Abstract

Let Φ be a unital completely positive map on the space of operators on some Hilbert space. We assume that Φ is almost idempotent, namely, $\|\Phi^2 - \Phi\|_{\text{cb}} \leq \eta$, and construct a corresponding “ ε - C^* algebra” for $\varepsilon = O(\eta)$. This type of structure has the axioms of a unital C^* algebra but the associativity and other axioms involving the multiplication and the unit hold up to ε . We further prove that any finite-dimensional ε - C^* algebra is $O(\varepsilon)$ -isomorphic to a genuine C^* algebra. These bounds are universal, i.e. do not depend on the dimensionality or other parameters.

The paper is organized as follows. In Section 1, the almost-idempotent channel problem is introduced from the quantum information perspective, and the corresponding algebra is constructed. The axioms of an ε - C^* algebra and the main approximation theorem are stated in Section 2, where the proof is also outlined. The proof occupies the bulk of the paper. Section 10 provides some details for Section 1. In particular, it is shown in 10.4 that the channel-related algebra satisfies the ε - C^* axioms.

1 Motivation: How to recognize an encoded subsystem?

Under favorable circumstances, some physical systems encode states and observables of smaller, “logical” systems. This may be arranged by design or happen naturally, for example, in so-called topological phases of matter that feature protected degrees of freedom. In practice, the encoding is always approximate and may also be implicit (especially if the system is natural rather than engineered). The informal goal of this paper is to reconstruct the logical algebra of observables in such a situation. This kind of task is common in quantum many-body physics, where identifying “effective degrees of freedom” is necessary for the understanding of complex systems. Recent work [1] provides a rigorous reconstruction of topological degrees of freedom in spin systems on a 2D lattice under specific conditions, which involve only exact equalities. We will formulate and solve the approximate reconstruction problem in an abstract form, in hope that the results could be applied broadly. However, let us begin with the ideal case, where everything is explicit and exact.

1.1 Encoding and decoding

In general, the logical algebra of observables is a finite-dimensional C^* algebra. As such, it is isomorphic to an algebra of the form $\mathcal{A} = \bigoplus_{j=1}^m \mathbf{B}(\mathcal{L}_j)$. (In general, $\mathbf{B}(\mathcal{L})$ denotes the algebra of bounded linear operators on a nonzero Hilbert space \mathcal{L} . In the finite-dimensional case, all linear operators are bounded.) A purely quantum system is described by a single space, whereas for a classical system, all spaces \mathcal{L}_j are one-dimensional. Logical observables are represented by their action on a code subspace \mathcal{M} of the physical Hilbert space \mathcal{H} (also finite-dimensional for simplicity) via an inclusion of unital C^* algebras $w: \mathcal{A} \rightarrow \mathbf{B}(\mathcal{M})$.

Proposition 1.1. *Let $\mathcal{L}_1, \dots, \mathcal{L}_m$ and \mathcal{M} be finite-dimensional Hilbert spaces, $\mathcal{A} = \bigoplus_{j=1}^m \mathbf{B}(\mathcal{L}_j)$, and let $w: \mathcal{A} \rightarrow \mathbf{B}(\mathcal{M})$ be a $*$ -homomorphism. Then there exist auxiliary Hilbert spaces \mathcal{E}_j and a unitary map W ,*

$$W = (W_1, \dots, W_m): \mathcal{M} \rightarrow \bigoplus_{j=1}^m \mathcal{L}_j \otimes \mathcal{E}_j, \quad W_j: \mathcal{M} \rightarrow \mathcal{L}_j \otimes \mathcal{E}_j. \quad (1.1)$$

such that

$$w(A_1, \dots, A_m) = \sum_{j=1}^m W_j^\dagger (A_j \otimes 1_{\mathcal{E}_j}) W_j \quad \text{for all } A = (A_1, \dots, A_m) \in \mathcal{A}. \quad (1.2)$$

The homomorphism w is injective if and only if $\mathcal{E}_j \neq 0$ for all j .

Proof. By definition, a $*$ -homomorphism $w: \mathcal{A} \rightarrow \mathbf{B}(\mathcal{M})$ makes \mathcal{M} into a $*$ -representation of \mathcal{A} . Such representations have the property that the orthogonal complement of any invariant subspace is also invariant. Thus, \mathcal{M} splits into irreducible representations of \mathcal{A} , i.e. copies of $\mathbf{B}(\mathcal{L}_j)$. If $\mathbf{B}(\mathcal{L}_j)$ occurs n_j times, we set $\mathcal{E}_j = \mathbb{C}^{n_j}$. The rest of the argument is straightforward. \square

States on an arbitrary C^* algebra \mathcal{B} belong to the space of linear functionals \mathcal{B}^* . Physically realizable transformations of states are known as *quantum channels*; they are dual to unital completely positive (UCP) maps of the corresponding algebras of observables. For example, dual to the inclusion w is state decoding $w^*: \mathbf{B}(\mathcal{M})^* \rightarrow \mathcal{A}^*$. If \mathcal{B} is finite-dimensional, then $\mathcal{B}^* \cong \mathcal{B}$, and therefore, states are represented by (block-diagonal) density matrices. In particular, a state on the algebra \mathcal{A} is given by a collection of positive Hermitian operators $\rho_j \in \mathbf{B}(\mathcal{L}_j)$ such that $\sum_{j=1}^m \text{Tr } \rho_j = 1$. Quantum channels are represented by completely positive trace-preserving (CPTP) maps of density matrices. Thus, the decoding map takes a density matrix $\rho \in \mathbf{B}(\mathcal{M})$ to $w^*(\rho) = (\rho_1, \dots, \rho_m)$, where $\rho_j = \text{Tr}_{\mathcal{E}_j}(W_j \rho W_j^\dagger)$.

State encoding, as well as the decoding of states beyond the code subspace, involves some arbitrary choices. The encoding map has the form

$$\text{Enc}: \mathcal{A}^* \rightarrow \mathbf{B}(\mathcal{H})^*, \quad \text{Enc}(\rho_1, \dots, \rho_m) = \sum_{j=1}^m J_{\mathcal{M}} W_j^\dagger (\rho_j \otimes \gamma_j) W_j J_{\mathcal{M}}^\dagger, \quad (1.3)$$

where γ_j is some density matrix on \mathcal{E}_j and $J_{\mathcal{M}}: \mathcal{M} \rightarrow \mathcal{H}$ is the inclusion map. We now define the decoding of density matrices $\rho \in \mathbf{B}(\mathcal{H})$. Let \mathcal{M}^\perp be the orthogonal complement of \mathcal{M} and $J_{\mathcal{M}^\perp}: \mathcal{M}^\perp \rightarrow \mathcal{H}$ the corresponding inclusion. Choose an arbitrary CPTP map $S: \mathbf{B}(\mathcal{M}^\perp)^* \rightarrow \mathcal{A}^*$,

Figure 1: (a) A system of spins (depicted as dots) on a topological disk with two holes; (b) Expanding the system by adding extra spins along the boundary.

which can be represented by its components, i.e. completely positive maps $S_j: \mathbf{B}(\mathcal{M}^\perp)^* \rightarrow \mathbf{B}(\mathcal{L}_j)^*$. Then the decoding map is also defined in terms of components:

$$\text{Dec}: \mathbf{B}(\mathcal{H})^* \rightarrow \mathcal{A}^*, \quad \text{Dec}_j(\rho) = \text{Tr}_{\mathcal{E}_j}(W_j J_{\mathcal{M}}^\dagger \rho J_{\mathcal{M}} W_j^\dagger) + S_j(J_{\mathcal{M}^\perp}^\dagger \rho J_{\mathcal{M}^\perp}). \quad (1.4)$$

One can readily see that $\text{Dec Enc} = 1_{\mathcal{A}^*}$. Therefore, the quantum channel $T = \text{Enc Dec}$ is idempotent, i.e. $T^2 = T$. Such a channel may be interpreted as a recovery from a correctable error, which has affected only the additional spaces \mathcal{E}_j rather than the information stored in \mathcal{L}_j . Indeed, T keeps the encoded information intact but resets \mathcal{E}_j to fixed states γ_j (thus preventing future errors from compounding the past errors); it also pushes the out-of-bounds state portion $\rho^\perp = J_{\mathcal{M}^\perp}^\dagger \rho J_{\mathcal{M}^\perp}$ to the code subspace. We will see that any idempotent channel $T: \mathbf{B}(\mathcal{H})^* \rightarrow \mathbf{B}(\mathcal{H})^*$ can be represented in the form Enc Dec . Thus, *an idempotent channel implicitly defines a logical algebra of observables*.

Physical example. Low-energy states of some local Hamiltonians in two spatial dimensions are described by unitary modular tensor categories (UMTCs). In particular, consider a spin system on a topological disk with two holes, see Figure 1a. Let \mathcal{H} be the full Hilbert space and \mathcal{M} the subspace of low-energy states. (It is beyond the scope of this paper to try to make this construction rigorous.) Then

$$\mathcal{M} \cong \bigoplus_{a,b,c} V_c^{ab} \otimes \mathcal{E}_{ab}^c, \quad V_c^{ab} = \mathcal{C}(c, a \otimes b), \quad (1.5)$$

where a, b, c run over the equivalence classes of simple objects of some UMTC \mathcal{C} . In physics, these are called “superselection sectors”; a and b are associated with the holes, c with the outer boundary, and V_c^{ab} is the corresponding “fusion space”. The logical algebra of observables is $\mathcal{A} = \bigoplus_{a,b,c} \mathbf{B}(V_c^{ab})$, whereas the spaces $\mathcal{E}_{ab}^c = \mathcal{E}_a \otimes \mathcal{E}_b \otimes \mathcal{E}^c$ describe non-universal boundary modes. To reconstruct \mathcal{A} , one may define an idempotent quantum channel $T = T_- T_+$, where T_+ corresponds to expanding the system as shown in Figure 1b using the methods of Ref. [1], and T_- is the operation of tracing out the added spins. The channel T resets the boundary states but does not affect the fusion spaces.

1.2 Idempotent and almost idempotent UCP maps

We will work with the duals of quantum channels, i.e. UCP maps $\Phi: \mathbf{B}(\mathcal{H}) \rightarrow \mathbf{B}(\mathcal{H})$. Such Φ is idempotent if and only if $T = \Phi^*$ is idempotent. The following structure theorem will be proved in Section 10.3. It is related to the characterization of operators that are invariant under an arbitrary finite-dimensional UCP map [2, Theorems 6.12 and Lemma 6.4] and of quantum channels stabilizing a given set of density matrices [3], [4, Theorem 10].

Theorem 1.2. *Let \mathcal{H} be a finite-dimensional Hilbert space and $\Phi: \mathbf{B}(\mathcal{H}) \rightarrow \mathbf{B}(\mathcal{H})$ an idempotent UCP map. Then there exist a subspace $\mathcal{M} \subseteq \mathcal{H}$ with the inclusion map $J_{\mathcal{M}}: \mathcal{M} \rightarrow \mathcal{H}$ and a C^* algebra \mathcal{A} with UCP maps Δ and Γ as described by the diagram*

$$\begin{array}{ccc} & \mathbf{B}(\mathcal{H}) & \\ \Delta \nearrow & \downarrow C_{\mathcal{M}} & \\ \mathcal{A} \xleftarrow{\Gamma} & \mathbf{B}(\mathcal{M}) & \end{array} \quad C_{\mathcal{M}}: X \mapsto J_{\mathcal{M}}^{\dagger} X J_{\mathcal{M}}, \quad (1.6)$$

such that

$$\Gamma C_{\mathcal{M}} \Delta = 1_{\mathcal{A}}, \quad \Delta \Gamma C_{\mathcal{M}} = \Phi. \quad (1.7)$$

Furthermore, $w = C_{\mathcal{M}} \Delta: \mathcal{A} \rightarrow \mathbf{B}(\mathcal{M})$ is a homomorphism of C^* algebras, and operators in the image of Δ are block-diagonal with respect to the decomposition $\mathcal{H} = \mathcal{M} \oplus \mathcal{M}^{\perp}$.

It will also be shown that $\text{Enc} = (\Gamma C_{\mathcal{M}})^*$ and $\text{Dec} = \Delta^*$ have the form (1.3) and (1.4), respectively. For now, let us discuss more general corollaries of Theorem 1.2. First, equations (1.7) imply that Δ is injective and that $\text{Im } \Delta = \text{Im } \Phi$, so \mathcal{A} may be identified with the vector space $\text{Im } \Phi$. For example, $A, B, AB \in \mathcal{A}$ are identified, respectively, with $X = \Delta(A)$, $Y = \Delta(B)$, and $Z = \Delta(AB)$. To represent the latter in a convenient form, we will use the second part of the theorem. It implies that $C_{\mathcal{M}}(Z) = C_{\mathcal{M}}(X) C_{\mathcal{M}}(Y) = C_{\mathcal{M}}(XY)$, and therefore,

$$Z = \Delta 1_{\mathcal{A}}(AB) = \Delta \Gamma C_{\mathcal{M}} \Delta(AB) = \Delta \Gamma C_{\mathcal{M}}(Z) = \Delta \Gamma C_{\mathcal{M}}(XY) = \Phi(XY). \quad (1.8)$$

The last equation means that upon the identification of \mathcal{A} with $\text{Im } \Phi$, the multiplication in \mathcal{A} becomes the *Choi-Effros product*,

$$X \star Y = \Phi(XY). \quad (1.9)$$

Choi and Effros showed that for any idempotent UCP map $\Phi: \mathbf{B}(\mathcal{H}) \rightarrow \mathbf{B}(\mathcal{H})$ and any underlying Hilbert space \mathcal{H} (not only a finite-dimensional one), the subspace $\mathcal{A} = \text{Im } \Phi = \text{Ker}(1 - \Phi) \subseteq \mathbf{B}(\mathcal{H})$ equipped with this product, together with the norm and the involution $X \mapsto X^{\dagger}$ inherited from $\mathbf{B}(\mathcal{H})$, satisfies all axioms of a C^* algebra [5, Theorem 3.1].

Physical applications require tolerance to small errors, so one should consider UCP maps that are only approximately idempotent. Moreover, meaningful properties do not change when the physical system is extended with new parts, as long as they do not interact with it. The second requirement suggests the use of the following definition [7]. A linear map $\Lambda: \mathcal{A}' \rightarrow \mathcal{A}''$ between two C^* algebras is called *completely bounded* if this *completely bounded norm* is finite:

$$\|\Lambda\|_{\text{cb}} = \sup_n \sup_{X \neq 0} \frac{\|(1_{\mathbf{B}(\mathbb{C}^n)} \otimes \Lambda)(X)\|}{\|X\|} \quad (X \in \mathbf{B}(\mathbb{C}^n) \otimes \mathcal{A}'). \quad (1.10)$$

(The results in this paper also hold for the norm $\sup_{X \neq 0} \|\Lambda(X)\|/\|X\|$.) The completely bounded norm in finite dimensions is efficiently computable using semidefinite programming [8, Chapter 3].

In quantum information literature, the dual norm for maps of linear functionals is used; it is denoted by $||| \cdot |||_1$ or $\| \cdot \|_\diamond$.

A UCP map $\Phi: \mathbf{B}(\mathcal{H}) \rightarrow \mathbf{B}(\mathcal{H})$ is called η -idempotent if $\|\Phi^2 - \Phi\|_{\text{cb}} \leq \eta$. A straightforward approach to such maps seems to be the approximation by idempotent maps. To this end, one could try to employ the function calculus for the Banach algebra of completely bounded linear maps on $\mathbf{B}(\mathcal{H})$ with the norm $\| \cdot \|_{\text{cb}}$. Specifically, let

$$\tilde{\Phi} = \theta(2\Phi - 1), \quad \text{where} \quad \theta(x) = \begin{cases} 1 & \text{if } x > 0, \\ 0 & \text{if } x < 0. \end{cases} \quad (1.11)$$

The basic properties of $\tilde{\Phi}$ follow from Proposition 3.1 and the fact that $\|\Phi\|_{\text{cb}} = 1$. Specifically, $\tilde{\Phi}$ is well-defined if $\eta < 1/4$; it is idempotent and satisfies the bound

$$\|\tilde{\Phi} - \Phi\|_{\text{cb}} \leq O(\eta). \quad (1.12)$$

Unfortunately, $\tilde{\Phi}$ is not guaranteed to be completely positive.

Example 1.3. Consider the UCP map

$$\Phi: \mathbf{B}(\mathbb{C}^2) \rightarrow \mathbf{B}(\mathbb{C}^2), \quad \Phi(X) = P_0 \text{Tr}(\gamma_0 X) + P_1 \text{Tr}(\gamma_1 X), \quad (1.13)$$

where

$$P_0 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad P_1 = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}, \quad \gamma_0 = \begin{pmatrix} 1-p & \sqrt{p(1-p)} \\ \sqrt{p(1-p)} & p \end{pmatrix}, \quad \gamma_1 = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \quad (1.14)$$

for a sufficiently small positive p . Then the map $\tilde{\Phi} = \theta(2\Phi - 1)$ acts as follows:

$$\tilde{\Phi}(X) = P_0 \text{Tr}(\gamma X) + P_1 \text{Tr}(\gamma_1 X), \quad (1.15)$$

where

$$\gamma = (1-p)^{-1}(\gamma_0 - p\gamma_1) = \begin{pmatrix} 1 & \sqrt{p/(1-p)} \\ \sqrt{p/(1-p)} & 0 \end{pmatrix} \quad (1.16)$$

is not positive.

Is it possible to approximate an almost-idempotent UCP map by an idempotent one in some other way? This seems to be an open problem; at least, I do not know of a solution. Nonetheless, one can use $\tilde{\Phi} = \theta(2\Phi - 1)$ to construct an approximate algebra of observables \mathcal{A} , and then show that it is $O(\eta)$ -isomorphic to some C^* algebra \mathcal{B} . As a vector space, \mathcal{A} is this:

$$\mathcal{A} = \text{Im } \tilde{\Phi} = \text{Ker}(1 - \tilde{\Phi}) \subseteq \mathbf{B}(\mathcal{H}). \quad (1.17)$$

The multiplication on it is defined by the equation

$$X \star Y = \tilde{\Phi}(XY) \quad (X, Y \in \mathcal{A}), \quad (1.18)$$

whereas the unit, the norm and the involution $X \mapsto X^\dagger$ are inherited from $\mathbf{B}(\mathcal{H})$. We now turn our attention to ε - C^* algebras and their approximation by C^* algebras. That \mathcal{A} is actually an $O(\eta)$ - C^* algebra will be shown later, in Section 10.4.

