Abstract

Unitary designs are essential tools in several quantum information protocols. Similarly to other design concepts, unitary designs are mainly used to facilitate averaging over a relevant space, in this case, the unitary group $\mathbf{U}(\mathbf{d})$. While it is known that exact unitary \mathbf{t} -designs exist for any degree \mathbf{t} and dimension \mathbf{d} , the most appealing type of designs, group designs (in which the elements of the design form a group), can provide at most $\mathbf{3}$ -designs. Moreover, even group $\mathbf{2}$ -designs can only exist in limited dimensions. In this paper, we present novel construction methods for creating *exact generalized group designs* based on the representation theory of the unitary group and its finite subgroups that overcome the 4-design-barrier of unitary group designs. Furthermore, a construction is presented for creating generalized group $\mathbf{2}$ -designs in arbitrary dimensions.

Keywords: Unitary \mathbf{t} -designs, Quantum gate sets, Representation theory

1 Introduction

Unitary t -designs were first introduced in Refs. [1, 2], and subsequently have become an essential tool within the field of quantum information science. These finite collections of d -dimensional unitary matrices possess a unique property: By twirling (i.e., averaging) a certain matrix with the t -fold tensor products of these unitary matrices, the result is equal to the twirling over the *entire* unitary group $U(d)$ with respect to the Haar measure. This property makes them advantageous to use in protocols requiring unitaries sampled randomly from the Haar measure, thus potentially decreasing the resources needed, as generic Haar random unitaries are hard to implement. Hence, unitary designs have wide-ranging applications in quantum information science, in particular for quantum process tomography and channel fidelity estimation [2, 3], the construction of unitary codes [4], derandomization of probabilistic constructions [5], entanglement detection [6], the study of quantum chaos [7, 8], randomized benchmarking [9, 10], and shadow estimation [11–14].

One of the most elegant methods for constructing unitary designs involves delving into the representation theory of finite groups. The collection of unitaries derived from any unitary irreducible representation of a finite group constitutes a 1-design, and given additional properties, these elements can potentially form a higher-degree unitary design [15]. We call such collections of unitaries that form a group (such as those coming from representations) *unitary group designs*. Notably, some of the most renowned families of unitary t -designs fall under the category of group designs: The Clifford group over finite fields, both in their multipartite and single-particle variants, provide elegant and practical 2-designs in prime power dimensions [16]. Consequently, they find applications in randomized benchmarking for both qubit and qudit systems [9, 10, 17]. The multipartite Clifford group for qubit systems even constitutes a unitary 3-design [18–20], proving to be advantageous, for instance, in single-shot shadow estimation [12–14].

The rotten apple that spoils the barrel is the fact that there does not exist group 4-designs (and thus higher-degree designs) [21]. Moreover, one can construct group 2-designs only for a few non-prime-power dimensions (in particular, one can define modular versions of the Clifford group for non-prime-power dimensions, however, these fail to be 2-designs [22]). This severely limits the use of group designs for tasks such as randomized benchmarking in these dimensions.

Constructing unitary t -designs using finite group representations will eventually fail because the t -fold tensor product of the chosen representation will decompose nontrivially on some of the $U(d)$ -irreducible subspaces in the t -fold tensor product space. Thus, our research was mainly focused on the behavior of the group representations on those $U(d)$ -irreducible subspaces. In this paper, we present novel construction methods for creating *generalized group designs* based on such representation theoretic considerations. This allows us to build higher-degree designs from lower ones and also a procedure is given for constructing 2-designs in arbitrary dimensions.

The structure of the paper is as follows: Section 2 contains necessary basic definitions regarding unitary designs; Section 3 provides a construction of t -designs from finite unitary subgroups and presents some examples for the construction; finally,

Section 4 describes an explicit construction for generalized group 2-designs in arbitrary dimensions.

2 Preliminaries

This section provides the essential definitions and statements employed in the proposed constructions. It is important to note, that this paper is mainly concerned with the construction of exact designs, but we provide a statement for the construction of unitary 2-designs from orthogonal ones, which holds in the approximate case as well. For concrete constructions regarding approximate designs, see Refs. [2, 23–25].

Several different but equivalent definitions can be found for unitary designs and group designs in the literature [26–28]. However, the notion of unitary t -designs, where the summation over the finite set is weighted with a certain weight function, is crucial for this paper since the constructions presented are generally of this type.

Definition 1 (Unitary t -design). *A finite set $\mathcal{V} \subset \mathrm{U}(d)$ with weight function $w : \mathcal{V} \rightarrow [0, 1]$ is called a unitary t -design if the following equation holds for any linear transformation M on $(\mathbb{C}^d)^{\otimes t}$:*

$$\sum_{V \in \mathcal{V}} w(V) V^{\otimes t} M (V^{\otimes t})^\dagger = \int_{U \in \mathrm{U}(d)} U^{\otimes t} M (U^{\otimes t})^\dagger dU, \quad (1)$$

where the integral on the right-hand side is taken over all elements in $\mathrm{U}(d)$ with respect to the Haar measure. The number t is called the degree of the design.

In this definition and the rest of the paper $\mathrm{U}(d)$ can be naturally identified with its defining representation. More concretely, $U^{\otimes t} = \Pi_\square(U)^{\otimes t}$ for $U \in \mathrm{U}(d)$, where Π_\square is the defining representation of $\mathrm{U}(d)$. Moreover, the weight function of a t -design \mathcal{V} is the constant function $w \equiv 1/|\mathcal{V}|$ unless otherwise stated. Finally, a weighted unitary t -design is called a *unitary group t -design* when it possesses a group structure. In our proposals, however, we will construct t -designs which are generalizations of group t -designs in the sense that they are constructed from products of finite groups:

Definition 2 (Generalized group t -design). *Let $\mathcal{V}_1, \dots, \mathcal{V}_\ell \subset \mathrm{U}(d)$ be finite subgroups. We call $\mathcal{V} := \mathcal{V}_1 \cdot \dots \cdot \mathcal{V}_\ell$ a generalized group t -design if \mathcal{V} forms a unitary t -design with weight function given by*

$$w(U) := \frac{\left| \left\{ (h_1, \dots, h_\ell) \in \mathcal{V}_1 \times \dots \times \mathcal{V}_\ell : \prod_{j=1}^\ell h_j = U \right\} \right|}{|\mathcal{V}_1| \cdots |\mathcal{V}_\ell|}. \quad (2)$$

Remark 1. The above careful definition of the weight function is needed as, in general, the product of finite subgroups of a group does not form a set whose cardinality is equal to the product of the cardinalities of the constituent subgroups.

3 Constructing higher-degree generalized group designs

Construction of unitary designs for general t and d is a mathematically challenging task [29]. A well-known example of a unitary design is the Clifford group, which constitutes a group 3-design for qubit systems [18–20], but this specific example does not generalize for higher-degree designs. Fortunately, using the representation theory of finite groups, one may discover group t -designs with $t = 1, 2, 3$ for specific dimensions. However, the construction of higher-degree group designs based on representation theory is impossible because of the nonexistence of group 4-designs in dimensions greater than 2 [21]. The resulting 4-design-barrier for group designs compelled us to search for higher-degree designs that are not group designs. In this section, we present a construction that pushes the 4-design-barrier further for unitary designs based on generalized group designs (see Def. 2).

