leq\left\|\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right\|_{\max }\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}} \leq \frac{\mu_{0} r \lambda_{\max }}{\sqrt{d_{1} d_{2}}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}}$.

Therefore,

$$
\begin{aligned}
& \left|\left\langle\Delta_{\tau}, \widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\rangle\right| \lesssim \frac{\eta_{\tau}}{\varepsilon_{\tau}}\left(\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }+\sigma \log ^{1 / 2} d_{1}\right) \sqrt{\frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}} \\
& \quad+\frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}}\left(\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{2}+\sigma^{2} \log d_{1}\right) \frac{\mu_{0} r \lambda_{\max }}{\sqrt{d_{1} d_{2}}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}} \\
& \lesssim \\
& \frac{\eta_{\tau}}{\varepsilon_{t}}\left(\mu_{0}^{1 / 2} r^{1 / 2} \kappa \prod_{k=1}^{\tau-1}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)^{1 / 2} \frac{\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}}{\sqrt{d_{2}}}+\sqrt{\sum_{k=1}^{\tau-1} \frac{\mu_{0} \kappa^{2} \eta_{k}^{2} r^{2} \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}^{2}}}\right. \\
& \left.\quad+\sigma \log ^{1 / 2} d_{1}\right) \sqrt{\frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}} \\
& \lesssim \\
& \quad \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}}\left(\mu_{0} r \kappa^{2} \prod_{k=1}^{\tau-1}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}}{d_{2}}+\sum_{k=1}^{\tau-1} \frac{\mu_{0} \kappa^{2} \eta_{k}^{2} r^{2} \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}^{2}}+\sigma^{2} \log ^{2} d_{1}\right) \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}} \log d_{1} \\
& \quad+\left(\prod_{k=1}^{\tau-1}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}+\sum_{k=1}^{\tau-1} \frac{\eta_{k}^{2} r \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}}\right) \log ^{-1} d_{1} .
\end{aligned}
$$

By dealing $\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{2} \lesssim \frac{\mu_{0}^{3 / 2} r^{3 / 2} \kappa \lambda_{\max }}{\sqrt{d_{1} d_{2}}}\left(\prod_{k=1}^{\tau-1}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)^{1 / 2} \frac{\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}}{\sqrt{d_{2}}}+\sqrt{\sum_{k=1}^{\tau-1} \frac{\eta_{k}^{2} r \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}^{2}}}\right)$ as before, the second inequality holds since the second order term will be dominated as long as $\eta_{\tau} \lesssim \frac{\varepsilon_{\tau} d_{1} d_{2}^{1 / 2}}{\mu_{0} r \kappa \lambda_{\max }}$ and $\frac{\lambda_{\min }^{2}}{\sigma^{2}} \gg \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}} \frac{\mu_{0} r \lambda_{\max }^{2} \log d_{1}}{d_{1} \kappa^{2}}$. And the third inequality holds by $2 a b \leq a^{2}+b^{2}$. As a result, we have the uniform bound of $\prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) A_{\tau}$ for $1 \leq \tau \leq t-1$,

$$
\begin{aligned}
& \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) A_{\tau} \lesssim \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right)\left(\mu_{0} r \kappa^{2} \prod_{k=1}^{\tau-1}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}}{d_{2}}\right. \\
& \left.\quad+\sum_{k=1}^{\tau-1} \frac{\mu_{0} \kappa^{2} \eta_{k}^{2} r^{2} \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}^{2}}+\sigma^{2} \log d_{1}\right) \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}} \log d_{1} \\
& \quad+\prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right)\left(\prod_{k=1}^{\tau-1}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}+\sum_{k=1}^{\tau-1} \frac{\eta_{k}^{2} r \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}}\right) \log ^{-1} d_{1} \\
& \lesssim \max _{\tau} \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}} \log d_{1}\left(\mu_{0} r \kappa^{2} \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}}{d_{2}}+\sum_{k=1}^{t-1} \frac{\mu_{0} \kappa^{2} \eta_{k}^{2} r^{2} \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}^{2}}+\sigma^{2} \log d_{1}\right) \\
& \quad+\left(\prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} r \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}}\right) \log ^{-1} d_{1}:=R_{A} .
\end{aligned}
$$

Similarly,

$$
\begin{aligned}
& \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) B_{\tau} \lesssim \max _{\tau} \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}}\left(\mu_{0} r \kappa^{2} \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}}{d_{2}}\right. \\
& \left.\quad+\sum_{k=1}^{t} \frac{\mu_{0} \kappa^{2} \eta_{k}^{2} r^{2} \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}^{2}}+\sigma^{2} \log d_{1}\right):=R_{B} .
\end{aligned}
$$

Obviously, the uniform bounds for $A_{t}$ and $B_{t}$ are the same as above.
step2: Calculating the variance
Denote the variance of $\prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) A_{\tau}$ as $\sigma_{A \tau}^{2}$,

$$
\begin{aligned}
& \sigma_{A \tau}^{2} \lesssim \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right)^{2} \mathbb{E}\left[\left.\frac{\mathbb{1}\left(a_{\tau}=1\right)}{\pi_{\tau}^{2}} \eta_{\tau}^{2}\left(\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right)^{2}\left\langle X_{\tau},\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right) \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\rangle^{2} \right\rvert\, \mathcal{F}_{\tau-1}\right] \\
& \quad+\prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right)^{2} \mathbb{E}\left[\left.\frac{\mathbb{1}\left(a_{\tau}=1\right)}{\pi_{\tau}^{2}} \eta_{\tau}^{2}\left(\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right)^{2}\left\langle X_{\tau}, \widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right)\right\rangle^{2} \right\rvert\, \mathcal{F}_{\tau-1}\right] \\
& \quad+\prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right)^{2} \mathbb{E}\left[\left.\frac{\mathbb{1}\left(a_{\tau}=1\right)}{\pi_{\tau}^{4}} \eta_{\tau}^{4}\left(\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right)^{4}\left\langle X_{\tau} \widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top} X_{\tau}, \widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\rangle^{2} \right\rvert\, \mathcal{F}_{\tau-1}\right]
\end{aligned}
$$

For the first expectation, we have

$$
\begin{aligned}
\mathbb{E} & {\left[\left.\frac{\mathbb{1}\left(a_{\tau}=1\right)}{\pi_{\tau}^{2}} \eta_{\tau}^{2}\left(\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right)^{2}\left\langle X_{\tau},\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right) \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\rangle^{2} \right\rvert\, \mathcal{F}_{\tau-1}\right] } \\
\leq & \frac{2 \eta_{\tau}^{2}}{\varepsilon_{\tau}} \mathbb{E}\left[\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle^{2} \mid \mathcal{F}_{t-1}\right]\left|\left\langle X_{\tau} \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}, \widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\rangle\right|^{2} \\
& +\frac{2 \eta_{\tau}^{2}}{\varepsilon_{\tau}} \mathbb{E}\left[\xi_{\tau}^{2}\right] \mathbb{E}\left(\left\langle X_{\tau},\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right) \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\rangle^{2} \mid \mathcal{F}_{\tau-1}\right) \\
\leq & \frac{2 \eta_{\tau}^{2}}{\varepsilon_{\tau}} \frac{1}{d_{1} d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}}^{2}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}}^{2}\left\|\widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|_{2, \max }^{2} \\
& +\frac{2 \eta_{\tau}^{2} \sigma^{2}}{\varepsilon_{\tau}} \frac{1}{d_{1} d_{2}} \sum_{i j}\left(\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right) \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right)_{i j}^{2} \\
\leq & \frac{2 \eta_{\tau}^{2}}{\varepsilon_{\tau}} \frac{1}{d_{1} d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}}^{4} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}}+\frac{2 \eta_{\tau}^{2} \sigma^{2}}{\varepsilon_{\tau}} \frac{1}{d_{1} d_{2}}\left\|\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right) \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|_{\mathrm{F}}^{2} \\
\leq & \frac{2 \eta_{\tau}^{2}}{\varepsilon_{\tau}} \frac{1}{d_{1} d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}}^{4} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}}+\frac{2 \eta_{\tau}^{2} \sigma^{2}}{\varepsilon_{\tau}} \frac{1}{d_{1} d_{2}}\left\|\widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|^{2}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}}^{2} \\
\leq & \frac{2 \eta_{\tau}^{2}}{\varepsilon_{\tau}} \frac{1}{d_{1} d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}}^{4} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}}+\frac{2 \eta_{\tau}^{2} \sigma^{2}}{\varepsilon_{\tau}} \frac{O\left(\lambda_{\max }^{2}\right)}{d_{1} d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}}^{2}
\end{aligned}
$$

By symmetry,

$$
\begin{aligned}
& \mathbb{E}\left[\left.\frac{\mathbb{1}\left(a_{\tau}=1\right)}{\pi_{\tau}^{2}} \eta_{\tau}^{2}\left(\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right)^{2}\left\langle X_{\tau}, \widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right)\right\rangle^{2} \right\rvert\, \mathcal{F}_{\tau-1}\right] \\
\leq & \frac{2 \eta_{\tau}^{2}}{\varepsilon_{\tau}} \frac{1}{d_{1} d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}}^{4} O\left(\frac{\mu_{0} r \lambda_{\max }^{2}}{d_{1}}\right)+\frac{2 \eta_{\tau}^{2} \sigma^{2}}{\varepsilon_{\tau}} \frac{O\left(\lambda_{\max }^{2}\right)}{d_{1} d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}}^{2}
\end{aligned}
$$

And the last expectation is

$$
\begin{aligned}
& \mathbb{E}\left[\left.\frac{\mathbb{1}\left(a_{\tau}=1\right)}{\pi_{\tau}^{4}} \eta_{\tau}^{4}\left(\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right)^{4}\left\langle X_{\tau} \widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top} X_{\tau}, \widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\rangle^{2} \right\rvert\, \mathcal{F}_{\tau-1}\right] \\
\lesssim & \frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3}}\left(\frac{1}{d_{1} d_{2}} \sum_{i j}\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right)^{4}+\sigma^{4}\right)\left\|\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right\|_{\max }^{2}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}}^{2} \\
\lesssim & \frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3}}\left(\frac{1}{d_{1} d_{2}} \sum_{i j}\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right)^{4}+\sigma^{4}\right)\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}}^{2} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{1} d_{2}} .
\end{aligned}
$$

This gives,
$\sigma_{A \tau}^{2} \lesssim \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right)^{2} \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}} \frac{1}{d_{1} d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}}^{4} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}}+\prod_{k=\tau+1}^{t}(1-f(\eta k))^{2} \frac{\eta_{\tau}^{2} \lambda_{\max }^{2} \sigma^{2}}{\varepsilon_{\tau} d_{1} d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}}^{2}$.
The fourth order terms is dominated as long as $\eta_{\tau} \lesssim \frac{\varepsilon_{\tau} d_{1} d_{2}^{1 / 2}}{\sqrt{d_{1} d_{2} \lambda_{\text {max }}}}$ and $\frac{\lambda_{\text {min }}^{2}}{\sigma^{2}} \gg \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}} \frac{\mu_{0} r \lambda_{\text {max }}^{2}}{d_{1} \kappa^{2}}$. Since $\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}}^{2} \leq \prod_{k=1}^{\tau-1}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}+\sum_{k=1}^{\tau-1} \frac{c_{2} \eta_{k}^{2} r \lambda_{\text {max }}^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}}$, we can further obtain

$$
\begin{aligned}
\sigma_{A \tau}^{2} \lesssim & \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}} \frac{1}{d_{1} d_{2}}\left(\prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)^{2}\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{4}+\left(\sum_{k=1}^{t} \frac{c_{2} \eta_{k}^{2} r \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}}\right)^{2}\right) \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}} \\
& +\frac{\eta_{\tau}^{2} \lambda_{\max }^{2} \sigma^{2}}{\varepsilon_{\tau} d_{1} d_{2}} \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}+\frac{\eta_{\tau}^{2} \lambda_{\max }^{2} \sigma^{2}}{\varepsilon_{\tau} d_{1} d_{2}} \sum_{k=1}^{t} \frac{c_{2} \eta_{k}^{2} r \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}}
\end{aligned}
$$

As a result,

$$
\begin{aligned}
\sqrt{\sum_{\tau=1}^{t} \sigma_{A \tau}^{2}} \lesssim & \sqrt{\sum_{\tau=1}^{t} \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}}} \frac{1}{\sqrt{d_{1} d_{2}}} \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2} O\left(\sqrt{\frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}}}\right) \\
& +\sqrt{\sum_{\tau=1}^{t} \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}}} \frac{1}{\sqrt{d_{1} d_{2}}} \sum_{k=1}^{t} \frac{c_{2} \eta_{k}^{2} r \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}} O\left(\sqrt{\frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}}}\right) \\
& +\prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2} \log ^{-1 / 2} d_{1}+\sum_{\tau=1}^{t} \frac{\eta_{\tau}^{2} \lambda_{\max }^{2} \sigma^{2} \log ^{3 / 2} d_{1}}{\varepsilon_{\tau} d_{1} d_{2}}
\end{aligned}
$$

where we apply inequality $2 a b \leq a^{2}+b^{2}$ to term $\sqrt{\sum_{\tau=1}^{t} \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}}} \sqrt{\frac{\lambda_{\max }^{2} \sigma^{2}}{d_{1} d_{2}}} \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)^{1 / 2} \| \widehat{U}_{0} \widehat{V}_{0}^{\top}-$ $M \|_{\mathrm{F}}$.