2 Main theorem and the proof strategy

Let ε be a sufficiently small nonnegative number. Individual definitions and statements will require (in many cases, implicitly) that ε be bounded by certain constants. For example, condition (2.5) below makes sense if $\varepsilon < 1$.

Definition 2.1. An ε -Banach algebra is a Banach space \mathcal{A} endowed with a bilinear multiplication map $\mathcal{A} \times \mathcal{A} \rightarrow \mathcal{A}$ such that

$$\|XY\| \leq (1 + \varepsilon)\|X\|\|Y\| \quad (X, Y \in \mathcal{A}), \quad (2.1)$$

$$\|(XY)Z - X(YZ)\| \leq \varepsilon\|X\|\|Y\|\|Z\| \quad (X, Y, Z \in \mathcal{A}). \quad (2.2)$$

Such an algebra is called ε' -commutative if

$$\|XY - YX\| \leq \varepsilon'\|X\|\|Y\| \quad (X, Y \in \mathcal{A}). \quad (2.3)$$

A $*\varepsilon$ -Banach algebra is a complex ε -Banach algebra with a conjugate linear involution $X \mapsto X^\dagger$ satisfying the equations

$$\|X^\dagger\| = \|X\|, \quad (XY)^\dagger = Y^\dagger X^\dagger \quad (X, Y \in \mathcal{A}). \quad (2.4)$$

An ε - C^* algebra is one with this additional property:

$$\|X^\dagger X\| \geq (1 - \varepsilon)\|X\|^2 \quad (X \in \mathcal{A}). \quad (2.5)$$

(A bound from the other side, $\|X^\dagger X\| \leq (1 + \varepsilon)\|X\|^2$, follows from (2.1) and (2.4).) We assume that all algebras are unital. The unit element $I \in \mathcal{A}$ should satisfy the approximate or exact conditions

$$\|XI - X\| \leq \varepsilon\|X\|, \quad \|IX - X\| \leq \varepsilon\|X\|, \quad \|\|I\| - 1\| \leq \varepsilon \quad (\text{by default}), \quad \text{or} \quad (2.6)$$

$$XI = X, \quad IX = X, \quad \|I\| = 1 \quad (\text{if specified}). \quad (2.7)$$

If the involution is defined, one also requires that $I^\dagger = I$.

(The exact unit condition (2.7) can be achieved by an $O(\varepsilon)$ -change of both the unit and the multiplication, see Proposition 4.1.)

Definition 2.2. A δ -homomorphism from an ε' -Banach algebra \mathcal{A}' to an ε'' -Banach algebra \mathcal{A}'' is a bounded linear map $v: \mathcal{A}' \rightarrow \mathcal{A}''$ that almost preserves the unit and the multiplication:

$$\|v(I) - I\| \leq \delta, \quad (2.8)$$

$$\|v(XY) - v(X)v(Y)\| \leq \delta\|X\|\|Y\| \quad (X, Y \in \mathcal{A}'). \quad (2.9)$$

A *non-unital* δ -homomorphism is defined by imposing only condition (2.9). In the $*$ -algebra setting, it is also required that $v(X^\dagger) = v(X)^\dagger$. A δ -inclusion is a δ -homomorphism such that

$$(1 - \delta)\|X\| \leq \|v(X)\| \leq (1 + \delta)\|X\| \quad (X \in \mathcal{A}'). \quad (2.10)$$

A δ -isomorphism is a bijective δ -inclusion.

Note that the inverse of a δ -isomorphism is a $(\delta + O(\delta^2))$ -isomorphism. Here and in general, each instance of big- O or similar notation stands for a concrete function, not depending on any additional data.

Theorem 2.3. *Any finite-dimensional ε - C^* algebra \mathcal{A} is $O(\varepsilon)$ -isomorphic to some C^* algebra \mathcal{B} . (Importantly, the implicit constant in $O(\varepsilon)$ does not depend on \mathcal{A} or its dimensionality.)*

The rest of this section is informal. A natural approach to proving theorem 2.3 would be to show that \mathcal{A} has trivial cohomology, or just that $H^3(\mathcal{A}, \mathcal{A}) = 0$. Here we are referring to the Hochschild cohomology of associative algebras or its Banach version [6], somehow adapted to ε -associativity. To see how it might work, consider the *associativity defect* of \mathcal{A} :

$$h: \mathcal{A}^3 \rightarrow \mathcal{A}, \quad h(X, Y, Z) = (XY)Z - X(YZ). \quad (2.11)$$

It satisfies the 3-cocycle equation,

$$Wh(X, Y, Z) - h(WX, Y, Z) + h(W, XY, Z) - h(W, X, YZ) + h(W, X, Y)Z = 0. \quad (2.12)$$

Note that $h(X, Y, Z)$ is small, being bounded by $\varepsilon \|X\| \|Y\| \|Z\|$. If it could be represented as a coboundary with $O(\varepsilon)$ relative accuracy,

$$h(X, Y, Z) = Xg(Y, Z) - g(XY, Z) + g(X, YZ) - g(X, Y)Z + O(\varepsilon^2) \|X\| \|Y\| \|Z\|, \quad (2.13)$$

then the modified multiplication $X \cdot Y = XY + g(X, Y)$ would be $O(\varepsilon^2)$ -associative. The iteration of this procedure would provide exact associativity.

An associative algebra \mathcal{A} has trivial Hochschild cohomology if there is a *diagonal*, i.e. an element $D = \sum_j A_j \otimes B_j \in \mathcal{A} \otimes \mathcal{A}$ satisfying the equations $\sum_j A_j \otimes B_j X = \sum_j X A_j \otimes B_j$ for all $X \in \mathcal{A}$ and $\sum_j A_j B_j = I$. Indeed, in this case, an arbitrary cocycle h is the coboundary of this g :

$$g(X, Y) = \sum_j A_j h(B_j, X, Y). \quad (2.14)$$

For finite-dimensional C^* algebras, a diagonal can be obtained as $D = \int dU (U^\dagger \otimes U)$, where the integral is taken with respect to the Haar measure on the unitary group. Unfortunately, naive constructions of the Haar measure (or just the diagonal) in the ε -associative setting have error bounds proportional to $n = \dim \mathcal{A}$. So the outlined procedure of fixing the multiplication works only if $\varepsilon < cn^{-1}$ for some constant c .

To actually prove the theorem, we take a different approach, but a cohomological argument is still used. We construct an $O(\varepsilon)$ -isomorphism between some C^* algebra \mathcal{B} and the ε - C^* algebra \mathcal{A} incrementally. Before the process is complete, the map $v: \mathcal{B} \rightarrow \mathcal{A}$ is an $O(\varepsilon)$ -inclusion, and we enlarge \mathcal{B} and modify v in little steps. This involves solving two problems. To even make the first step, from $\mathcal{B}_0 = \mathbb{C}$ to $\mathcal{B}_1 = \mathbb{C} \oplus \mathbb{C}$, we need to find a *nontrivial projection* in \mathcal{A} . An approximate projection, satisfying the conditions $P^\dagger = P$ and $\|P^2 - P\| \leq \delta$ for a suitable constant δ , is sufficient as long as P is not too close to $\pm I$. The existence of such a projection (assuming that $\dim \mathcal{A} > 1$) is the first important lemma. We prove it by first constructing (in Section 5) an approximate unitary group $\mathcal{U} \subseteq \mathcal{A}$ as a C^1 manifold using standard analytic methods such as the implicit function theorem. The group laws are satisfied with $O(\varepsilon)$ accuracy, and therefore,

they also hold up to homotopy. Now, P is a projection if and only if $U = 2P - I$ is Hermitian and $U^2 = I$. In other words, U is a fixed point of the inversion map $\sigma: U \mapsto U^{-1}$ acting on \mathcal{U} . We show that σ has sufficiently many (i.e. more than two) fixed points using the Lefschetz-Hopf theorem and certain properties of H-spaces (see Section 6).

Once the lemma is proved, we can keep building the finite-dimensional C^* algebra \mathcal{B} in a similar fashion. At each step, \mathcal{B} is described by a partitioned index set and the basis $\{E_{jk}\}$ with j and k in the same part. The multiplication rules are $E_{jk}E_{lm} = \delta_{kl}E_{jm}$. At the beginning of the incremental process, the parts are singletons so that all basis elements are diagonal and \mathcal{B} is commutative. Each step involves replacing some j and the corresponding E_{jj} with $\{j', j''\}$ and $E_{j'j'} + E_{j''j''}$, respectively. When that is no longer possible, we add off-diagonal elements, E_{jk} with $j \neq k$, until $v: \mathcal{B} \rightarrow \mathcal{A}$ becomes bijective. The detailed argument is structured in terms of *merging* (Corollary 9.2) and *extension* (Lemma 9.4) procedures.

The second problem is to control errors. We must make sure that v is a δ_0 -inclusion for some fixed $\delta_0 = O(\varepsilon)$. Simply extending the current v to a new, larger \mathcal{B} gives a δ -inclusion for δ greater than δ_0 . Thus, we need the following *error reduction* result (Corollary 8.3): if there exists a δ -inclusion of a finite-dimensional C^* algebra \mathcal{B} into an ε - C^* algebra \mathcal{A} for δ less than a certain constant, then there is also an δ_0 -inclusion, where $\delta_0 = O(\varepsilon)$ does not depend on δ . This can be shown by cohomological methods because \mathcal{B} does have a diagonal. Similar results are found in the literature; they are concerned with the existence of a C^* subalgebra near an approximate C^* subalgebra [9] and a homomorphism of C^* algebras near an approximately multiplicative map [10]. Our argument is similar to the proof of Theorem 3.1 in [10] but actually simpler due to the finite dimensionality condition.

3 Some analytic tools

The study of approximate algebras naturally involves ordinary (real or complex) Banach algebras. For many purposes, the coefficient field does not matter. Indeed, any complex Banach algebra can be considered with real coefficients. Conversely, an arbitrary real Banach algebra \mathcal{A} can be extended to a complex Banach algebra, namely, $\mathcal{B} = \mathbb{C} \otimes_{\mathbb{R}} \mathcal{A}$ with the projective tensor norm,

$$\|Z\| = \inf \left\{ \sum_j |c_j| \|X_j\| : \sum_j c_j \otimes X_j = Z \right\} \quad (c_j \in \mathbb{C}, X_j \in \mathcal{A}). \quad (3.1)$$

Note that the inclusion map $\mathcal{A} \rightarrow \mathcal{B}$ preserves the norm, and if $X \in \mathcal{A}$ is invertible in \mathcal{B} , then $X^{-1} \in \mathcal{A}$.

Let \mathcal{B} be a Banach algebra and f a function of one complex variable represented by its Taylor series $f(x) = \sum_{n=0}^{\infty} a_n(x - x_0)^n$ with the convergence radius $\geq r$. Then $f(X)$ is well-defined, commutes with X , and satisfies a certain bound for all elements $X \in \mathcal{B}$ sufficiently close to x_0I :

$$f(X) = a_0I + \sum_{n=1}^{\infty} a_n(X - x_0I)^n \quad \text{if } \|X - x_0I\| < r, \quad (3.2)$$

$$\|f(X) - f(x_0I)\| \leq \sum_{n=1}^{\infty} |a_n| \|X - x_0I\|^n. \quad (3.3)$$

For example, let α be an arbitrary complex number, x_0 a positive number, and let $f(x) = x^\alpha$. Then $f(X)$ is well-defined if $\|X - x_0 I\| < x_0$. Expanding around an arbitrary element X_0 is more complex, but $X^{-1} = X_0^{-1}(I + (X - X_0)X_0^{-1})^{-1}$ exists if $\|X - X_0\| < \|X_0^{-1}\|^{-1}$.

These are some interesting and useful functions:

$$|X| = (X^2)^{1/2}, \quad \text{sgn}(X) = X(X^2)^{-1/2} \quad (\|X^2 - x_0^2 I\| < x_0^2). \quad (3.4)$$

If X is an approximate solution of the equation $X^2 = I$, then a nearby exact solution, commuting with X , is given by $\text{sgn}(X)$. Indeed, $\text{sgn}(X)^2 = I$ for all X , and

$$\|\text{sgn}(X) - X\| \leq \|X\| O(\|X^2 - I\|) \quad \text{if } \|X^2 - I\| < 1. \quad (3.5)$$

Proposition 3.1. *Let P be an element of a Banach algebra such that $\|P^2 - P\| \leq \delta < 1/4$, and let*

$$\tilde{P} = \theta(2P - I), \quad \text{where } \theta(X) = \frac{1}{2}(I + \text{sgn}(X)). \quad (3.6)$$

Then $\tilde{P}^2 = \tilde{P}$, \tilde{P} commutes with P , and $\|\tilde{P} - P\| \leq \|2P - I\| O(\delta)$.

Proof. The statement follows from the preceding discussion applied to $X = 2P - I$, which satisfies the inequality $\|X^2 - I\| \leq 4\delta < 1$. \square

For a more complete picture, let us mention the spectrum and the holomorphic function calculus [11, chapter 3]. (We have not found use of these methods due to their fragility in the approximate setting and the lack of a $*$ -representation, which could alleviate it.) The *spectrum* of an element $X \in \mathcal{B}$,

$$\text{spec}(X) = \text{spec}_{\mathcal{B}}(X) = \{\lambda \in \mathbb{C} : X - \lambda I \text{ is not invertible in } \mathcal{B}\}, \quad (3.7)$$

is a nonempty closed subset of \mathbb{C} contained in the disk $\{\lambda \in \mathbb{C} : |\lambda| \leq \|X\|\}$. Note that even in the algebra of operators acting in a finite-dimensional Hilbert space, $\text{spec}(X)$ can be very sensitive to perturbations (unless we assume that X is normal). For example, consider this X , where t is small:

$$X = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ t & 0 & 0 \end{pmatrix}, \quad \text{spec}(X) = \{t^{1/3}, e^{2\pi i/3}t^{1/3}, e^{-2\pi i/3}t^{1/3}\}. \quad (3.8)$$

Any function f holomorphic on an open set S can be applied to Banach algebra elements whose spectrum is contained in S . Specifically,

$$f(X) = \frac{1}{2\pi i} \int_C (zI - X)^{-1} f(z) dz, \quad (3.9)$$

where C is the union of closed oriented curves enclosing $\text{spec}(X)$ and contained in S . The spectral mapping theorem asserts that $\text{spec}(f(x)) = f(\text{spec}(x))$. For example $|X|$ and $\text{sgn}(X)$ are defined for all X such that $\text{spec}(X) \subseteq \{\lambda \in \mathbb{C} : \Re \lambda \neq 0\}$, or equivalently, $\text{spec}(X^2) \subseteq \mathbb{C} \setminus (-\infty, 0]$.

If an element X_0 with $\text{spec}(X_0) \subseteq S$ is fixed, then $f \mapsto f(X_0)$ is a homomorphism of the algebra of functions holomorphic on S to the closed subalgebra of \mathcal{B} generated by X_0 . This subalgebra is obviously commutative. If both f and X_0 are fixed, then $f(X)$ admits a Taylor expansion in $X - X_0$, provided $\|X - X_0\| < \delta$, where δ is sufficiently small. (The terms in that Taylor series

are general degree n functions, not just $a_n(X - X_0)^n$.) One may set $\delta = \min_{z \in C} \|(zI - X_0)^{-1}\|^{-1}$, but this number is often difficult to estimate.

Let us now discuss more general functions on Banach spaces. We will use the notation

$$B_r^M(x_0) = \{x \in M : d(x_0, x) < r\}, \quad \bar{B}_r^M(x_0) = \{x \in M : d(x_0, x) \leq r\} \quad (x_0 \in M) \quad (3.10)$$

for open and closed balls in a metric space M . Let \mathcal{A} and \mathcal{B} be Banach spaces, and $f: B_r^{\mathcal{A}}(x_0) \rightarrow \mathcal{B}$ a continuously differentiable map. The Frechet derivative of f at point x is denoted by $\partial_x f(x)$ or $\frac{\partial f(x)}{\partial x}$; it is a linear map from \mathcal{A} to \mathcal{B} . Functions of multiple variables are understood as maps of direct sums of Banach spaces, equipped with an arbitrary norm between the maximum and the sum norms.

The inverse function theorem asserts that if $\frac{\partial f(x)}{\partial x}|_{x=x_0}$ is bijective, then f has a continuously differentiable inverse in some neighborhood of $f(x_0)$. An explicit bound on the size of that neighborhood is given by the next lemma, which implies the theorem and is useful on its own right. The implicit function theorem is derived from the inverse function theorem by the standard argument.

Lemma 3.2. *Let $V: \mathcal{A} \rightarrow \mathcal{B}$ be a linear isomorphism of Banach spaces and $f: B_r^{\mathcal{A}}(x_0) \rightarrow \mathcal{B}$ a continuously differentiable function such that¹*

$$\|V^{-1}\partial_x f(x) - 1\| \leq c \quad (x \in B_r^{\mathcal{A}}(x_0)),$$

where $0 \leq c < 1$. Then

1. *f is injective and satisfies the inequality*

$$(1 - c)\|x_1 - x_2\| \leq \|V^{-1}(f(x_1) - f(x_2))\| \leq (1 + c)\|x_1 - x_2\| \quad (x_1, x_2 \in B_r^{\mathcal{A}}(x_0));$$

2. *The image of f includes $f(x_0) + V(B_{(1-c)r}^{\mathcal{A}}(0))$.*

Proof. For each given y , the equation $f(x) = y$ is equivalent to x being a fixed point of the function

$$g_y(x) = x + V^{-1}(y - f(x)) \quad (x \in B_r^{\mathcal{A}}(x_0)).$$

Due to the hypothesis, the norm of the derivative of g_y is at most c . Therefore, $\|g_y(x_1) - g_y(x_2)\| \leq c\|x_1 - x_2\|$, which can be written as $\|a - b\| \leq c\|a\|$, where $a = x_1 - x_2$ and $b = V^{-1}(f(x_1) - f(x_2))$. It follows that $(1 - c)\|a\| \leq \|b\| \leq (1 + c)\|a\|$, which is exactly the inequality in part 1 of the lemma.

Part 2 asserts that the equation $f(x) = y$ has a solution for any y such that $\|V^{-1}(y - f(x_0))\| < (1 - c)r$. To show this, we note that if $\|x - x_0\| < r$, then

$$\|g_y(x) - x_0\| \leq \|g_y(x) - g_y(x_0)\| + \|g_y(x_0) - x_0\| < c\|x - x_0\| + (1 - c)r \leq r.$$

Hence, g_y maps the ball $B_r^{\mathcal{A}}(x_0)$ to itself. The fixed point can be obtained as the limit of the sequence $x_n = g_y(x_{n-1})$. It is a Cauchy sequence because $\|x_n - x_{n-1}\| < rc^{n-1}$. \square

¹Here $1 = 1_{\mathcal{A}}$ stands for the identity operator on \mathcal{A} . (We use I for the units of abstract algebras, which are not automatically defined and need to be specified.)

