## Abstract

In the recently discovered kagome superconductor  $AV_3Sb_5$  (A = K, Rb, and Cs), the superconductivity is intertwined with an unconventional charge density wave order. Its pairing symmetry remains elusive owing to the lack of direct measurement of the superconducting gap in the momentum space. In this letter, utilizing laser-based ultrahigh-resolution and low-temperature angle-resolved photoemission spectroscopy, we observe anisotropic Cooper pairing in kagome superconductor CsV<sub>3</sub>Sb<sub>5</sub>. We detect a highly anisotropic superconducting gap structure with an anisotropy over 80% and the gap maximum along the V-V bond direction on a Fermi surface originated from the 3*d*-orbital electrons of the V kagome lattice. It is in stark contrast to the isotropic superconducting gap structure on the other Fermi surface that is occupied by Sb 5*p*-orbital electrons. Our observation of the anisotropic Cooper pairing in pristine CsV<sub>3</sub>Sb<sub>5</sub> is fundamental for understanding intertwined orders in the ground state of kagome superconductors.

Kagome lattice is a combination of corner-shared triangles and hexagons. Such a unique structure causes geometrical frustration in the spin degree of freedom and the destructive quantum interference in the electronic wavefunctions [1-3]. The latter generates the localized density of states inside the hexagons and introduces a topological flat band. In addition, because of the similar group symmetry with graphene, there are a Dirac cone and van Hove singularities (VHS) in the electronic band structure. Therefore, kagome lattice materials provide an ideal platform for studying the interplay between topology, correlations, and the emergent novel electronic orders [4-6]. While the kagome lattice materials have existed for a long time,  $AV_3Sb_5$  (A = K, Rb, and Cs) with a kagome lattice was recently discovered to be a superconductor, in which many interesting phenomena [7-9], such as giant anomalous Hall effect [10,11], unconventional charge density wave (CDW) [12-15], electronic nematicity [16-18], and pair density wave [19,20], have been observed. Owing to these exotic phenomena,  $AV_3Sb_5$  family superconductor attracts considerable attentions and is being intensively studied.

As a new superconductor with novel physical properties, one of the most important issues is the superconducting (SC) gap symmetry because it is fundamental in clarifying the microscopic pairing mechanism and interplays between multiple electronic orders. Our previous ARPES studies on niobium-doped  $Cs(V_{0.93}Nb_{0.07})_3Sb_5$  and tantalum-doped  $Cs(V_{0.86}Ta_{0.14})_3Sb_5$  suggest an isotropic and nodeless SC gap structure in both cases [21]. Such a SC gap structure gets in line with the observations of the Hebel-Slichter coherent peak in the spin-lattice relaxation rate revealed by the NMR studies of  $CsV_3Sb_5$  [22] and the exponentially temperature-dependent magnetic penetration depth [23,24]. However, certain V-shaped gaps, as well as residual Fermilevel states measured by scanning tunnelling spectroscopy [19,25,26] in  $CsV_3Sb_5$  seem to support a scenario of the anisotropic SC gap structure. Moreover, it has been reported that the anisotropy in the SC gap of  $CsV_3Sb_5$  can be suppressed by chemical substitution or impurity injection [27,28]. Therefore, to pin down the gap symmetry, the direct measurement of the SC gap structure in non-doped  $CsV_3Sb_5$  is highly desired.

In this study, we have used ultra-high resolution and low-temperature laser-based angleresolved photoemission spectroscopy (ARPES) to directly measure the SC gap in the momentum space of kagome superconductor CsV<sub>3</sub>Sb<sub>5</sub> [29]. We choose high-quality single crystals which has a relatively higher SC transition temperature  $T_c \simeq 3.2$  K [29] to ensure the accuracy of the SC gap measurements. Figure 1(a) shows the crystal structure of CsV<sub>3</sub>Sb<sub>5</sub>, which belongs to the space group P6/mmm. The vanadium atoms form a kagome lattice. As the phase diagram shown in Fig. 1(b), in addition to the SC transition, CsV<sub>3</sub>Sb<sub>5</sub> has a CDW transition around  $T_{CDW} \simeq 94$  K. The SC phase has two domes with applying pressure and chemical doping [30-32], implying an unconventional interplay between SC and CDW orders. The inset of Fig. 1(b) shows the schematic Fermi surface (FS) of CsV<sub>3</sub>Sb<sub>5</sub>, comprising a circular pocket and hexagonal pocket at the center of the Brillouin Zone (BZ), and a triangular pocket at the BZ corner. By performing careful ARPES measurements along these three FS sheets, we observe an isotropic SC gap structure on the circular and triangular FS sheets. Strikingly, a strongly anisotropic SC gap is observed with the gap maximum along V-V bond direction on the hexagonal FS originated from the 3*d*-orbital electrons of V kagome lattice. The direct observation of the anisotropic Cooper pairing lays a foundation to comprehensively understand the pairing symmetry and mechanism of kagome superconductors.