Similarly, denote the variance of $\prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) B_{\tau}$ as $\sigma_{B \tau}^{2}$, it can be shown that,

$$
\begin{aligned}
\sigma_{B \tau}^{2} \lesssim & \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right)^{2} \frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3}}\left(\mathbb{E}\left[\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle^{4} \mid \mathcal{F}_{\tau-1}\right] \max \left(\left\|\widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|_{2, \max }^{4},\left\|\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right\|_{2, \max }^{4}\right)\right. \\
& \left.+\mathbb{E}\left[\xi_{\tau}^{4}\right] \max \left(\mathbb{E}\left[\left\|X_{\tau} \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|_{\mathrm{F}}^{4} \mid \mathcal{F}_{\tau-1}\right], \mathbb{E}\left[\left\|\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top} X_{\tau}\right\|_{\mathrm{F}}^{4} \mid \mathcal{F}_{\tau-1}\right]\right)\right) \\
\lesssim & \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right)^{2} \frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3}}\left(\frac{1}{d_{1} d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}}^{2}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{2} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{4}}{d_{2}^{2}}+\sigma^{4} \frac{\mu_{0} r \lambda_{\max }^{4}}{d_{2}^{2}}\right) \\
\lesssim & \frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3}} \frac{1}{d_{1} d_{2}^{2}}\left(\prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} r \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}}\right)^{2} \frac{\mu_{0}^{3} r^{3} \kappa^{2} \lambda_{\max }^{4}}{d_{2}^{2}}+\frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3}} \sigma^{4} \frac{\mu_{0} r \lambda_{\max }^{4}}{d_{2}^{2}}
\end{aligned}
$$

where the second term in the second last inequality comes from $\mathbb{E}\left(\left\|X_{\tau} \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|_{\mathrm{F}}^{4} \mid \mathcal{F}_{\tau-1}\right) \leq$ $\mathbb{E}\left(\left\|X_{\tau} \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|_{\mathrm{F}}^{2} \mid \mathcal{F}_{\tau-1}\right)\left\|\widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|_{2, \text { max }}^{2} \leq \frac{r O\left(\lambda_{\max }^{2}\right)}{d_{2}} O\left(\frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}}\right)$. And in the last inequality we again use $\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\text {max }}^{2} \lesssim \frac{\mu_{0} r \kappa^{2}}{d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\mathrm{F}}^{2} \lesssim \mu_{0} r \kappa^{2} \prod_{k=1}^{\tau-1}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\left\|\widehat{U}_{0} \hat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}}{d_{2}}+$ $\sum_{k=1}^{\tau-1} \frac{\mu_{0} \kappa^{2} \eta_{k}^{2} r^{2} \lambda_{\text {max }}^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}^{2}}$. Therefore, $\sqrt{\sum_{\tau=1}^{t} \sigma_{B \tau}^{2}} \lesssim \sqrt{\sum_{\tau=1}^{t} \frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3}}} \frac{1}{d_{1} d_{2}^{1 / 2}}\left(\prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \| \widehat{U}_{0} \widehat{V}_{0}^{\top}-\right.$ $\left.M \|_{\mathrm{F}}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} r \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}}\right) \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}}+\sqrt{\sum_{\tau=1}^{t} \frac{\eta_{T}^{4}}{\varepsilon_{T}^{3}}} \frac{\mu_{0} r \lambda_{\max }^{2} \sigma^{2}}{d_{2}}$.
step3: Concentration
From the calculation in step2, $R_{A} \log d_{1}+\sqrt{\sum_{\tau=1}^{t} \sigma_{A \tau}^{2} \log d_{1}} \lesssim \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}+$ $\sum_{k=1}^{t} \frac{c_{2} \eta_{k}^{2} r \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}}$ and $R_{B} \log d_{1}+\sqrt{\sum_{\tau=1}^{t} \sigma_{B \tau}^{2} \log d_{1}} \lesssim \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}+$ $\sum_{k=1}^{t} \frac{c_{2} \eta_{k}^{2} r \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}}$ as long as 1. $\max _{\tau \leq t} \frac{\eta_{T}^{2}}{\varepsilon_{\tau}^{2}} \leq \sum_{\tau=1}^{t} \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}}, 2 . \eta_{\tau} \lesssim \frac{\varepsilon_{\tau} d_{2}}{\sqrt{\mu_{0} r} \lambda_{\max } \log ^{1 / 2} d_{1}}$,
$3 . \sum_{\tau=1}^{t} \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}} \lesssim \frac{d_{1} d_{2}^{2}}{\mu_{0} r \lambda_{\max }^{2} \log d_{1}}, 4 . \quad \sum_{\tau=1}^{t} \frac{\eta_{T}^{4}}{\varepsilon_{T}^{3}} \lesssim \frac{d_{1}^{2} d_{2}^{3}}{\mu_{0}^{2} r^{2} \lambda_{\max }^{4} \log d_{1}}, 5 . \sqrt{\sum_{\tau=1}^{t} \frac{\eta_{T}^{4}}{\varepsilon_{\tau}^{3}}} \lesssim \sum_{\tau=1}^{t} \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}}$. Under the stepsize and SNR conditions in Theorem 1, all of them can be satisfied.
By martingale Bernstein inequality, with probability at least $1-d_{1}^{-200}$,

$$
\begin{aligned}
& \sum_{\tau=1}^{t-1} \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) A_{\tau}+A_{t} \lesssim \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} r \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}} \\
& \sum_{\tau=1}^{t-1} \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) B_{\tau}+B_{t} \lesssim \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} r \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}}
\end{aligned}
$$

## B. 2 Proof of Lemma 2

Proof. For any $l$ in $\left[d_{1}\right]$,

$$
\left\|e_{l}^{\top} \widehat{U}_{t} \widehat{V}_{t}^{\top}\right\|^{2}=e_{l}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-\Delta_{t}\right)\left(\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top}-\Delta_{t}^{\top}\right) e_{l}=\left\|e_{l}^{\top} \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}\right\|^{2}-2 e_{l}^{\top} \Delta_{t} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l}+\left\|e_{l}^{\top} \Delta_{t}\right\|^{2}
$$

This leads to

$$
\mathbb{E}\left[\left\|e_{l}^{\top} \widehat{U}_{t} \widehat{V}_{t}^{\top}\right\|^{2} \mid \mathcal{F}_{t-1}\right]=\left\|e_{l}^{\top} \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}\right\|^{2}-2 \mathbb{E}\left[e_{l}^{\top} \Delta_{t} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l} \mid \mathcal{F}_{t-1}\right]+\mathbb{E}\left[\left\|e_{l}^{\top} \Delta_{t}\right\|^{2} \mid \mathcal{F}_{t-1}\right] .
$$

We first compute $2 \mathbb{E}\left[e_{l}^{\top} \Delta_{t} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l} \mid \mathcal{F}_{t-1}\right]$. Denote $\delta_{i j}=\mathbb{1}(i=j)$, then

$$
\begin{aligned}
& 2 \mathbb{E}\left(e_{l}^{\top} \Delta_{t} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l} \mid \mathcal{F}_{t-1}\right)=2 \mathbb{E}\left[\left.e_{l}^{\top} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}} \eta_{t}\left(\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M, X_{t}\right\rangle-\xi_{t}\right) X_{t} \widehat{V}_{t-1} \widehat{V}_{t-1}^{\top} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l} \right\rvert\, \mathcal{F}_{t-1}\right] \\
& \quad+2 \mathbb{E}\left[\left.e_{l}^{\top} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}} \eta_{t}\left(\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M, X_{t}\right\rangle-\xi_{t}\right) \widehat{U}_{t-1} \widehat{U}_{t-1}^{\top} X_{t} V_{t-1} U_{t-1}^{\top} e_{l} \right\rvert\, \mathcal{F}_{t-1}\right] \\
& \quad-2 \mathbb{E}\left[\left.e_{l}^{\top} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}^{2}} \eta_{t}^{2}\left(\left\langle U_{t-1} V_{t-1}^{\top}-M, X_{t}\right\rangle-\xi_{t}\right)^{2} X_{t} V_{t-1} U_{t-1}^{\top} X_{t} V_{t-1} U_{t-1}^{\top} e_{l} \right\rvert\, \mathcal{F}_{t-1}\right] \\
& \geq \\
& \geq \frac{2 \eta_{t}}{d_{1} d_{2}} e_{l}^{\top}\left(U_{t-1} V_{t-1}^{\top}-M\right) \widehat{V}_{t-1} \widehat{V}_{t-1}^{\top} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l}+\frac{2 \eta_{t}}{d_{1} d_{2}} e_{l}^{\top} \widehat{U}_{t-1} \widehat{U}_{t-1}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right) \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l} \\
& \quad-\frac{4 \eta_{t}^{2}}{\varepsilon_{t} d_{1} d_{2}} \sum_{i j} \delta_{i l}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)_{i j}^{2}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}\right)_{i j}^{2}-\frac{4 \eta_{t}^{2} \sigma^{2}}{\varepsilon_{t} d_{1} d_{2}} \sum_{i j} \delta_{i l}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}\right)_{i j}^{2} \\
& \geq \\
& \geq \frac{\eta_{t} \lambda_{\min }}{d_{1} d_{2}} e_{l}^{\top} \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l}-\frac{4 \eta_{t} \lambda_{\max }}{d_{1} d_{2}} e_{l}^{\top} M \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l}+\frac{\eta_{t} \lambda_{\min }}{d_{1} d_{2}} e_{l}^{\top} \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l} \\
& \quad-\frac{4 \eta_{t} \lambda_{\max }}{d_{1} d_{2}} e_{l}^{\top} M \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l}-\frac{4 \eta_{t}^{2}}{\varepsilon_{t} d_{1} d_{2}} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{4}}{d_{1}^{2}}-\frac{4 \eta_{t}^{2} \sigma^{2}}{\varepsilon_{t} d_{1} d_{2}} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{1}} \\
& \geq \\
& \geq \frac{2 \eta_{t} \lambda_{\min }}{d_{1} d_{2}}\left\|e_{l}^{\top} \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}\right\|^{2}-\frac{8 \eta_{t} \lambda_{\max }}{d_{1} d_{2}} \frac{\sqrt{\mu \mu_{0} r \lambda_{\max }^{2}}}{d_{1}}-\frac{4 \eta_{t}^{2}}{\varepsilon_{t} d_{1} d_{2}} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{4}}{d_{1}^{2}}-\frac{4 \eta_{t}^{2} \sigma^{2}}{\varepsilon_{t} d_{1} d_{2}} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{1}} .
\end{aligned}
$$

The second order term in the second last inequality comes from $\sum_{i j} \delta_{i l}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)_{i j}^{2}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}\right)_{i j}^{2} \leq$ $\left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\|_{2, \max }^{2}\left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}\right\|_{2, \max }^{2}$. And the other term is similar. The last inequality holds since $e_{l}^{\top} M \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l} \leq\left\|e_{l}^{\top} M\right\|\left\|\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l}\right\|$ and $\left\|e_{l}^{\top} M\right\| \leq \sqrt{\frac{\mu r \lambda_{\text {max }}^{2}}{d_{1}}}$ while $\left\|\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l}\right\| \leq \sqrt{\frac{\mu_{0} r \lambda_{\text {max }}^{2}}{d_{1}}}$. Then we compute $\mathbb{E}\left(\left\|e_{l}^{\top} \Delta_{t}\right\|^{2} \mid \mathcal{F}_{t-1}\right)$. Since $(a+b+c)^{2} \leq 3 a^{2}+3 b^{2}+3 c^{2}$,
$\mathbb{E}\left(\left\|e_{l}^{\top} \Delta_{t}\right\|^{2} \mid \mathcal{F}_{t-1}\right) \leq 3 \mathbb{E}\left[\left.e_{l}^{\top} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}^{2}} \eta_{t}^{2}\left(\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M, X_{t}\right\rangle-\xi_{t}\right)^{2} X_{t} \widehat{V}_{t-1} \widehat{V}_{t-1}^{\top} \widehat{V}_{t-1} \widehat{V}_{t-1}^{\top} X_{t}^{\top} e_{l} \right\rvert\, \mathcal{F}_{t-1}\right]$

$$
\begin{aligned}
& +3 \mathbb{E}\left[\left.e_{l}^{\top} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}^{2}} \eta_{t}^{2}\left(\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M, X_{t}\right\rangle-\xi_{t}\right)^{2} \widehat{U}_{t-1} \widehat{U}_{t-1}^{\top} X_{t} X_{t}^{\top} \widehat{U}_{t-1} \widehat{U}_{t-1}^{\top} e_{l} \right\rvert\, \mathcal{F}_{t-1}\right] \\
& +3 \mathbb{E}\left[\left.e_{l}^{\top} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}^{4}} \eta_{t}^{4}\left(\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M, X_{t}\right\rangle-\xi_{t}\right)^{4} X_{t} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} X_{t} X_{t}^{\top} \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top} X_{t}^{\top} e_{l} \right\rvert\, \mathcal{F}_{t-1}\right] .
\end{aligned}
$$

The first term can be written as,

$$
\begin{aligned}
& 3 \mathbb{E}\left[\left.e_{l}^{\top} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}^{2}} \eta_{t}^{2}\left(\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M, X_{t}\right\rangle-\xi_{t}\right)^{2} X_{t} \widehat{V}_{t-1} \widehat{V}_{t-1}^{\top} \widehat{V}_{t-1} \widehat{V}_{t-1}^{\top} X_{t}^{\top} e_{l} \right\rvert\, \mathcal{F}_{t-1}\right] \\
& \leq \frac{6 \eta_{t}^{2}}{\varepsilon_{t} d_{1} d_{2}} \sum_{i j}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)_{i j}^{2} \delta_{i l}\left\|e_{j}^{\top} \widehat{V}_{t-1} \widehat{V}_{t-1}^{\top}\right\|^{2}+\frac{6 \eta_{t}^{2}}{\varepsilon_{t} d_{1} d_{2}} \sigma^{2} \sum_{i j} \delta_{i l}\left\|e_{j}^{\top} \widehat{V}_{t-1} \widehat{V}_{t-1}^{\top}\right\|^{2} \\
& \leq \frac{6 \eta_{t}^{2}}{\varepsilon_{t} d_{1} d_{2}} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}}\left\|e_{l}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)\right\|^{2}+\frac{6 \eta_{t}^{2}}{\varepsilon_{t} d_{1}} \frac{\mu_{0} r \lambda_{\max }^{2} \sigma^{2}}{d_{2}} \\
& \leq \frac{6 \eta_{t}^{2}}{\varepsilon_{t} d_{1} d_{2}} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{4}}{d_{1} d_{2}}+\frac{6 \eta_{t}^{2}}{\varepsilon_{t} d_{1}} \frac{\mu_{0} r \lambda_{\max }^{2} \sigma^{2}}{d_{2}} .
\end{aligned}
$$

Similarly,

$$
\begin{aligned}
& 3 \mathbb{E}\left[\left.e_{l}^{\top} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}^{2}} \eta_{t}^{2}\left(\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M, X_{t}\right\rangle-\xi_{t}\right)^{2} \widehat{U}_{t-1} \widehat{U}_{t-1}^{\top} X_{t} X_{t}^{\top} \widehat{U}_{t-1} \widehat{U}_{t-1}^{\top} e_{l} \right\rvert\, \mathcal{F}_{t-1}\right] \\
& \leq \frac{6 \eta_{t}^{2}}{\varepsilon_{t} d_{1} d_{2}} \sum_{i j}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)_{i j}^{2}\left(\widehat{U}_{t-1} \widehat{U}_{t-1}^{\top}\right)_{l i}^{2}+\frac{6 \eta_{t}^{2} \sigma^{2}}{\varepsilon_{t} d_{1} d_{2}} \sum_{i j}\left(\widehat{U}_{t-1} \widehat{U}_{t-1}^{\top}\right)_{l i}^{2} \\
& \leq \frac{6 \eta_{t}^{2}}{\varepsilon_{t} d_{1} d_{2}} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{4}}{d_{1}^{2}}+\frac{6 \eta_{t}^{2} \sigma^{2}}{\varepsilon_{t} d_{1}} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{1}} .
\end{aligned}
$$