For an illustration of the outlined methods, let us calculate $\partial_X \operatorname{sgn}(X)$ in a Banach algebra \mathcal{B} . To this end, we consider the map

$$f: \mathcal{B} \times \mathcal{B} \times \mathcal{B} \rightarrow \mathcal{B} \times \mathcal{B}, \quad f(X, Y_1, Y_2) = (Y_1 Y_2 - I, XY_2 - Y_1 X). \quad (3.11)$$

For each given X such that $\operatorname{sgn}(X)$ is well-defined, the equation $f(X, Y_1, Y_2) = 0$ has a solution $Y_1 = Y_2 = \operatorname{sgn}(X)$. By the implicit function theorem, this solution can be continued to nearby values of X if $\frac{\partial f(X, Y_1, Y_2)}{\partial(Y_1, Y_2)}$ is nondegenerate, i.e. maps $\mathcal{B} \times \mathcal{B}$ bijectively onto itself. It is evident that

$$\frac{\partial f(X, Y_1, Y_2)}{\partial(Y_1, Y_2)} = \begin{pmatrix} \partial_{Y_1}(Y_1 Y_2 - I) & \partial_{Y_2}(Y_1 Y_2 - I) \\ \partial_{Y_1}(XY_2 - Y_1 X) & \partial_{Y_2}(XY_2 - Y_1 X) \end{pmatrix} = \begin{pmatrix} R_{Y_2} & L_{Y_1} \\ -R_X & L_X \end{pmatrix},$$

where L_A and R_A denote the operators of multiplication by A on the left and on the right, respectively. If $Y_1 = Y_2 = \operatorname{sgn}(X)$, then all elements of the matrix commute, and its inverse is computed easily:

$$\left(\frac{\partial f(X, Y_1, Y_2)}{\partial(Y_1, Y_2)} \Big|_{Y_1=Y_2=\operatorname{sgn}(X)} \right)^{-1} = \begin{pmatrix} L_X & -L_{\operatorname{sgn}(X)} \\ R_X & R_{\operatorname{sgn}(X)} \end{pmatrix} (L_X R_{\operatorname{sgn}(X)} + L_{\operatorname{sgn}(X)} R_X)^{-1}.$$

The operator $L_X R_{\operatorname{sgn}(X)} + L_{\operatorname{sgn}(X)} R_X = L_{\operatorname{sgn}(X)}(L_{|X|} + R_{|X|})R_{\operatorname{sgn}(X)}$ is invertible if $\|X^2 - I\| < 1$ because this condition implies (via a special case of inequality (3.3), $\|Z^{1/2} - I\| \leq 1 - (1 - \|Z - I\|)^{1/2}$ with $Z = X^2$) that $\||X| - I\| < 1$. Now that the solution of the equation $f(X, Y_1, Y_2) = 0$ is given by an implicit function, $(Y_1, Y_2) = g(X) = (\operatorname{sgn}(X), \operatorname{sgn}(X))$, we can compute its derivative:

$$\frac{\partial g(X)}{\partial X} = \left(- \left(\frac{\partial f(X, Y_1, Y_2)}{\partial(Y_1, Y_2)} \right)^{-1} \frac{\partial f(X, Y_1, Y_2)}{\partial X} \right) \Big|_{(Y_1, Y_2)=g(X)}.$$

Thus,

$$\partial_X \operatorname{sgn}(X) = \frac{1 - L_{\operatorname{sgn}(X)} R_{\operatorname{sgn}(X)}}{L_{|X|} + R_{|X|}} \quad \text{if } \|X^2 - I\| < 1. \quad (3.12)$$

Remark 3.3. The system of equations $Y_1 Y_2 = I$, $XY_2 = Y_1 X$ has a unique solution with Y_1 and Y_2 close to X in any ε -Banach algebra, provided $\|X^2 - I\|$ is sufficiently small. However, in general, $Y_1 \neq Y_2$. Even the single equation $Y^2 = I$ may not have a solution sufficiently close to X . Indeed, suppose that the norm of X is bounded by a constant, $\|X^2 - I\| \leq O(\varepsilon)$, and there is a Y such that $Y^2 = I$ and $\|Y - X\| \leq O(\varepsilon)$. Representing X as $Y + Z$ with $\|Z\| \leq O(\varepsilon)$, we readily see that $\|XX^2 - X^2X\| \leq O(\varepsilon^2)$. But such a bound may not hold in an arbitrary ε -Banach algebra. For this reason, Proposition 3.1 does not generalize to the ε -Banach or even the ε - C^* setting, and we will have to work with approximate projections.

4 Basic properties of ε -Banach algebras

For each element X of an ε -Banach algebra \mathcal{A} , the operators of left and right multiplication by X are defined in the standard way:

$$L_X(Z) = XZ, \quad R_X(Z) = ZX \quad (Z \in \mathcal{A}). \quad (4.1)$$

Since \mathcal{A} is a Banach space, linear operators on it have a standard norm,

$$\|w\| = \sup_{\|Z\| \leq 1} \|w(Z)\|, \quad w: \mathcal{A} \rightarrow \mathcal{A}, \quad (4.2)$$

and bounded linear operators form a Banach algebra. It follows from equation (2.1) that

$$\|L_X\| \leq (1 + \varepsilon)\|X\|, \quad \|R_X\| \leq (1 + \varepsilon)\|X\|. \quad (4.3)$$

Applying L_X and R_X to the unit element gives these inequalities:

$$\|L_X\| \geq (1 - O(\varepsilon))\|X\|, \quad \|R_X\| \geq (1 - O(\varepsilon))\|X\| \quad (\text{in general}), \quad (4.4)$$

$$\|L_X\| \geq \|X\|, \quad \|R_X\| \geq \|X\| \quad (\text{if the unit is exact}). \quad (4.5)$$

Furthermore, the approximate associativity axiom (2.2) implies that for all $X, Y \in \mathcal{A}$,

$$\|L_X L_Y - L_{XY}\| \leq \varepsilon \|X\| \|Y\|, \quad \|R_X R_Y - R_{YX}\| \leq \varepsilon \|X\| \|Y\|, \quad (4.6)$$

$$\|L_X R_Y - R_Y L_X\| \leq \varepsilon \|X\| \|Y\|. \quad (4.7)$$

Note that the operator L_X (and similarly, R_X) is invertible if and only if the equation $XY = Z$ (respectively, $YX = Z$) has a unique solution Y for all $Z \in \mathcal{A}$.

Proposition 4.1. *Let \mathcal{A} be an ε -Banach algebra with unit I . Then there exist a new unit $J \in \mathcal{A}$ and a new multiplication denoted by a dot that make \mathcal{A} into an $O(\varepsilon)$ -Banach algebra with exact unit while being $O(\varepsilon)$ -close to the original unit and multiplication:*

$$\|J - I\| \leq O(\varepsilon), \quad \|X \cdot Y - XY\| \leq O(\varepsilon)\|X\|\|Y\| \quad (X, Y \in \mathcal{A}). \quad (4.8)$$

This transformation respects the involution if one is present, i.e. $J^\dagger = J$ and $(X \cdot Y)^\dagger = Y^\dagger \cdot X^\dagger$.

Proof. If $\varepsilon = 0$, then the original unit and multiplication work, so suppose that $\varepsilon > 0$. First, we find a (unique) solution of the equation $J^2 = J$ such that $\|J - I\| < 2\varepsilon$. The function $f: X \mapsto X^2 - X: B_{2\varepsilon}^A(I) \rightarrow \mathcal{A}$ has Frechet derivative $\partial_X f(X) = L_X + R_X - 1$. The domain restriction $X \in B_{2\varepsilon}^A(I)$ implies the bound

$$\|L_X - 1\| \leq \|L_{X-I}\| + \|L_I - 1\| \leq (1 + \varepsilon)2\varepsilon + \varepsilon \leq O(\varepsilon),$$

where we have used the inequality $L_{X-I} \leq (1 + \varepsilon)\|X - I\|$ and the axiom $\|IY - Y\| \leq \varepsilon\|Y\|$ for all Y . The bound $\|R_X - 1\| \leq O(\varepsilon)$ is obtained in the same way, and $\|f(I)\|$ is easily estimated. Thus,

$$\|\partial_X f(X) - 1\| \leq O(\varepsilon), \quad \|f(I)\| \leq O(\varepsilon).$$

By Lemma 3.2, f is injective and its image contains 0, which provides the desired solution.

The new multiplication is given by the formula

$$X \cdot Y = R_J^{-1}(X) L_J^{-1}(Y). \quad (4.9)$$

It is evident that $L_J^{-1}(J) = J = R_J^{-1}(J)$; hence, $X \cdot J = X = J \cdot X$. All other requirements are also met. \square

5 Approximate unitary group

Let \mathcal{A} be an ε - C^* algebra with exact unit. The sets of Hermitian and anti-Hermitian elements in \mathcal{A} are denoted by \mathcal{H} and $i\mathcal{H}$, respectively. An element $U \in \mathcal{A}$ is called *unitary* if $U^\dagger U = I$ and U also has a right inverse. The set of unitary elements is denoted by \mathcal{U} . Clearly, $\mathcal{U} = \bar{\mathcal{U}}_0$, where

$$\bar{\mathcal{U}}_\delta = \{X \in \mathcal{A} : \|X^\dagger X - I\| \leq 2\delta \text{ and } X \text{ has a right inverse}\}. \quad (5.1)$$

(A sufficient condition for the existence of a right inverse is that L_X is invertible.) The analogous set \mathcal{U}_δ is defined by the inequality $\|X^\dagger X - I\| < 2\delta$. We assume that ε and δ are bounded by suitable positive constants, ε_{\max} and δ_{\max} , and will show that \mathcal{U} is a C^1 manifold with a tubular neighborhood \mathcal{U}_{δ_1} , where $0 < \delta_1 \leq \delta_{\max}$ (see Proposition 5.3).

Lemma 5.1. *If $X \in \bar{\mathcal{U}}_\delta$, then $\|X\| \leq 1 + O(\delta + \varepsilon)$. Furthermore, the operator L_X is invertible, and*

$$\|L_X^{-1}\| \leq 1 + O(\delta + \varepsilon), \quad \|L_X^{-1} - L_{X^\dagger}\| \leq O(\delta + \varepsilon). \quad (5.2)$$

Proof. The condition $\|X^\dagger X - I\| \leq 2\delta$ implies that $\|X^\dagger X\| \leq 1 + 2\delta$. On the other hand, \mathcal{A} is an ε - C^* algebra, so $\|X^\dagger X\| \geq (1 - \varepsilon)\|X\|^2$. It follows that $\|X\| \leq ((1 + 2\delta)/(1 - \varepsilon))^{1/2} \leq 1 + O(\delta + \varepsilon)$.

To show that L_X is invertible, let us first use the fact that X has a right inverse, i.e. that $XY = I$ for some Y . We have

$$\|X^\dagger - Y\| = \|X^\dagger(XY) - Y\| \leq \|(X^\dagger X - I)Y\| + O(\varepsilon)\|X\|^2\|Y\| \leq (2\delta + O(\varepsilon))\|Y\|,$$

and therefore, $\|X^\dagger\| \geq (1 - 2\delta - O(\varepsilon))\|Y\|$. But $\|X^\dagger\| = \|X\| \leq 1 + O(\delta + \varepsilon)$, which gives the bound $\|Y\| \leq 1 + O(\delta + \varepsilon)$. The latter implies that

$$\|L_X L_Y - 1\| = \|L_X L_Y - L_{XY}\| \leq \varepsilon\|X\|\|Y\| < 1,$$

provided ε and δ are small enough. Thus, $L_X L_Y$ is invertible, and so $L_Y(L_X L_Y)^{-1}$ is a right inverse of L_X . Similarly, $(L_{X^\dagger} L_X)^{-1} L_{X^\dagger}$ is a left inverse of L_X , where the existence of $(L_{X^\dagger} L_X)^{-1}$ follows from the inequality

$$\|L_{X^\dagger} L_X - 1\| \leq \|L_{X^\dagger} L_X - L_{X^\dagger X}\| + \|L_{X^\dagger X} - L_I\| \leq \varepsilon\|X\|^2 + (1 + \varepsilon)\|X^\dagger X - I\| \leq 2\delta + O(\varepsilon).$$

We conclude that $L_X^{-1} = (L_{X^\dagger} L_X)^{-1} L_{X^\dagger}$ and that $\|(L_{X^\dagger} L_X)^{-1} - 1\| \leq O(\delta + \varepsilon)$, from which inequalities (5.2) are obtained easily. \square

Let us introduce local coordinates around each element $V \in \mathcal{U}_{\delta_{\max}}$:

$$\varphi_V(X) = L_V^{-1}(X - V) \quad (\varphi_V: \mathcal{A} \rightarrow \mathcal{A}), \quad \varphi_V^{-1}(A) = V(I + A). \quad (5.3)$$

The corresponding transition functions,

$$\Phi_{V,W} = \varphi_V \varphi_W^{-1}, \quad \Phi_{V,W}(A) = L_V^{-1}(W(I + A) - V), \quad (5.4)$$

have derivative close to the identity, provided V and W are close to each other:²

$$\partial_A \Phi_{V,W}(A) = L_V^{-1} L_W = 1 + O(\|W - V\|). \quad (5.5)$$

²Here, $O(\eta)$ stands for some operator of norm $\leq O(\eta)$. We will use similar notation for matrices of partial derivatives. As long as errors are estimated up to a constant factor, it does not matter what matrix norm is used.

In some situations, it is convenient to separate the tangential and normal coordinates:

$$A = A^{\parallel} + A^{\perp} \quad (A^{\parallel} \in i\mathcal{H}, \quad A^{\perp} \in \mathcal{H}), \quad \text{i.e.} \quad A^{\parallel} = \frac{1}{2}(A - A^{\dagger}), \quad A^{\perp} = \frac{1}{2}(A + A^{\dagger}). \quad (5.6)$$

If $A = \varphi_V(X)$, the corresponding A^{\parallel} and A^{\perp} are denoted by $\varphi_V^{\parallel}(X)$ and $\varphi_V^{\perp}(X)$, respectively. We will parametrize unitary elements U in a neighborhood of V by $\varphi_V^{\parallel}(U)$. The condition that U is unitary is expressed by the equation $f(U) = 0$, where

$$f(X) = \frac{1}{2}(X^{\dagger}X - I), \quad f: \mathcal{A} \rightarrow \mathcal{H}. \quad (5.7)$$

In local coordinates, the function f takes the form

$$f_V(A) := f(\varphi_V^{-1}(A)) = \frac{1}{2}((I + A^{\dagger})V^{\dagger})(V(I + A)) - I. \quad (5.8)$$

Lemma 5.2. *Let $V \in \bar{\mathcal{U}}_{\delta}$, and let A^{\parallel} and A^{\perp} range over all anti-Hermitian and Hermitian elements, respectively, of norm $< 2\delta$. Then for each A^{\parallel} , the equation $f_V(A^{\parallel} + A^{\perp}) = 0$ has a unique solution $A^{\perp} = g_V(A^{\parallel})$. The function g_V is continuously differentiable and satisfies the bounds*

$$g_V(A^{\parallel}) = -f(V) + O(\varepsilon\delta + \delta^2), \quad \frac{\partial g_V(A^{\parallel})}{\partial A^{\parallel}} = O(\delta + \varepsilon). \quad (5.9)$$

Proof. Using approximate associativity, we obtain the estimate

$$f_V(A) = \frac{1}{2}(V^{\dagger}V - I + (V^{\dagger}V)A + A^{\dagger}(V^{\dagger}V) + A^{\dagger}(V^{\dagger}V)A + O(\varepsilon\delta)) = \frac{1}{2}(V^{\dagger}V - I) + A^{\perp} + O(\varepsilon\delta + \delta^2),$$

which implies that if $f_V(A) = 0$, then $A^{\perp} = -f(V) + O(\varepsilon\delta + \delta^2)$. By a similar calculation,

$$\partial_A f_V(A) : Z \rightarrow \frac{1}{2}(((I + A^{\dagger})V^{\dagger})(VZ) + (Z^{\dagger}V^{\dagger})(V(I + A))) = \frac{1}{2}(Z + Z^{\dagger}) + O(\delta + \varepsilon)\|Z\|,$$

and hence,

$$\frac{\partial f_V(A^{\parallel} + A^{\perp})}{\partial(A^{\parallel}, A^{\perp})} = (0, 1) + O(\delta + \varepsilon) \quad (A^{\parallel} \in B_{2\delta}^{i\mathcal{H}}(0), \quad A^{\perp} \in B_{2\delta}^{\mathcal{H}}(0)),$$

where $(0, 1)$ stands for the row vector of partial derivatives. By Lemma 3.2, for each given A^{\parallel} , the map $A^{\perp} \mapsto f_V(A^{\parallel} + A^{\perp})$ is injective and its image includes the set $f_V(A^{\parallel}) + B_{2\delta(1-O(\delta+\varepsilon))}^{\mathcal{H}}(0)$. Since $\|f_V(A^{\parallel})\| \leq \delta + O(\varepsilon\delta + \delta^2)$, this set contains 0, and so the equation $f_V(A^{\parallel} + A^{\perp}) = 0$ has a unique solution, denoted by $g_V(A^{\parallel})$. The bound on its derivative follows from the formula

$$\frac{\partial g_V(A^{\parallel})}{\partial A^{\parallel}} = \left(- \left(\frac{\partial f(A^{\parallel} + A^{\perp})}{\partial A^{\perp}} \right)^{-1} \frac{\partial f(A^{\parallel} + A^{\perp})}{\partial A^{\parallel}} \right) \Big|_{A^{\perp} = g_V(A^{\parallel})}.$$

□

The tangent space $T_U \mathcal{U}$ of the manifold \mathcal{U} at point U is the image of the following map, which preserves the norm up to a $1 + O(\varepsilon)$ factor:

$$\frac{\partial \varphi_U^{-1}(A^\parallel + g_U(A^\parallel))}{\partial A^\parallel} = L_U \left(1 + \frac{\partial g_U(A^\parallel)}{\partial A^\parallel} \right) : i\mathcal{H} \rightarrow \mathcal{A}. \quad (5.10)$$

Thus, $T_U \mathcal{U}$ is a closed subspace of \mathcal{A} , which is almost-isometrically identified with $i\mathcal{H}$ by an analogue of the Maurer-Cartan form, i.e. the inverse of the previous map:

$$\omega_U = \frac{\partial \varphi_U^\parallel(X)}{\partial X} \Big|_{X=U} : Z \mapsto (L_U^{-1}(Z))^\parallel, \quad \omega_U : T_U \mathcal{U} \rightarrow i\mathcal{H}. \quad (5.11)$$

Proposition 5.3. *The polar map $(U, H) \mapsto UH$ diffeomorphically maps $\mathcal{U} \times B_\delta^{\mathcal{H}}(I)$ onto some $S \subseteq \mathcal{A}$ such that $\mathcal{U}_{\delta - O(\varepsilon\delta + \delta^2)} \subseteq S \subseteq \mathcal{U}_{\delta + O(\varepsilon\delta + \delta^2)}$.*

Proof. Let us use a variant of the polar map, $(U, Q) \mapsto U(I + Q)$ for $U \in \mathcal{U}$ and $Q \in B_{1.5\delta}^{\mathcal{H}}(0)$. First, we note that if $V = U(I + Q)$ for some U and Q , then $\|V - U\| = \|UQ\| \leq 1.5\delta + O(\varepsilon\delta + \delta^2)$, or in local coordinates,

$$\|\varphi_V(U)\| = \|L_V^{-1}(U - V)\| \leq 1.5\delta + O(\varepsilon\delta + \delta^2) < 2\delta.$$

Therefore, for the purpose of finding the inverse image of V under the polar map, it is sufficient to consider all elements $U = \varphi_V^{-1}(A)$ with $A = A^\parallel + A^\perp$ such that $A^\parallel \in B_{2\delta}^{i\mathcal{H}}(0)$ and $A^\perp \in B_{2\delta}^{\mathcal{H}}(0)$. By Lemma 5.2, the condition $U^\dagger U = I$ is equivalent to $A^\perp = g_V(A^\parallel)$, so U is parametrized by A^\parallel :

$$U = \varphi_V^{-1}(A) = V(I + A), \quad \text{where } A = A^\parallel + g_V(A^\parallel) \quad (A^\parallel \in B_{2\delta}^{i\mathcal{H}}(0)).$$

It is also convenient to represent the value of the polar map in the same coordinates:

$$B = \varphi_V(U(I + Q)) = L_V^{-1}((V(I + A))(I + Q) - V) = A + Q + L_V^{-1}((VA)Q).$$

The condition $V = U(I + Q)$ is equivalent to $B = 0$.