First, another characterization of unitary t -designs (equivalent to Def. 1) is presented based on representation theory (see also, Appendix of [15]). Consider the t -fold tensor product of the defining representation of $U(d)$: the underlying vector space $(\mathbb{C}^d)^{\otimes t}$ splits up under the action of $U(d)$ into the different isotypic components labeled by Young diagrams as

$$(\mathbb{C}^d)^{\otimes t} = \bigoplus_{\gamma \in \Gamma} \mathcal{K}_\gamma \otimes \mathcal{H}_\gamma, \quad (3)$$

where Γ is the set of Young diagrams with t number of boxes and at most d rows, \mathcal{H}_γ carries the $U(d)$ -irrep labeled by the Young diagram γ and \mathcal{K}_γ is the multiplicity space where $U(d)$ acts trivially [30]. Let us denote by P_γ the projection corresponding to the $V_\gamma := \mathcal{K}_\gamma \otimes \mathcal{H}_\gamma$ subspace. As previously mentioned, we present another equivalent characterization of unitary t -designs, which may be easily justified using Schur's lemma:

Proposition 1. *A finite set $\mathcal{V} \subset U(d)$ and a weight function $w : \mathcal{V} \rightarrow [0, 1]$ forms a unitary t -design if and only if the following equation is true for all linear transformations M on $(\mathbb{C}^d)^{\otimes t}$:*

$$\sum_{V \in \mathcal{V}} w(V) V^{\otimes t} M (V^{\otimes t})^\dagger = \bigoplus_{\gamma \in \Gamma} \frac{\text{Tr}_{\mathcal{H}_\gamma}(P_\gamma M P_\gamma)}{\dim \mathcal{H}_\gamma} \otimes \mathbb{1}_{\mathcal{K}_\gamma}, \quad (4)$$

where we used the notation as before, and $\text{Tr}_{\mathcal{H}_\gamma}$ is the partial trace over \mathcal{H}_γ of operators supported on the subspace V_γ .

Based on Proposition 1 the condition for a finite subgroup of the unitary group to be a unitary t -design can be reformulated to require that the appropriate irreducible subspaces of the unitary group remain irreducible when restricted to this finite subgroup. In light of this, the 4-design-barrier can be formulated in the following way: there is no finite subgroup of $U(d)$ such that all irreps of $U(d)$ labeled by Young diagrams with 4 boxes, restricted to this subgroup, remain irreducible if $d > 2$. The idea behind our construction is to find a subgroup $G_\gamma < U(d)$ for each Young diagram γ with t boxes and at most d rows, such that the irrep of $U(d)$ corresponding to γ

remains irreducible when restricted to G_γ . From these irreps, one can attempt to create a generalized unitary group t -design for $t \geq 4$. The fly in the ointment is that the irreducible subspace corresponding to such irreps might appear elsewhere in the irreducible decomposition of the t -fold tensor product of $U(d)$ upon restriction. This leads to a non-trivial intertwiner between these irreducible subspaces when averaging, ruining the construction. To rescue this idea, we aim to exclude these situations by taking the product of these finite unitary subgroups in such an order that additional multiplicities cannot occur. This line of thought is organized in the following theorem.

Theorem 1. *Let Π_\square denote the defining representation of the unitary group $U(d)$. Let Γ denote the partially ordered set of all Young diagrams corresponding to the irreducible representations appearing in the irreducible decomposition of $\Pi_\square^{\otimes t}$, with a descending order in the dimension of the corresponding irrep, and let $\ell := |\Gamma|$. Suppose that for each representation labeled by the Young diagram $\gamma \in \Gamma$:*

1. *There is a finite subgroup $G_\gamma < U(d)$ such that $\Pi_\gamma|_{G_\gamma}$ is an irreducible representation. Take one such G_γ for each $\gamma \in \Gamma$ and arrange them in a partially ordered set G according to the partial order on Γ .*
2. *For representations labeled by $\eta \in \Gamma$ with $\dim \Pi_\eta = \dim \Pi_\gamma$, equivalence on the restriction $\Pi_\eta|_{G_\gamma} \cong \Pi_\gamma|_{G_\gamma}$ implies that $\gamma = \eta$.*

Then the product $G_{\gamma_\ell} \cdot \dots \cdot G_{\gamma_1}$ forms a generalized group t -design.

Proof. Consider a matrix $M \in \mathbb{C}^{d^t \times d^t}$. The twirling over the product can be written as

$$\begin{aligned} & \sum_{U \in \prod_{j=1}^{\ell} G_{\gamma_j}} w(U) U^{\otimes t} M (U^{\otimes t})^\dagger \\ &= \frac{1}{|G_{\gamma_\ell}|} \sum_{U_\ell \in G_{\gamma_\ell}} \dots \frac{1}{|G_{\gamma_1}|} \sum_{U_1 \in G_{\gamma_1}} U_\ell^{\otimes t} \dots U_1^{\otimes t} M (U_1^{\otimes t})^\dagger \dots (U_\ell^{\otimes t})^\dagger. \end{aligned} \quad (5)$$

The series of the inner sums are denoted as

$$M^{(k)} := \frac{1}{|G_{\gamma_k}|} \sum_{U_k \in G_{\gamma_k}} \dots \frac{1}{|G_{\gamma_1}|} \sum_{U_1 \in G_{\gamma_1}} U_k^{\otimes t} \dots U_1^{\otimes t} M (U_1^{\otimes t})^\dagger \dots (U_k^{\otimes t})^\dagger, \quad (6)$$

and $M^{(0)} := M$. When $\dim \Pi_{\gamma_1} \neq \dim \Pi_{\gamma_2}$, then it must be that $\dim \Pi_{\gamma_1} > \dim \Pi_{\gamma_2}$, but then by dimension comparison the representation $\Pi_{\gamma_1}|_{G_{\gamma_1}}$ does not appear in the subsequent parts of the irreducible decomposition. Otherwise, for any other diagram $\eta \in \Gamma$ such that $\dim \Pi_{\gamma_1} = \dim \Pi_\eta$, by assumption when restricting to G_{γ_1} , the resulting restricted representations will be inequivalent. Hence, by performing the first twirling, we get an expression of the form

$$M^{(1)} = \frac{\text{Tr}_{\mathcal{H}_{\gamma_1}}(P_{\gamma_1} M P_{\gamma_1})}{\dim \mathcal{H}_{\gamma_1}} \otimes \mathbb{1}_{\mathcal{H}_{\gamma_1}} \oplus B^{(1)}, \quad (7)$$

where $B^{(1)}$ is some matrix corresponding to the subsequent representations. Twirling with the next group G_{γ_2} averages the previous contributions, i.e.,

$$M^{(2)} = M_1^{(2)} \oplus M_2^{(2)} \oplus B^{(2)}, \quad (8)$$

where

$$\begin{aligned} M_1^{(2)} &= \frac{1}{|G_{\gamma_2}|} \sum_{U \in G_{\gamma_2}} \Pi_{\gamma_1}^{\oplus n_1}(U) \left(\frac{\text{Tr}_{\mathcal{H}_{\gamma_1}}(P_{\gamma_1} M P_{\gamma_1})}{\dim \mathcal{H}_{\gamma_1}} \otimes \mathbb{1}_{\mathcal{H}_{\gamma_1}} \right) \Pi_{\gamma_1}^{\oplus n_1}(U^\dagger) \\ &= \frac{\text{Tr}_{\mathcal{H}_{\gamma_1}}(P_{\gamma_1} M P_{\gamma_1})}{\dim \mathcal{H}_{\gamma_1}} \otimes \mathbb{1}_{\mathcal{H}_{\gamma_1}}, \end{aligned} \quad (9)$$