And the last fourth order term can be bounded in the same way. Moreover, the first order term $\frac{8 \eta_{t} \lambda_{\text {max }}}{d_{1} d_{2}} \frac{\sqrt{\mu \mu_{0}} r \lambda_{\text {max }}^{2}}{d_{1}}$ will dominate all the higher order terms as long as $\eta_{t} \lesssim \frac{\varepsilon_{t} d_{2}}{\mu_{0} r \lambda_{\text {max }}}$ and $\frac{\lambda_{\text {min }}^{2}}{\sigma^{2}} \gg$ $\frac{\eta_{t}}{\varepsilon_{t}} \frac{\lambda_{\max } d_{1}}{\kappa}$. So the sum of all the higher order terms will be less than $\frac{2 \eta_{t} \lambda_{\text {max }}}{d_{1} d_{2}} \frac{\sqrt{\mu \mu_{0}} r \lambda_{\text {max }}^{2}}{d_{1}}$. Recall $f\left(\eta_{t}\right)=\frac{\eta_{t} \lambda_{\text {min }}}{d_{1} d_{2}}$. Overall, we have

$$
\begin{aligned}
\left\|e_{l}^{\top} U_{t} V_{t}^{\top}\right\|^{2}= & \left\|e_{l}^{\top} \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}\right\|^{2}-2 e_{l}^{\top} \Delta_{t} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l}+\left\|e_{l}^{\top} \Delta_{t}\right\|^{2} \\
= & \left\|e_{l}^{\top} \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}\right\|^{2}-2\left(e_{l}^{\top} \Delta_{t} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l}-\mathbb{E}\left(e_{l}^{\top} \Delta_{t} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l} \mid \mathcal{F}_{t-1}\right)\right) \\
& +\left(\left\|e_{l}^{\top} \Delta_{t}\right\|^{2}-\mathbb{E}\left(\left\|e_{l}^{\top} \Delta_{t}\right\|^{2} \mid \mathcal{F}_{t-1}\right)\right)-2 \mathbb{E}\left(e_{l}^{\top} \Delta_{t} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l} \mid \mathcal{F}_{t-1}\right)+\mathbb{E}\left(\left\|e_{l}^{\top} \Delta_{t}\right\|^{2} \mid \mathcal{F}_{t-1}\right) \\
\leq & \left(1-f\left(\eta_{t}\right)\right)\left\|e_{l}^{\top} \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}\right\|^{2}+\frac{10 \eta_{t} \sqrt{\mu \mu_{0}} r \lambda_{\max }^{3}}{d_{1}^{2} d_{2}} \\
& +\underbrace{2\left(\mathbb{E}\left(e_{l}^{\top} \Delta_{t} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l} \mid \mathcal{F}_{t-1}\right)-e_{l}^{\top} \Delta_{t} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l}\right)}_{A_{t}}+\underbrace{\left(\left\|e_{l}^{\top} \Delta_{t}\right\|^{2}-\mathbb{E}\left(\left\|e_{l}^{\top} \Delta_{t}\right\|^{2} \mid \mathcal{F}_{t-1}\right)\right)}_{B_{t}} \\
\leq & \left(1-f\left(\eta_{t}\right)\right)\left(1-f\left(\eta_{t-1}\right)\right)\left\|e_{l}^{\top} \widehat{U}_{t-2} \widehat{V}_{t-2}^{\top}\right\|^{2}+\left(1-f\left(\eta_{t-1}\right)\right) \frac{10 \eta_{t-1} \sqrt{\mu \mu_{0}} r \lambda_{\max }^{3}}{d_{1}^{2} d_{2}}+\frac{10 \eta_{t} \sqrt{\mu \mu_{0}} r \lambda_{\max }^{3}}{d_{1}^{2} d_{2}} \\
& +\left(1-f\left(\eta_{t}\right)\right)\left(A_{t-1}+B_{t-1}\right)+\left(A_{t}+B_{t}\right) \\
\leq & \prod_{\tau=1}^{t}\left(1-f\left(\eta_{\tau}\right)\right)\left\|e_{l}^{\top} \widehat{U}_{0} \widehat{V}_{0}^{\top}\right\|^{2}+\sum_{\tau=1}^{t} \frac{10 \eta_{\tau} \sqrt{\mu \mu_{0}} r \lambda_{\max }^{3}}{d_{1}^{2} d_{2}}+\sum_{\tau=1}^{t} A_{\tau}+\sum_{\tau=1}^{t} B_{\tau} .
\end{aligned}
$$

It can be shown that the first term is less than $\frac{1}{6} \frac{\mu_{0} r \lambda_{\text {max }}^{2}}{d_{1}}$. The second term will be less than $\frac{1}{2} \frac{\mu_{0} r \lambda_{\text {max }}^{2}}{d_{1}}$ as long as $\mu_{0}=100 \mu$ and $\sum_{\tau=1}^{t} \eta_{\tau} \leq \frac{d_{1} d_{2}}{2 \lambda_{\text {max }}}$, which is satisfied under the stepsize condition
in Theorem 1. Then we need to show $\sum_{\tau=1}^{t} A_{\tau} \leq \frac{1}{6} \frac{\mu_{0} r \lambda_{\text {max }}^{2}}{d_{1}}$ and $\sum_{\tau=1}^{t} B_{\tau} \leq \frac{1}{6} \frac{\mu_{0} r \lambda_{\text {max }}^{2}}{d_{1}}$.
Similar as the proof of Lemma 1, we first derive the uniform bound for $A_{\tau}$ and $B_{\tau}$. Under $\mathcal{E}_{\tau-1}$, obviously, $\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{2} \lesssim \frac{\lambda_{\text {max }}^{2}}{d_{1} d_{2}}$. We use this trivial bound in the following calculation.

$$
\begin{aligned}
\left|e_{l}^{\top} \Delta_{\tau} \widehat{V}_{\tau-1} \hat{U}_{\tau-1}^{\top} e_{l}\right| \leq & \left|e_{l}^{\top} \frac{\mathbb{1}\left(a_{\tau}=1\right)}{\pi_{\tau}} \eta_{\tau}\left(\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right) X_{\tau} \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top} \widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top} e_{l}\right| \\
& +\left|e_{l}^{\top} \frac{\mathbb{1}\left(a_{\tau}=1\right)}{\pi_{\tau}} \eta_{\tau}\left(\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right) \widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top} X_{\tau} \widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top} e_{l}\right| \\
& +\left|e_{l}^{\top} \frac{\mathbb{1}\left(a_{\tau}=1\right)}{\pi_{\tau}^{2}} \eta_{\tau}^{2}\left(\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right)^{2} X_{\tau} \widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top} X_{\tau} \widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top} e_{l}\right| \\
\leq & \frac{2 \eta_{\tau}}{\varepsilon_{\tau}}\left|\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right| \max \left|e_{j}^{\top} \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top} \widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top} e_{l}\right| \\
& +\frac{2 \eta_{\tau}}{\varepsilon_{\tau}}\left|\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right|\left\|e_{l}^{\top} \widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top} X_{\tau}\right\|\| \| \widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top} e_{l} \| \\
& +\frac{4 \eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}}\left|\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right|^{2} \max _{j}\left\|e_{j}^{\top} \widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top} X_{\tau}\right\|\left\|\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top} e_{l}\right\| \\
\leq & \frac{2 \eta_{\tau}}{\varepsilon_{\tau}}\left(\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }+\sigma \log ^{1 / 2} d_{1}\right) \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{1} d_{2}} \\
& +\frac{2 \eta_{\tau}}{\varepsilon_{\tau}}\left(\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }+\sigma \log ^{1 / 2} d_{1}\right) \sqrt{\frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{1} d_{2}}} \sqrt{\frac{\mu_{0} r \lambda_{\max }^{2}}{d_{1}}} \\
& +\frac{4 \eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}}\left(\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{2}+\sigma^{2} \log d_{1}\right) \sqrt{\frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{1} d_{2}}} \sqrt{\frac{\mu_{0} r \lambda_{\max }^{2}}{d_{1}}} \\
\lesssim & \frac{\eta_{\tau}}{\varepsilon_{\tau}}\left(\frac{\lambda_{\max }}{\sqrt{d_{1} d_{2}}}+\sigma \log ^{1 / 2} d_{1}\right) \sqrt{\frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{1} d_{2}}} \sqrt{\frac{\mu_{0} r \lambda_{\max }^{2}}{d_{1}}} .
\end{aligned}
$$

The first order term dominates as long as $\eta_{\tau} \lesssim \frac{\varepsilon_{\tau} \sqrt{d_{1} d_{2}}}{\lambda_{\max }}$ and $\frac{\lambda_{\min }^{2}}{\sigma^{2}} \gg \frac{\eta_{\tau}^{2} \lambda_{\max }^{2} \log d_{1}}{\kappa}$. Then

$$
A_{\tau} \lesssim \max _{\tau} \frac{\eta_{\tau}}{\varepsilon_{\tau}}\left(\frac{\lambda_{\max }}{\sqrt{d_{1} d_{2}}}+\sigma \log ^{1 / 2} d_{1}\right) O\left(\sqrt{\frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{1} d_{2}}}\right) O\left(\sqrt{\frac{\mu_{0} r \lambda_{\max }^{2}}{d_{1}}}\right):=R_{A} .
$$

For $\left\|e_{l}^{\top} \Delta_{\tau}\right\|^{2}$, we also have

$$
\begin{aligned}
& \left\|e_{l}^{\top} \Delta_{\tau}\right\|^{2} \lesssim\left|e_{l}^{\top} \frac{\mathbb{1}\left(a_{\tau}=1\right)}{\pi_{\tau}^{2}} \eta_{\tau}^{2}\left(\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right)^{2} X_{\tau} \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top} \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top} X_{\tau}^{\top} e_{l}\right| \\
& \quad+\left|e_{l}^{\top} \frac{\mathbb{1}\left(a_{\tau}=1\right)}{\pi_{\tau}^{2}} \eta_{\tau}^{2}\left(\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right)^{2} \widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top} X_{\tau} X_{\tau}^{\top} \widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top} e_{l}\right| \\
& \quad+\left|e_{l}^{\top} \frac{\mathbb{1}\left(a_{\tau}=1\right)}{\pi_{\tau}^{4}} \eta_{\tau}^{4}\left(\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right)^{4} X_{\tau} \widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top} X_{\tau} X_{\tau}^{\top} \widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top} X_{\tau}^{\top} e_{l}\right| \\
& \lesssim \\
& \lesssim \eta_{\tau}^{2} \mid\left\langle\left\langle\widehat{U}_{\tau-1}^{2} \widehat{V}_{\tau-1}^{\top}-M, X_{t}\right\rangle-\left.\xi_{t}\right|^{2} \max _{j}\right| e_{j}^{\top} \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top} \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top} e_{j} \mid \\
& \quad+\frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}}\left|\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right|^{2}\left\|e_{l}^{\top} \widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top} X_{\tau}\right\|^{2} \\
& \quad+\frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{4}}\left|\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right|^{4} \max _{j}\left\|e_{j}^{\top} \widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top} X_{\tau}\right\|^{2} \\
& \lesssim \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}}\left(\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{2}+\sigma^{2} \log d_{1}\right) \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{2}^{2}}+\frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}}\left(\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{2}+\sigma^{2} \log d_{1}\right) \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{1}^{2}} \\
& \quad+\frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{4}}\left(\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{4}+\sigma^{4} \log ^{2} d_{1}\right) \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{1} d_{2}} \\
& \lesssim \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}}\left(\frac{\lambda_{\max }^{2}}{d_{1} d_{2}}+\sigma^{2} \log d_{1}\right) \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{2}^{2}} .
\end{aligned}
$$

The second order term dominates as long as $\eta_{\tau} \lesssim \frac{\varepsilon_{\tau} d_{1}}{\lambda_{\max }}$ and $\frac{\lambda_{\min }^{2}}{\sigma^{2}} \gg \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}} \frac{\lambda_{\max }^{2}}{\kappa^{2}} \log d_{1}$. Then

$$
B_{\tau} \lesssim \max _{\tau} \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}}\left(\frac{\lambda_{\max }^{2}}{d_{1} d_{2}}+\sigma^{2} \log d_{1}\right) O\left(\frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{2}^{2}}\right):=R_{B} .
$$

The variance of $A_{\tau}$ and $B_{\tau}$, denoted as $\sigma_{A \tau}^{2}$ and $\sigma_{B \tau}^{2}$, can be calculated as before.

$$
\begin{aligned}
\sigma_{A \tau}^{2} \lesssim & \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau} d_{1} d_{2}} \sum_{i j}\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right)_{i j}^{2} \delta_{i l}\left(\widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top} \widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{j l}^{2} \\
& +\frac{\eta_{\tau}^{2}}{\varepsilon_{\tau} d_{1} d_{2}} \sum_{i j}\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right)_{i j}^{2}\left(\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{l i}^{2}\left(\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{j l}^{2} \\
& +\frac{\eta_{\tau}^{2} \sigma^{2}}{\varepsilon_{\tau} d_{1} d_{2}} \sum_{i j} \delta_{i l}\left(\widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top} \widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{j l}^{2}+\frac{\eta_{\tau}^{2} \sigma^{2}}{\varepsilon_{\tau} d_{1} d_{2}} \sum_{i j}\left(\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{l i}^{2}\left(\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{j l}^{2} \\
\lesssim & \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau} d_{1} d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{2} \sum_{i j} \delta_{i l}\left(\widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top} \widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{j l}^{2} \\
& +\frac{\eta_{\tau}^{2}}{\varepsilon_{\tau} d_{1} d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{2}\left\|\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right\|_{\max }^{2} \sum_{i j}\left(\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{j l}^{2} \\
& +\frac{\eta_{\tau}^{2} \sigma^{2}}{\varepsilon_{\tau} d_{1} d_{2}} \sum_{i j} \delta_{i l}\left(\widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top} \widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{j l}^{2}+\frac{\eta_{\tau}^{2} \sigma^{2}}{\varepsilon_{\tau} d_{1} d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right\|_{\max }^{2} \sum_{i j}\left(\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{j l}^{2} \\
\lesssim & \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau} d_{1} d_{2}} \frac{\lambda_{\max }^{2}}{d_{1} d_{2}} \frac{\mu_{0} r \lambda_{\max }^{4}}{d_{1}}+\frac{\eta_{\tau}^{2}}{\varepsilon_{\tau} d_{2}} \frac{\lambda_{\max }^{2}}{d_{1} d_{2}} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{1}^{2}} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{1}} \\
& +\frac{\eta_{\tau}^{2} \sigma^{2}}{\varepsilon_{\tau} d_{1} d_{2}} \frac{\mu_{0} r \lambda_{\max }^{4}}{d_{1}}+\frac{\eta_{\tau}^{2} \sigma^{2}}{\varepsilon_{\tau} d_{2}} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{1}^{2}} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{1}},
\end{aligned}
$$

where we apply $\sum_{i j} \delta_{i l}\left(\widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top} \widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{j l}^{2}=\left\|e_{l} \widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top} \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|^{2} \leq\left\|e_{l} \widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|^{2}\left\|\widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|^{2}$ $\lesssim \frac{\mu_{0} r \lambda_{\text {max }}^{2}}{d_{1}} \lambda_{\text {max }}^{2}$ in the last inequality.
Similarly,

$$
\begin{aligned}
\sigma_{B \tau}^{2} \lesssim & \frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3} d_{1} d_{2}} \sum_{i j}\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right)_{i j}^{4} \delta_{i l}\left\|e_{j}^{\top} \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|^{4}+\frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3} d_{1} d_{2}} \sigma^{4} \sum_{i j} \delta_{i l}\left\|e_{j}^{\top} \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|^{4} \\
& +\frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3} d_{1} d_{2}} \sum_{i j}\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right)_{i j}^{4}\left(\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{l i}^{4}+\frac{\eta_{\tau}^{4} \sigma^{4}}{\varepsilon_{\tau}^{3} d_{1} d_{2}} \sum_{i j}\left(\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{l i}^{4} \\
\lesssim & \frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3} d_{1} d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{4} \sum_{i j} \delta_{i l} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{4}}{d_{2}^{2}}+\frac{\eta_{\tau}^{4} \sigma^{4}}{\varepsilon_{\tau}^{3} d_{1} d_{2}} \sum_{i j} \delta_{i l} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{4}}{d_{2}^{2}} \\
& +\frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3} d_{1} d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{4}\left\|\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right\|_{\max }^{2} \sum_{i j}\left(\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{l i}^{2} \\
& +\frac{\eta_{\tau}^{4} \sigma^{4}}{\varepsilon_{\tau}^{3} d_{1} d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right\|_{\max }^{2} \sum_{i j}\left(\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{l i}^{2} \\
\lesssim & \frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3} d_{1}} \frac{\lambda_{\max }^{4}}{d_{1}^{2} d_{2}^{2}} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{4}}{d_{2}^{2}}+\frac{\eta_{\tau}^{4} \sigma^{4}}{\varepsilon_{\tau}^{3} d_{1}} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{4}}{d_{2}^{2}} \\
& +\frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3} d_{1}} \frac{\lambda_{\max }^{4}}{d_{1}^{2} d_{2}^{2}} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{1}^{2}} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{1}}+\frac{\eta_{\tau}^{4} \sigma^{4}}{\varepsilon_{\tau}^{3} d_{1}} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{1}^{2}} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{1}} .
\end{aligned}
$$