As a function of A and Q , the element B has the following derivatives:

$$\frac{\partial B}{\partial A} = 1 + L_V^{-1}R_Q L_V = 1 + O(\delta), \quad \frac{\partial B}{\partial Q} = 1 + L_V^{-1}L_{VA} = 1 + O(\delta).$$

Expressing B as $B^\parallel + B^\perp$ and A as $A^\parallel + g_V(A^\parallel)$, we may regard (B^\parallel, B^\perp) as a function of (A^\parallel, Q) . Using Lemma 5.2, we get these bounds:

$$(B^\parallel, B^\perp) = (A^\parallel, -f(V) + Q) + O(\varepsilon\delta + \delta^2), \quad \frac{\partial(B^\parallel, B^\perp)}{\partial(A^\parallel, Q)} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + O(\varepsilon + \delta). \quad (5.12)$$

The second bound implies that (i) the map $p_V : (A^\parallel, Q) \mapsto (B^\parallel, B^\perp)$ is a diffeomorphism. Due to both bounds and Lemma 3.2, the equation $p_V(A^\parallel, Q) = 0$ has a solution if $\|f(V)\|$ is less than 1.5δ by an $O(\varepsilon\delta + \delta^2)$ margin; furthermore, (ii) if $\|f(V)\| < \delta_-$ for a certain $\delta_- = \delta - O(\varepsilon\delta + \delta^2)$, then $\|Q\| < \delta$. Conversely, (iii) if $\|Q\| < \delta$, then $\|f(V)\| < \delta + O(\varepsilon\delta + \delta^2)$. The statements (i)–(iii) are exactly what we needed to prove. \square

The inverse of the polar map is a pair of functions $u: \mathcal{U}_{\delta_{\max}} \rightarrow \mathcal{U}$ and $h: \mathcal{U}_{\delta_{\max}} \rightarrow \mathcal{H}$ such that $X = u(X)h(X)$ for all X . Proposition 5.3 implies that if $X \in \bar{\mathcal{U}}_\delta$, then

$$\|X - u(X)\| \leq \delta + O(\varepsilon\delta + \delta^2). \quad (5.13)$$

The derivatives of v and h are easy to estimate in the local coordinates based at an arbitrary point V in an $O(\delta)$ -neighborhood of U . Let us reuse the calculation from the previous proof, where $B^\parallel = \varphi_V^\parallel(X)$, $B^\perp = \varphi_V^\perp(X)$, $A^\parallel = \varphi_V^\parallel(u(X))$, and $Q = h(X) - I$. Inverting the derivative in equation (5.12), we get

$$\frac{\partial(\varphi_V^\parallel(u(X)), h(X))}{\partial(\varphi_V^\parallel(X), \varphi_V^\perp(X))} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + O(\varepsilon + \delta). \quad (5.14)$$

We are now in a position to define an approximate group structure on \mathcal{U} . The unit $e \in \mathcal{U}$, the multiplication map $\mu: \mathcal{U} \times \mathcal{U} \rightarrow \mathcal{U}$, and the inversion map $\sigma: \mathcal{U} \rightarrow \mathcal{U}$ are defined as follows:

$$e = I, \quad \mu(U, V) = u(UV), \quad \sigma(U) = u(U^\dagger). \quad (5.15)$$

It is evident that if $U, V \in \mathcal{U}$, then $UV \in \bar{\mathcal{U}}_{O(\varepsilon)}$. Similarly,

$$UU^\dagger = L_U L_{U^\dagger}(I) = I - L_U(L_U^{-1} - L_{U^\dagger})(I) = I + O(\varepsilon)$$

due to the second inequality in (5.2), so $U^\dagger \in \bar{\mathcal{U}}_{O(\varepsilon)}$. To deal with the map u in equation (5.15), we may work in $\bar{\mathcal{U}}_{\delta_0}$, where δ_0 is chosen such that $\delta_0 = O(\varepsilon)$ and

$$UV \in \bar{\mathcal{U}}_{\delta_0}, \quad U^\dagger \in \bar{\mathcal{U}}_{\delta_0} \quad \text{for all } U, V \in \mathcal{U}. \quad (5.16)$$

Thus, we obtain the approximate group laws

$$d(\mu(\mu(U, V), W), \mu(U, \mu(V, W))) \leq O(\varepsilon), \quad (5.17)$$

$$d(\mu(\sigma(U), U), e) \leq O(\varepsilon), \quad d(\mu(U, \sigma(U)), e) \leq O(\varepsilon), \quad (5.18)$$

where $d(X, Y) = \|X - Y\|$ is the metric on \mathcal{U} . And, of course,

$$\mu(e, U) = \mu(U, e) = U, \quad \sigma(e) = e. \quad (5.19)$$

Various derivatives are perturbed by $1 + O(\varepsilon)$ factors relative to what one would expect in a Lie group. Thus,

$$\left. \frac{\partial \varphi_{\mu(U, V)}^\parallel(\mu(X, Y))}{\partial \varphi_U^\parallel(X)} \right|_{X=U, Y=V} = L_V^{-1} R_V + O(\varepsilon), \quad \left. \frac{\partial \varphi_{\mu(U, V)}^\parallel(\mu(X, Y))}{\partial \varphi_U^\parallel(X)} \right|_{X=U, Y=V} = 1 + O(\varepsilon), \quad (5.20)$$

$$\left. \frac{\partial \varphi_{\sigma(U)}^\parallel(\sigma(X))}{\partial \varphi_U^\parallel(X)} \right|_{X=U} = -L_U R_U^{-1} + O(\varepsilon). \quad (5.21)$$

From the topological perspective, \mathcal{U} is an up-to-homotopy group, or an associative H-space with an inversion map. Let us elaborate on that. By definition, an *H-space* is a topological space

M with a basepoint e and a continuous multiplication map $\mu: M \rightarrow M$ such that $\mu(e, e) = e$ and

$$(x \mapsto \mu(x, e)) \sim (x \mapsto x) \sim (x \mapsto \mu(e, x)), \quad (5.22)$$

where “ $f \sim g$ ” means that f and g are homotopic through basepoint-preserving maps. The multiplication on \mathcal{U} satisfies this condition because the maps in questions are equal. An H-space M is called *associative* if

$$((x, y, z) \mapsto \mu(\mu(x, y), z)) \sim ((x, y, z) \mapsto \mu(x, \mu(y, z))). \quad (5.23)$$

In our case, the homotopy can be constructed by projecting the straight path between $\mu(\mu(x, y), z)$ and $\mu(x, \mu(y, z))$ onto \mathcal{U} using the map u . An *inversion map* is a continuous basepoint-preserving map $\sigma: M \rightarrow M$ such that

$$(x \mapsto \mu(\sigma(x), x)) \sim (x \mapsto e) \sim (x \mapsto \mu(x, \sigma(x))). \quad (5.24)$$

These properties also hold for \mathcal{U} . Surprisingly, the topological argument in the next section does not require associativity, and of the two homotopies in (5.24), only the first is used. When only the existence of that homotopy is required, σ is called a *left inversion map*.

6 The existence of a nontrivial projection

A *projection* in an ε - C^* algebra \mathcal{A} is a Hermitian element P such that $P^2 = P$. Such elements are generally hard to come by, see Remark 3.3, so will content ourselves with δ -*projections* for sufficiently small δ . They are defined by the conditions

$$P^\dagger = P, \quad \|P^2 - P\| \leq \delta. \quad (6.1)$$

It follows from the second condition that

$$(1 - \varepsilon)\|P\|^2 - \delta \leq \|P\| \leq (1 + \varepsilon)\|P\|^2 + \delta,$$

and hence,

$$\|P\| \leq O(\delta) \quad \text{or} \quad \|\|P\| - 1\| \leq O(\delta + \varepsilon). \quad (6.2)$$

A δ -projection is called *nonvanishing* if the second alternative holds. If P is a δ -projection, then $I - P$ is a δ' -projection, where $\delta' = \delta$ if \mathcal{A} has exact unit and $\delta' = \delta + O(\varepsilon)$ in general. A δ -projection P is called *nontrivial* if both P and $I - P$ are nonvanishing.

Lemma 6.1. *Any ε - C^* algebra \mathcal{A} such that $1 < \dim \mathcal{A} < \infty$ has a nontrivial $O(\varepsilon)$ -projection.*

Proof by reduction to a topological statement. Without loss of generality, we may assume that \mathcal{A} has exact unit. An element $P \in \mathcal{A}$ is a projection if and only if $X = 2P - I$ is Hermitian and satisfies the equation $X^2 = I$. Equivalently, X is both Hermitian and unitary. An approximate version of these conditions,

$$\|U^\dagger - U\| \leq \delta \quad (U \in \mathcal{U}), \quad (6.3)$$

implies that $P = \frac{1}{4}(2I + U + U^\dagger)$ is an $O(\delta + \varepsilon)$ -projection. In particular, fixed points of the inversion map σ , i.e. solutions of the equation

$$\sigma(U) = U \quad (U \in \mathcal{U}), \quad (6.4)$$

satisfy inequality (6.3) with $\delta = O(\varepsilon)$. Note that the trivial fixed points I and $-I$ are isolated because the derivative of σ is $O(\varepsilon)$ -close to -1 in local coordinates in constant-size neighborhoods

of $\pm I$. It follows that any other fixed point is at least constant distance away from $\pm I$, and therefore, corresponds to a nontrivial $O(\varepsilon)$ -projection. It suffices to show that such a fixed point exists.

To simplify the problem a bit, let us consider the manifold $\check{\mathcal{U}} = \mathcal{U}_e / \mathrm{U}(1)$, where \mathcal{U}_e is the connected component of \mathcal{U} containing the unit element, and the quotient is taken with respect to the equivalence relation $U \equiv cU$ for $c \in \mathrm{U}(1) = \{c \in \mathbb{C} : |c| = 1\}$. The maps μ and σ preserve this equivalence relation, giving rise to some maps $\check{\mu}$ and $\check{\sigma}$ on $\check{\mathcal{U}}$. A point $\check{U} \in \check{\mathcal{U}}$ is a fixed point of $\check{\sigma}$ if and only if it is the equivalence class of some $U \in \mathcal{U}_e$ such that $\sigma(U) = e^{i\phi}U$ ($\phi \in \mathbb{R}$). It corresponds to two fixed point of U , namely, $e^{i\phi/2}U$ and $-e^{i\phi/2}U$. We will show that if $n = \dim \mathcal{A}$ is finite but greater than 1, and thus, $0 < \dim \check{\mathcal{U}} = n - 1 < \infty$, then $\check{\sigma}$ has some fixed point $\check{U} \neq \check{e}$ (where \check{e} is the equivalence class of $e = I$, the unit of \mathcal{U} and the original algebra).

Let us list and explain the properties of $\check{\mathcal{U}}$ and $\check{\sigma}$ that are needed to complete the proof:

1. $\check{\mathcal{U}}$ is a compact C^1 manifold. Indeed, \mathcal{U} is a C^1 manifold. Being a bounded closed subset of a finite-dimensional Banach space, it is compact, and so is its connected component \mathcal{U}_e . The space $\check{\mathcal{U}}$ is the quotient of \mathcal{U}_e by a smooth free action of $\mathrm{U}(1)$; this action is proper because $\mathrm{U}(1)$ is compact. By the quotient manifold theorem [12, theorem 21.10], $\check{\mathcal{U}}$ is a C^1 manifold, and its compactness follows from the compactness of \mathcal{U}_e .
2. $\check{\mathcal{U}}$ is orientable because the Maurer-Cartan form on \mathcal{U} trivializes the tangent bundles of both \mathcal{U} and $\check{\mathcal{U}}$.
3. $\check{\sigma}: \check{\mathcal{U}} \rightarrow \check{\mathcal{U}}$ is a C^1 map with an isolated fixed point \check{e} . (A fixed point of a map f is called *isolated* if $\det(1 - f'(x)) \neq 0$, where $f'(x)$ is the tangent map, expressed as $\partial_y f(y)|_{y=x}$ in local coordinates.) Furthermore, $\det(1 - \check{\sigma}'(\check{e})) > 0$ because in local coordinates, $\partial_x \check{\sigma}(x)|_{x=\check{e}} = -1 + O(\varepsilon)$.
4. $\check{\mathcal{U}}$ is connected.
5. $\check{\mathcal{U}}$ is homeomorphic to a finite CW complex. This follows from the first property because every compact C^1 manifold admits a finite triangulation.
6. $\check{\mathcal{U}}$ is an H-space with the base point \check{e} , the multiplication map $\check{\mu}$, and a left inversion map $\check{\sigma}$.

In general, the number of fixed points of a smooth map f on a compact orientable manifold M can be estimated using the Lefschetz-Hopf theorem. It asserts that if f has a finite number of fixed points and they are all isolated, then

$$\sum_{x \in \mathrm{Fix}(f)} \mathrm{ind}(f, x) = \Lambda(f). \quad (6.5)$$

The *fixed point index* $\mathrm{ind}(f, x)$ and the *Lefschetz number* $\Lambda(f)$ are defined as follows:

$$\mathrm{ind}(f, x) = \mathrm{sgn} \det(1 - f'(x)), \quad f'(x): T_x M \rightarrow T_x M, \quad (6.6)$$

$$\Lambda(f) = \sum_k (-1)^k \mathrm{Tr} f^{*k}, \quad f^{*k}: H^k(M; \mathbb{R}) \rightarrow H^k(M; \mathbb{R}), \quad (6.7)$$

where f^{*k} is the induced cohomology map in dimension k . Applying this theorem to $\check{\sigma}: \check{\mathcal{U}} \rightarrow \check{\mathcal{U}}$, let us suppose for a moment that \check{e} is the only fixed point. It is isolated and has index 1. On

the other hand, Proposition 6.2 below implies that the Lefschetz number $\Lambda(\check{\sigma})$ equals the sum of the Betti numbers, $\sum_k \dim H^k(\check{\mathcal{U}}; \mathbb{R})$. This sum is at least 2 because $H^k(\check{\mathcal{U}}; \mathbb{R}) \neq 0$ for $k = 0$ and $k = \dim \check{\mathcal{U}} > 0$. We have arrived at a contradiction, indicating that $\check{\sigma}$ has another fixed point. \square

Proposition 6.2. *Let M be a connected CW complex such that $\dim H^*(M; \mathbb{R}) < \infty$. If M is an H-space with a left inversion map σ , then $\text{Tr } \sigma^{*k} = (-1)^k \dim H^k(M; \mathbb{R})$.*

To make a long story short, σ^{*k} is represented by a triangular matrix with $(-1)^k$ on the diagonal using Hopf's structure theorem and the augmentation filtration. The long story begins with some background information. A homogeneous element a of the cohomology space $A^k = H^k(M; \mathbb{R})$ is said to have dimension $|a| = k$. The graded space $A = \bigoplus_k A^k$ is a ring (or an \mathbb{R} -algebra) with respect to the cup product, which has the property $a \smile b = (-1)^{|a||b|} b \smile a$. The sign in this formula should be attributed to the swap map of the graded tensor product,

$$\text{SWAP}: A \otimes A \rightarrow A \otimes A, \quad a \otimes b \mapsto (-1)^{|a||b|} b \otimes a. \quad (6.8)$$

With this understanding, the cup product is commutative because $\smile = \smile \circ \text{SWAP}$, where the second expression means the swap map followed by

$$\smile: A \otimes A \rightarrow A. \quad (6.9)$$

The swap map is used in many other cases. For example, to give $A \otimes A$ the structure of an algebra, one has to swap b and c in the expression $(a \otimes b) \smile (c \otimes d)$. The result is $(-1)^{|b||c|} (a \smile c) \otimes (b \smile d)$.