since $\Pi_{\gamma_j}^{\oplus n_j}(U) = \mathbb{1}_{\mathcal{K}_{\gamma_j}} \otimes \Pi_{\gamma_j}(U)$. This means, that the resulting matrix on the subspaces corresponding to lower indices in Γ is invariant under subsequent twirling. Moreover,

$$\begin{aligned} M_2^{(2)} &= \frac{1}{|G_{\gamma_1}|} \sum_{U \in G_{\gamma_1}} \frac{\text{Tr}_{\mathcal{H}_{\gamma_2}}(\Pi_{\gamma_2}^{\oplus n_2}(U) P_{\gamma_2} M P_{\gamma_2} \Pi_{\gamma_2}^{\oplus n_2}(U^\dagger))}{\dim \mathcal{H}_{\gamma_2}} \otimes \mathbb{1}_{\mathcal{H}_{\gamma_2}} \\ &= \frac{\text{Tr}_{\mathcal{H}_{\gamma_2}}(P_{\gamma_2} M P_{\gamma_2})}{\dim \mathcal{H}_{\gamma_2}} \otimes \mathbb{1}_{\mathcal{H}_{\gamma_2}}, \end{aligned} \quad (10)$$

due to the cyclic property of the partial trace.

Inductively, for an index $1 < k \leq \ell$, we may calculate

$$M^{(k)} = \bigoplus_{j=1}^k \frac{\text{Tr}_{\mathcal{H}_{\gamma_j}}(P_{\gamma_j} M P_{\gamma_j})}{\dim \mathcal{H}_{\gamma_j}} \otimes \mathbb{1}_{\mathcal{H}_{\gamma_j}} \oplus B^{(k)}, \quad (11)$$

as the previously accounted direct summands corresponding to invariant subspaces remain invariant under twirling. Finally, we get that

$$M^{(\ell)} = \bigoplus_{\gamma \in \Gamma} \frac{\text{Tr}_{\mathcal{H}_{\gamma}}(P_{\gamma} M P_{\gamma})}{\dim \mathcal{H}_{\gamma}} \otimes \mathbb{1}_{\mathcal{H}_{\gamma}}, \quad (12)$$

hence the product $G_{\gamma_\ell} \cdot \dots \cdot G_{\gamma_1}$ forms a unitary t -design by Proposition 1. \square

Remark 2. The generalized group t -design defined in Theorem 1 can be reduced by noting that consecutive groups that are isomorphic are redundant, and one may choose only one of them from subsequences of this property.

Theorem 1 enables us to search for examples of unitary t -designs using character theory. In particular, for some low-dimensional 2- and 3-design constructions a similar technique was used in Ref. [31]. To be explicit, given a finite group G with a d dimensional unitary irrep σ one can examine whether the representation labeled by the Young diagram γ with t boxes and at most d rows remains irreducible when

restricted to $\sigma(G)$. This representation is irreducible if the corresponding character is irreducible which can be verified based on Theorem 2.7.9 from Ref. [32]. Using this idea, we have found the following examples of unitary 4-designs in the GAP system [33]:

Example 1 (4-design in 6 dimension). Any of the 6-dimensional irreducible representations of the group "S3x6_1.U4(3).2.2" or the group "6.U6(2)M6" remain irreducible on the subspaces corresponding to $\boxplus, \boxtimes, \boxminus, \boxdot$ and the irreps corresponding to \boxplus and \boxminus are not equivalent to the irrep with dimension 105 appearing in the irreducible decomposition of the representation corresponding to \boxtimes , and these are also inequivalent to each other. Meanwhile, the 22nd irreducible representation of the group "2.J2" is irreducible when restricted to the subspace corresponding to \boxtimes . This results in several different 4-designs in 6 dimensions by Theorem 1.

Example 2 (4-design in 12 dimension). The 153rd irreducible representation of the group "6.Suz" remains irreducible on the subspaces corresponding to $\boxtimes, \boxplus, \boxminus$ and \boxdot . Meanwhile, the standard representation of the alternating group on 13 elements is irreducible on the subspace corresponding to \boxdot . From these two unitary representations, a unitary 4-design can be constructed in 12 dimensions by Theorem 1.

4 Constructing 2-designs in arbitrary dimension

In prime power dimensions, the Clifford groups provide examples of unitary 2-designs [9, 10]. An inductive construction for t -designs in arbitrary dimensions is provided in Ref. [29]. However, for general dimensions, an explicit non-inductive construction for 2-designs is not known. In this section, we provide a construction for generalized group 2-designs for dimension $d \geq 5$. Using this construction together with the Clifford group, one can explicitly construct 2-designs in arbitrary dimensions. The presented construction makes use of the notion of orthogonal designs, which we need to introduce first.

4.1 Orthogonal designs

The concept of a unitary t -design, which is based on the unitary group, may be naturally defined for other groups as well. For our purposes, the orthogonal group $O(d)$ will be of main concern.

Definition 3 (Orthogonal t -design). *A finite set $\mathcal{V} \subseteq O(d)$ with weight function $w : \mathcal{V} \rightarrow [0, 1]$ is called a weighted orthogonal t -design if the following equation holds for any linear transformation M on $(\mathbb{C}^d)^{\otimes t}$:*

$$\sum_{V \in \mathcal{V}} w(V) V^{\otimes t} M (V^{\otimes t})^\dagger = \int_{O \in O(d)} O^{\otimes t} M (O^{\otimes t})^\dagger dO, \quad (13)$$

where the integral on the right-hand side is taken over all elements in $O(d)$ with respect to the Haar measure. The number t is called the degree of the design.

Denote $\mathcal{T}_{O(d)}(M) := \int_{O(d)} O^{\otimes 2} M (O^\dagger)^{\otimes 2} dO$ and $\mathcal{T}_{U(d)}(M) := \int_{U(d)} U^{\otimes 2} M (U^\dagger)^{\otimes 2} dU$. Moreover, for a finite subset $\mathcal{V} \subset U(d)$ with weight function w , define $\mathcal{F}_{\mathcal{V}}(M) := \sum_{U \in \mathcal{V}} w(U) U^{\otimes 2} M (U^\dagger)^{\otimes 2}$. Here, we are considering approximate 2-designs, since the main statement of this section holds in this general setting. We can characterize these using the diamond norm as follows [25].

Definition 4 (ϵ -approximate unitary 2-design). *We call a finite subset $\mathcal{V} \subset U(d)$ an ϵ -approximate unitary 2-design for some $\epsilon > 0$ when*

$$\|\mathcal{T}_{U(d)} - \mathcal{F}_{\mathcal{V}}\|_{\diamond} < \epsilon, \quad (14)$$

where $\|\cdot\|_{\diamond}$ is the diamond norm.

Remark 3. The definition of ϵ -approximate unitary design can be generalized to ϵ -approximate orthogonal design naturally.