We first map out the FS, which is important to study the SC gap structure for a multiband system. As shown in Fig. 2 (a), the ARPES intensity integration near the Fermi level ( $E_F$ ) fits well with the calculated FS contours [33,34] as drawn in the inset of Fig.1(b). Following the previous study [21,35], the FS sheets in this study are marked as  $\alpha$ ,  $\beta$ , and  $\delta$  for the central circular, hexagonal pockets, and outer triangular pockets, respectively. Figure 2(b) shows the *E-k* map of the purple and brown cuts in Fig. 2(a) taken by *s*- and *p*-polarized light, respectively. The bands of  $\beta$  FS have stronger intensity with *s*-polarization, while the bands of  $\delta$  FS have stronger intensity with *s*-polarization in orbital components for these two FS sheets and is helpful to distinguish the bands corresponding to  $\beta$  and  $\delta$  FS sheets.

Next, we study the SC gap in the momentum space. In Fig. 2(c)-(e), we show the symmetrized energy distribution curves (EDCs) at the Fermi momentum ( $k_F$ ) positions along with  $\alpha$ ,  $\beta$ , and  $\delta$  FS sheets. These EDCs are taken at T = 2 K, below  $T_c$  of approximately 3.2 K. For clarity, the  $k_F$  positions are marked as the FS angle  $\varphi$  defined in Fig. 2(a). While the detectable momentum of the 5.8-eV laser is restricted, the measured area spans over a 60-degree range of the FS angle, surpassing the minimum requirement for the six-fold symmetry. Clearly, the SC gap on  $\alpha$  and  $\delta$  FS is nearly isotropic as proved by the similar shallows near  $E_F$  in the symmetrized EDCs shown in Fig. 2(c) and Fig. 2(e), respectively. Remarkably, as the symmetrized EDCs of  $\beta$  FS shown in Fig. 2(d), the SC gap is strongly dependent with the FS angle. The maximum of the SC gap is observed at  $k_F$  positions along with  $\Gamma$ -M direction. As the temperature-dependent EDCs at  $k_F$  position of approximately 210° shown in Fig. 2(f), the SC gap is far smaller than the experimental energy resolution, suggestive of a possible node.

By fitting the EDCs to a Bardeen-Cooper-Schrieffer spectral function [29], we quantitively extracted the SC gap magnitude. The obtained SC gap magnitude as a function of the FS angle is summarized in Fig. 3(b). The corresponding  $k_F$  positions are shown in Fig. 3(a) as open black circles. As shown in Fig. 3(b), the SC gap structure of  $\beta$  FS has a large anisotropy over approximately 80%, while the SC gaps on  $\alpha$  and  $\delta$  FS sheets are isotropic. The distribution of the SC gap magnitudes in the in-plane momentum space is summarized in Fig. 3(c) by symmetrizing the SC gap distribution on measured  $k_F$  positions following the six-fold symmetry.

It is of notice that by integrating the SC gaps on three FS sheets, the anisotropy is kept since the isotropic SC gaps on  $\alpha$  and  $\delta$  FS sheets do not contribute any features. Thus, our result is consistent with the overall anisotropic SC gap structure deduced from the field-angle-resolved calorimetry measurements [36], as well as the V-shaped local density of states measured by scanning tunneling spectroscopy [19,25,26]. On the other hand, the observed isotropic SC gap on  $\alpha$  FS occupied by Sb 5p orbital electrons is consistent with the observation of Hebel-Slichter coherent peak in the spin-lattice relaxation rate from <sup>121/123</sup>Sb nuclear quadrupole resonance measurements [22]. Considering our previous results of the isotropic SC gap for chemically substituted CsV<sub>3</sub>Sb<sub>5</sub>[21], in which the V kagome lattice is expanded by the partial substitutions of Nb or Ta with larger atomic radius, it is suggested that the anisotropy in the SC gap is sensitive to the kagome lattice geometry. This is consistent with the previous magnetic penetration depth measurements [27] reported that the SC gap becomes more and more isotropic with increasing impurities by electron irradiation.

The observed SC gap structures on these three FS sheets provide intuition that the Cooper pairing of Sb 5*p* electrons tends to be isotropic, while the Cooper pairing of V 3*d* electrons tends to be anisotropic. The isotropic SC gap is observed on  $\alpha$  FS since it is mainly occupied by Sb 5*p*<sub>z</sub> electrons [34,37,38]. While both  $\beta$  and  $\delta$  FS sheets are mainly occupied by V 3*d* electrons [38,39], there is a significant difference on the SC gap structure that the  $\delta$  FS has a nearly isotropic SC gap while  $\beta$  FS has a strong anisotropic SC gap structure. This stark difference can be understood by including the anisotropic CDW gap. According to the band calculations considering the orbital contributions [37], these two Fermi surfaces are mainly occupied by V 3*d* electrons but with a partial occupation from Sb 5*p* electrons. Furthermore, the CDW order gaps are observed for the V 3*d* electrons on  $\delta$  FS sheet but no CDW gap is observable for  $\beta$  FS, evidenced by the laser-ARPES measurements [35]. Therefore, the SC gap on  $\delta$  FS could be induced by pairing residual Sb 5*p* electrons, giving out an isotropic gap. Then, the anisotropic gap observed on  $\beta$  FS should be dominatly from the V 3*d* electronic pairing.