Another important operation is the cross product $\times: H^*(M; \mathbb{R}) \otimes H^*(M; \mathbb{R}) \rightarrow H^*(M \times M; \mathbb{R})$. In fact, the cup product is obtained as the composition of the cross product with the cohomology map induced by the diagonal, $x \mapsto (x, x): M \rightarrow M \times M$. The cross product is a homomorphism of graded algebras; it is an isomorphism if M is a CW complex and $H^k(M; \mathbb{R})$ is finite-dimensional for each k . (The last statement is a variant of the Kunneth theorem, see Theorem 3.16 in [13].) If M is an H-space with the multiplication map μ , there is also the induced cohomology map $\mu^*: H^*(M; \mathbb{R}) \rightarrow H^*(M \times M; \mathbb{R})$. Combining it with the inverse of the cross product gives a *comultiplication*

$$\Delta: A \rightarrow A \otimes A. \quad (6.10)$$

There is also a *counit* $\tau: A \rightarrow \mathbb{R}$, which is induced by the map of an abstract point (with the cohomology space \mathbb{R}) to the basepoint $e \in M$. The axiom (5.22) of an H-space implies that³

$$(\text{id} \otimes \tau) \circ \Delta = \text{id} = (\tau \otimes \text{id}) \circ \Delta. \quad (6.11)$$

This property is dual to that of an algebra unit, in particular, of $I \in A$:

$$I \smile a = a = a \smile I. \quad (6.12)$$

The comultiplication is compatible with the cup product and the unit; namely, it is a homomorphism between graded algebras A and $A \otimes A$:

$$\Delta \circ \smile = (\smile \otimes \smile) \circ (\text{id} \otimes \text{SWAP} \otimes \text{id}) \circ (\Delta \otimes \Delta), \quad \Delta(I) = I \otimes I. \quad (6.13)$$

³In this discussion, we denote identity maps by “id” to avoid any confusion.

(In simpler terms, the first equation reads: $\Delta(a \smile b) = \Delta(a) \smile \Delta(b)$ for all $a, b \in A$.) The counit is also compatible, being an augmentation of the algebra A :

$$\tau \circ \smile = \tau \otimes \tau, \quad \tau(I) = I. \quad (6.14)$$

The “ \smile ” symbol is often omitted for brevity, i.e. one writes ab instead of $a \smile b$. Note that while the cup product is associative and commutative, the comultiplication may not be coassociative or cocommutative. It is coassociative (cocommutative) if the map μ is associative (resp. commutative) up to homotopy. Let us call a vector space (over \mathbb{R} or some other field) with a unit, a multiplication, a counit, and a comultiplication satisfying equations (6.11)–(6.14) a *bialgebra*.⁴

If the H -space M is connected, the corresponding bialgebra splits (as a graded \mathbb{R} -space) as $A = \mathbb{R} \oplus A^+$, where $A^+ = \bigoplus_{k>0} A^k$. Furthermore, the unit of A coincides with the unit of \mathbb{R} , and the counit acts as the identity map on \mathbb{R} and vanishes on A^+ . We say that in this situation, A is a *connected commutative associative bialgebra*.⁵ The connectivity together with equation (6.14) has an important corollary for the comultiplication. Specifically, applying the maps $\text{id} \otimes \tau$ and $\tau \otimes \text{id}$ to $\Delta(a)$ for $a \in A^+$, one finds that

$$\Delta(a) = a \otimes I + I \otimes a + \sum_j a'_j \otimes a''_j \quad (a, a'_j, a''_j \in A^+). \quad (6.15)$$

A fundamental theorem of Hopf (Theorem 3C.4 in [13]) asserts that every connected commutative associative bialgebra over a field of characteristic 0 is isomorphic, as a graded algebra, to the free commutative associative algebra on some homogeneous generators x_j . As a vector space, it is spanned by monomials $x_{j_1}^{p_1} \cdots x_{j_s}^{p_s}$ with $p_r \in \{1, 2, \dots\}$ if $|x_{j_r}|$ is even and $p_r = 1$ if $|x_{j_r}|$ is odd, because the square of an odd-dimensional element is 0. Finally, we take into account the condition $\dim A < \infty$. It excludes the existence of even-dimensional generators.

Thus, if M is a connected CW complex and an H -space, and the cohomology algebra $A = H^*(M; \mathbb{R})$ is finite-dimensional, then A is isomorphic as a graded algebra to the exterior algebra on some odd-dimensional generators x_1, \dots, x_m . Note that this property does not completely determine the comultiplication or the map σ^* we are interested in. To proceed, we need another standard construction, the *augmentation filtration* $A \supseteq A^+ \supseteq (A^+)^2 \supseteq (A^+)^3 \supseteq \dots$, where $(A^+)^p$ is the ideal of A generated by products of p homogeneous elements of positive dimension. Similarly, the algebra $A \otimes A$ is filtered by the ideal $(A \otimes A)^+ = \sum_{k'+k''>0} A^{k'} \otimes A^{k''}$ and its powers. In this notation, $\Delta(x_j)$ is congruent to $x_j \otimes I + I \otimes x_j$ modulo $((A \otimes A)^+)^2$. One can also determine $\Delta(x_1^{p_1} \cdots x_m^{p_m})$ modulo $((A \otimes A)^+)^{\sum_i p_i + 1}$. For each k , we define the filtration

$$A^k = F^{0,k} \supseteq F^{1,k-1} \supseteq \dots \supseteq F^{k,0} \supseteq F^{k+1,-1} = 0, \quad \text{where } F^{p,q} = (A^+)^p \cap A^{p+q}. \quad (6.16)$$

Proof of Proposition 6.2. On general grounds, the cohomology map σ^* induced by $\sigma: M \rightarrow M$ is an endomorphism of $A = H^*(M; \mathbb{R})$. Therefore, the obvious inclusion $\sigma^*(A^+) \subseteq A^+$ implies that $\sigma^*((A^+)^p) \subseteq (A^+)^p$ for all p . It follows that each individual map $\sigma^{*k}: A^k \rightarrow A^k$ preserves the

⁴We depart from the convention that bialgebras are both associative and coassociative. Milnor and Moore in their comprehensive study of graded Hopf algebras [14] called the more general algebraic structure “quasi-Hopf algebra”. Unfortunately, both this term and “quasi-bialgebra” have received much more specific meanings.

⁵Hatcher [13, section 3.C] uses the term “Hopf algebra”. The structure in question meets the standard definition of a Hopf algebra (including the existence of an antipode [14]) if the comultiplication is coassociative.

filtration (6.16), and so there are well-defined maps of the quotient spaces:

$$\sigma^{*(p,q)}: E^{p,q} \rightarrow E^{p,q}, \quad \text{where } E^{p,q} = F^{p,q}/F^{p+1,q-1}. \quad (6.17)$$

In these terms, the trace can be expressed as follows:

$$\text{Tr } \sigma^{*k} = \sum_{p+q=k} \text{Tr } \sigma^{*(p,q)}. \quad (6.18)$$

Now, the condition that σ is a left inversion map means that $x \mapsto \mu(\sigma(x), x)$ is homotopic to $x \mapsto e$ through basepoint-preserving maps. The corresponding cohomology maps are equal. Note that $x \mapsto \mu(\sigma(x), x)$ is the composition of three maps: $x \mapsto (x, x)$, $\sigma \times \text{id}$, and μ . Therefore,

$$\smile \circ (\sigma^* \otimes \text{id}) \circ \Delta = I \circ \tau, \quad (6.19)$$

where $I \in A$ on the right-hand side is interpreted as a map from \mathbb{R} to A . Combining the last equation with (6.15), we get

$$\sigma^*(a) + a + \sum_j \sigma^*(a'_j) a''_j = 0 \quad (a, a'_j, a''_j \in A^+). \quad (6.20)$$

In particular, if $a = x_l$ is one of the generators of A , then $\sigma^*(a)$ is congruent to $-a$ modulo $(A^+)^2$. This condition determines $\sigma^*(a)$ for all basis elements of A modulo a suitable ideal:

$$\sigma^*(x_1^{p_1} \cdots x_m^{p_m}) \equiv (-1)^p x_1^{p_1} \cdots x_m^{p_m} \pmod{(A^+)^{p+1}}, \quad p_1, \dots, p_m \in \{0, 1\}, \quad p = \sum_l p_l. \quad (6.21)$$

Note that $(-1)^p = (-1)^{|x_1^{p_1} \cdots x_m^{p_m}|}$ because all generators are odd-dimensional. On the other hand, the elements $x_1^{p_1} \cdots x_m^{p_m} \pmod{(A^+)^{p+1}}$ form a basis of the bigraded algebra $\bigoplus_{p,q} E^{p,q}$. Thus, $\sigma^{*(p,q)} = (-1)^{p+q} \text{id}$. In combination with (6.18), this implies that $\text{Tr } \sigma^{*k} = (-1)^k \dim A^k$. \square

7 Subspaces associated with projections

To each pair of projections (P, Q) in a C^* algebra \mathcal{B} , one assigns the vector space $\mathcal{S}_{P,Q} = \{PXQ : X \in \mathcal{B}\}$. In this section, we discuss an approximate version of this construction. Recall that a δ -projection in an ε - C^* algebra \mathcal{A} is a Hermitian element P such that $\|P^2 - P\| \leq \delta$. For each pair (P, Q) of δ -projections, there are two slightly different maps that could be called “compressions”: $L_P R_Q: X \mapsto P(XQ)$ and $R_Q L_P: X \mapsto (PX)Q$. We will use their symmetric combination, $\frac{1}{2}(L_P R_Q + R_Q L_P)$. It is an $O(\delta + \varepsilon)$ -idempotent element of the algebra of operators acting on \mathcal{A} , and therefore, can be approximated by an idempotent using Proposition 3.1. The *compression map* thus defined,

$$C_{P,Q}: \mathcal{A} \rightarrow \mathcal{A}, \quad C_{P,Q} = \theta(L_P R_Q + R_Q L_P - 1), \quad (7.1)$$

satisfies the equations

$$C_{P,Q}^2 = C_{P,Q}, \quad C_{P,Q}(X)^\dagger = C_{Q,P}(X^\dagger) \quad (X \in \mathcal{A}), \quad (7.2)$$

and both $\|L_P R_Q - C_{P,Q}\|$ and $\|R_Q L_P - C_{P,Q}\|$ are bounded by $O(\delta + \varepsilon)$. The image of this map, $\mathcal{S}_{P,Q} = \text{Im } C_{P,Q} = \text{Ker}(1 - C_{P,Q})$, is a closed linear subspace of \mathcal{A} . There is a variant of

this construction where only L_P or only R_Q is applied, and one writes $C_{P,1}, \mathcal{S}_{P,1}$ or $C_{1,Q}, \mathcal{S}_{1,Q}$, respectively. (This is the same as $C_{P,I}$, etc. if the unit is exact.)

When $P = Q$, the abbreviations C_P, \mathcal{S}_P are used. It is clear that $\mathcal{S}_P = 0$ if and only if P is sufficiently close to 0 as described by the first alternative in (6.2). (Recall that in the opposite case, we call P “nonvanishing”.) Similarly, $C_P = 1$ and $\mathcal{S}_P = \mathcal{A}$ if and only if P is close to I . If $\dim \mathcal{S}_P = 1$, we say that P is a *one-dimensional δ -projection*.

If P_1, P, Q_1, Q are δ -projections such that $\|P_1P - P_1\| \leq \delta$ and $\|Q_1Q - Q_1\| \leq \delta$, then \mathcal{S}_{P_1, Q_1} is almost contained in $\mathcal{S}_{P, Q}$. Indeed, if $X = C_{P_1, Q_1}(X)$, there is a chain of approximate equalities with $O(\delta + \varepsilon)\|X\|$ accuracy: $X \approx P_1(XQ_1) \approx (PP_1)(X(Q_1Q)) \approx P(XQ) \approx C_{P, Q}(X)$. Thus,

$$\|C_{P, Q}(X) - X\| \leq O(\delta + \varepsilon)\|X\| \quad (X \in \mathcal{S}_{P_1, Q_1}). \quad (7.3)$$

For any triple (P, Q, R) of δ -projections, one defines the *compressed product* between elements of the corresponding subspaces:

$$(X, Y) \mapsto X \cdot Y : \mathcal{S}_{P, Q} \times \mathcal{S}_{Q, R} \rightarrow \mathcal{S}_{P, R}, \quad X \cdot Y = C_{P, R}(XY). \quad (7.4)$$

It is close to the ambient product in \mathcal{A} , namely, $\|X \cdot Y - XY\| \leq O(\delta + \varepsilon)\|X\|\|Y\|$. If P is a nonvanishing projection, the compressed product turns the Banach space \mathcal{S}_P (which is close under the involution $X \mapsto X^\dagger$) into an $O(\delta + \varepsilon)$ - C^* algebra with unit $\tilde{P} = C_P(P)$.

Let us now discuss some additive properties and then examine the compressed product more closely. If P_1 and P_2 are δ -projections and $\|P_1P_2\| \leq \delta$, then $P = P_1 + P_2$ is an $O(\delta)$ -projection and $\|P_jP - P_j\| \leq O(\delta)$ for $j = 1, 2$. The following lemma includes a stronger hypothesis and other details that are ultimately not important. In fact, the lemma will be used for $p, q \leq 2$, so all reasonable variants of the inequalities involved differ only by constant factors.

Lemma 7.1. *Let P, \dots, P_p and Q_1, \dots, Q_q be Hermitian elements of an ε - C^* algebra \mathcal{A} such that*

$$\|P_jP_l - \delta_{jl}P_l\| \leq \delta, \quad \|Q_kQ_m - \delta_{km}Q_m\| \leq \delta.$$

Suppose that $P = \sum_j P_j$ and $Q = \sum_k Q_k$ are δ -projections satisfying the additional conditions $\|P_jP - P_j\| \leq \delta$ and $\|Q_kQ - Q_k\| \leq \delta$, and that $pq(\delta + \varepsilon)$ is less than a certain constant. Let

$$\alpha_{jk} : X \mapsto C_{P, Q}(X) : \mathcal{S}_{P_j, Q_k} \rightarrow \mathcal{S}_{P, Q}, \quad \alpha = \sum_{j,k} \alpha_{jk} : \bigoplus_{j,k} \mathcal{S}_{P_j, Q_k} \rightarrow \mathcal{S}_{P, Q}. \quad (7.5)$$

Then α is a linear bijection satisfying the bounds

$$\|\alpha\| \leq pq + O(pq(\delta + \varepsilon)), \quad \|\alpha^{-1}\| \leq 1 + O(pq(\delta + \varepsilon)), \quad (7.6)$$

where $\bigoplus_{j,k} \mathcal{S}_{P_j, Q_k}$ is equipped with the maximum norm, $\|(X_{11}, \dots, X_{pq})\| = \max_{j,k} \|X_{jk}\|$.

Proof. Let $(X_{11}, \dots, X_{pq}) \in \bigoplus_{j,k} \mathcal{S}_{P_j, Q_k}$. The conditions on P and Q imply $\|C_{P, Q}(X_{jk}) - X_{jk}\| \leq O(\delta + \varepsilon)\|X_{jk}\|$. Since $\alpha(X_{11}, \dots, X_{pq}) = \sum_{j,k} C_{P, Q}(X_{jk})$, we get the required bound on $\|\alpha\|$.

Now, let

$$\beta_{jk} : X \mapsto C_{P_j, Q_j}(X) : \mathcal{S}_{P, Q} \rightarrow \mathcal{S}_{P_j, Q_k}, \quad \beta = \sum_{j,k} \beta_{jk} : \mathcal{S}_{P, Q} \rightarrow \bigoplus_{j,k} \mathcal{S}_{P_j, Q_k}.$$

Then $\beta_{jk}\alpha_{lm}(X_{lm}) = \delta_{jl}\delta_{km}X_{lm} + O(\delta + \varepsilon)\|X_{lm}\|$. Hence, $\beta\alpha_{lm}(X_{lm})$ is approximately equal to $(\dots, 0, X_{lm}, 0, \dots)$, with the error bounded by $O(\delta + \varepsilon)\|X_{lm}\|$. It follows that $\beta\alpha = 1 + \gamma$, where

1 stands for the identity map on $\bigoplus_{j,k} \mathcal{S}_{P_j, Q_k}$ and $\|\gamma\| \leq pqO(\delta + \varepsilon)$. The last number is less than 1 by one of the hypotheses, so $\beta\alpha$ is invertible and $(\beta\alpha)^{-1}\beta$ is a left inverse of α . As a separate consideration,

$$\|\alpha_{jk}\beta_{jk}(X) - (P_j X)Q_k\| \leq O(\delta + \varepsilon)\|X\|,$$

and hence, $\|\alpha\beta - 1\| \leq pqO(\delta + \varepsilon)$, where 1 is the identity map on $\mathcal{S}_{P,Q}$. Similarly to the previous argument, $\alpha\beta$ is invertible and $\beta(\alpha\beta)^{-1}$ is a right inverse of α . Of course, the two inverses are equal to each other. Thus, $\|\alpha^{-1}\| \leq (1 + O(pq(\delta + \varepsilon)))\|\beta\|$, and it is evident that $\|\beta\| \leq 1 + O(\delta + \varepsilon)$. This gives the required bound on $\|\alpha^{-1}\|$. \square

Lemma 7.2. *Let P and Q be δ -projections in an ε - C^* algebra. If Q is one-dimensional, then $\mathcal{S}_{P,Q}$ is a Hilbert space with the inner product $\langle \cdot, \cdot \rangle$ defined by the equation*

$$Y^\dagger \cdot X = \langle Y, X \rangle \tilde{Q} \quad (X, Y \in \mathcal{S}_{P,Q}), \quad (7.7)$$

where $Y^\dagger \cdot X = C_Q(Y^\dagger X)$ and $\tilde{Q} = C_Q(Q)$. Furthermore,

$$|\langle X, X \rangle - \|X\|^2| \leq O(\delta + \varepsilon)\|X\|^2 \quad (X \in \mathcal{S}_{P,Q}). \quad (7.8)$$

Proof. The inner product $\langle Y, X \rangle$ defined by (7.7) is linear in X and conjugate linear in Y , and the complex conjugate of $\langle Y, X \rangle$ equals $\langle X, Y \rangle$. The positivity and the completeness axioms of a Hilbert space follow from (7.8), so it is sufficient to prove the latter. For this purpose, we may replace the space $\mathcal{S}_{P,Q}$ with $\mathcal{S}_{1,Q}$ because the former is almost contained in the latter, namely, $\|C_{1,Q}(X) - X\| \leq O(\delta + \varepsilon)\|X\|$ for all $X \in \mathcal{S}_{P,Q}$.