To relate orthogonal 2-designs to unitary 2-designs, we need to consider the following statement.

Proposition 2. *Twirling with the unitary group can be decomposed into two consecutive twirlings with the orthogonal group, i.e.,*

$$\mathcal{T}_{U(d)} = \mathcal{T}_{O(d)^W} \circ \mathcal{T}_{O(d)}, \quad (15)$$

where $O(d)^W := \{WOW^\dagger : O \in O(d)\}$ and W is defined on the basis elements $\{|j\rangle\}_{j=0}^{d-1}$ as

$$W|j\rangle = \omega^{\alpha j}|j\rangle, \quad (16)$$

where $\omega = e^{\frac{2\pi i}{2d}}$ and $\alpha \in [0, 1]$ is a root of the equation $\left| \frac{\omega^{2\alpha d} - 1}{\omega^{2\alpha} - 1} \right|^2 = \frac{2d}{d+1}$.

Proof. Let Φ_{\square} denote the defining representation of the orthogonal group with respect to the basis $\{|j\rangle\}_{j=0}^{d-1}$. This can be embedded into the defining representation of the unitary group. The irreducible decomposition of $\Phi_{\square}^{\otimes 2}$ is the following:

$$\Phi_{\square}^{\otimes 2} \cong \Phi_t \oplus \Phi_r \oplus \Phi_{\square}, \quad (17)$$

where Φ_t is the trivial representation acting on the subspace spanned by $|\psi\rangle = \frac{1}{\sqrt{d}} \sum_{j=0}^{d-1} |j\rangle \otimes |j\rangle$. The representations $\Phi_t \oplus \Phi_r$ and Φ_{\square} act on the symmetric subspace V_{\square} and on the antisymmetric subspace V_{\square} , respectively. The projections to these subspaces are $P_t = |\psi\rangle\langle\psi|$, $P_r = P_{\square} - P_t$ and P_{\square} , respectively.

Twirling a matrix M on $(\mathbb{C}^d)^{\otimes t}$ with the orthogonal group $O(d)$ results in

$$\overline{M} := \mathcal{T}_{O(d)}(M) \cong \frac{\text{Tr}(P_t M)}{\text{Tr}(P_t)} \mathbb{1}_t \oplus \frac{\text{Tr}(P_r M)}{\text{Tr}(P_r)} \mathbb{1}_r \oplus \frac{\text{Tr}(P_{\square} M)}{\text{Tr}(P_{\square})} \mathbb{1}_{\square}. \quad (18)$$

Applying the second twirling channel $\mathcal{T}_{O(d)W}$ leaves the coefficient of the antisymmetric subspace invariant, and only modifies the coefficients of the remaining subspaces as

$$(\mathcal{T}_{O(d)W} \circ \mathcal{T}_{O(d)})(M) \cong \frac{\text{Tr}(P_t^{W \otimes 2} \overline{M})}{\text{Tr}(P_t)} \mathbb{1}_t \oplus \frac{\text{Tr}(P_r^{W \otimes 2} \overline{M})}{\text{Tr}(P_r)} \mathbb{1}_r \oplus \frac{\text{Tr}(P_{\square} \overline{M})}{\text{Tr}(P_{\square})} \mathbb{1}_{\square}. \quad (19)$$

One may directly calculate that

$$\text{Tr}(P_t^{W \otimes 2} P_t) = \frac{1}{d^2} \left| \frac{\omega^{2\alpha d} - 1}{\omega^{2\alpha} - 1} \right|^2 = \frac{2}{d(d+1)}, \quad (20)$$

where in the last equality we used the condition for α . By substituting this into Eq. 19, the coefficients of the irreducible subspaces in the symmetric subspace are equal for all transformations M . \square

Lemma 1. *Consider a finite subset $\mathcal{V} \in O(d)$ and $\epsilon > 0$. If*

$$\|\mathcal{T}_{O(d)}(M) - \mathcal{F}_{\mathcal{V}}(M)\|_1 < \epsilon \quad (21)$$

for any linear transformation M , then

$$\|\mathcal{T}_{U(d)}(M) - \mathcal{F}_{W \cdot \mathcal{V}}(M)\|_1 < 2\epsilon, \quad (22)$$

where $W \in U(d)$ is defined in Proposition 2.

Proof. The integral $\mathcal{T}_{U(d)}$ can be written of two consequent integral $\mathcal{T}_{O(d)W} \circ \mathcal{T}_{O(d)}$ based on Proposition 2, while $\mathcal{F}_{W \cdot \mathcal{V}}$ is the same channel as $\mathcal{F}_{W} \circ \mathcal{F}_{\mathcal{V}}$.

$$\begin{aligned} \|\mathcal{T}_{U(d)}(M) - \mathcal{F}_{W \cdot \mathcal{V}}(M)\|_1 &\leq \|\mathcal{T}_{O(d)W}(\mathcal{T}_{O(d)}(M)) - \mathcal{F}_W(\mathcal{T}_{O(d)}(M))\|_1 \\ &\quad + \|\mathcal{F}_W(\mathcal{T}_{O(d)}(M) - \mathcal{F}_{\mathcal{V}}(M))\|_1 < 2\epsilon, \end{aligned} \quad (23)$$

since the first term is less than ϵ by the unitary conjugation invariance of the 1-norm and by the assumption in Eq. (21). Moreover, for the second term, an upper bound can be given by

$$\|\mathcal{F}_W(\mathcal{T}_{O(d)}(M) - \mathcal{F}_{\mathcal{V}}(M))\|_1 \leq \sum_{U \in \mathcal{V}^W} w(U) \underbrace{\left\| U^{\otimes 2} (\mathcal{T}_{O(d)}(M) - \mathcal{F}_{\mathcal{V}}(M)) (U^\dagger)^{\otimes 2} \right\|_1}_{< \epsilon} < \epsilon. \quad (24)$$

\square

As a corollary, from an ϵ -approximate orthogonal 2-design one can construct a $2d^2\epsilon$ -approximate unitary 2-design, using Def. 4.

Corollary 1. Consider a finite subset $\mathcal{V} \in \mathcal{O}(d)$ as before. If \mathcal{V} is an ϵ -approximate orthogonal 2-design for some $\epsilon > 0$, then $\mathcal{V}^W \cdot \mathcal{V}$ is a $2d^2\epsilon$ -approximate unitary 2-design with the concrete unitary $W \in \mathcal{U}(d)$ described in Lemma 1.