From the calculation above, $R_{A} \log d+\sqrt{\sum_{\tau=1}^{t} \sigma_{A \tau}^{2} \log d_{1}} \lesssim \frac{\mu_{0} r \lambda_{\text {max }}^{2}}{d_{1}}$ and $R_{B} \log d+\sqrt{\sum_{\tau=1}^{t} \sigma_{B \tau}^{2} \log d_{1}} \lesssim$ $\frac{\mu_{0} r \lambda_{\text {max }}^{2}}{d_{1}}$ as long as $1 \cdot \max _{\tau} \frac{\eta_{\tau}}{\varepsilon_{\tau}} \lesssim \frac{d_{2}^{3 / 2}}{\sqrt{\mu_{0} r} \log d_{1} \lambda_{\text {max }}}, 2 . \frac{\lambda_{\min }^{2}}{\sigma^{2}} \gg \max _{\tau} \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}} \frac{\mu_{0} r \lambda_{\text {max }}^{2} \log ^{3} d_{1}}{d_{2}^{2} \kappa^{2}}, 3 \cdot \sum_{\tau=1}^{t} \frac{\eta_{T}^{2}}{\varepsilon_{\tau}^{1}} \lesssim \frac{d_{1} d_{2}^{2}}{\mu_{0} r \lambda_{\max }^{2}}$,
 fied under the stepsize and SNR conditions in Theorem 1.
As a result, by Bernstein inequality, with probability at least $1-d_{1}^{-200}$,

$$
\sum_{\tau=1}^{t} A_{\tau} \leq \frac{1}{6} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{1}}
$$

And with probability at least $1-d_{1}^{-200}$,

$$
\sum_{\tau=1}^{t} B_{\tau} \leq \frac{1}{6} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{1}}
$$

Finally, combine all the results above and the union bound, we can obtain that with probability at least $1-d_{1}^{-200}$,

$$
\left\|e_{l}^{\top} \widehat{U}_{t} V_{t}^{\top}\right\|^{2} \leq \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{1}}
$$

By symmetry, following the same arguments, we have for $\forall j \in\left[d_{2}\right]$, with the same probability,

$$
\left\|e_{j}^{\top} \widehat{V}_{t} \widehat{U}_{t}^{\top}\right\|^{2} \leq \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{2}}
$$

## B. 3 Proof of Lemma 3

Proof. For any $l$ in $\left[d_{1}\right]$,

$$
\begin{aligned}
\left\|e_{l}^{\top}\left(\widehat{U}_{t} \widehat{V}_{t}^{\top}-M\right)\right\|^{2} & =e_{l}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M-\Delta_{t}\right)\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M^{\top}-\Delta_{t}^{\top}\right) e_{l} \\
& =\left\|e_{l}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)\right\|^{2}-2 e_{l}^{\top} \Delta_{t}\left(\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top}-M^{\top}\right) e_{l}+\left\|e_{l}^{\top} \Delta_{t}\right\|^{2} .
\end{aligned}
$$

This leads to
$\mathbb{E}\left(\left\|e_{l}^{\top} \widehat{U}_{t} \widehat{V}_{t}^{\top}\right\|^{2} \mid \mathcal{F}_{t-1}\right)=\left\|e_{l}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)\right\|^{2}-2 \mathbb{E}\left[e_{l}^{\top} \Delta_{t}\left(\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top}-M^{\top}\right) e_{l} \mid \mathcal{F}_{t-1}\right]+\mathbb{E}\left[\left\|e_{l}^{\top} \Delta_{t}\right\|^{2} \mid \mathcal{F}_{t-1}\right]$.

We first compute $2 \mathbb{E}\left[e_{l}^{\top} \Delta_{t}\left(\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top}-M^{\top}\right) e_{l} \mid \mathcal{F}_{t-1}\right]$.

$$
\begin{aligned}
& 2 \mathbb{E}\left[e_{l}^{\top} \Delta_{t}\left(\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top}-M^{\top}\right) e_{l} \mid \mathcal{F}_{t-1}\right] \\
= & 2 \mathbb{E}\left[\left.e_{l}^{\top} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}} \eta_{t}\left(\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M, X_{t}\right\rangle-\xi_{t}\right) X_{t} \widehat{V}_{t-1} \widehat{V}_{t-1}^{\top}\left(\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top}-M^{\top}\right) e_{l} \right\rvert\, \mathcal{F}_{t-1}\right] \\
& +2 \mathbb{E}\left[\left.e_{l}^{\top} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}} \eta_{t}\left(\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M, X_{t}\right\rangle-\xi_{t}\right) \widehat{U}_{t-1} \widehat{U}_{t-1}^{\top} X_{t}\left(\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top}-M^{\top}\right) e_{l} \right\rvert\, \mathcal{F}_{t-1}\right] \\
& -2 \mathbb{E}\left[\left.e_{l}^{\top} \frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}^{2}} \eta_{t}^{2}\left(\left\langle\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}, X_{t}\right\rangle-\xi_{t}\right)^{2} X_{t} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} X_{t}\left(\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top}-M^{\top}\right) e_{l} \right\rvert\, \mathcal{F}_{t-1}\right] \\
\geq & \frac{2 \eta_{t}}{d_{1} d_{2}} e_{l}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right) \widehat{V}_{t-1} \widehat{V}_{t-1}^{\top}\left(\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top}-M^{\top}\right) e_{l} \\
& +\frac{2 \eta_{t}}{d_{1} d_{2}} e_{l}^{\top} \widehat{U}_{t-1} \widehat{U}_{t-1}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)\left(\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top}-M^{\top}\right) e_{l} \\
& \left.-\frac{4 \eta_{t}^{2}}{\varepsilon_{t} d_{1} d_{2}} \sum_{i j} \delta_{i l}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)_{i j}^{3}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}\right)_{i j}-\frac{4 \eta_{t}^{2} \sigma^{2}}{\varepsilon_{t} d_{1} d_{2}} \sum_{i j} \delta_{i l} \widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}\right)_{i j}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)_{i j} \\
\geq & \frac{\eta_{t} \lambda_{\min }}{d_{1} d_{2}} e_{l}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)\left(\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top}-M^{\top}\right) e_{l}+\frac{\eta_{t} \lambda_{\min }}{d_{1} d_{2}} e_{l}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)\left(\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top}-M^{\top}\right) e_{l} \\
& -\frac{4 \eta_{t}^{2}}{\varepsilon_{t} d_{1} d_{2}} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{1} d_{2}}\left\|e_{l}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)\right\|^{2}-\frac{4 \eta_{t}^{2} \sigma^{2}}{\varepsilon_{t} d_{1}} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{1} d_{2}} \\
\geq & \frac{2 \eta_{t} \lambda_{\min }}{d_{1} d_{2}}\left\|e_{l}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)\right\|^{2}-\frac{4 \eta_{t}^{2}}{\varepsilon_{t} d_{1} d_{2}} O\left(\frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{1} d_{2}}\right)\left\|e_{l}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)\right\|^{2}-\frac{4 \eta_{t}^{2} \sigma^{2}}{\varepsilon_{t} d_{1}} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{1} d_{2}} .
\end{aligned}
$$

The first second order term in the second last inequality comes from $\sum_{i j} \delta_{i l}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)_{i j}^{3}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}\right)_{i j} \leq$ $\left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right\|_{\max }\left\|\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}\right\|_{\max } \sum_{i j} \delta_{i l}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)_{i j}^{2} \leq O\left(\frac{\mu_{0}^{2} r^{2} \lambda_{\text {max }}^{2}}{d_{1} d_{2}}\right)\left\|e_{l}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)\right\|^{2}$.
And the other term is similar.
For $\mathbb{E}\left(\left\|e_{l}^{\top} \Delta_{t}\right\|^{2} \mid \mathcal{F}_{t-1}\right)$, analogous to the calculation before, we also have

$$
\mathbb{E}\left(\left\|e_{l}^{\top} \Delta_{t}\right\|^{2} \mid \mathcal{F}_{t-1}\right) \lesssim \frac{\eta_{t}^{2}}{\varepsilon_{t} d_{1} d_{2}} \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{1}}\left\|e_{l}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)\right\|^{2}+\frac{\eta_{t}^{2} \sigma^{2} \mu_{0} r \lambda_{\max }^{2}}{\varepsilon_{t} d_{1} d_{2}}
$$

Recall $f\left(\eta_{t}\right)=\frac{\eta_{t} \lambda_{\min }}{2 d_{1} d_{2}}$. Then for some constant $c_{2}$,

$$
\begin{aligned}
-2 \mathbb{E}\left(e_{l}^{\top} \Delta_{t} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l} \mid \mathcal{F}_{t-1}\right)+\mathbb{E}\left(\left\|e_{l}^{\top} \Delta_{t}\right\|^{2} \mid \mathcal{F}_{t-1}\right) & \leq-2 f\left(\eta_{t}\right)\left\|e_{l}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)\right\|^{2}+\frac{c_{2} \eta_{t}^{2} \sigma^{2} \mu_{0} r \lambda_{\max }^{2}}{\varepsilon_{t} d_{1} d_{2}} \\
& \leq-f\left(\eta_{t}\right)\left\|e_{l}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)\right\|^{2}+\frac{c_{2} \eta_{t}^{2} \sigma^{2} \mu_{0} r \lambda_{\max }^{2}}{\varepsilon_{t} d_{1} d_{2}}
\end{aligned}
$$

We again use telescoping to derive

$$
\begin{aligned}
\| e_{l}^{\top} & \left(U_{t} V_{t}^{\top}-M\right)\left\|^{2}=\right\| e_{l}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)\left\|^{2}-2 e_{l}^{\top} \Delta_{t}\left(\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top}-M^{\top}\right) e_{l}+\right\| e_{l}^{\top} \Delta_{t} \|^{2} \\
= & \left\|e_{l}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)\right\|^{2}-2\left(e_{l}^{\top} \Delta_{t}\left(\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top}-M^{\top}\right) e_{l}-\mathbb{E}\left(e_{l}^{\top} \Delta_{t}\left(\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top}-M^{\top}\right) e_{l} \mid \mathcal{F}_{t-1}\right)\right) \\
& +\left(\left\|e_{l}^{\top} \Delta_{t}\right\|^{2}-\mathbb{E}\left[\left\|e_{l}^{\top} \Delta_{t}\right\|^{2} \mid \mathcal{F}_{t-1}\right]\right)-2 \mathbb{E}\left[e_{l}^{\top} \Delta_{t} \widehat{V}_{t-1} \widehat{U}_{t-1}^{\top} e_{l} \mid \mathcal{F}_{t-1}\right]+\mathbb{E}\left[\left\|e_{l}^{\top} \Delta_{t}\right\|^{2} \mid \mathcal{F}_{t-1}\right] \\
\leq & \left(1-f\left(\eta_{t}\right)\right)\left\|e_{l}^{\top}\left(\widehat{U}_{t-1} \widehat{V}_{t-1}^{\top}-M\right)\right\|^{2}+\frac{c_{2} \eta_{t}^{2} \sigma^{2} \mu_{0} r \lambda_{\max }^{2}}{\varepsilon_{t} d_{1} d_{2}} \\
& +\underbrace{2\left(\mathbb{E}\left(e_{l}^{\top} \Delta_{t}\left(\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top}-M^{\top}\right) e_{l} \mid \mathcal{F}_{t-1}\right)-e_{l}^{\top} \Delta_{t}\left(\widehat{V}_{t-1} \widehat{U}_{t-1}^{\top}-M^{\top}\right) e_{l}\right)}_{A_{t}}+\underbrace{\left(\left\|e_{l}^{\top} \Delta_{t}\right\|^{2}-\mathbb{E}\left[\left\|e_{l}^{\top} \Delta_{t}\right\|^{2} \mid \mathcal{F}_{t-1}\right]\right)}_{B_{t}} \\
\leq & \left(1-f\left(\eta_{t}\right)\right)\left(1-f\left(\eta_{t-1}\right)\right)\left\|e_{l}^{\top}\left(\widehat{U}_{t-2} \widehat{V}_{t-2}^{\top}-M\right)\right\|^{2}+\left(1-f\left(\eta_{t}\right)\right) \frac{c_{2} \eta_{t-1}^{2} \sigma^{2} \mu_{0} r \lambda_{\max }^{2}}{\varepsilon_{t-1} d_{1} d_{2}} \\
& +\frac{c_{2} \eta_{t}^{2} \sigma^{2} \mu_{0} r \lambda_{\max }^{2}}{\varepsilon_{t} d_{1} d_{2}}+\left(1-f\left(\eta_{t}\right)\right)\left(A_{t-1}+B_{t-1}\right)+\left(A_{t}+B_{t}\right) \\
\leq & \prod_{\tau=1}^{t}\left(1-f\left(\eta_{\tau}\right)\right)\left\|e_{l}^{\top}\left(\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right)\right\|^{2}+\sum_{\tau=1}^{t-1} \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) \frac{c_{2} \eta_{\tau}^{2} \sigma^{2} \mu_{0} r \lambda_{\max }^{2}}{\varepsilon_{\tau} d_{1} d_{2}} \\
& +\frac{c_{2} \eta_{t}^{2} \sigma^{2} \mu_{0} r \lambda_{\max }^{2}}{\varepsilon_{t} d_{1} d_{2}}+\sum_{\tau=1}^{t-1} \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) A_{\tau}+A_{t}+\sum_{\tau=1}^{t-1} \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) B_{\tau}+B_{t} \\
\leq & \prod_{\tau=1}^{t}\left(1-f\left(\eta_{\tau}\right)\right) \frac{\mu_{0} r \lambda_{\max }^{2}}{d_{1}}+\sum_{\tau=1}^{t} \frac{c_{2} \eta_{\tau}^{2} \sigma^{2} \mu_{0} r \lambda_{\max }^{2} \log ^{2} d_{1}}{\varepsilon_{\tau} d_{1} d_{2}} \\
& +\sum_{\tau=1}^{t-1} \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) A_{\tau}+A_{t}+\sum_{\tau=1}^{t-1} \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) B_{\tau}+B_{t} .
\end{aligned}
$$

The first term $\left\|e_{l}^{\top}\left(\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right)\right\|^{2} \lesssim \frac{\mu_{0} r \lambda_{\text {max }}^{2}}{d_{1}}$ under the incoherence condition of $U_{0}$ and $V_{0}$. Next, we derive the uniform bound for $\prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) A_{\tau}$ and $\prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{k}\right)\right) B_{\tau}$.