The observation of the anisotropic Cooper pairing in CsV<sub>3</sub>Sb<sub>5</sub> kagome superconductor is in good agreement with theoretical predictions under the mechanism of paramagnon interference [40]. The unique geometrical frustration of kagome lattice prohibits the freezing of paramagnons and promotes the quantum interference among them, providing the sizable intersite scattering. The smectic bond order is therefore realized. The bond-order fluctuations naturally mediate strong pairing glue that leads to both nodal s-wave and p-wave pairing states. Particularly, the nodal s-wave pairing state, which shows a node along  $\Gamma K$  direction and a maximum along V-V bond direction ( $\Gamma M$ ), is highly consistent with our observation of SC gap structure on  $\beta$  FS originated from 3*d* electrons of V kagome lattice. Moreover, such a nodal s-wave gap can be gradually quenched by inducing nonmagnetic dilute V-site impurities, and finally lead to an isotropic gap function [40]. This, again, is highly reproduced by our previous

high-resolution ARPES observations of isotropic SC gap in 7%-Nb and 14%-Ta doped samples [21]. By summarizing these findings on pristine and chemically substituted  $CsV_3Sb_5$  compounds, we present the experimental demonstration of such a nodal-nodeless transition in SC gap function tuned by dilute V-site impurity effects, supporting the pairing glued by bond-order fluctuations.

In summary, we have investigated the SC gap distribution in the momentum space of kagome superconductor  $CsV_3Sb_5$  by high-resolution ARPES measurements. Remarkably, a strongly anisotropic SC gap is observed on the FS occupied by 3*d* electrons of V kagome lattice. The anisotropy is over 80% and the gap maximum occurs along V-V bond direction ( $\Gamma$ M direction in momentum space). Combined with our previous observations of fully isotropic SC gap in chemically substituted  $CsV_3Sb_5$ , in which the V atoms are partially substituted by Nb or Ta atoms, the anisotropic Cooper pairing is frail to the distribution of the kagome lattice geometry. Overall, our direct observation of the strongly anisotropic Cooper pairing in kagome superconductor  $CsV_3Sb_5$  lays a foundation to further understand the nature of kagome superconductivity.

Fig. 1. (a) Crystal structure of  $CsV_3Sb_5$  viewed from the perpendicular direction to the layer. (b) The phase diagram of  $CsV_3Sb_5$  with Nb and Ta substitutions. SC and CDW refer to superconducting and charge density wave orders, respectively. Red and blue arrows indicate positions in the phase diagram at  $Cs(V_{0.93}Nb_{0.07})_3Sb_5$  and  $Cs(V_{0.86}Ta_{0.14})_3Sb_5$ . Inset is a calculated Fermi surface of  $CsV_3Sb_5$ . Each band consists of the orbits shown in the figure, and there are multiple van Hove singularities at the M point.

Fig. 2. (a) Fermi surface (FS) mapping of CsV<sub>3</sub>Sb<sub>5</sub>. Color lines in the figure represents the Fermi surface contours from the band calculations. The black open circles correspond to  $k_F$  positions where the energy distribution curves (EDCs) are plotted. (b) Energy-momentum (*E*-k) maps along with the purple and brown cuts in (a) obtained with *s*- and *p*-polarization, respectively. (c-e) Symmetrized EDCs measured at T = 2 K in different  $k_F$  positions for  $\alpha$ ,  $\beta$ , and  $\delta$  FS sheets, respectively. The  $k_F$  positions are marked as FS angle ( $\varphi$ ) as defined in (a). (f), (g) Temperature dependent EDCs along with  $\Gamma$ K and  $\Gamma$ M direction on  $\beta$  FS, respectively. Black lines on the top of the EDCs at 2 K are the best fits to BCS spectral function.

Fig. 3. (a) A summary of  $k_F$  positions, where the SC gap is measured. The color lines are the Fermi surface contours of CsV<sub>3</sub>Sb<sub>5</sub>. (b) Fitted SC gap magnitudes on three FS sheets plotted as a function of FS angle ( $\varphi$ ) as defined in (a). The yellow circles in (a) mark the momentum positions with a minimum SC gap, while the brown circles mark the momentum location of VHS. (c) Schematic plot of the SC gap distribution in the in-plane momentum space of CsV<sub>3</sub>Sb<sub>5</sub>.