Proof. We can write the diamond norm as

$$\|\mathcal{T}_{\mathcal{U}(d)} - \mathcal{F}_{\mathcal{V}^W \cdot \mathcal{V}}\|_{\diamond} := \max_{\rho \in \mathcal{S}(\mathcal{H} \otimes \mathcal{K})} \|(\mathbb{1} \otimes \mathcal{T}_{\mathcal{U}(d)})(\rho) - (\mathbb{1} \otimes \mathcal{F}_{\mathcal{V}^W \cdot \mathcal{V}})(\rho)\|_1, \quad (25)$$

where $\mathcal{H} \cong \mathcal{K} \cong \mathbb{C}^d$. We can use the following well-known inequality for the diamond norm:

$$\|\mathcal{T}_{\mathcal{U}(d)} - \mathcal{F}_{\mathcal{V}^W \cdot \mathcal{V}}\|_{\diamond} \leq d \|C(\mathcal{T}_{\mathcal{U}(d)}) - C(\mathcal{F}_{\mathcal{V}^W \cdot \mathcal{V}})\|_1, \quad (26)$$

where C denotes

$$C(\Psi) := \frac{1}{d} \sum_{1 \leq i, j \leq n} |i\rangle\langle j| \otimes \Psi(|i\rangle\langle j|), \quad (27)$$

where Ψ denotes a quantum channel. By direct calculation, we get

$$\begin{aligned} \|\mathcal{T}_{\mathcal{U}(d)} - \mathcal{F}_{\mathcal{V}^W \cdot \mathcal{V}}\|_{\diamond} &\leq \left\| \sum_{1 \leq i, j \leq d} |i\rangle\langle j| \otimes (\mathcal{T}_{\mathcal{U}(d)} - \mathcal{F}_{\mathcal{V}^W \cdot \mathcal{V}})(|i\rangle\langle j|) \right\|_1 \\ &\leq \sum_{1 \leq i, j \leq d} \| |i\rangle\langle j| \otimes (\mathcal{T}_{\mathcal{U}(d)} - \mathcal{F}_{\mathcal{V}^W \cdot \mathcal{V}})(|i\rangle\langle j|) \|_1 \\ &\leq \sum_{1 \leq i, j \leq d} \underbrace{\|(\mathcal{T}_{\mathcal{U}(d)} - \mathcal{F}_{\mathcal{V}^W \cdot \mathcal{V}})(|i\rangle\langle j|)\|_1}_{< 2\epsilon} \\ &< 2d^2\epsilon. \end{aligned} \quad (28)$$

In the last step, we used Lemma 1 together with

$$\|\mathcal{T}_{\mathcal{O}(d)} - \mathcal{F}_{\mathcal{V}}\|_{\diamond} < \epsilon \implies \|\mathcal{T}_{\mathcal{O}(d)}(\rho) - \mathcal{F}_{\mathcal{V}}(\rho)\|_1 < \epsilon, \quad (29)$$

for any density operator ρ . \square

As a special case, an exact orthogonal 2-design yields an exact unitary 2-design.

Theorem 2. Consider an orthogonal 2-design $\mathcal{V} \subset \mathcal{O}(d)$. Then there exists a unitary $W \in \mathcal{U}(d)$ such that the set $\mathcal{V}^W \cdot \mathcal{V}$ forms a generalized unitary 2-design.

Proof. Trivial based on Corollary 1 by taking $\epsilon \rightarrow 0$. \square

4.2 Unitary 2-designs from the alternating group

In this section, we provide a construction method for unitary 2-designs using Theorem 2. The construction is based on the irreducible decomposition of a certain representation of A_{d+1} , the alternating group of degree $d+1$:

Definition 5. The alternating group of degree n denoted by A_n is the group of even permutations of n elements.

For our purposes, the natural representation of the alternating group of degree $d + 1$ is used, where $d \geq 5$.

Definition 6. *The natural representation of the alternating group A_{d+1} is the group homomorphism $\Pi_n : A_{d+1} \rightarrow \text{U}(d + 1)$. The representation acts on a fixed basis $\{|e_i\rangle\}_{i=1}^{d+1}$ by permuting the basis vectors as*

$$\Pi_n(\pi)(|e_i\rangle) = \pi \cdot |e_i\rangle = |e_{\pi(i)}\rangle. \quad (30)$$

This representation decomposes into the direct sum of the trivial and standard representations, $\Pi_n \cong \Pi_t \oplus \Pi_s$. The representation Π_s is the one acting on the orthogonal complement of the one-dimensional trivial subspace spanned by the single vector

$$|\psi\rangle := \frac{1}{\sqrt{d+1}} \sum_{i=1}^{d+1} |e_i\rangle. \quad (31)$$

We define a generator set of the vector space orthogonal to the subspace spanned by $|\psi\rangle$ with the following vectors

$$|v_j\rangle := |e_j\rangle - \frac{1}{\sqrt{d+1}} |\psi\rangle. \quad (32)$$

When $d = \dim \Pi_s \geq 5$, the 2-fold tensor product of the standard representation Π_s can be decomposed as

$$\Pi_s \otimes \Pi_s \cong \Pi_{\square\square} \oplus \Pi_{\square} \cong \Pi_t \oplus \Pi_s \oplus \Pi_r \oplus \Pi_{\square}, \quad (33)$$

where Π_t, Π_s, Π_r and Π_{\square} are irreducible representations [30]. The projections corresponding to the invariant subspaces on the RHS of Eq. (33) are denoted with P_t, P_s, P_r and P_{\square} , respectively. The subspaces supporting these projections can be expressed by

$$\begin{aligned} V_t \oplus V_s &= \text{span} \left(\{|v_j\rangle \otimes |v_j\rangle\}_{j=1}^{d+1} \right), \\ V_t &= \text{span} \left(\sum_{j=1}^{d+1} |v_j\rangle \otimes |v_j\rangle \right). \end{aligned} \quad (34)$$

Based on Eq. (33), if one were to use the set $\mathcal{V} = \{\Pi_s(g) : g \in A_{d+1}\}$ of d -dimensional orthogonal matrices as a 2-design, one would get to the following for any given matrix $M \in \mathbb{C}^{d^2 \times d^2}$:

$$\sum_{U \in \mathcal{V}} w(U) (U \otimes U) M (U \otimes U)^\dagger = c_t P_t + c_s P_s + c_r P_r + c_{\square} P_{\square}, \quad (35)$$

where the parameters $c_i, i \in \{t, s, r, \square\}$ come from the trace of M on the appropriate subspace.

Similarly to Theorem 2 the construction of a weighted unitary 2-design from the alternating group relies on the fact that one can find an appropriate transformation (denoted by $O \in O(d)$ in Lemma 2) such that the operators \mathcal{V} multiplied by \mathcal{V}^O (which denotes the same operators, conjugated by O) together forms an orthogonal 2-design. Using the aforementioned theorem, it can be transformed into a unitary 2-design as presented in Figure 1.

Lemma 2. *Given $\mathcal{V} = \{H_s(g) : g \in A_{d+1}\}$ and any matrix $M \in \mathbb{C}^{d^2 \times d^2}$, there exists an $O \in O(d)$ such that:*

$$\sum_{U \in \mathcal{V}^O \cdot \mathcal{V}} w(U)(U \otimes U)M(U \otimes U)^\dagger = c_t P_t^{O^{\otimes 2}} + \lambda (P_s^{O^{\otimes 2}} + P_r^{O^{\otimes 2}}) + c_{\boxplus} P_{\boxplus}^{O^{\otimes 2}}, \quad (36)$$

where the weight function w is defined as in Eq. (2),

$$P_i^{O^{\otimes 2}} := O^{\otimes 2} P_i (O^{\otimes 2})^T, \quad i \in \{t, s, r, \boxplus\}, \quad (37)$$

and

$$\lambda = \frac{c_s \text{Tr } P_s + c_r \text{Tr } P_r}{\text{Tr}(P_s + P_r)}. \quad (38)$$