$$
\begin{aligned}
&\left|e_{l}^{\top} \Delta_{\tau}\left(\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}-M^{\top}\right) e_{l}\right| \leq\left|e_{l}^{\top} \frac{\mathbb{1}\left(a_{\tau}=1\right)}{\pi_{\tau}} \eta_{\tau}\left(\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right) X_{\tau} \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\left(\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}-M^{\top}\right) e_{l}\right| \\
& \quad+\left|e_{l}^{\top} \frac{\mathbb{1}\left(a_{\tau}=1\right)}{\pi_{\tau}} \eta_{\tau}\left(\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{\tau}\right\rangle-\xi_{\tau}\right) \widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top} X_{\tau}\left(\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}-M^{\top}\right) e_{l}\right| \\
&+\left|e_{l}^{\top} \frac{\mathbb{1}\left(a_{\tau}=1\right)}{\pi_{\tau}^{2}} \eta_{\tau}^{2}\left(\left\langle\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M, X_{t}\right\rangle-\xi_{\tau}\right)^{2} X_{\tau} \widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top} X_{\tau}\left(\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}-M^{\top}\right) e_{l}\right| \\
& \leq \frac{2 \eta_{\tau}}{\varepsilon_{\tau}}\left(\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }+\sigma \log ^{1 / 2} d_{1}\right)\left\|\widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|_{\max }\left\|\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}-M^{\top}\right\|_{\max } \\
&+\frac{2 \eta_{\tau}}{\varepsilon_{\tau}}\left(\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }+\sigma \log ^{1 / 2} d_{1}\right)\left\|\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right\|_{\max }\left\|\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}-M\right\|_{\max } \\
& \left.+\frac{4 \eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}} \right\rvert\,\left(\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{2}+\sigma^{2} \log d_{1}\right)\left\|\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right\|_{\max }\left\|\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}-M\right\|_{\max } \\
& \lesssim \frac{\eta_{\tau}}{\varepsilon_{\tau}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{2} \frac{\mu_{0} r \lambda_{\max }}{d_{2}}+\frac{\eta_{\tau}}{\varepsilon_{\tau}} \sigma \log ^{1 / 2} d_{1}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max } \frac{\mu_{0} r \lambda_{\max }}{d_{2}} \\
& \quad+\frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}}\left\|\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}-M\right\|_{\max }^{2} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{1} d_{2}}+\frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}} \sigma^{2} \log d_{1}\left\|\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}-M\right\|_{\max } \frac{\mu_{0} r \lambda_{\max }}{\sqrt{d_{1} d_{2}}} \\
& \lesssim \frac{\eta_{\tau}}{\varepsilon_{\tau}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{2} \frac{\mu_{0} r \lambda_{\max }}{d_{2}}+\frac{\eta_{\tau}}{\varepsilon_{\tau}} \sigma \log ^{1 / 2} d_{1}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max } \frac{\mu_{0} r \lambda_{\max }}{d_{2}} .
\end{aligned}
$$

The first order terms dominate as long as $\eta_{\tau} \lesssim \frac{\varepsilon_{\tau} d_{1}}{\mu_{0} r \lambda_{\max }}$ and $\frac{\lambda_{\min }^{2}}{\sigma^{2}} \gg \frac{\eta_{T}^{2}}{\varepsilon_{\tau}^{2}} \frac{\lambda_{\max }^{2} \log d_{1}}{\kappa^{2}}$.
Since $\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\text {max }}^{2} \lesssim \prod_{k=1}^{\tau-1}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\operatorname{poly}(\kappa, \mu, r) \lambda_{\text {min }}^{2}}{d_{1} d_{2}}+\sum_{k=1}^{\tau-1} \frac{\eta_{k}^{2} \operatorname{poly}(\kappa, \mu, r) \lambda_{\text {max }}^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{1} d_{2}^{2}}$ under event $\mathcal{E}_{\tau-1}$, and applying $2 a b \leq a^{2}+b^{2}$ to term $\frac{\eta_{\tau}}{\varepsilon_{\tau}} \sigma \log ^{1 / 2} d_{1}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max } \frac{\mu_{0} r \lambda_{\max }}{d_{2}}$, we have

$$
\begin{aligned}
& \prod_{k=\tau+1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)\left|e_{l}^{\top} \Delta_{\tau}\left(\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}-M^{\top}\right) e_{l}\right| \lesssim \max _{\tau} \frac{\eta_{\tau}}{\varepsilon_{\tau}}\left(\prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\operatorname{poly}(\kappa, \mu, r) \lambda_{\min }^{2}}{d_{1} d_{2}}\right. \\
& \left.+\sum_{k=1}^{t} \frac{\eta_{k}^{2} \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1} \operatorname{poly}(\kappa, \mu, r)}{\varepsilon_{k} d_{1} d_{2}^{2}}\right) \frac{\mu_{0} r \lambda_{\max }}{d_{2}}+\prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\operatorname{poly}(\kappa, \mu, r) \lambda_{\min }^{2}}{d_{1} d_{2}} \\
& \quad+\sum_{k=1}^{t} \frac{\eta_{k}^{2} \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1} \operatorname{poly}(\kappa, \mu, r)}{\varepsilon_{k} d_{1} d_{2}^{2}}+\max _{\tau} \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}} \sigma^{2} \log d_{1} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{2}^{2}}:=R_{A} .
\end{aligned}
$$

Similarly, we can obtain

$$
\begin{aligned}
& \prod_{k=\tau+1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right)\left\|e_{l}^{\top} \Delta_{\tau}\right\|^{2} \lesssim \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}}\left(\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{2}+\sigma^{2} \log d_{1}\right)\left(\left\|\widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|_{\max }^{2}+\left\|\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right\|_{\max }^{2}\right) \\
& \quad \lesssim \max _{\tau} \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}}\left(\prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\operatorname{poly}(\kappa, \mu, r) \lambda_{\min }^{2}}{d_{1} d_{2}} O\left(\frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{2}^{2}}\right)+\sum_{k=1}^{t} \frac{\eta_{k}^{2} \operatorname{poly}(\kappa, \mu, r) \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{1} d_{2}^{2}}\right) \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{2}^{2}} \\
& \quad+\max _{\tau} \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}} \sigma^{2} \log d_{1} O\left(\frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{2}}{d_{2}^{2}}\right):=R_{B} .
\end{aligned}
$$

Then we calculate their conditional variance, respectively. Denote the variance of $\prod_{k=\tau+1}^{t}(1-$ $\left.f\left(\eta_{\tau}\right)\right) A_{\tau}$ and $\prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{\tau}\right)\right) B_{\tau}$ as $\sigma_{A \tau}^{2}$ and $\sigma_{B \tau}^{2}$, we have

$$
\begin{aligned}
\sigma_{A \tau}^{2} \lesssim & \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{\tau}\right)\right)^{2}\left(\frac{\eta_{\tau}^{2}}{\varepsilon_{\tau} d_{1} d_{2}} \sum_{i j}\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right)_{i j}^{2} \delta_{i l}\left(\widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\left(\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}-M^{\top}\right)\right)_{j l}^{2}\right. \\
& +\frac{\eta_{\tau}^{2}}{\varepsilon_{\tau} d_{1} d_{2}} \sum_{i j}\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right)_{i j}^{2}\left(\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{l i}^{2}\left(\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}-M^{\top}\right)_{j l}^{2} \\
& \left.+\frac{\eta_{\tau}^{2} \sigma^{2}}{\varepsilon_{\tau} d_{1} d_{2}} \sum_{i j} \delta_{i l}\left(\widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\left(\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}-M^{\top}\right)\right)_{j l}^{2}+\frac{\eta_{\tau}^{2} \sigma^{2}}{\varepsilon_{\tau} d_{1} d_{2}} \sum_{i j}\left(\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{l i}^{2}\left(\widehat{V}_{\tau-1} \widehat{U}_{\tau-1}^{\top}-M^{\top}\right)_{j l}^{2}\right) \\
\lesssim & \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{\tau}\right)\right)^{2}\left(\frac{\eta_{\tau}^{2}}{\varepsilon_{\tau} d_{1} d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{2}\left\|\widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|^{2}\left\|e_{l}\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right)\right\|^{2}\right. \\
& +\frac{\eta_{\tau}^{2}}{\varepsilon_{\tau} d_{1} d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{4} \sum_{i j}\left(\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{l i}^{2} \\
& \left.+\frac{\eta_{\tau}^{2} \sigma^{2}}{\varepsilon_{\tau} d_{1} d_{2}}\left\|\widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|^{2}\left\|e_{l}\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right)\right\|^{2}+\frac{\eta_{\tau}^{2} \sigma^{2}}{\varepsilon_{\tau} d_{1} d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{2} \sum_{i j}\left(\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{l i}^{2}\right) .
\end{aligned}
$$

Notice that, $\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\text {max }}^{2}\left\|e_{l}\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right)\right\|^{2} \lesssim \frac{1}{d_{2}}\left(\prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\operatorname{poly}(\mu, r, \kappa) \lambda_{\text {min }}^{2}}{d_{1}}+\right.$ $\left.\sum_{k=1}^{t} \frac{\eta_{k}^{2} \operatorname{poly}(\kappa, \mu, r) \lambda_{\text {max }}^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{1} d_{2}}\right)^{2}$ and $\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{4} \lesssim \frac{1}{d_{2}^{2}}\left(\prod_{k=1}^{\tau-1}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\operatorname{poly}(\mu, r, \kappa) \lambda_{\text {min }}^{2}}{d_{1}}\right.$ $\left.+\sum_{k=1}^{\tau-1} \frac{\eta_{k}^{2} \operatorname{poly}(\kappa, \mu, r) \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{1} d_{2}}\right)^{2}$ under event $\mathcal{E}_{\tau-1}$. As a result,

$$
\begin{aligned}
\sigma_{A \tau}^{2} \lesssim & \frac{\eta_{\tau}^{2} \lambda_{\max }^{2}}{\varepsilon_{\tau} d_{1} d_{2}^{2}}\left(\prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\operatorname{poly}(\mu, r, \kappa) \lambda_{\min }^{2}}{d_{1}}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} \operatorname{poly}(\kappa, \mu, r) \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{1} d_{2}}\right)^{2} \\
& +\frac{\eta_{\tau}^{2} \sigma^{2} \lambda_{\max }^{2}}{\varepsilon_{\tau} d_{1} d_{2}}\left(\prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\operatorname{poly}(\mu, r, \kappa) \lambda_{\min }^{2}}{d_{1}}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} \operatorname{poly}(\kappa, \mu, r) \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{1} d_{2}}\right) .
\end{aligned}
$$

Similarly,

$$
\begin{aligned}
\sigma_{B \tau}^{2} \lesssim & \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{\tau}\right)\right)^{2}\left(\frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3} d_{1} d_{2}} \sum_{i j}\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right)_{i j}^{4} \delta_{i l}\left\|e_{j}^{\top} \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|^{4}+\frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3} d_{1} d_{2}} \sigma^{4} \sum_{i j} \delta_{i l}\left\|e_{j}^{\top} \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|^{4}\right. \\
& \left.+\frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3} d_{1} d_{2}} \sum_{i j}\left(\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right)_{i j}^{4}\left(\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{l i}^{4}+\frac{\eta_{\tau}^{4} \sigma^{4}}{\varepsilon_{\tau}^{3} d_{1} d_{2}} \sum_{i j}\left(\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{l i}^{4}\right) \\
\lesssim & \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{\tau}\right)\right)^{2}\left(\frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3} d_{1} d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{4} \sum_{i j} \delta_{i l}\left\|e_{j}^{\top} \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|^{4}+\frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3} d_{1} d_{2}} \sigma^{4} \sum_{i j} \delta_{i l}\left\|e_{j}^{\top} \widehat{V}_{\tau-1} \widehat{V}_{\tau-1}^{\top}\right\|^{4}\right. \\
& \left.+\frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3} d_{1} d_{2}}\left\|\widehat{U}_{\tau-1} \widehat{V}_{\tau-1}^{\top}-M\right\|_{\max }^{4} \sum_{i j}\left(\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{l i}^{4}+\frac{\eta_{\tau}^{4} \sigma^{4}}{\varepsilon_{\tau}^{3} d_{1} d_{2}} \sum_{i j}\left(\widehat{U}_{\tau-1} \widehat{U}_{\tau-1}^{\top}\right)_{l i}^{4}\right) \\
\lesssim & \frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3}} \frac{\mu_{0}^{2} r^{2} \lambda_{\max }^{4}}{d_{1} d_{2}^{4}}\left(\prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\operatorname{poly}(\mu, r, \kappa) \lambda_{\min }^{2}}{d_{1}}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} \operatorname{poly}(\kappa, \mu, r) \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{1} d_{2}}\right)^{2} \\
& +\frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3}} \frac{\sigma^{4} \mu_{0}^{2} r^{2} \lambda_{\max }^{4}}{d_{1} d_{2}^{3}} .
\end{aligned}
$$

From the calculation above, $R_{A} \log d_{1}+\sqrt{\sum_{\tau=1}^{t} \sigma_{A \tau}^{2} \log d_{1}} \lesssim \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\operatorname{poy}(\mu, r, \kappa)\left\|\widehat{U}_{0} \widehat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}}{d_{1}}+$ $\sum_{k=1}^{t} \frac{\eta_{k}^{2} \lambda_{\max }^{2} \sigma^{\sigma^{2}} \log ^{2} d_{1} \operatorname{poly}(\kappa, \mu, r)}{\varepsilon_{k} d_{1} d_{2}}$ and $R_{B} \log d_{1}+\sqrt{\sum_{\tau=1}^{t} \sigma_{B \tau}^{2} \log d_{1}} \lesssim \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\operatorname{poly}(\mu, r, \kappa)\left\|\widehat{O}_{0} \hat{V}_{0}^{\top}-M\right\|_{\mathrm{F}}^{2}}{d_{1}}+$ $\sum_{k=1}^{t} \frac{\eta_{k}^{2} \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1} \operatorname{poly}(\kappa, \mu, r)}{\varepsilon_{k} d_{1} d_{2}}$ as long as 1. $\eta_{\tau} \lesssim \frac{\varepsilon_{\tau} d_{2}^{3 / 2}}{\mu_{0} r \lambda_{\max }}, 2 . \max \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}^{2}} \leq \sum_{\tau=1}^{t} \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}}, 3 . \quad \sum_{\tau=1}^{t} \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}} \lesssim$ $\frac{d_{1} d_{2}^{2}}{\lambda_{\text {max }}^{2} \log d_{1}}, 4$. $\sum_{\tau=1}^{t} \frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3}} \lesssim \frac{d_{1} d_{2}^{4}}{\mu_{0}^{2} r^{2} \lambda_{\text {max }}^{4} \log d_{1}}, 5 . \sum_{\tau=1}^{t} \frac{\eta_{\tau}^{4}}{\varepsilon_{\tau}^{3}} \leq\left(\sum_{\tau=1}^{t} \frac{\eta_{\tau}^{2}}{\varepsilon_{\tau}}\right)^{2}$. All of them can be satisfied under the stepsize and SNR conditions in Theorem 1 .
By Bernstein inequality, with probability at least $1-d_{1}^{-2}, \sum_{\tau=1}^{t-1} \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{\tau}\right)\right) A_{\tau}+A_{t} \lesssim$ $\prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\operatorname{poly}(\mu, r, \kappa) \lambda_{\min }^{2}}{d_{1}}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} \operatorname{poly}(\kappa, \mu, r) \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{1} d_{2}}$ and $\sum_{\tau=1}^{t-1} \prod_{k=\tau+1}^{t}\left(1-f\left(\eta_{\tau}\right)\right) B_{\tau}+B_{t} \lesssim$ $\prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\operatorname{poly}(\mu, r, k) \lambda_{\text {min }}^{2}}{d_{1}}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} \operatorname{poly}(\kappa, \mu, r) \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{1} d_{2}}$.
Finally, we conclude that, with probability at least $1-t d_{1}^{-200}$,

$$
\left\|e_{l}^{\top}\left(\widehat{U}_{t} \widehat{V}_{t}^{\top}-M\right)\right\|^{2} \lesssim \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\operatorname{poly}(\mu, r, \kappa) \lambda_{\min }^{2}}{d_{1}}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} \operatorname{poly}(\kappa, \mu, r) \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{1} d_{2}} .
$$