It is evident that $\|X^\dagger \cdot X\|$ and $\|\tilde{Q}\|$ are $O(\varepsilon + \delta)$ -close to $\|X\|^2$ and 1, respectively; therefore,

$$|\langle X, X \rangle - \|X\|^2| \leq O(\delta + \varepsilon)\|X\|^2 \quad (X \in \mathcal{S}_{1,Q}). \quad (7.9)$$

This inequality implies that if $\langle X, X \rangle = 0$, then $X = 0$. To show the positivity, let us assume the opposite, i.e. that $\langle X, X \rangle < 0$ for some $X \in \mathcal{S}_{1,Q}$. Note that $\langle Q', Q' \rangle > 0$ for $Q' = C_{1,Q}(Q)$. Now, consider the expression $f(t) = \langle X + tQ', X + tQ' \rangle$ for $t \in [0, \infty)$. The function f is continuous and changes sign from negative at $t = 0$ to positive at sufficiently large t ; hence, it vanishes at some $t > 0$. It follows that $X = -tQ'$, and therefore, $\langle X, X \rangle > 0$, in contradiction with our previous assumption. Thus, $\langle X, X \rangle \geq 0$ for all X , and so (7.8) follows from (7.9). \square

Lemma 7.3. *Let P, Q, R be δ -projections in an ε - C^* algebra. If Q is one-dimensional, then*

$$|\|X \cdot Y\| - \|X\|\|Y\|| \leq O(\delta + \varepsilon)\|X\|\|Y\| \quad (X \in \mathcal{S}_{P,Q}, \quad Y \in \mathcal{S}_{Q,R}).$$

Proof. Note that $\|X \cdot Y\| \approx \|XY\| \approx \sqrt{\|(XY)^\dagger(XY)\|}$ with $O(\delta + \varepsilon)\|X\|\|Y\|$ accuracy. Now,

$$(XY)^\dagger(XY) = Y^\dagger((X^\dagger X)Y) + O(\varepsilon)\|X\|^2\|Y\|^2 = \|X\|^2 Y^\dagger Y + O(\delta + \varepsilon)\|X\|^2\|Y\|^2$$

because $X^\dagger X \approx X^\dagger \cdot X = \langle X, X \rangle \tilde{Q} \approx \|X\|^2 \tilde{Q}$ with $O(\delta + \varepsilon)\|X\|^2$ accuracy. \square

Lemma 7.4. *If P and Q are one-dimensional δ -projections in an ε - C^* algebra, then $\dim \mathcal{S}_{P,Q} \leq 1$.*

Proof. Let us suppose the contrary. Since Q is one-dimensional, there exist two elements $X, Y \in \mathcal{S}_{P,Q}$ that are orthogonal and have unit length with respect to the inner product (7.7). Thus, $Y^\dagger \cdot X = 0$ while $\|X\|$ and $\|Y\|$ being $O(\delta + \varepsilon)$ -close to 1. But this contradicts Lemma 7.3 (for the projections Q, P, Q) because P is one-dimensional. \square

One-dimensional δ -projections P and Q are called *equivalent* if $\dim \mathcal{S}_{P,Q} = 1$. This is indeed an equivalence relation; in particular, it is transitive due to Lemma 7.3.

8 Properties and approximation of δ -homomorphisms

We first consider general properties of δ -homomorphisms between ε - C^* algebras. The approximation of δ -homomorphisms by $O(\varepsilon)$ -homomorphisms is discussed in the case where the domain is a finite-dimensional C^* algebra. As before, all statements are implicitly quantified like this: “There exist some positive constants ε_{\max} and δ_{\max} such that for all $\varepsilon \leq \varepsilon_{\max}$ and $\delta \leq \delta_{\max}$. . .” Only in Corollary 8.3, which is directly used in the proof of the main theorem, the constants are explicit.

Proposition 8.1. *If $v: \mathcal{A}' \rightarrow \mathcal{A}''$ is a δ -homomorphism of ε - C^* algebras, then $\|v\| \leq 1 + O(\delta + \varepsilon)$. Furthermore, if $\|v(X)\| \geq \eta\|X\|$ for all X , where $\eta > 2\delta$, then v is an $O(\delta + \varepsilon)$ -inclusion.*

Proof. Let

$$a = \inf\{\|v(X)\|/\|X\| : X \neq 0\}, \quad b = \|v\| = \sup\{\|v(X)\|/\|X\| : X \neq 0\}.$$

Due to the C^* property and the δ -homomorphism condition $\|v(X^\dagger X) - v(X)v(X)^\dagger\| \leq \delta\|X\|^2$, we have

$$(1 - \varepsilon)\|X\|^2 \leq \|X^\dagger X\| \leq (1 + \varepsilon)\|X\|^2, \\ \sqrt{(\|v(X^\dagger X)\| - \delta\|X\|^2)/(1 + \varepsilon)} \leq \|v(X)\| \leq \sqrt{(\|v(X^\dagger X)\| + \delta\|X\|^2)/(1 - \varepsilon)}.$$

From these inequalities and the fact that $a\|X^\dagger X\| \leq \|v(X^\dagger X)\| \leq b\|X^\dagger X\|$, we obtain the bound $\sqrt{((1 - \varepsilon)a - \delta)/(1 + \varepsilon)}\|X\| \leq \|v(X)\| \leq \sqrt{((1 + \varepsilon)b + \delta)/(1 - \varepsilon)}\|X\|$. Thus,

$$a \geq \sqrt{((1 - \varepsilon)a - \delta)/(1 + \varepsilon)}, \quad b \leq \sqrt{((1 + \varepsilon)b + \delta)/(1 - \varepsilon)}.$$

The second inequality makes sense if $\varepsilon < 1$ and implies that $b \leq 1 + O(\delta + \varepsilon)$. Similarly, the first inequality is valid if $a > 2\delta$ and $\varepsilon < 1/2$, and in this case, $a \geq 1 - O(\delta + \varepsilon)$. \square

Lemma 8.2. *For any δ -homomorphism v from a finite-dimensional C^* algebra \mathcal{B} to an ε - C^* algebra \mathcal{A} , there is an $O(\varepsilon)$ -homomorphism $\tilde{v}: \mathcal{B} \rightarrow \mathcal{A}$ such that $\|\tilde{v}(X) - v(X)\| \leq O(\delta)\|X\|$ for all $X \in \mathcal{B}$.*

The proof involves the concept of diagonal, which we now elaborate on. For arbitrary Banach algebras \mathcal{A} and \mathcal{B} , the projective tensor product $\mathcal{A} \hat{\otimes} \mathcal{B}$ is also a Banach algebra. In more detail, $\mathcal{A} \hat{\otimes} \mathcal{B}$ is the completion of $\mathcal{A} \otimes \mathcal{B}$ endowed with the projective tensor norm,

$$\|C\| = \inf \left\{ \sum_j \|A_j\| \|B_j\| : \sum_j A_j \otimes B_j = C \right\} \quad (A_j \in \mathcal{A}, B_j \in \mathcal{B}), \quad (8.1)$$

which has the property $\|C''C'''\| \leq \|C''\|\|C'''\|$. For arbitrary $\tilde{D} = \sum_j A_j \otimes B_j \in \mathcal{B} \otimes \mathcal{B}$ and $X \in \mathcal{B}$, we write

$$X\tilde{D} = \sum_j XA_j \otimes B_j, \quad \tilde{D}X = \sum_j A_j \otimes B_jX, \quad p(\tilde{D}) = \sum_j A_jB_j. \quad (8.2)$$

These operations extend from $\mathcal{B} \otimes \mathcal{B}$ to $\mathcal{B} \hat{\otimes} \mathcal{B}$. An element $D \in \mathcal{B} \hat{\otimes} \mathcal{B}$ is called a *diagonal* if

$$XD = DX \quad \text{for all } X \in \mathcal{B}, \quad p(D) = I. \quad (8.3)$$

(Johnson used a weaker concept of approximate diagonal [15, definition 1.1], which is better suited for the infinite-dimensional setting.) Every finite-dimensional C^* algebra has a diagonal, namely,

$D = \int dU (U^\dagger \otimes U)$, where the integral is taken with respect to the Haar measure on the unitary group. Note that $\|D\| = 1$ because the integral can be approximated by finite sums, i.e. convex combinations of $U^\dagger \otimes U$. Due to Caratheodory's theorem and the compactness of the unitary group, D itself is representable as a finite sum:

$$D = \sum_j A_j \otimes B_j, \quad \sum_j \|A_j\| \|B_j\| = 1. \quad (8.4)$$

For the algebra of operators acting on a d -dimensional Hilbert space, a representation of this form is given by generalized Pauli operators S_{jk} :

$$D = \sum_{j=0}^{d-1} \sum_{k=0}^{d-1} \frac{S_{jk}^\dagger}{d} \otimes \frac{S_{jk}}{d}, \quad \langle e_l, S_{jk} e_m \rangle = e^{2\pi i k m / d} \delta_{l, m+j \bmod d}, \quad (8.5)$$

where $\langle e_l, S_{jk} e_m \rangle$ are the matrix elements of S_{jk} in some orthonormal basis $\{e_0, \dots, e_{d-1}\}$. Since any finite-dimensional C^* algebra is isomorphic to a direct product of matrix algebras, the corresponding diagonal can be obtained as a product of generalized Pauli constructions.

Proof of Lemma 8.2. Let g be the *multiplicativity defect* of v :

$$g: \mathcal{B} \times \mathcal{B} \rightarrow \mathcal{A}, \quad g(X, Y) = v(XY) - v(X)v(Y). \quad (8.6)$$

By a simple calculation using the associativity of \mathcal{B} , the ε -associativity of \mathcal{A} , and the bound $\|v\| \leq \text{const}$ (which follows from Proposition 8.1), we obtain an approximate 2-cocycle equation:

$$\begin{aligned} & v(X)g(Y, Z) - g(XY, Z) + g(X, YZ) - g(X, Y)v(Z) \\ &= -v((XY)Z - X(YZ)) + (v(X)v(Y))v(Z) - v(X)(v(Y)v(Z)) \\ &= O(\varepsilon)\|X\|\|Y\|\|Z\|. \end{aligned} \quad (8.7)$$

Now, let $D \in \mathcal{B} \otimes \mathcal{B}$ be a diagonal of the form (8.4), and let us define a new linear map,

$$v_1: \mathcal{B} \rightarrow \mathcal{A}, \quad v_1(X) = v(X) + \sum_j v(A_j)g(B_j, X). \quad (8.8)$$

We compute its multiplicativity defect to linear order in g , estimating the quadratic term as $O(\delta^2)\|X\|\|Y\|$ and using the identity $\sum_j XA_j \otimes B_j = \sum_j A_j \otimes B_j X$, the cocycle equation, and the formula $\sum_j A_j B_j = I$, in this order:

$$\begin{aligned} g_1(X, Y) &= v_1(XY) - v_1(X)v_1(Y) \\ &= g(X, Y) + \sum_j \left(v(A_j)g(B_j, XY) - (v(A_j)g(B_j, X))v(Y) - v(X)(v(A_j)g(B_j, Y)) \right) \\ &\quad + O(\delta^2)\|X\|\|Y\| \\ &= g(X, Y) + \sum_j v(A_j) \left(g(B_j, XY) - g(B_j, X)v(Y) - g(B_j X, Y) \right) + O(\delta^2 + \varepsilon\delta)\|X\|\|Y\| \\ &= g(X, Y) - \sum_j v(A_j) \left(v(B_j)g(X, Y) \right) + O(\delta^2 + \varepsilon)\|X\|\|Y\| \\ &= O(\delta^2 + \varepsilon)\|X\|\|Y\|. \end{aligned} \quad (8.9)$$

(The equation $\sum_j \|A_j\| \|B_j\| = 1$ and the condition that v is a δ -homomorphism have been used multiple times.) Thus, v_1 is a δ_1 -homomorphism for $\delta_1 = O(\delta^2 + \varepsilon)$. It is also evident from equation (8.8) that $\|v_1 - v\| \leq O(\delta)$.

Iterating the procedure as in Newton's method, we obtain some v_s for $s = 1, 2, \dots$. If $\varepsilon > 0$, a suitable $\tilde{v} = v_s$ (with the corresponding δ_s bounded by $O(\varepsilon)$) is obtained after a finite number of steps. If $\varepsilon = 0$, then $\tilde{v} = \lim_{s \rightarrow \infty} v_s$ is a homomorphism of C^* algebras. (This is a special case of Theorem 3.1 from [10].) \square

We will use the following corollary of Lemma 8.2 and Proposition 8.1, where all constants are mentioned explicitly.

Corollary 8.3 (Error reduction). *There exist some positive constants ε_{\max} , δ_{\max} , and c_0 such that for all $\varepsilon < \varepsilon_{\max}$, if a finite-dimensional C^* algebra \mathcal{B} is δ_{\max} -included into an ε - C^* algebra \mathcal{A} , there is also a $c_0\varepsilon$ -inclusion. If the original inclusion is bijective, then so is the new inclusion.*

9 Proof of the main theorem

The proof of Theorem 2.3 involves finding nontrivial projections in algebras of the form \mathcal{S}_P defined at the beginning of Section 7. We also need some merging and extension lemmas.

Lemma 9.1. *Let Π_1, Π_2 be projections in a C^* algebra \mathcal{B} such that $\Pi_1 + \Pi_2 = I$, and similarly, let P_1, P_2 be δ -projections in an ε - C^* algebra \mathcal{A} such that $\|P_1 + P_2 - I\| \leq \delta$. Consider some linear maps $\gamma_{jk} : \mathcal{S}_{\Pi_j, \Pi_k} \rightarrow \mathcal{S}_{P_j, P_k}$ (for $j, k \in \{1, 2\}$) satisfying the following conditions:*

$$\|\gamma_{jj}(\Pi_j) - P_j\| \leq \delta, \quad (9.1)$$

$$\|\gamma_{jl}(XY) - \gamma_{jk}(X) \cdot \gamma_{kl}(Y)\| \leq \delta \|X\| \|Y\| \quad (X \in \mathcal{S}_{\Pi_j, \Pi_k}, Y \in \mathcal{S}_{\Pi_k, \Pi_l}), \quad (9.2)$$

$$(1 - \delta)\|X\| \leq \|\gamma_{jk}(X)\| \leq (1 + \delta)\|X\| \quad (X \in \mathcal{S}_{\Pi_j, \Pi_k}). \quad (9.3)$$

(The dot in (9.2) denotes the compressed product (7.4).) Then the combined map

$$\gamma : \begin{pmatrix} X_{11} & X_{12} \\ X_{21} & X_{22} \end{pmatrix} \mapsto \sum_{j,k} \gamma_{jk}(X_{jk}) : \mathcal{B} \rightarrow \mathcal{A} \quad (X_{jk} \in \mathcal{S}_{\Pi_j, \Pi_k}) \quad (9.4)$$

is an $O(\delta + \varepsilon)$ -inclusion. If all maps γ_{jk} are bijective, then γ is also bijective.

Proof. Let μ be the canonical bijection from \mathcal{B} to $\bigoplus_{j,k} \mathcal{S}_{\Pi_j, \Pi_k}$ equipped with the maximum norm. In this notation, $\gamma = \alpha(\sum_{j,k} \gamma_{jk})\mu$, where α is defined by equation (7.5). Equations (9.1)–(9.3) imply that γ is an $O(\delta)$ -homomorphism. It follows from equation (9.3) and Lemma 7.1 that $a\|X\| \leq \|\gamma(X)\| \leq b\|X\|$ for all $X \in \mathcal{B}$, where a and b are some positive constants. Thus, γ is an $O(\delta + \varepsilon)$ -inclusion due to Proposition 8.1. If all maps γ_{jk} are bijective, then the direct sum $\sum_{j,k} \gamma_{jk}$ is also bijective, and so is γ because both α and μ are linear bijections. \square

Corollary 9.2 (Merging). *Let \mathcal{B}_1 and \mathcal{B}_2 be C^* algebras, and let P_1, P_2 be δ -projections in an ε - C^* algebra \mathcal{A} such that $\|P_1 + P_2 - I\| \leq \delta$. Consider some δ -inclusions $v_j : \mathcal{B}_j \rightarrow \mathcal{S}_{P_j}$ (for $j = 1, 2$). Then the combined map*

$$v : (X_1, X_2) \mapsto v_1(X_1) + v_2(X_2) : \mathcal{B}_1 \oplus \mathcal{B}_2 \rightarrow \mathcal{A} \quad (9.5)$$

is an $O(\delta + \varepsilon)$ -inclusion. If v_1, v_2 are bijective and $\mathcal{S}_{P_1, P_2} = 0$, then v is also bijective.

The second application of Lemma 9.1 involves an auxiliary statement about δ -projections $P_1, \dots, P_p, Q_1, \dots, Q_q$ satisfying certain conditions, which will be formulated in terms of inclusions of finite-dimensional commutative C^* algebras. Such an algebra \mathcal{B} is described by a *projection basis* $\{\Pi_1, \dots, \Pi_n\} \subseteq \mathcal{B}$ such that $\Pi_j^\dagger = \Pi_j$, $\Pi_j \Pi_k = \delta_{jk} \Pi_k$, and $\sum_{j=1}^n \Pi_j = I$.

Lemma 9.3. *Let \mathcal{B} and \mathcal{C} be commutative C^* algebras with projection bases $\{\Pi_1, \dots, \Pi_p\} \subseteq \mathcal{B}$ and $\{\Sigma_1, \dots, \Sigma_p\} \subseteq \mathcal{C}$, respectively. Consider non-unital δ -inclusions $v: \mathcal{B} \rightarrow \mathcal{A}$ and $w: \mathcal{C} \rightarrow \mathcal{A}$, where \mathcal{A} is an ε - C^* algebra. Let $P_j = v(\Pi_j)$, $Q_k = w(\Sigma_k)$, and also $P = v(I_{\mathcal{B}})$, $Q = w(I_{\mathcal{C}})$. Then there is a bounded linear bijection between $\mathcal{S}_{P,Q}$ and $\bigoplus_{j,k} \mathcal{S}_{P_j, Q_k}$; in particular, $\dim \mathcal{S}_{P,Q} = \sum_{j,k} \dim \mathcal{S}_{P_j, Q_k}$.*

Proof. The non-unital δ -inclusion condition implies that P_j and P_k , as well as $P_{[1,j]} = \sum_{r=1}^j P_r$ and $Q_{[1,k]} = \sum_{s=1}^k Q_s$, are δ -projections. Furthermore, $\|P_{[1,j-1]} P_j\| \leq \delta$ and $\|Q_{[1,k-1]} Q_k\| \leq \delta$. By Lemma 7.1, there is a bounded linear bijection between $\mathcal{S}_{P_j, Q_{[1,k]}}$ and $\mathcal{S}_{P_j, Q_{[1,k-1]}} \oplus \mathcal{S}_{P_j, Q_k}$ for each k . The composition of these bijections yields a bijection between $\mathcal{S}_{P_j, Q}$ and $\bigoplus_k \mathcal{S}_{P_j, Q_k}$. Similarly, a bijection exists between $\mathcal{S}_{P_{[1,j]}, Q}$ and $\mathcal{S}_{P_{[1,j-1]}, Q} \oplus \mathcal{S}_{P_j, Q}$ for each j , and thus, between $\mathcal{S}_{P,Q}$ and $\bigoplus_j \mathcal{S}_{P_j, Q}$. This immediately implies the required statement. \square

Let us denote the C^* algebra of bounded operators acting on a Hilbert space \mathcal{L} by $\mathbf{B}(\mathcal{L})$. An important special case is the matrix algebra $\mathbf{M}_n = \mathbf{B}(\mathbb{C}^n)$. We consider higher-dimensional spaces as extensions of lower-dimensional spaces, i.e. $\mathbb{C}^1 \subset \mathbb{C}^2 \subset \dots$. Thus, $\mathbf{M}_1 \subset \mathbf{M}_2 \subset \dots$. The algebra \mathbf{M}_n has a standard basis $\{E_{jk} : j, k = 1, \dots, n\}$ with the relations

$$E_{jk} E_{lm} = \delta_{kl} E_{jm}, \quad E_{jk}^\dagger = E_{kj}, \quad I = \sum_j E_{jj}. \quad (9.6)$$

It contains an n -dimensional commutative subalgebra, which consists of diagonal matrices and has a projection basis $\{E_{jj} : j = 1, \dots, n\}$.