Proof. The sum on the LHS of Eq. (36) can be split into two sums due to function w :

$$\begin{aligned} & \sum_{U \in \mathcal{V}^O \cdot \mathcal{V}} w(U)(U \otimes U)M(U \otimes U)^\dagger \\ &= \frac{1}{|\mathcal{V}^O|} \sum_{U \in \mathcal{V}^O} (U \otimes U) \left(\frac{1}{|\mathcal{V}|} \sum_{V \in \mathcal{V}} (V \otimes V)M(V \otimes V)^\dagger \right) (U \otimes U)^\dagger. \end{aligned} \quad (39)$$

Then, the inner sum can be written as it was in Eq. 35:

$$\overline{M} := \frac{1}{|\mathcal{V}|} \sum_{V \in \mathcal{V}} (V \otimes V)M(V \otimes V)^\dagger = c_t P_t + c_s P_s + c_r P_r + c_{\boxplus} P_{\boxplus}, \quad (40)$$

where $c_i = \frac{\text{Tr}(P_i M)}{\text{Tr } P_i}$ for any $i \in \{t, s, r, \boxplus\}$. After the inner sum has been done, the outer sum can be written as:

$$\sum_{U \in \mathcal{V}^O \cdot \mathcal{V}} w(U)(U \otimes U)M(U \otimes U)^\dagger = c'_t P_t^{O^{\otimes 2}} + c'_s P_s^{O^{\otimes 2}} + c'_r P_r^{O^{\otimes 2}} + c'_{\boxplus} P_{\boxplus}^{O^{\otimes 2}}, \quad (41)$$

Given that O is orthogonal in the underlying basis, we have that $P_t = P_t^{O^{\otimes 2}}$ and $P_{\boxplus} = P_{\boxplus}^{O^{\otimes 2}}$. Therefore, the coefficients c_t, c_{\boxplus} remain the same after the outer sum:

$c'_t = c_t$ and $c'_\square = c_\square$. However, the coefficients of P_s and P_r change to the following:

$$c'_s = \frac{\text{Tr}(P_s^{O^{\otimes 2}} \overline{M})}{\text{Tr} P_s^{O^{\otimes 2}}}, \quad \text{and} \quad c'_r = \frac{\text{Tr}(P_r^{O^{\otimes 2}} \overline{M})}{\text{Tr} P_r^{O^{\otimes 2}}}. \quad (42)$$

These are equal when:

$$\frac{\text{Tr}(P_s^{O^{\otimes 2}} (c_s P_s + c_r P_r))}{\text{Tr} P_s^{O^{\otimes 2}}} = \frac{\text{Tr}(P_r^{O^{\otimes 2}} (c_s P_s + c_r P_r))}{\text{Tr} P_r^{O^{\otimes 2}}}. \quad (43)$$

Introducing the notation $g(O) := \text{Tr}(P_s^{O^{\otimes 2}} P_s)$, one has that:

$$\begin{aligned} \text{Tr}(P_s^{O^{\otimes 2}} P_r) &= \text{Tr}(P_r^{O^{\otimes 2}} P_s) = d - g(O), \\ \text{Tr}(P_r^{O^{\otimes 2}} P_r) &= \frac{(d+1)(d-2)}{2} - d + g(O). \end{aligned} \quad (44)$$

If $c_s \neq c_r$ then the following requirement is given for $g(O)$:

$$g(O) \stackrel{!}{=} q := \frac{2d^2}{(d+2)(d-1)}. \quad (45)$$

If $c_s = c_r$ then the value of $g(O)$ can be chosen freely, and therefore will be chosen to be the one above. However, $O \in O(d)$ transforms the standard representation Π_s of A_{d+1} , and it is more convenient to work with a corresponding transformation of the defining representation Π_d that leaves the trivial subspace invariant. More concretely, one can map an orthogonal transformation $O \in O(d)$ to an orthogonal transformation $Q \in O(d+1)$ that leaves the subspace spanned by $|\psi\rangle$ unchanged. This relationship can be given by the embedding $\iota : O(d) \rightarrow O(d+1)$ as

$$\iota(O) = O \oplus |\psi\rangle\langle\psi|. \quad (46)$$

Accordingly, if there exists a $Q \in O(d+1)$, such that $Q|\psi\rangle = |\psi\rangle$, then there exists $O \in O(d)$, such that $\iota(O) = Q$. Now we may restate the question of finding $O \in O(d)$ such that $g(O) = q$ to finding such $Q \in O(d+1)$. The proof of the existence of such $Q \in O(d+1)$ is postponed until Proposition 3. \square

The requirement is to find an appropriate $O \in O(d)$, such that $g(O) = q$. The main concept behind the construction is to find a continuous path $\phi : [0, 1] \rightarrow O(d)$ such that the image of this path under the mapping g contains q . Then, there exists O_0 and O_1 , such that $g(O_1) < q < g(O_0)$, and by the continuity of g , we find $t \in [0, 1]$ such that $g(\phi(t)) = q$. The orthogonal matrix where this equality is attained can be used to construct an orthogonal 2-design.

Construction 1 (Shifted Real Discrete Fourier Transform). Consider a $(d + 2)$ -dimensional DFT matrix, which has the form

$$\text{DFT}_{d+2} := \begin{bmatrix} 1 & 1 & \cdots & 1 \\ 1 & \omega_{d+2}^{1 \cdot 1} & \cdots & \omega_{d+2}^{1 \cdot (d+1)} \\ \vdots & \vdots & \ddots & \vdots \\ 1 & \omega_{d+2}^{(d+1) \cdot 1} & \cdots & \omega_{d+2}^{(d+1) \cdot (d+1)} \end{bmatrix}, \quad (47)$$

where $\omega_{d+2} := e^{i2\pi \frac{1}{d+2}}$. Take the minor matrix where the first row and column are omitted to obtain

$$\text{LDFT}_{d+1} := \begin{bmatrix} \omega_{d+2}^{1 \cdot 1} & \cdots & \omega_{d+2}^{1 \cdot (d+1)} \\ \vdots & \ddots & \vdots \\ \omega_{d+2}^{(d+1) \cdot 1} & \cdots & \omega_{d+2}^{(d+1) \cdot (d+1)} \end{bmatrix}. \quad (48)$$

Then consider the matrix

$$\text{SDFT}_{d+1} := a\text{LDFT}_{d+1} + bE_{d+1}, \quad a = \frac{1}{\sqrt{d+2}}, \quad b = \frac{a+1}{d+1}, \quad (49)$$

where E_{d+1} is the $(d+1) \times (d+1)$ matrix of ones, i.e., $E_{ij} = 1$. It can easily be verified that the SDFT matrix is unitary since we know that

$$\begin{aligned} \text{LDFT}_{d+1}^\dagger \text{LDFT}_{d+1} &= (d+2)\mathbb{1}_{d+1} - E_{d+1}, \\ E_{d+1} \text{LDFT}_{d+1} &= \text{LDFT}_{d+1} E_{d+1} = -E_{d+1}, \\ E_{d+1}^2 &= (d+1)E_{d+1}, \end{aligned} \quad (50)$$

and hence we can write

$$\begin{aligned} \text{SDFT}_{d+1}^\dagger \text{SDFT}_{d+1} &= a^2((d+2)\mathbb{1}_{d+1} - E_{d+1}) + b^2(d+1)E_{d+1} - 2abE_{d+1} \\ &= \mathbb{1}_{d+1} + ((d+1)b^2 - a^2 - 2ab)E_{d+1} = \mathbb{1}_{d+1}. \end{aligned} \quad (51)$$