By symmetry, following the same arguments, we can prove with same probability, for any $j \in\left[d_{2}\right]$,

$$
\left\|e_{j}^{\top}\left(\widehat{V}_{t} \hat{U}_{t}^{\top}-M^{\top}\right)\right\|^{2} \lesssim \prod_{k=1}^{t}\left(1-\frac{f\left(\eta_{k}\right)}{2}\right) \frac{\operatorname{poly}(\mu, r, \kappa) \lambda_{\min }^{2}}{d_{2}}+\sum_{k=1}^{t} \frac{\eta_{k}^{2} \operatorname{poly}(\kappa, \mu, r) \lambda_{\max }^{2} \sigma^{2} \log ^{2} d_{1}}{\varepsilon_{k} d_{2}^{2}}
$$

## B. 4 Proof of Lemma 4

Proof. Denote $S^{2}=1 / T^{\gamma}\left\|P_{\Omega_{1}}\left(P_{M}(Q)\right)\right\|_{\mathrm{F}}^{2}+C_{\gamma}\left\|P_{\Omega_{0}}\left(P_{M}(Q)\right)\right\|_{\mathrm{F}}^{2}$. By definition,

$$
\begin{aligned}
& \frac{\sqrt{\frac{T^{1-\gamma}}{d_{1} d_{2}}}\left(\left\langle L L^{\top} \widehat{Z}_{1} R_{\perp} R_{\perp}^{\top}, Q\right\rangle+\left\langle L_{\perp} L_{\perp}^{\top} \widehat{Z}_{1} R R^{\top}, Q\right\rangle+\left\langle L L^{\top} \widehat{Z}_{1} R R^{\top}, Q\right\rangle\right)}{\sigma S} \\
& \quad=\frac{\sqrt{\frac{1}{T^{1+\gamma}}} \sum_{t=T_{0}+1}^{T} \frac{b \sqrt{d_{1} d_{2}} \mathbb{1}\left(a_{t}=1\right)}{\pi_{t}} \xi_{t}\left\langle X_{t}, \mathcal{P}_{M}(Q)\right\rangle}{\sigma S} .
\end{aligned}
$$

Next, we apply Theorem 3.2 and Corollary 3.1 in Hall and Heyde 2014, the Martingale Central Limit Theorem to show the asymptotic normality.

Step1: checking Lindeberg condition
For any $\delta>0$,

$$
\begin{aligned}
& \sum_{t=T_{0}+1}^{T} \mathbb{E}\left[\left.\frac{b^{2} d_{1} d_{2} \mathbb{1}\left(a_{t}=1\right)}{\sigma^{2} S^{2} T^{1+\gamma} \pi_{t}^{2}} \xi_{t}^{2}\left\langle X_{t}, \mathcal{P}_{M}(Q)\right\rangle^{2} \times \mathbb{1}\left(\left|\xi_{t} \frac{\sqrt{d_{1} d_{2}} \mathbb{1}\left(a_{t}=1\right)\left\langle X_{t}, \mathcal{P}_{M}(Q)\right\rangle}{\sigma S \sqrt{T^{1+\gamma}} \pi_{t}}\right|>\delta\right) \right\rvert\, \mathcal{F}_{t-1}\right] \\
\leq & \frac{b^{2} d_{1} d_{2}}{\sigma^{2} S^{2} T^{1+\gamma}} \sum_{t=T_{0}+1}^{T} \mathbb{E}\left[\left.\frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}^{2}} \xi_{t}^{2}\left\langle X_{t}, \mathcal{P}_{M}(Q)\right\rangle^{2} \times \mathbb{1}\left(\left|\xi_{t}\left\langle X_{t}, \mathcal{P}_{M}(Q)\right\rangle\right|>\frac{\sigma S \delta \sqrt{T^{1+\gamma}} \varepsilon_{t}}{2 \sqrt{d_{1} d_{2}}}\right) \right\rvert\, \mathcal{F}_{t-1}\right] \\
\lesssim & \frac{b^{2} d_{1} d_{2}}{\sigma^{2} S^{2} T^{1+\gamma}} \sum_{t=T_{0}+1}^{T} \frac{2}{\varepsilon_{t}} \max _{X \in \mathcal{X}}\left\langle X, \mathcal{P}_{M}(Q)\right\rangle^{2} \times \sqrt{\mathbb{E}\left[\mathbb{1}\left(\left|\xi_{t}\left\langle X_{t}, \mathcal{P}_{M}(Q)\right\rangle\right|>\frac{\sigma S \delta \sqrt{T^{1+\gamma}} \varepsilon_{t}}{2 \sqrt{d_{1} d_{2}}}\right)\right]},
\end{aligned}
$$

where in the last inequality we use $\mathbb{E}[X Y] \leq \sqrt{\mathbb{E}\left[X^{2}\right] \mathbb{E}\left[Y^{2}\right]}$. By incoherence condition,

$$
\max _{X \in \mathcal{X}}\left|\left\langle X, \mathcal{P}_{M}(Q)\right\rangle\right| \lesssim \sqrt{\frac{\mu r}{d_{2}}}\left\|\mathcal{P}_{M}(Q)\right\|_{\mathrm{F}}
$$

Moreover, since $\xi_{t}$ is a subGaussian random variable, so the product $\xi_{t}\left\langle X_{t}, \mathcal{P}_{M}(Q)\right\rangle$ has subGaussian tail probability

$$
\mathbb{P}\left(\left|\xi_{t}\left\langle X_{t}, \mathcal{P}_{M}(Q)\right\rangle\right|>\frac{\sigma S \delta \sqrt{T^{1+\gamma}} \varepsilon_{t}}{2 \sqrt{d_{1} d_{2}}}\right)<2 e^{-\frac{\sigma^{2} S^{2} \delta^{2} T^{1+\gamma_{\varepsilon_{t}^{2}}^{2}}}{8 d_{1} d_{2} \nu^{2}}}
$$

where $\nu$ is the subGaussian parameter of order $O\left(\sqrt{\frac{\mu r}{d_{2}}}\left\|\mathcal{P}_{M}(Q)\right\|_{\mathrm{F}} \sigma\right)$. Notice that $T^{1+\gamma} \varepsilon_{t}^{2} \leq$ $T^{1+\gamma} \varepsilon_{T}^{2}=O\left(T^{1-\gamma}\right)$. By property of exponential function, $\frac{d_{1} d_{2} \sigma^{2}}{\sigma^{2} S^{2} T^{1+\gamma}} \frac{\mu r}{d_{2}}\left\|\mathcal{P}_{M}(Q)\right\|_{\mathrm{F}}^{2} \sum_{t=T_{0}+1}^{T} \frac{2}{\varepsilon_{t}} 2 e^{-\frac{\sigma^{2} S^{2} \delta^{2} T^{1+\gamma} \varepsilon_{t}^{2}}{16 d_{1} d_{2} \nu^{2}}}$ converges to 0 as long as $\frac{d_{1}}{T^{1-\gamma}} \rightarrow 0$. Then the Lindeberg condition is satisfied.
Step2: calculating the variance
Next, we show the conditional variance equals to 1 . Recall the definition $\Omega_{1}=\{X \in \mathcal{X}$ :

$$
\begin{aligned}
& \left.\left\langle M_{1}-M_{0}, X\right\rangle>\delta_{T, d_{1}, d_{2}}\right\}, \Omega_{0}=\left\{X \in \mathcal{X}:\left\langle M_{1}-M_{0}, X\right\rangle<\delta_{T, d_{1}, d_{2}}\right\} \text { and } \Omega_{\emptyset}=X \cup\left(\Omega_{1} \cup \Omega_{0}\right)^{c} \text {. Then } \\
& \frac{b^{2} d_{1} d_{2}}{\sigma^{2} S^{2} T^{1+\gamma}} \sum_{t=T_{0}+1}^{T} \mathbb{E}\left[\left.\frac{\mathbb{1}\left(a_{t}=1\right)}{\pi_{t}^{2}} \xi_{t}^{2}\left\langle X_{t}, \mathcal{P}_{M}(Q)\right\rangle^{2} \right\rvert\, \mathcal{F}_{t-1}\right] \\
& =\frac{b^{2}}{\sigma^{2} S^{2} T^{1+\gamma}} \sigma^{2} \sum_{t=T_{0}+1}^{T} \sum_{X \in \Omega_{1}} \mathbf{1}\left(\left\langle\widehat{M}_{1, t-1}-\widehat{M}_{0, t-1}, X\right\rangle>0\right) \frac{1}{1-\frac{\varepsilon_{t}}{2}}\left\langle X, \mathcal{P}_{M}(Q)\right\rangle^{2} \\
& \quad+\mathbf{1}\left(\left\langle\widehat{M}_{1, t-1}-\widehat{M}_{0, t-1}, X\right\rangle<0\right) \frac{1}{\frac{\varepsilon_{t}}{2}}\left\langle X, \mathcal{P}_{M}(Q)\right\rangle^{2} \\
& \quad+\sum_{X \in \Omega_{0}} \mathbf{1}\left(\left\langle\widehat{M}_{1, t-1}-\widehat{M}_{0, t-1}, X\right\rangle>0\right) \frac{1}{1-\frac{\varepsilon_{t}}{2}}\left\langle X, \mathcal{P}_{M}(Q)\right\rangle^{2}+\mathbf{1}\left(\left\langle\widehat{M}_{1, t-1}-\widehat{M}_{0, t-1}, X\right\rangle<0\right) \frac{1}{\frac{\varepsilon_{t}}{2}}\left\langle X, \mathcal{P}_{M}(Q)\right\rangle^{2} \\
& \quad+\sum_{X \in \Omega_{\emptyset}} \mathbf{1}\left(\left\langle\widehat{M}_{1, t-1}-\widehat{M}_{0, t-1}, X\right\rangle>0\right) \frac{1}{1-\frac{\varepsilon_{t}}{2}}\left\langle X, \mathcal{P}_{M}(Q)\right\rangle^{2}+\mathbf{1}\left(\left\langle\widehat{M}_{1, t-1}-\widehat{M}_{0, t-1}, X\right\rangle<0\right) \frac{1}{\frac{\varepsilon_{t}}{2}}\left\langle X, \mathcal{P}_{M}(Q)\right\rangle^{2} .
\end{aligned}
$$

The next Lemma shows the convergence of the indicator function.
Lemma 8. Given any $X \in \Omega_{1} \cup \Omega_{0}$, we have for any $T_{0}+1 \leq t \leq T$, with probability at least $1-8 t d_{1}^{-200}$,

$$
\mathbb{1}\left(\left\langle\widehat{M}_{i, t}-\widehat{M}_{1-i, t}, X\right\rangle>0\right)=\mathbb{1}\left(\left\langle M_{i}-M_{1-i}, X\right\rangle>0\right) .
$$

Under this result, $\sum_{X \in \Omega_{i}} \mathbf{1}\left(\left\langle\widehat{M}_{i, t-1}-\widehat{M}_{1-i, t-1}, X\right\rangle>0\right)\left\langle X, \mathcal{P}_{M}(Q)\right\rangle^{2} \rightarrow\left\|P_{\Omega_{i}}\left(P_{M}(Q)\right)\right\|_{\mathrm{F}}^{2}$ and $\sum_{X \in \Omega_{1-i}} \mathbf{1}\left(\left\langle\widehat{M}_{i, t-1}-\widehat{M}_{1-i, t-1}, X\right\rangle>0\right)\left\langle X, \mathcal{P}_{M}(Q)\right\rangle^{2} \rightarrow 0$ for $i=0,1$.
Note that $\frac{b}{T} \sum_{t=T_{0}+1}^{T} 1 /\left(1-\varepsilon_{t} / 2\right) \rightarrow 1$ and $\frac{b}{T^{1+\gamma}} \sum_{t=T_{0}+1}^{T} 2 / \varepsilon_{t} \rightarrow \frac{2}{c_{2}(1+\gamma)}$ when $\varepsilon_{t}=c_{2} t^{-\gamma}$. And by Assumption 1. $\sum_{X \in \Omega_{\emptyset}} \mathbf{1}\left(\left\langle\widehat{M}_{1, t-1}-\widehat{M}_{0, t-1}, X\right\rangle>0\right) \frac{1}{1-\frac{\varepsilon \epsilon}{2}}\left\langle X, \mathcal{P}_{M}(Q)\right\rangle^{2}+\mathbf{1}\left(\left\langle\widehat{M}_{1, t-1}-\widehat{M}_{0, t-1}, X\right\rangle<\right.$ 0) $\frac{1}{\frac{\varepsilon_{t}}{2}}\left\langle X, \mathcal{P}_{M}(Q)\right\rangle^{2} \leq 2 / \varepsilon_{t}\left\|\mathcal{P}_{\Omega_{\emptyset}}\left(\mathcal{P}_{M}(Q)\right)\right\|_{\mathrm{F}}^{2}$ is negligible. Then the conditional variance will converge in probability to 1 . It follows

$$
\frac{\sum_{t=T_{0}+1}^{T} \frac{d_{1} d_{2} \mathbb{1}\left(a_{t}=1\right)}{\pi_{t}} \xi_{t}\left\langle X_{t}, \mathcal{P}_{M}(Q)\right\rangle}{\sigma S \sqrt{d_{1} d_{2} / T^{1-\gamma}}} \rightarrow N(0,1)
$$

when $T, d_{1}, d_{2} \rightarrow \infty$.