Lemma 9.4 (Extension). *Let \mathcal{A} be an ε - C^* algebra, and let $P, Q \in \mathcal{A}$ be δ -projections such that $\|P + Q - I\| \leq \delta$. Suppose that $v: \mathbf{M}_n \rightarrow \mathcal{S}_P$ is a δ -isomorphism, $\dim \mathcal{S}_Q = 1$, and $\mathcal{S}_{P,Q} \neq 0$. Then v can be extended to an $O(\delta + \varepsilon)$ -isomorphism $v_+: \mathbf{M}_{n+1} \rightarrow \mathcal{A}$.*

Proof. First, we consider the four subspaces associated with P and Q . The subspace \mathcal{S}_P is an $O(\delta + \varepsilon)$ - C^* algebra with unit $\tilde{P} = C_P(P)$ and multiplication $A \cdot B = C_P(AB)$, which are $O(\delta + \varepsilon)$ close to P and the ambient multiplication in \mathcal{A} , respectively. (Thus, the composition of the δ -isomorphism $v: \mathbf{M}_n \rightarrow \mathcal{S}_P$ with the standard inclusion of \mathcal{S}_P into \mathcal{A} is a non-unital $O(\delta + \varepsilon)$ -inclusion.) By Lemma 7.2, $\mathcal{S}_{P,Q}$ is a Hilbert space. Let us determine its dimensionality. Since $v: \mathbf{M}_n \rightarrow \mathcal{S}_P$ is a δ -isomorphism, the elements $P_j = v(E_{jj})$ are one-dimensional δ -projections in \mathcal{S}_P , which are equivalent to each other. Hence, P_1, \dots, P_n are equivalent one-dimensional $O(\delta + \varepsilon)$ -projections in \mathcal{A} , implying that either $\dim \mathcal{S}_{P_j, Q} = 0$ for all j or $\dim \mathcal{S}_{P_j, Q} = 1$ for all j . Using Lemma 9.3, we conclude that $\dim \mathcal{S}_{P,Q}$ is either 0 or n . The first possibility contradicts the hypothesis of the Lemma; thus, $\dim \mathcal{S}_{P,Q} = n$. The Hilbert space $\mathcal{S}_{Q,P}$ is dual to $\mathcal{S}_{P,Q}$. Finally, \mathcal{S}_Q may be identified with the set of complex numbers such that $1 \in \mathbb{C}$ corresponds to $\tilde{Q} = C_Q(Q)$.

The construction of v_+ involves the algebra $\mathbf{B}(\mathcal{S}_{P,Q})$, and thus, the Euclidean norm $\|Y\|_E = \sqrt{\langle Y, Y \rangle}$ for $Y \in \mathcal{S}_{P,Q}$. By equation (7.8), $\|Y\|_E$ is equal to $\|Y\|$ up to a $1 \pm O(\varepsilon + \delta)$ factor. The left action of \mathcal{S}_P on $\mathcal{S}_{P,Q}$,

$$(X, Y) \mapsto X \cdot Y : \mathcal{S}_P \times \mathcal{S}_{P,Q} \rightarrow \mathcal{S}_{P,Q}, \quad X \cdot Y = C_{P,Q}(XY), \quad (9.7)$$

defines an $O(\delta + \varepsilon)$ -homomorphism $w: \mathcal{S}_P \rightarrow \mathbf{B}(\mathcal{S}_{P,Q})$. The composition $wv: \mathbf{M}_n \rightarrow \mathbf{B}(\mathcal{S}_{P,Q})$ is an $O(\delta + \varepsilon)$ -homomorphism of C^* algebras. By Lemma 8.2, it can be approximated by an actual homomorphism $\mu: \mathbf{M}_n \rightarrow \mathbf{B}(\mathcal{S}_{P,Q})$ with $O(\delta + \varepsilon)$ accuracy, which means that⁶

$$\|\mu(A)Y - v(A) \cdot Y\|_{\mathbf{E}} \leq O(\delta + \varepsilon)\|A\|\|Y\|_{\mathbf{E}} \quad (A \in \mathbf{M}_n, Y \in \mathcal{S}_{P,Q}). \quad (9.8)$$

Since \mathbf{M}_n has no nontrivial ideals, μ is injective. It is actually an isomorphism because both $\mathbf{M}_n = \mathbf{B}(\mathbb{C}^n)$ and $\mathbf{B}(\mathcal{S}_{P,Q})$ are n^2 -dimensional. It follows that μ is induced by some unitary transformation $U: \mathbb{C}^n \rightarrow \mathcal{S}_{P,Q}$, that is, $\mu(A) = UAU^\dagger$ for all $A \in \mathbf{M}_n$. We are now ready to define the required extension $v_+: \mathbf{M}_{n+1} \rightarrow \mathcal{A}$:

$$v_+: \begin{pmatrix} A & \xi \\ \eta & c \end{pmatrix} \mapsto v(A) + U\xi + \eta U^\dagger + c\tilde{Q} \quad (A \in \mathbf{M}_n, \xi \in \mathbb{C}^n, \eta \in (\mathbb{C}^n)^*, c \in \mathbb{C}). \quad (9.9)$$

Elements of \mathbf{M}_n , \mathbb{C}^n , $(\mathbb{C}^n)^*$, \mathbb{C} may be referred to as matrices, vectors (columns), covectors (rows), and numbers, respectively.

The last part of the proof is concerned with the application of Lemma 9.1. In the present case,

$$\mathcal{B} = \mathbf{M}_{n+1}, \quad \Pi_1 = \sum_{j=1}^{n-1} E_{jj}, \quad \Pi_2 = E_{nn}, \quad P_1 = P, \quad P_2 = Q,$$

and $\gamma = v_+$ is built of

$$\gamma_{11} = v, \quad \gamma_{12}: \xi \mapsto U\xi, \quad \gamma_{21}: \eta \mapsto \eta U^\dagger, \quad \gamma_{22}: c \mapsto c\tilde{Q}.$$

We need to check conditions (9.1)–(9.3), where δ may be replaced with a suitable $\delta' = O(\delta + \varepsilon)$. The first condition is obvious. Checking (9.3) takes a bit of care but is also easy. In particular, the norm of the element $\gamma_{12}(\xi) = U\xi \in \mathcal{S}_{P,Q} \subseteq \mathcal{A}$ should be compared with $\|\xi\|$. These numbers are almost equal because the latter is equal to the Euclidean norm of $U\xi$, and the Euclidean norm and the \mathcal{A} norm are close to each other. Condition (9.2) involves 8 cases. The $j = k = l = 1$ case (pertaining to matrix-matrix multiplication) is

$$\|v(AB) - v(A) \cdot v(B)\| \leq \delta' \|A\| \|B\| \quad (A, B \in \mathbf{M}_n),$$

This estimate is one of the δ' -homomorphism axioms, and so it is true. The matrix-vector case,

$$\|UA\xi - v(A) \cdot (U\xi)\| \leq \delta' \|A\| \|\xi\| \quad (A \in \mathbf{M}_n, \xi \in \mathcal{S}_{P,Q}),$$

follows from (9.8), where $\mu(A) = UAU^\dagger$ and $Y = U\xi$. The covector-matrix case is dual to that, and the covector-vector multiplication is just the inner product on the Hilbert space $\mathcal{S}_{P,Q}$. The vector-number, number-number, and number-covector cases are trivial. Thus, it remains to consider the vector-covector product and prove the inequality

$$\|v(\xi\eta) - (U\xi) \cdot (\eta U^\dagger)\| \leq \delta' \|\xi\| \|\eta\| \quad (\xi \in \mathcal{S}_{P,Q}, \eta \in \mathcal{S}_{Q,P}). \quad (9.10)$$

To this end, we will use the left action $w(X)$ of $X = v(\xi\eta) - (U\xi) \cdot (\eta U^\dagger) \in \mathcal{S}_P$ on $\mathcal{S}_{P,Q}$. The homomorphism $w: \mathcal{S}_P \rightarrow \mathbf{B}(\mathcal{S}_{P,Q})$ (defined by the left action (9.7) of all elements of \mathcal{S}_P) is,

⁶This and subsequent equations involve two multiplications: the compressed product denoted by a dot and the product of maps of Hilbert spaces, e.g. $\mu(A)Y$. As is usual, Hilbert space elements such as $Y \in \mathcal{S}_{P,Q}$ may be treated as maps from \mathbb{R} to that space. In this notation, $\langle Z, Y \rangle = Z^\dagger Y$.

actually, an $O(\delta + \varepsilon)$ -isomorphism. Indeed, wv is $O(\delta + \varepsilon)$ -close to the isomorphism μ , and v is a δ -isomorphism by the hypothesis of the lemma. Thus, the norm of X is equal, up to a $1 \pm O(\delta + \varepsilon)$ factor, to $\|w(X)\| = \sup\{\|X \cdot Y\|_{\mathcal{E}}/\|Y\|_{\mathcal{E}} : Y \in \mathcal{S}_{P,Q}, Y \neq 0\}$, where $\|Y\|_{\mathcal{E}}$ is equal to $\|Y\|$ up to the same factor. We now estimate $X \cdot Y$ with $O(\delta + \varepsilon)\|\xi\|\|\eta\|\|Y\|$ accuracy using equation (9.8):

$$\begin{aligned} (v(\xi\eta) - (U\xi) \cdot (\eta U^\dagger)) \cdot Y &\approx \mu(\xi\eta)Y - (U\xi) \cdot ((\eta U^\dagger) \cdot Y) \\ &\approx (U\xi\eta U^\dagger)Y - (U\xi) \cdot (\langle (\eta U^\dagger)^\dagger, Y \rangle \tilde{Q}) \\ &\approx (U\xi - (U\xi) \cdot \tilde{Q})(\eta U^\dagger Y) \approx 0. \end{aligned}$$

Thus, $\|(v(\xi\eta) - (U\xi) \cdot (\eta U^\dagger)) \cdot Y\| \leq O(\delta + \varepsilon)\|\xi\|\|\eta\|\|Y\|$ for all $Y \in \mathcal{S}_{P,Q}$, which implies (9.10). \square

Proof of Theorem 2.3. Let c_0 be the constant from Corollary 8.3. We will construct a $c_0\varepsilon$ -isomorphism v from some C^* algebra \mathcal{B} to the ε - C^* algebra \mathcal{A} in three stages. The first stage yields a $c_0\varepsilon$ -inclusion $v_{\text{comm}}: \mathcal{B}_{\text{comm}} \rightarrow \mathcal{A}$, where $\mathcal{B}_{\text{comm}}$ is a commutative C^* algebra. The second stage involves the parallel construction of $c_0\varepsilon'$ -isomorphisms from some matrix algebras to approximate direct summands of \mathcal{A} . At the third stage, those algebras and isomorphisms are merged.

Stage 1: Let $v_{\text{comm}}: \mathcal{B}_{\text{comm}} \rightarrow \mathcal{A}$ be a $c_0\varepsilon$ -inclusion of a commutative C^* algebra of maximum dimensionality into \mathcal{A} . Then \mathcal{B} has a projections basis $\{\Pi_1, \dots, \Pi_m\}$. It is evident that each $P_j = v_{\text{comm}}(\Pi_j)$ is an $O(\varepsilon)$ -projection. We now show that these projections are one-dimensional.

Let us suppose the opposite. Without loss of generality, we may assume that the last projection fails to be one-dimensional, i.e. $\dim \mathcal{S}_{P_m} > 1$. Recall that, \mathcal{S}_{P_m} is an $O(\varepsilon)$ - C^* algebra with unit $\tilde{P}_m = C_{P_m}(P_m)$. By Lemma 6.1, there exists an $O(\varepsilon)$ -projection $P' \in \mathcal{S}_{P_m}$ such that both P' and $P'' = \tilde{P}_m - P'$ are nonvanishing, i.e. sufficiently far from 0. Note that $P' + P'' = \tilde{P}_m$ is $O(\varepsilon)$ -close to P_m . Let $\mathcal{B}_{\text{comm}}^{(1)}$ and $\mathcal{B}_{\text{comm}}^{(2)}$ be the commutative C^* algebras with projection bases $\{\Pi_1, \dots, \Pi_{m-1}\}$ and $\{\Pi', \Pi''\}$, and let $P_{[1, m-1]} = \sum_{j=1}^{m-1} P_j$. We now $O(\varepsilon)$ -include $\mathcal{B}_{\text{comm}}^{(1)}$ and $\mathcal{B}_{\text{comm}}^{(2)}$ into $\mathcal{S}_{P_{[1, m-1]}}$ and \mathcal{S}_{P_m} , respectively:

$$\begin{aligned} v_{\text{comm}}^{(1)}(\Pi_j) &= C_{P_{[1, m-1]}}(P_j) \in \mathcal{S}_{P_{[1, m-1]}} \quad \text{for } j = 1, \dots, m-1, \\ v_{\text{comm}}^{(2)}(\Pi') &= P' \in \mathcal{S}_{P_m}, \quad v_{\text{comm}}^{(2)}(\Pi'') = P'' \in \mathcal{S}_{P_m}. \end{aligned}$$

Merging $v_{\text{comm}}^{(1)}$ and $v_{\text{comm}}^{(2)}$ using Corollary 9.2, we obtain an $O(\varepsilon)$ -inclusion $v_{\text{comm}}^+: \mathcal{B}_{\text{comm}}^+ \rightarrow \mathcal{A}$, where $\mathcal{B}_{\text{comm}}^+ = \mathcal{B}_{\text{comm}}^{(1)} \oplus \mathcal{B}_{\text{comm}}^{(2)}$. Due to Corollary 8.3, there also exists a $c_0\varepsilon$ -inclusion of $\mathcal{B}_{\text{comm}}^+$ into \mathcal{A} . But this contradicts the maximum dimensionality assumption.

Setup for stages 2 and 3: Because v_{comm} is a $c_0\varepsilon$ -inclusion, the sum of $P_j = v_{\text{comm}}(\Pi_j)$ over an arbitrary subset of $\{1, \dots, m\}$ is a $c_0\varepsilon$ -projection. Let $\varepsilon' = O(\varepsilon)$ denote a suitable upper bound such that $\varepsilon' \geq c_0\varepsilon$, and moreover, \mathcal{S}_P for any $c_0\varepsilon$ -projection P is an ε' - C^* algebra. The indices j of the one-dimensional projections P_j are subdivided into equivalence classes such that $\dim \mathcal{S}_{P_j, P_k}$ is 1 if j and k are in the same class and 0 otherwise. Associated with each equivalence class C are the $c_0\varepsilon$ -projection $P_C = \sum_{j \in C} P_j$ and the ε' - C^* algebra \mathcal{S}_{P_C} .

Stage 2: Each equivalence class C is considered separately. Without loss of generality, we may assume that $C = \{1, \dots, s\}$. Let

$$\Pi_{[1, r]} = \sum_{j=1}^r \Pi_j, \quad P_{[1, r]} = \sum_{j=1}^r P_j, \quad \mathcal{A}_r = \mathcal{S}_{P_{[1, r]}} \quad (r = 1, \dots, s).$$

Note that $P_{[1,r]}$ is a $c_0\varepsilon$ -projection, \mathcal{A}_r is an ε' - C^* algebra, and $\mathcal{A}_s = \mathcal{S}_{P_C}$. We construct $c_0\varepsilon'$ -isomorphisms $v_r: \mathbf{M}_r \rightarrow \mathcal{A}_r$ for $r = 1, \dots, s$ inductively. To obtain v_r from v_{r-1} , we first fit v_{r-1} , $P_{[1,r-1]}$, and P_r into \mathcal{A}_r by applying the compression map $C_{P_{[1,r]}}$:

$$v'_{r-1}: X \mapsto C_{P_{[1,r]}}(v(X)), \quad P'_{[1,r-1]} = C_{P_{[1,r]}}(P_{[1,r-1]}), \quad P'_r = C_{P_{[1,r]}}(P_r).$$

Then we extend the $O(\varepsilon)$ -isomorphism $v'_{r-1}: \mathbf{M}_{r-1} \rightarrow \mathcal{A}'_{r-1}$ to an $O(\varepsilon)$ -isomorphism $v_{r-1}^+: \mathbf{M}_r \rightarrow \mathcal{A}_r$ using Lemma 9.4. Finally, we use Corollary 8.3 to replace v_{r-1}^+ with a $c_0\varepsilon'$ -isomorphism v_r .

Stage 3. At this point, we have constructed $c_0\varepsilon'$ -isomorphisms $v_C: \mathbf{M}_{|C|} \rightarrow \mathcal{S}_{P_C}$ for all equivalence classes C . Note that by Lemma 9.3, $\mathcal{S}_{P_C, P_D} = 0$ if the classes C and D are distinct. This allows us to successively merge the isomorphisms v_C for different C . Each step includes the application of Corollary 9.2 followed by the use of Corollary 8.3 to reduce the errors. \square

10 Details on unital completely positive maps

Here we derive the properties of idempotent and almost idempotent UCP maps that were mentioned in Section 1.2 without proofs. Our main focus is on the finite-dimensional case. Some results can be extended to infinite dimensions with a bit of work, but we discuss such generalizations separately so as not to complicate the basic arguments.