Hence, the SDFT matrix is unitary, however, it is not real-valued in general. To construct an orthogonal matrix using SDFT, we use the following unitary transformation:

$$R_{d+1} = \frac{1+i}{2}\mathbb{1}_{d+1} + \frac{1-i}{2}T_{d+1}, \quad (52)$$

where T_{d+1} is a permutation matrix with ones in the anti-diagonal, $(T_{d+1})_{i,j} = \delta_{i+j,d+2}$. Then we define the Shifted Real Discrete Fourier Transform (SRDFT) as

$$\text{SRDFT}_{d+1} := R_{d+1}\text{SDFT}_{d+1}. \quad (53)$$

This is indeed real-valued since one can easily verify that $R_{d+1}\text{LDFT}_{d+1}$ is real-valued by looking at the components:

$$(R_{d+1}\text{LDFT}_{d+1})_{ij} = \frac{1+i}{2}\omega_{d+2}^{ij} + \frac{1-i}{2}\omega_{d+2}^{-ij} = \text{Re}\left((1+i)\omega_{d+2}^{ij}\right). \quad (54)$$

It is also easy to verify that this matrix leaves the 1-dimensional subspace spanned by $|\psi\rangle$ invariant, that is $\text{SRDFT}_{d+1}|\psi\rangle = |\psi\rangle$. For this, we only have to verify that the rows in the matrix sum to 1 for all j :

$$\sum_{i=1}^{d+1}(\text{SRDFT}_{d+1})_{ij} = (d+1)b - a = 1, \quad (55)$$

where we used that $\sum_{i=1}^{d+1}\omega_{d+2}^{ij} = -1$ for all j .

Now we turn to the construction of a continuous path that connects the identity to the SRDFT_{d+1} matrix:

Lemma 3. *For each dimension $d+1$, there exists a permutation matrix S_{d+1} such that there is a continuous path $\phi : [0, 1] \rightarrow \text{O}(d+1)$ connecting the identity to $S_{d+1}\text{SRDFT}_{d+1}$, such that*

$$\phi(t)|\psi\rangle = |\psi\rangle, \quad \forall t \in [0, 1]. \quad (56)$$

Proof. Since SRDFT_{d+1} is orthogonal, $\det(\text{SRDFT}_{d+1}) = \pm 1$. When $\det(\text{SRDFT}_{d+1}) = 1$, take $S_{d+1} = \mathbb{1}_{d+1}$, otherwise take any odd permutation matrix, so that $\det(S_{d+1}\text{SRDFT}_{d+1}) = 1$. Then $S_{d+1}\text{SRDFT}_{d+1} \in \text{SO}(d+1)$, which is a compact connected Lie group, hence, for every group element there is an element $X \in \mathfrak{so}(d+1)$ such that $\exp(X) = S_{d+1}\text{SRDFT}_{d+1}$. Numerically it can be calculated by [34]. Then the path can be defined as

$$\begin{aligned} \phi : [0, 1] &\rightarrow \text{O}(d+1), \\ t &\mapsto \exp(tX), \end{aligned} \quad (57)$$

which fulfils the condition $\phi(t)|\psi\rangle = |\psi\rangle$, since $X|\psi\rangle = 0$. \square

The orthogonal transformation required for Lemma 2 is given by the following proposition:

Proposition 3. *For $d \geq 5$ there exists an $O \in \text{O}(d)$ such that*

$$g(O) = q, \quad (58)$$

where q is a dimension-dependent constant defined by Eq. (45)

Proof. Since $\text{SRDFT}_{d+1}|\psi\rangle = |\psi\rangle$, there is an orthogonal matrix $O \in \text{O}(d)$, for which $\iota(O) = \text{SRDFT}_{d+1}$, and one can also show that the composition $f := g \circ \iota^{-1}$ is

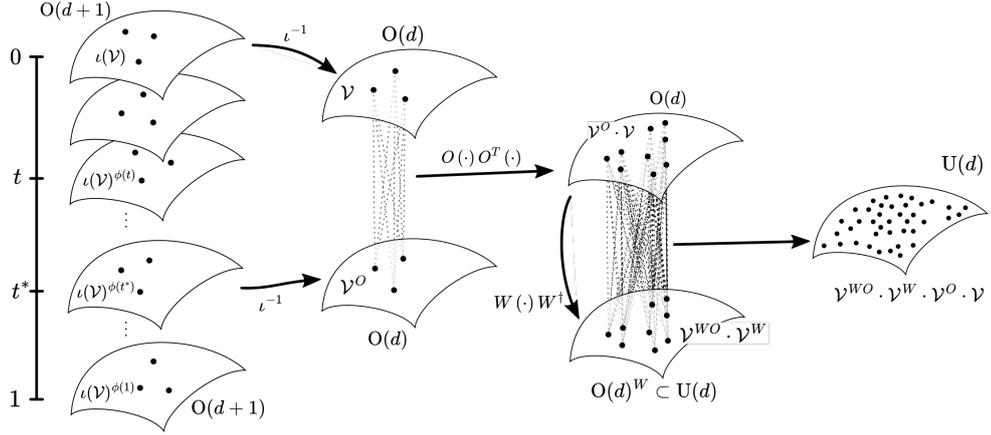

Fig. 1 Illustration of the construction of a 2-design in arbitrary dimension. On the left side, the one-parameter subgroup ϕ of $O(d+1)$ is visualized, with its continuous action by conjugation on $\iota(\mathcal{V})$ where \mathcal{V} is the set of orthogonal matrices which constitute the standard representation of A_{d+1} . Next, $\iota(\mathcal{V})$ and $\iota(\mathcal{V})^{\phi(t^*)}$ are projected to the orthogonal group $O(d)$, where ι^{-1} is the preimage of the embedding ι , yielding \mathcal{V} and \mathcal{V}^O with $O := \iota(\phi(t^*))$, respectively. The lines between \mathcal{V} and \mathcal{V}^O illustrate the elementwise products, forming an orthogonal 2-design. Finally, using a transformation $W \in U(d)$, we construct a unitary t -design based on Theorem 2

well-defined. Next, we use the following inequality:

$$f(\text{SRDFT}_{d+1}) < q, \quad (59)$$

which is proved in Appendix A for brevity. Therefore the function $f \circ \phi : [0, 1] \rightarrow \mathbb{R}$ defines a continuous function with its image containing q . \square

Remark 4. To give an explicit form of $O \in O(d)$ in Proposition 3, we need to obtain an eigenvector decomposition of SRDFT_{d+1} . This decomposition can be constructed using known eigenvector decompositions of DFT [35], see Appendix B. However, SRDFT_{d+1} is not always in the connected component of $O(d+1)$. In dimensions $d+1 = 1, 3 \pmod{4}$, instead of the permutation prescribed in Lemma 3, we can use $-\text{SRDFT}_{d+1}$, which lies in the connected component of $O(d+1)$.