## B. 5 Proof of Lemma 5

Proof. By definition,

$$
\begin{aligned}
& \left\langle L L^{\top} \widehat{Z}_{2} R_{\perp} R_{\perp}^{\top}, Q\right\rangle+\left\langle L_{\perp} L_{\perp}^{\top} \widehat{Z}_{2} R R^{\top}, Q\right\rangle+\left\langle L L^{\top} \widehat{Z}_{2} R R^{\top}, Q\right\rangle=\left\langle\widehat{Z}_{2}, \mathcal{P}_{M}(Q)\right\rangle \\
& \quad=\frac{b}{T} \sum_{t=T_{0}+1}^{T} \frac{d_{1} d_{2} \mathbb{1}\left(a_{t}=1\right)}{\pi_{t}}\left\langle\widehat{\Delta}_{t-1}, X_{t}\right\rangle\left\langle X_{t}, \mathcal{P}_{M}(Q)\right\rangle-\left\langle\widehat{\Delta}_{t-1}, \mathcal{P}_{M}(Q)\right\rangle .
\end{aligned}
$$

Then we prove its upper bound. For any $T_{0}+1 \leq t \leq T$,

$$
\begin{aligned}
& \frac{b}{T}\left|\frac{d_{1} d_{2} \mathbb{1}\left(a_{t}=1\right)}{\pi_{t}}\left\langle\widehat{\Delta}_{t-1}, X_{t}\right\rangle\left\langle X_{t}, \mathcal{P}_{M}(Q)\right\rangle-\left\langle\widehat{\Delta}_{t-1}, \mathcal{P}_{M}(Q)\right\rangle\right| \\
& \quad \leq \frac{b d_{1} d_{2}}{T} \frac{2}{\varepsilon_{t}}\left\|\widehat{\Delta}_{t-1}\right\|_{\max } \sqrt{\frac{\mu r}{d_{2}}}\left\|\mathcal{P}_{M}(Q)\right\|_{\mathrm{F}}+\frac{1}{T} \sqrt{d_{1} d_{2}}\left\|\widehat{\Delta}_{t-1}\right\|_{\max }\left\|\mathcal{P}_{M}(Q)\right\|_{\mathrm{F}} \\
& \quad \lesssim \frac{d_{1} d_{2}^{1 / 2} \sqrt{\mu r}}{T^{1-\gamma}}\left\|\widehat{\Delta}_{t-1}\right\|_{\max }\left\|\mathcal{P}_{M}(Q)\right\|_{\mathrm{F}} \lesssim \frac{d_{1} d_{2}^{1 / 2} \sqrt{\mu r} \sigma}{T^{1-\gamma}}\left\|\mathcal{P}_{M}(Q)\right\|_{\mathrm{F}} .
\end{aligned}
$$

Moreover,

$$
\begin{aligned}
\mathbb{E} & {\left[\left.\frac{b^{2} d_{1}^{2} d_{2}^{2} \mathbb{1}\left(a_{t}=1\right)}{T^{2} \pi_{t}^{2}}\left\langle\widehat{\Delta}_{t-1}, X_{t}\right\rangle^{2}\left\langle X_{t}, \mathcal{P}_{M}(Q)\right\rangle^{2} \right\rvert\, \mathcal{F}_{t-1}\right] \leq \frac{b^{2} d_{1} d_{2}}{T^{2}}\left\|\widehat{\Delta}_{t-1}\right\|_{\max }^{2} \mathbb{E}\left[\left.\frac{1}{\pi_{t}}\left\langle X_{t}, \mathcal{P}_{M}(Q)\right\rangle^{2} \right\rvert\, \mathcal{F}_{t-1}\right] } \\
= & \frac{b^{2} d_{1} d_{2}}{T^{2}}\left\|\widehat{\Delta}_{t-1}\right\|_{\max }^{2} \sum_{X \in \mathcal{X}} \mathbf{1}\left(\left\langle\widehat{M}_{1, t-1}-\widehat{M}_{0, t-1}, X\right\rangle>0\right) \frac{1}{1-\frac{\varepsilon_{t}}{2}}\left\langle X, \mathcal{P}_{M}(Q)\right\rangle^{2} \\
& +\mathbf{1}\left(\left\langle\widehat{M}_{1, t-1}-\widehat{M}_{0, t-1}, X\right\rangle\langle 0) \frac{1}{\frac{\varepsilon_{t}}{2}}\left\langle X, \mathcal{P}_{M}(Q)\right\rangle^{2}\right. \\
& \lesssim \frac{d_{1}^{2} d_{2} r \log ^{4} d_{1} \sigma^{2}}{T^{3-\gamma}} \sum_{X \in \mathcal{X}} \mathbf{1}\left(\left\langle\widehat{M}_{1, t-1}-\widehat{M}_{0, t-1}, X\right\rangle>0\right) \frac{1}{1-\frac{\varepsilon_{t}}{2}}\left\langle X, \mathcal{P}_{M}(Q)\right\rangle^{2} \\
& +\mathbf{1}\left(\left\langle\widehat{M}_{1, t-1}-\widehat{M}_{0, t-1}, X\right\rangle\langle 0) \frac{1}{\frac{\varepsilon_{t}}{2}}\left\langle X, \mathcal{P}_{M}(Q)\right\rangle^{2} .\right.
\end{aligned}
$$

Denote $S_{T}^{2}:=\frac{1}{T^{1+\gamma}} \sum_{t=T_{0}+1}^{T} \sum_{X \in \mathcal{X}} \mathbf{1}\left(\left\langle\widehat{M}_{1, t-1}-\widehat{M}_{0, t-1}, X\right\rangle>0\right) \frac{1}{1-\frac{\varepsilon_{t}}{2}}\left\langle X, \mathcal{P}_{M}(Q)\right\rangle^{2}+\mathbf{1}\left(\left\langle\widehat{M}_{1, t-1}-\right.\right.$ $\left.\left.\widehat{M}_{0, t-1}, X\right\rangle<0\right) \frac{1}{\frac{\varepsilon_{t}}{2}}\left\langle X, \mathcal{P}_{M}(Q)\right\rangle^{2}$. By martingale Bernstein inequality, with probability at least $1-d_{1}^{-10}$,

$$
\left|\frac{1}{T} \sum_{t=T_{0}+1}^{T} \frac{d_{1} d_{2} \mathbb{1}\left(a_{t}=1\right)}{\pi_{t}}\left\langle\widehat{\Delta}_{t-1}, X_{t}\right\rangle\left\langle X_{t}, \mathcal{P}_{M}(Q)\right\rangle-\left\langle\widehat{\Delta}_{t-1}, \mathcal{P}_{M}(Q)\right\rangle\right| \lesssim \sqrt{\frac{d_{1}^{2} d_{2} \log ^{5} d_{1}}{T^{2-2 \gamma}} \sigma S_{T} .}
$$

As we have shown in the proof of Lemma 4, $S_{T} \rightarrow S$ when $T, d_{1}, d_{2} \rightarrow \infty$. Then $\frac{\sum_{t=T_{0}+1}^{T} \xrightarrow[d_{1} d_{2} \Perp\left(a_{t}=1\right)]{\pi_{t}}\left\langle\widehat{\Delta}_{t-1}, X_{t}\right\rangle\left\langle X_{t}, \mathcal{P}_{M}(Q)\right\rangle-\left\langle\widehat{\Delta}_{t-1}, \mathcal{P}_{M}(Q)\right\rangle}{\sigma S \sqrt{d_{1} d_{2} / T^{1-\gamma}}} \xrightarrow{p} 0$ as long as $\frac{d_{1} \log ^{5} d_{1}}{T^{1-\gamma}} \rightarrow 0$.

## B. 6 Proof of Lemma 6

Proof. We first state the following Lemmas.
Lemma 9. Under the conditions in Theorem 3, with probability at least $1-d_{1}^{-3}$,

$$
\|\widehat{Z}\| \lesssim \sqrt{\frac{d_{1}^{2} d_{2} \log d_{1}}{T^{1-\gamma}}} \sigma
$$

Lemma 10. Under the conditions in Theorem 3, with probability at least $1-5 d_{1}^{-2}$,

$$
\begin{aligned}
& \left\|\widehat{L} \widehat{L}^{\top}-L L^{\top}\right\|_{2, \max } \lesssim \frac{\sigma}{\lambda_{\min }} \sqrt{\frac{d_{1}^{2} d_{2} \log d_{1}}{T^{1-\gamma}}} \sqrt{\frac{\mu r}{d_{1}}} \\
& \left\|\widehat{R} \widehat{R}^{\top}-R R^{\top}\right\|_{2, \max } \lesssim \frac{\sigma}{\lambda_{\min }} \sqrt{\frac{d_{1}^{2} d_{2} \log d_{1}}{T^{1-\gamma}}} \sqrt{\frac{\mu r}{d_{2}}} .
\end{aligned}
$$

Notice that

$$
\left|\left\langle\widehat{L} \widehat{L}^{\top} \widehat{Z} \widehat{R} \widehat{R}^{\top}-L L^{\top} \widehat{Z} R R^{\top}, Q\right\rangle\right| \leq\|Q\|_{\ell_{1}}\left\|\widehat{L} \widehat{L}^{\top} \widehat{Z} \widehat{R} \widehat{R}^{\top}-L L^{\top} \widehat{Z} R R^{\top}\right\|_{\max }
$$

Now by triangular inequality,

$$
\begin{aligned}
\left\|\widehat{L} \widehat{L}^{\top} \widehat{Z} \widehat{R} \widehat{R}^{\top}-L L^{\top} \widehat{Z} R R^{\top}\right\|_{\max } \leq & \left\|\left(\widehat{L} \widehat{L}^{\top}-L L^{\top}\right) \widehat{Z} R R^{\top}\right\|_{\max }+\left\|L L^{\top} \widehat{Z}\left(\widehat{R} \widehat{R}^{\top}-R R^{\top}\right)\right\|_{\max } \\
& +\left\|\left(\widehat{L} \widehat{L}^{\top}-L L^{\top}\right) \widehat{Z}\left(\widehat{R} \widehat{R}^{\top}-R R^{\top}\right)\right\|_{\max } \\
\leq & \|\widehat{Z}\|\left(\left\|\widehat{L} \widehat{L}^{\top}-L L^{\top}\right\|_{2, \max }\|R\|_{2, \max }+\left\|\widehat{R} \widehat{R}^{\top}-R R^{\top}\right\|_{2, \max }\|L\|_{2, \max }\right) \\
& +\|\widehat{Z}\|\| \| \widehat{L} \widehat{L}^{\top}-L L^{\top}\left\|_{2, \max }\right\| \widehat{R} \widehat{R}^{\top}-R R^{\top} \|_{2, \max } \\
\leq & \frac{\sigma^{2}}{\lambda_{\min }} \frac{\mu r d_{1}^{3 / 2} d_{2}^{1 / 2} \log d_{1}}{T^{1-\gamma}} .
\end{aligned}
$$

Then as long as $\frac{\|Q\|_{\ell_{1}}}{\sqrt{1 / T^{\gamma}\left\|P_{\Omega_{1}}\left(P_{M}(Q)\right)\right\|_{\mathrm{F}}^{2}+C_{\gamma}\left\|P_{\Omega_{0}}\left(P_{M}(Q)\right)\right\|_{\mathrm{F}}^{2}}} \frac{\sigma}{\lambda_{\text {min }}} \sqrt{\frac{r^{2} d_{1}^{2} \log d_{1}}{T^{1-\gamma}}} \rightarrow 0$, we prove the claimed results.

## B. 7 Proof of Lemma 7

Proof. Similarly as the proof of Lemma 6. we again define events $\mathcal{E}_{0}=\left\{\|\widehat{Z}\| \lesssim \sqrt{\frac{d_{1}^{2} d_{2} \log d_{1}}{T^{1-\gamma}}} \sigma:=\delta\right\}$, $\mathcal{E}_{1}=\left\{\left\|\widehat{L} \widehat{L}^{\top}-L L^{\top}\right\|_{2, \max } \lesssim \frac{\sigma}{\lambda_{\min }} \sqrt{\frac{d_{1}^{2} d_{2} \log d_{1}}{T^{1-\gamma}}} \sqrt{\frac{\mu r}{d_{1}}},\left\|\widehat{R} \widehat{R}^{\top}-R R^{\top}\right\|_{2, \max } \lesssim \frac{\sigma}{\lambda_{\text {min }}} \sqrt{\frac{d_{1}^{2} d_{2} \log d_{1}}{T^{1-\gamma}}} \sqrt{\frac{\mu r}{d_{2}}}\right\}$. Then by Lemma 5 and Lemma 6 in Xia and Yuan 2021, under the $\mathcal{E}_{0}$ and $\mathcal{E}_{1}$,

$$
\begin{aligned}
\left|\sum_{k=2}^{\infty}\left\langle\left(\mathcal{S}_{A, k}(\widehat{E}) A \Theta \Theta^{\top}+\Theta \Theta^{\top} A \mathcal{S}_{A, k}(\widehat{E})\right), \widetilde{Q}\right\rangle\right| & \lesssim\|Q\|_{\ell_{1}} \frac{\mu r}{\lambda_{\min } \sqrt{d_{1} d_{2}}} \delta^{2} \\
& =\|Q\|_{\ell_{1}} \frac{\sigma^{2}}{\lambda_{\min }} \frac{\mu r d_{1}^{3 / 2} d_{2}^{1 / 2} \log d_{1}}{T^{1-\gamma}},
\end{aligned}
$$

and

$$
\begin{aligned}
\left|\left\langle\left(\widehat{\Theta} \widehat{\Theta}^{\top}-\Theta \Theta^{\top}\right) A\left(\widehat{\Theta} \widehat{\Theta}^{\top}-\Theta \Theta^{\top}\right), \widetilde{Q}\right\rangle\right| & \lesssim\|Q\|_{\ell_{1}}\|\Lambda\|\left\|\widehat{L} \widehat{L}^{\top}-L L^{\top}\right\|_{2, \max }\left\|\widehat{R} \widehat{R}^{\top}-R R^{\top}\right\|_{2, \max } \\
& \leq\|Q\|_{\ell_{1}} \frac{\sigma^{2}}{\lambda_{\min }} \frac{\mu r \kappa d_{1}^{3 / 2} d_{2}^{1 / 2} \log d_{1}}{T^{1-\gamma}}
\end{aligned}
$$

Then as long as $\frac{\|Q\|_{\ell_{1}}}{\sqrt{1 / T^{\gamma}\left\|P_{\Omega_{1}}\left(P_{M}(Q)\right)\right\|_{\mathrm{F}}^{2}+C_{\gamma}\left\|P_{\Omega_{0}}\left(P_{M}(Q)\right)\right\|_{F}^{2}}} \frac{\sigma}{\lambda_{\text {min }}} \sqrt{\frac{r^{2} d_{1}^{2} \log d_{1}}{T^{1-\gamma}}} \rightarrow 0$, we prove the claimed results.

## B. 8 Proof of Lemma 8

Proof. Without loss of generality, we just prove the $i=1$ case and $i=0$ case can be shown following the same arguments.
Recall $\delta$ defined in Theorem 3. Suppose $\left\langle M_{1}-M_{0}, X\right\rangle>0$, then we have for any $T_{0}+1 \leq t \leq T$,

$$
\begin{aligned}
\left\langle\widehat{M}_{1, t}-\widehat{M}_{0, t}, X\right\rangle & =\left\langle\widehat{M}_{1, t}-M_{1}, X\right\rangle+\left\langle M_{0}-\widehat{M}_{0, t}, X\right\rangle+\left\langle M_{1}-M_{0}, X\right\rangle \\
& \geq\left\langle M_{1}-M_{0}, X\right\rangle-2 \delta>0
\end{aligned}
$$

with probability at least $1-8 t d_{1}^{-200}$. The second inequality comes from the gap condition in Assumption 1. As a result, with the same probability, $\mathbb{1}\left(\left\langle\widehat{M}_{1, t}-\widehat{M}_{0, T}, X\right\rangle>0\right)=\mathbb{1}\left(\left\langle M_{1}-M_{0}, X\right\rangle>\right.$ $0)$.