Theorem 3. *Let $d \geq 5$. Given the set of operators in the d dimensional standard representation of A_{d+1} denoted by \mathcal{V} , there exists appropriate transformations W and O such that the product $\mathcal{V}^{WO} \cdot \mathcal{V}^W \cdot \mathcal{V}^O \cdot \mathcal{V}$ forms a weighted unitary 2-design in d dimensions with weights given by Eq. (2).*

Proof. Trivial based on Theorem 2 and Lemma 2. \square

5 Summary and Outlook

The current paper establishes the concept of a generalized group t -design and provides several construction methods. One such construction is enabled by Theorem 1, establishing a procedure for constructing a generalized group t -design using finite groups whose representations admit an easily verifiable property. Moreover, we provide some

examples of novel 4-design constructions using this procedure. Another notable construction is given in Theorem 3, which allows one to give an explicit generalized group 2-design in arbitrary dimensions. The statement builds on the previous procedure yielding generalized group t -designs together with the fact that a unitary 2-design may be constructed from an orthogonal 2-design.

There is an abundance of possible research directions based on group representations and the ideas presented here. As a start, we plan to carry out a thorough search through the finite groups using the GAP system to identify cases where 5- or higher-degree-designs could be constructed using Theorem 1. On the more ambitious side, one could envision obtaining a construction for 3-designs for general dimensions in a similar way to Theorem 3. A further research direction is to examine the consequences of our 2- and higher-degree-design constructions in applications such as quantum process tomography, randomized benchmarking, and (thrifty) shadow estimation.

Statements and Declarations

Conflict of interest: The authors declare that they have no conflict of interest.

Appendix A Proof that the Shifted Real Discrete Fourier Transform gives a lower bound to q

Given the following definition for f :

$$f(Q) := \text{Tr} \left(P_s Q^{\otimes 2} P_s (Q^{\otimes 2})^T \right), \quad (\text{A1})$$

and the matrix SRDFT_{d+1} detailed in Construction 1, the following proposition is true:

Proposition 4. *For $d \geq 5$ the following equation is satisfied:*

$$f(\text{SRDFT}_{d+1}) < \frac{2d^2}{(d+2)(d-1)} = q. \quad (\text{A2})$$

Before the proof, consider the following lemma:

Lemma 4. *Let $Q \in O(d+1)$ and such that $Q|\psi\rangle = |\psi\rangle$. Then, the following is true:*

$$f(Q) = \frac{(d+1)^2 \sum_{j,k=1}^{d+1} Q_{jk}^3 \left(Q_{jk} - \frac{4}{d+1} \right) - d^2 + 6d + 3}{(d-1)^2}, \quad (\text{A3})$$

Proof. We use the notation described in Section 4.2. According to Eq. (34), one can write P_s as

$$P_s = \frac{1}{d-1} \sum_{j,k=1}^{d+1} |v_j \otimes v_j\rangle \langle v_j \otimes v_j| - |v_j \otimes v_j\rangle \langle v_k \otimes v_k|, \quad (\text{A4})$$

and substituting this into Eq. (A1) we get an expression for $f(Q)$:

$$f(Q) = \frac{1}{(d-1)^2} \sum_{j,k,l,m=1}^{d+1} \left(\langle v_j | Q^T | v_l \rangle^2 - \langle v_k | Q^T | v_l \rangle^2 \right) \left(\langle v_l | Q | v_j \rangle^2 - \langle v_m | Q | v_j \rangle^2 \right). \quad (\text{A5})$$

In this expression, we can substitute the v_j vectors from Eq. (32). Moreover, since $Q|\psi\rangle = |\psi\rangle$, we can also use the fact that $\langle v_l | Q | v_j \rangle = \langle v_l | Q | e_j \rangle$ to obtain

$$\langle v_j | Q | e_k \rangle = \left(\langle e_j | - \frac{1}{d+1} \sum_{\ell=1}^{d+1} \langle e_\ell | \right) Q | e_k \rangle = Q_{jk} - \frac{1}{d+1} \underbrace{\sum_{\ell=1}^{d+1} Q_{lk}}_{=1} = Q_{jk} - \frac{1}{d+1}. \quad (\text{A6})$$

From this, we obtain the desired formula by direct calculation using the orthogonality of Q . \square

Using this, the proof of Proposition 4 is the following:

Proof. Using Lemma 4 and the definition of SRDFT_{d+1} , we get by direct calculation that

$$f(\text{SRDFT}_{d+1}) = \frac{(d+1)^4 + (4 - \tau_{d+1})(d+1)^2 - 4\sigma_{d+1}(d+1) - 8}{2(d+2)^2(d-1)^2}, \quad (\text{A7})$$

where

$$\sigma_n = \begin{cases} n+2 & \text{if } (n+1) \equiv 0 \pmod{3}, \\ -n & \text{otherwise,} \end{cases}$$

$$\tau_n = \begin{cases} 1 & \text{if } (n+1) \equiv 2 \pmod{4}, \\ 2n+3 & \text{if } (n+1) \equiv 0 \pmod{4}, \\ -n & \text{otherwise.} \end{cases} \quad (\text{A8})$$

From now on, we have to deal with the cases depending on d in σ_{d+1} and τ_{d+1} . Luckily, it is enough to verify for the cases where $\sigma_{d+1} = \tau_{d+1} = -(d+1)$ since in the other cases the numerator will be strictly smaller. Hence, when $2, 3 \nmid (d+2)$, we have to verify that

$$f(\text{SRDFT}_{d+1}) = \frac{(d+1)^3 + 8(d+1) - 8}{2(d+2)(d-1)^2} \leq \frac{2d^2}{(d+1)(d-1)} = q, \quad (\text{A9})$$

which is true when $d \geq 1$. □

Appendix B Eigenvector decomposition of SRDFT matrices

The eigenvector decomposition of the SRDFT_{d+1} matrices can be derived from the eigenvector decomposition of the DFT_{d+2} matrix, as follows. Consider

$$\text{SRDFT}_{d+1} = a \left(\frac{1+i}{2} \text{LDFT}_{d+1} + \frac{1-i}{2} \text{LDFT}_{d+1}^\dagger \right) + bE, \quad (\text{B10})$$

with the same notations as in Construction 1. An orthogonal eigenvector decomposition of DFT_{d+2} can be given by

$$v_j = \begin{bmatrix} 0 \\ c_{1,j} \\ \vdots \\ c_{d+1,j} \end{bmatrix}, \quad v_+ = \begin{bmatrix} \alpha_+ \\ 1 \\ \vdots \\ 1 \end{bmatrix}, \quad v_- = \begin{bmatrix} \alpha_- \\ 1 \\ \vdots \\ 1 \end{bmatrix}, \quad (1 \leq j \leq d) \quad (\text{B11})$$

where $\alpha_{\pm} = 1 \pm \sqrt{d+2}$. Then, since

$$c_j = \begin{bmatrix} c_{1,j} \\ \vdots \\ c_{d+1,j} \end{bmatrix}, \quad c_{d+1} = \begin{bmatrix} 1 \\ \vdots \\ 1 \end{bmatrix}, \quad (1 \leq j \leq d) \quad (\text{B12})$$

will be eigenvectors of LDFT_{d+1} , they will also be eigenvectors of SRDFT_{d+1} since $Ec_j = (d+1)\delta_{j,d+1}c_{d+1}$. The set of orthogonal eigenvectors $C = (c_{ij})_{i,j=1}^{d+1}$ will yield an eigenvalue decomposition of SRDFT_{d+1} .