## B. 9 Proof of Lemma 9

Proof. We first look at $\left\|\widehat{Z}_{1}\right\|=\left\|\frac{b}{T} \sum_{t=T_{0}+1}^{T} \frac{d_{1} d_{2} \mathbf{1}\left(a_{t}=1\right)}{\pi_{t}} \xi_{t} X_{t}\right\|$.
Since $\xi_{t}$ is subGaussian random variable, then for any $T_{0}+1 \leq t \leq T$,

$$
\left\|\left\|\frac{b}{T} \frac{d_{1} d_{2} \mathbf{1}\left(a_{t}=1\right)}{\pi_{t}} \xi_{t} X_{t}\right\|\right\|_{\psi_{2}} \leq \frac{2 b d_{1} d_{2}}{T \varepsilon_{t}}\left\|\xi_{t}\right\|_{\psi_{2}} \lesssim \frac{d_{1} d_{2} \sigma}{T^{1-\gamma}} .
$$

Meanwhile,

$$
\begin{aligned}
& \sum_{t=T_{0}+1}^{T} \mathbb{E}\left[\left.\frac{b^{2}}{T^{2}} \frac{d_{1}^{2} d_{2}^{2} \mathbf{1}\left(a_{t}=1\right)}{\pi_{t}^{2}} \xi_{t}^{2} X_{t} X_{t}^{\top} \right\rvert\, \mathcal{F}_{t-1}\right] \leq \frac{b^{2} d_{1}^{2} d_{2}^{2}}{T^{2}} \sum_{t=T_{0}+1}^{T} \frac{2}{\varepsilon_{t}} \sigma^{2} \mathbb{E}\left[X_{t} X_{t}^{\top}\right] \\
& \quad=\frac{b^{2} d_{1}^{2} d_{2}^{2}}{T^{2}} \sum_{t=1}^{T} \frac{2}{\varepsilon_{t}} \sigma^{2} \frac{1}{d_{1}} \boldsymbol{I}_{d_{1}} \lesssim \frac{d_{1} d_{2}^{2} \sigma^{2}}{T^{1-\gamma}} \boldsymbol{I}_{d_{1}} .
\end{aligned}
$$

By symmetry, we can have

$$
\begin{aligned}
\max \{ & \left\|\sum_{t=T_{0}+1}^{T} \mathbb{E}\left[\left.\frac{b^{2}}{T^{2}} \frac{d_{1}^{2} d_{2}^{2} \mathbf{1}\left(a_{t}=1\right)}{\pi_{t}^{2}} \xi_{t}^{2} X_{t} X_{t}^{\top} \right\rvert\, \mathcal{F}_{t-1}\right]\right\|, \\
& \left.\left\|\sum_{t=T_{0}+1}^{T} \mathbb{E}\left[\left.\frac{b^{2}}{T^{2}} \frac{d_{1}^{2} d_{2}^{2} \mathbf{1}\left(a_{t}=1\right)}{\pi_{t}^{2}} \xi_{t}^{2} X_{t}^{\top} X_{t} \right\rvert\, \mathcal{F}_{t-1}\right]\right\|\right\} \lesssim \frac{d_{1}^{2} d_{2} \sigma^{2}}{T^{1-\gamma}} .
\end{aligned}
$$

Then by matrix Bernstein inequality, with probability at least $1-d_{1}^{-2}$,

$$
\left\|\widehat{Z}_{1}\right\| \lesssim \frac{d_{1} d_{2} \sigma}{T^{1-\gamma}} \log d_{1}+\sqrt{\frac{d_{1}^{2} d_{2} \sigma^{2} \log d_{1}}{T^{1-\gamma}}} \lesssim \sqrt{\frac{d_{1}^{2} d_{2} \log d_{1}}{T^{1-\gamma}}} \sigma .
$$

The first term will be dominated by the second term since $T \gg d_{1}^{1 /(1-\gamma)} \log ^{3} d_{1}$.
To prove the upper bound for $\left\|\widehat{Z}_{2}\right\|=\left\|\frac{b}{T} \sum_{t=T_{0}+1}^{T} \frac{d_{1} d_{2} 1\left(a_{t}=1\right)}{\pi_{t}}\left\langle\widehat{\Delta}_{t-1}, X_{t}\right\rangle X_{t}-\widehat{\Delta}_{t-1}\right\|$, we follow the same arguments by observing that for any $T_{0}+1 \leq t \leq T$,

$$
\begin{aligned}
\left\|\frac{b}{T}\left(\frac{d_{1} d_{2} \mathbf{1}\left(a_{t}=1\right)}{\pi_{t}}\left\langle\widehat{\Delta}_{t-1}, X_{t}\right\rangle X_{t}-\widehat{\Delta}_{t-1}\right)\right\| & \leq \frac{b d_{1} d_{2}}{T} \frac{2}{\varepsilon_{t}}\left\|\widehat{\Delta}_{t-1}\right\|_{\max }+\frac{b}{T}\left\|\widehat{\Delta}_{t-1}\right\| \\
& \lesssim \frac{d_{1} d_{2}}{T^{1-\gamma}}\left\|\widehat{\Delta}_{t-1}\right\|_{\max }+\frac{\sqrt{d_{1} d_{2}}}{T}\left\|\widehat{\Delta}_{t-1}\right\|_{\max } \lesssim \frac{d_{1} d_{2} \sigma}{T^{1-\gamma}} .
\end{aligned}
$$

The second inequality comes from the fact that $\left\|\widehat{\Delta}_{t-1}\right\| \leq \sqrt{d_{1} d_{2}}\left\|\widehat{\Delta}_{t-1}\right\|_{\text {max }}$, and in the last inequality we again use $\left\|\widehat{\Delta}_{t-1}\right\|_{\max } \lesssim \sigma$.
Meanwhile,

$$
\begin{aligned}
& \left\|\frac{b^{2}}{T^{2}} \sum_{t=T_{0}+1}^{T} \mathbb{E}\left[\left.\left(\frac{d_{1} d_{2} \mathbf{1}\left(a_{t}=1\right)}{\pi_{t}}\left\langle\widehat{\Delta}_{t-1}, X_{t}\right\rangle X_{t}-\widehat{\Delta}_{t-1}\right)\left(\frac{d_{1} d_{2} \mathbf{1}\left(a_{t}=1\right)}{\pi_{t}}\left\langle\widehat{\Delta}_{t-1}, X_{t}\right\rangle X_{t}-\widehat{\Delta}_{t-1}\right)^{\top} \right\rvert\, \mathcal{F}_{t-1}\right]\right\| \\
& \leq \frac{b^{2}}{T^{2}} \sum_{t=T_{0}+1}^{T}\left\|\mathbb{E}\left[\left.\frac{d_{1}^{2} d_{2}^{2} \mathbf{1}\left(a_{t}=1\right)}{\pi_{t}^{2}}\left\langle\widehat{\Delta}_{t-1}, X_{t}\right\rangle^{2} X_{t} X_{t}^{\top} \right\rvert\, \mathcal{F}_{t-1}\right]\right\|+\left\|\widehat{\Delta}_{t-1}\right\|^{2} \\
& \leq \frac{b^{2}}{T^{2}} \sum_{t=T_{0}+1}^{T} \frac{2 d_{1}^{2} d_{2}^{2}}{\varepsilon_{t}}\left\|\widehat{\Delta}_{t-1}\right\|_{\max }^{2}\left\|\mathbb{E}\left(X_{t} X_{t}^{\top}\right)\right\|+d_{1} d_{2}\left\|\widehat{\Delta}_{t-1}\right\|_{\max }^{2} \lesssim \frac{d_{1} d_{2}^{2} \sigma^{2}}{T^{1-\gamma}} .
\end{aligned}
$$

Finally, by matrix Bernstein inequality, with probability $1-d_{1}^{-2}$,

$$
\left\|\widehat{Z}_{2}\right\| \lesssim \sqrt{\frac{d_{1}^{2} d_{2} \log d_{1}}{T^{1-\gamma}}} \sigma
$$

## B. 10 Proof of Lemma 10

Proof. Consider the event in Theorem 9

$$
\mathcal{E}=\left\{\|\widetilde{Z}\| \lesssim \sqrt{\frac{d_{1}^{2} d_{2} \log d_{1}}{T^{1-\gamma}}} \sigma\right\} .
$$

The following proof is adapted from Theorem 4 and Lemma 9 in Xia and Yuan 2021. We adapt it to martingale version. Under $\mathcal{E}$, we have $\|\widehat{Z}\| \lesssim \sqrt{\frac{d_{1}^{2} d_{2} \log d_{1}}{T^{1-\gamma}}} \sigma \lesssim \lambda_{\text {min }}=: \delta$. As long as $\sqrt{\frac{d_{1}^{2} d_{2} \log d_{1}}{T^{1-\gamma}}} \sigma \lesssim$ $\lambda_{\text {min }}$, we have $\|\widehat{E}\|=\|\widehat{Z}\| \lesssim \lambda_{\text {min }}$. Recall the $\mathfrak{P}^{-s}$ for $s \geq 0$ and $\mathfrak{P}^{\perp}$ defined in the proof of Theorem 3. Following the proof in Xia and Yuan 2021, it suffices to show under $\mathcal{E}$, there exist absolute constants $C_{1}, C_{2}>0$ so that for all $k \geq 0$, the following bounds hold with probability at least
$1-2(k+1) d_{1}^{-2}$,

$$
\begin{aligned}
& \max _{j \in\left[d_{1}\right]}\left\|e_{j}^{\top} \mathfrak{P}^{\perp}\left(\mathfrak{P}^{\perp} \widehat{E} \mathfrak{P}^{\perp}\right)^{k} \widehat{E} \Theta\right\| \leq C_{1}\left(C_{2} \delta\right)^{k+1} \sqrt{\frac{\mu r}{d_{1}}}, \\
& \max _{j \in\left[d_{2}\right]}\left\|e_{j+d_{1}}^{\top} \mathfrak{P}^{\perp}\left(\mathfrak{P}^{\perp} \widehat{E} \mathfrak{P}^{\perp}\right)^{k} \widehat{E} \Theta\right\| \leq C_{1}\left(C_{2} \delta\right)^{k+1} \sqrt{\frac{\mu r}{d_{2}}} .
\end{aligned}
$$

Here we only present the proof for $k=0$ and the cases $k \geq 1$ can be similarly extended. Clearly, for $j \in\left[d_{1}\right]$,

$$
\left\|e_{j}^{\top} \mathfrak{P}^{\perp} \widehat{E} \Theta\right\| \leq\left\|e_{j}^{\top} \Theta \Theta^{\top} \widehat{E} \Theta\right\|+\left\|e_{j}^{\top} \widehat{E} \Theta\right\| \leq \delta \sqrt{\frac{\mu r}{d_{1}}}+\left\|e_{j}^{\top} \widehat{E} \Theta\right\|=\delta \sqrt{\frac{\mu r}{d_{1}}}+\left\|e_{j}^{\top} \widehat{Z} R\right\|
$$

We write

$$
\begin{aligned}
e_{j}^{\top} \widehat{Z} R= & \frac{b}{T}\left(\sum_{t=T_{0}+1}^{T} \frac{d_{1} d_{2} \mathbb{1}\left(a_{t}=1\right)}{\pi_{t}} \xi_{t} e_{j}^{\top} X_{t} R\right. \\
& \left.+\sum_{t=T_{0}+1}^{T} \frac{d_{1} d_{2} \mathbb{1}\left(a_{t}=1\right)}{\pi_{t}}\left\langle\widehat{\Delta}_{t-1}, X_{t}\right\rangle e_{j}^{\top} X_{t} R-e_{j} \widehat{\Delta}_{t-1} R\right) .
\end{aligned}
$$

Obviously, for any $T_{0}+1 \leq t \leq T$,

$$
\left\|\left\|\frac{b d_{1} d_{2} \mathbb{1}\left(a_{t}=1\right)}{T \pi_{t}} e_{j}^{\top} \xi_{t} X_{t} R\right\|\right\|_{\psi_{2}} \lesssim \frac{d_{1} d_{2}}{T^{1-\gamma}} \sigma\|R\|_{2, \max } \leq \frac{d_{1} d_{2}}{T^{1-\gamma}} \sigma \sqrt{\frac{\mu r}{d_{2}}}
$$

and

$$
\mathbb{E}\left[\left.\frac{b^{2} d_{1}^{2} d_{2}^{2} \mathbb{1}\left(a_{t}=1\right)}{T^{2} \pi_{t}^{2}} \xi_{t}^{2} e_{j}^{\top} X_{t} R R^{\top} X_{t}^{\top} e_{j} \right\rvert\, \mathcal{F}_{t-1}\right] \lesssim \frac{t^{\gamma} \sigma^{2} d_{1} d_{2}}{T^{2}} \operatorname{tr}\left(R R^{\top}\right) \leq \frac{t^{\gamma} r \sigma^{2} d_{1} d_{2}}{T^{2}}
$$

Then by martingale Bernstein inequality, with probability at least $1-d_{1}^{-3}$,

$$
\left\|\frac{b}{T} \sum_{t=T_{0}+1}^{T} \frac{d_{1} d_{2} \mathbb{1}\left(a_{t}=1\right)}{\pi_{t}} \xi_{t} e_{j}^{\top} X_{t} R\right\| \lesssim \sqrt{\frac{r d_{1} d_{2} \log d_{1}}{T^{1-\gamma}}} \sigma .
$$

Similarly, with the same probability,

$$
\left\|\frac{b}{T} \sum_{t=T_{0}+1}^{T} \frac{d_{1} d_{2} \mathbb{1}\left(a_{t}=1\right)}{\pi_{t}}\left\langle\widehat{\Delta}_{t-1}, X_{t}\right\rangle e_{j}^{\top} X_{t} R-e_{j} \widehat{\Delta}_{t-1} R\right\| \lesssim \sqrt{\frac{r d_{1} d_{2} \log d_{1}}{T^{1-\gamma}}} \sigma .
$$

Then we can conclude that

$$
\left\|e_{j}^{\top} \widehat{Z} R\right\| \lesssim \sqrt{\frac{r d_{1} d_{2} \log d_{1}}{T^{1-\gamma}}} \sigma
$$

with probability at least $1-3 d_{1}^{-3}$. Taking union bound,

$$
\begin{aligned}
& \mathbb{P}\left(\max _{j \in\left[d_{1}\right]}\left\|e_{j}^{\top} \mathfrak{P}^{\perp} \widehat{E} \Theta\right\| \gtrsim \delta \sqrt{\frac{\mu r}{d_{1}}}\right) \leq 3 d_{1}^{-2}, \\
& \mathbb{P}\left(\max _{j \in\left[d_{2}\right]}\left\|e_{j}^{\top} \mathfrak{P}^{\perp} \widehat{E} \Theta\right\| \gtrsim \delta \sqrt{\frac{\mu r}{d_{2}}}\right) \leq 3 d_{1}^{-2} .
\end{aligned}
$$

Then following the proof of Lemma 4 in Xia and Yuan 2021,

$$
\mathbb{P}\left(\left.\left\|\widehat{L} \hat{L}^{\top}-L L^{\top}\right\|_{2, \max } \gtrsim \frac{\sigma}{\lambda_{\min }} \sqrt{\frac{d_{1}^{2} d_{2} \log d_{1}}{T^{1-\gamma}}} \sqrt{\frac{\mu r}{d_{1}}} \right\rvert\, \mathcal{E}\right) \leq 5 d_{1}^{-2} \log ^{2} d_{1} .
$$

And similarly we can prove the statement for $\left\|\widehat{R} \widehat{R}^{\top}-R R^{\top}\right\|_{2, \max }$.