10.1 The Choi and Stinespring representations

If \mathcal{K} and \mathcal{H} are finite-dimensional Hilbert spaces, then any UCP map $\Phi: \mathbf{B}(\mathcal{K}) \rightarrow \mathbf{B}(\mathcal{H})$ admits a *Choi representation*

$$\Phi(X) = V^\dagger(X \otimes 1_{\mathcal{F}})V, \quad V^\dagger V = 1_{\mathcal{H}}, \quad \text{where } V: \mathcal{H} \rightarrow \mathcal{K} \otimes \mathcal{F}. \quad (10.1)$$

It can be constructed canonically using the auxiliary space $\mathcal{F} = (\mathcal{K})^* \otimes \mathcal{H}$. (Choi's original construction [16] was formulated in terms of matrices, but it does have the form $V^\dagger(X \otimes 1_{\mathcal{F}})V$.) Equation (10.1) can also be represented graphically, using the vertical dimension for the tensor product:

$$\Phi(X) = \text{---} \bullet \text{---} \textcircled{X} \text{---} \bullet \text{---}, \quad \text{---} \bullet \text{---} \bullet \text{---} = \text{---}, \quad \text{where } \begin{array}{c} \mathcal{F} \\ \curvearrowright \\ \kappa \text{---} \bullet \end{array} \text{---} \mathcal{H} = V. \quad (10.2)$$

In infinite dimensions, even special UCP maps $\mathbf{B}(\mathcal{K}) \rightarrow \mathbb{C}$, i.e. states on $\mathbf{B}(\mathcal{K})$, are not necessarily representable in that way. For example, a state may vanish on all compact operators, which precludes its representation by a unit vector $V \in \mathcal{K} \hat{\otimes} \mathcal{F}$. That said, any state can be represented by a unit vector in some Hilbert space via the Gelfand-Naimark-Segal (GNS) construction.

Let \mathcal{A} be a C^* algebra, I its unit, \mathcal{H} a Hilbert space, and $\Phi: \mathcal{A} \rightarrow \mathbf{B}(\mathcal{H})$ a UCP map. A *Stinespring representation* of Φ has the general form

$$\Phi(X) = V^\dagger u(X) V, \quad (10.3)$$

where $u: \mathcal{A} \rightarrow \mathbf{B}(\mathcal{G})$ is a $*$ -homomorphism and $V: \mathcal{H} \rightarrow \mathcal{G}$ is an isometry. The *canonical Stinespring representation* [17], [7, Theorem 4.1] is a generalization of the GNS construction. It uses

the space $\tilde{\mathcal{G}} = \mathcal{A} \otimes \mathcal{H}$ with the possibly degenerate inner product

$$\langle B \otimes \eta, A \otimes \xi \rangle = \eta^\dagger \Phi(B^\dagger A) \xi \quad (A, B \in \mathcal{A}, \quad \xi, \eta \in \mathcal{H}). \quad (10.4)$$

The space \mathcal{G} is the completion of the quotient of $\tilde{\mathcal{G}}$ by the null subspace, and u and V are defined as follows:

$$u(C)(A \otimes \xi) = CA \otimes \xi, \quad V\xi = I \otimes \xi. \quad (10.5)$$

Proposition 10.1. *Let $J: \mathcal{L} \rightarrow \mathcal{K}$ be an isometry, $w: \mathbf{B}(\mathcal{L}) \rightarrow \mathbf{B}(\mathcal{H})$ a $*$ -homomorphism, and let (\mathcal{G}, u, V) be the canonical Stinespring representation of the UCP map $\Phi: X \mapsto w(J^\dagger X J)$. Then the following diagrams commute:*

$$\begin{array}{ccc} \mathbf{B}(\mathcal{K}) & \xrightarrow{u} & \mathbf{B}(\mathcal{G}) \\ \downarrow X \mapsto J^\dagger X J & \searrow \Phi & \downarrow X \mapsto V^\dagger X V \\ \mathbf{B}(\mathcal{L}) & \xrightarrow{w} & \mathbf{B}(\mathcal{H}) \end{array} \quad \begin{array}{ccc} \mathbf{B}(\mathcal{K}) & \xrightarrow{u} & \mathbf{B}(\mathcal{G}) \\ \uparrow Y \mapsto JYJ^\dagger & & \uparrow Y \mapsto VYV^\dagger \\ \mathbf{B}(\mathcal{L}) & \xrightarrow{w} & \mathbf{B}(\mathcal{H}) \end{array} \quad (10.6)$$

The commutativity of the first diagram follows immediately from the hypothesis and the general form (10.3) of a Stinespring representation. The second diagram, specific to the canonical Stinespring representation, is not necessary to achieve our goals but offers some convenience.

Proof. The commutativity of the second diagram means that these maps are equal:

$$s', s'': \mathbf{B}(\mathcal{L}) \rightarrow \mathbf{B}(\mathcal{G}), \quad s'(Y) = u(JYJ^\dagger), \quad s''(Y) = Vw(Y)V^\dagger. \quad (10.7)$$

To prove that $s' = s''$, it is sufficient to show that

$$\langle B \otimes \eta, u(JYJ^\dagger)(A \otimes \xi) \rangle = \langle B \otimes \eta, Vw(Y)V^\dagger(A \otimes \xi) \rangle$$

for all $A, B \in \mathbf{B}(\mathcal{K})$, $\xi, \eta \in \mathcal{H}$, and $Y \in \mathbf{B}(\mathcal{L})$. The expression with $u(JYJ^\dagger)$ is easy to evaluate:

$$\begin{aligned} \langle B \otimes \eta, u(JYJ^\dagger)(A \otimes \xi) \rangle &= \eta^\dagger \Phi(B^\dagger JYJ^\dagger A) \xi = \eta^\dagger w(J^\dagger B^\dagger JYJ^\dagger AJ) \xi \\ &= \eta^\dagger w(J^\dagger B^\dagger J) w(Y) w(J^\dagger AJ) \xi = \eta^\dagger \Phi(B^\dagger) w(Y) \Phi(A) \xi. \end{aligned} \quad (10.8)$$

To evaluate $\langle B \otimes \eta, VZV^\dagger(A \otimes \xi) \rangle$ for an arbitrary $Z \in \mathbf{B}(\mathcal{H})$, we represent Z as the limit of some net (Z_α) in the weak operator topology such that each Z_α has finite rank. For a rank 1 operator, $Z = \mu\nu^\dagger$, the calculation is straightforward:

$$\langle B \otimes \eta, V\mu\nu^\dagger V^\dagger(A \otimes \xi) \rangle = \langle B \otimes \eta, I \otimes \mu \rangle \langle I \otimes \nu, A \otimes \xi \rangle = \eta^\dagger \Phi(B^\dagger) \mu \nu^\dagger \Phi(A) \xi.$$

Extending to finite rank operators by linearity and to arbitrary $Z \in \mathbf{B}(\mathcal{H})$ using the limit, we get

$$\langle B \otimes \eta, VZV^\dagger(A \otimes \xi) \rangle = \eta^\dagger \Phi(B^\dagger) Z \Phi(A) \xi. \quad (10.9)$$

It remains to substitute $w(Y)$ for Z and see that the right-hand sides of (10.8) and (10.9) are equal. \square

10.2 Some other properties of UCP maps

The following inequality holds for any UCP map $\Phi: \mathcal{A} \rightarrow \mathcal{B}$ between C^* algebras:

$$\Phi(X^\dagger) \Phi(X) \leq \Phi(X^\dagger X). \quad (10.10)$$

(It means that the right-hand side minus the left-hand side is a positive element of \mathcal{B} .) Indeed, consider the matrix

$$Z = \begin{pmatrix} X^\dagger X & X^\dagger \\ X & I_{\mathcal{A}} \end{pmatrix} = \begin{pmatrix} X^\dagger \\ I_{\mathcal{A}} \end{pmatrix} \begin{pmatrix} X & I_{\mathcal{A}} \end{pmatrix} \geq 0,$$

which may be regarded as an element of $\mathbf{M}_2 \otimes \mathcal{A}$. (Recall that $\mathbf{M}_n = \mathbf{B}(\mathbb{C}^n)$ denotes the algebra of matrices with complex entries.) Since Φ is completely positive, we have $(1_{\mathbf{M}_2} \otimes \Phi)(Z) \geq 0$, and hence,

$$\begin{aligned} 0 &\leq \begin{pmatrix} -I_{\mathcal{B}} & \Phi(X^\dagger) \end{pmatrix} (1_{\mathbf{M}_2} \otimes \Phi)(Z) \begin{pmatrix} -I_{\mathcal{B}} \\ \Phi(X) \end{pmatrix} = \begin{pmatrix} -I_{\mathcal{B}} & \Phi(X^\dagger) \end{pmatrix} \begin{pmatrix} \Phi(X^\dagger X) & \Phi(X^\dagger) \\ \Phi(X) & \Phi(I_{\mathcal{A}}) \end{pmatrix} \begin{pmatrix} -I_{\mathcal{B}} \\ \Phi(X) \end{pmatrix} \\ &= \Phi(X^\dagger X) - \Phi(X^\dagger) \Phi(X). \end{aligned}$$

Equation (10.10) (together with the positivity of Φ) implies that $\|\Phi(X)\| \leq \|X\|$. Of course, this argument is also applicable to $1_{\mathbf{M}_n} \otimes \Phi$; therefore

$$\|\Phi\|_{\text{cb}} \leq 1. \quad (10.11)$$

Let \mathcal{K} and \mathcal{H} be finite-dimensional Hilbert spaces, and $\Phi: \mathbf{B}(\mathcal{K}) \rightarrow \mathbf{B}(\mathcal{H})$ a UCP map. The *carrier* of Φ is the support of $\Phi^*(\rho_0)$, where ρ_0 is an arbitrary full-rank density matrix on \mathcal{H} .

Lemma 10.2. *The carrier of a UCP map $\Phi: \mathbf{B}(\mathcal{K}) \rightarrow \mathbf{B}(\mathcal{H})$ with the Choi representation (\mathcal{F}, V) is the smallest subspace $\mathcal{M} \subseteq \mathcal{K}$ such that $\mathcal{M} \otimes \mathcal{F}$ contains the image of V . In other words, an arbitrary subspace $\mathcal{M}' \subseteq \mathcal{K}$ contains the carrier if and only if $\mathcal{M}' \otimes \mathcal{F} \supseteq \text{Im } V$.*

Proof. Let $\mathcal{M}' \subseteq \mathcal{K}$, and let us denote the orthogonal projection onto \mathcal{M}' by $\Pi_{\mathcal{M}'}$. The subspace \mathcal{M}' contains the carrier, i.e. the support of $\rho_1 = \Phi^*(\rho_0)$, if and only if $\text{Tr}((1 - \Pi_{\mathcal{M}'})\rho_1) = 0$. Since $\text{Tr}((1 - \Pi_{\mathcal{M}'})\Phi^*(\rho_0)) = \text{Tr}(\Phi(1 - \Pi_{\mathcal{M}'})\rho_0)$, the density matrix ρ_0 has full rank, and $\Phi(1 - \Pi_{\mathcal{M}'})) \geq 0$, the vanishing of the trace is equivalent to the vanishing of the whole operator $\Phi(1 - \Pi_{\mathcal{M}'})$. The latter is equal to $Z^\dagger Z$ for $Z = ((1 - \Pi_{\mathcal{M}'}) \otimes 1_{\mathcal{F}})V$. Thus, \mathcal{M}' contains the carrier if and only if $Z = 0$, which is the same as $\mathcal{M}' \otimes \mathcal{F} \supseteq \text{Im } V$. \square

Corollary 10.3. *Let \mathcal{M} be the carrier of a UCP map $\Phi: \mathbf{B}(\mathcal{K}) \rightarrow \mathbf{B}(\mathcal{H})$ with the Choi representation (\mathcal{F}, V) . Then an operator $X \in \mathbf{B}(\mathcal{K})$ annihilates all vectors in \mathcal{M} if and only if $(X \otimes 1_{\mathcal{F}})V = 0$.*

Proof. The two conditions in question can be written as $\text{Ker } X \supseteq \mathcal{M}$ and $(\text{Ker } X) \otimes \mathcal{F} \supseteq \text{Im } V$, respectively. By Lemma 10.2, these conditions are equivalent. \square

For another corollary, Φ is determined by its action on operators on its carrier via the equation

$$\Phi(X) = \Phi(\Pi_{\mathcal{M}} X \Pi_{\mathcal{M}}) \quad (X \in \mathbf{B}(\mathcal{K})). \quad (10.12)$$

Indeed, $\Phi(X) = V^\dagger (X \otimes 1_{\mathcal{F}}) V = V^\dagger (\Pi_{\mathcal{M}} \otimes 1_{\mathcal{F}}) (X \otimes 1_{\mathcal{F}}) (\Pi_{\mathcal{M}} \otimes 1_{\mathcal{F}}) V = \Phi(\Pi_{\mathcal{M}} X \Pi_{\mathcal{M}})$.

10.3 The structure of finite-dimensional idempotent UCP maps

Let \mathcal{H} be a finite-dimensional Hilbert space and $\Phi: \mathbf{B}(\mathcal{H}) \rightarrow \mathbf{B}(\mathcal{H})$ an idempotent UCP map. The equation $\Phi^2(X) = \Phi(X)$ can be expressed diagrammatically by analogy with (10.2):

$$\text{---} \bullet \text{---} \overset{\text{---}}{\text{---}} \bullet \text{---} \textcircled{X} \text{---} \bullet \text{---} \bullet \text{---} = \text{---} \bullet \text{---} \textcircled{X} \text{---} \bullet \text{---} . \quad (10.13)$$

The next equation follows from the previous one:

$$\text{---} \bullet \text{---} \textcircled{X} \text{---} \bullet \text{---} \overset{\text{---}}{\text{---}} \bullet \text{---} \bullet \text{---} = \text{---} \bullet \text{---} \bullet \text{---} \textcircled{X} \text{---} \bullet \text{---} \bullet \text{---} . \quad (10.14)$$

Indeed, let Z be the difference between the left-hand side and the right-hand side. Then

$$\begin{aligned} Z^\dagger Z = & \text{---} \bullet \text{---} \bullet \text{---} \textcircled{X^\dagger} \text{---} \bullet \text{---} \textcircled{X} \text{---} \bullet \text{---} \bullet \text{---} - \text{---} \bullet \text{---} \bullet \text{---} \textcircled{X^\dagger} \text{---} \bullet \text{---} \textcircled{X} \text{---} \bullet \text{---} \bullet \text{---} \\ & - \text{---} \bullet \text{---} \textcircled{X^\dagger} \text{---} \bullet \text{---} \textcircled{X} \text{---} \bullet \text{---} \bullet \text{---} + \text{---} \bullet \text{---} \textcircled{X^\dagger} \text{---} \bullet \text{---} \bullet \text{---} \textcircled{X} \text{---} \bullet \text{---} \bullet \text{---} \end{aligned}$$

is zero because all four terms (without the signs) are equal to $\Phi(\Phi(X^\dagger)\Phi(X))$.

Lemma 10.4. *Let \mathcal{H} be a finite-dimensional Hilbert space and $\Phi: \mathbf{B}(\mathcal{H}) \rightarrow \mathbf{B}(\mathcal{H})$ an idempotent UCP map with the image $\mathcal{A} \subseteq \mathbf{B}(\mathcal{H})$ and carrier $\mathcal{M} \subseteq \mathcal{H}$. Then operators in \mathcal{A} do not mix \mathcal{M} and \mathcal{M}^\perp . Furthermore, the Choi-Effros product $\Phi(XY)$ restricted to \mathcal{M} coincides with the usual operator product:*

$$\Phi(XY)|_{\mathcal{M}} = (XY)|_{\mathcal{M}} = X|_{\mathcal{M}}Y|_{\mathcal{M}} \quad (X, Y \in \mathcal{A}), \quad (10.15)$$

where $X|_{\mathcal{M}} = J_{\mathcal{M}}^\dagger X J_{\mathcal{M}}$ and $J_{\mathcal{M}}: \mathcal{M} \rightarrow \mathcal{H}$ is the inclusion of Hilbert spaces.

Proof. The statement that operators in \mathcal{A} do not mix \mathcal{M} and \mathcal{M}^\perp means that for any $X \in \mathcal{A}$, we have $(1 - \Pi_{\mathcal{M}})X\Pi_{\mathcal{M}} = 0$. By Corollary 10.3, an equivalent condition is $((1 - \Pi_{\mathcal{M}})X \otimes 1_{\mathcal{F}})V = 0$. To prove this equation, let us denote its left-hand side by C and calculate $C^\dagger C$:

$$\begin{aligned} C^\dagger C &= V^\dagger (X^\dagger (1 - \Pi_{\mathcal{M}})X \otimes 1_{\mathcal{F}}) V = \text{---} \bullet \text{---} \textcircled{X^\dagger} \text{---} \boxed{1 - \Pi_{\mathcal{M}}} \text{---} \textcircled{X} \text{---} \bullet \text{---} \\ &= \text{---} \bullet \text{---} \bullet \text{---} \textcircled{X^\dagger} \text{---} \bullet \text{---} \boxed{1 - \Pi_{\mathcal{M}}} \text{---} \bullet \text{---} \textcircled{X} \text{---} \bullet \text{---} \bullet \text{---} \\ &= \text{---} \bullet \text{---} \textcircled{X^\dagger} \text{---} \bullet \text{---} \boxed{1 - \Pi_{\mathcal{M}}} \text{---} \bullet \text{---} \textcircled{X} \text{---} \bullet \text{---} \bullet \text{---} = 0. \end{aligned}$$

(In the second line, we have used the equations $\Phi^2 = \Phi$ and $X = \Phi(X)$, and in the last line, (10.14) and the equation $((1 - \Pi_{\mathcal{M}}) \otimes 1_{\mathcal{F}})V = 0$.)

We now prove the relation between the Choi-Effros product and the usual operator product of $X, Y \in \mathcal{A}$. By the previous argument, X splits as $X|_{\mathcal{M}} \oplus X|_{\mathcal{M}^\perp}$ and Y splits as $Y|_{\mathcal{M}} \oplus Y|_{\mathcal{M}^\perp}$. Therefore, $(XY)|_{\mathcal{M}} = X|_{\mathcal{M}}Y|_{\mathcal{M}}$. To show that $\Phi(XY)|_{\mathcal{M}} = (XY)|_{\mathcal{M}}$, we apply Corollary 10.3

again. Thus, the equation in question becomes $(\Phi(XY) \otimes 1_{\mathcal{F}})V = (XY \otimes 1_{\mathcal{F}})V$. In this form, it is derived using (10.14) as well as the equations $X = \Phi(X)$, $Y = \Phi(Y)$, and $\Phi^2 = \Phi$:

$$(\Phi(XY) \otimes 1_{\mathcal{F}})V = \text{---} \bullet \text{---} \overset{\text{---}}{\text{---}} \bullet \text{---} \textcircled{X} \text{---} \bullet \text{---} \overset{\text{---}}{\text{---}} \bullet \text{---} \textcircled{Y} \text{---} \bullet \text{---} = \text{---} \bullet \text{---} \textcircled{X} \text{---} \bullet \text{---} \textcircled{Y} \text{---} \bullet \text{---} = (XY \otimes 1_{\mathcal{F}})V.$$

□

Proof of Theorem 1.2. Let \mathcal{M} and \mathcal{A} be the carrier and the image of Φ , respectively, and let $J_{\mathcal{M}}: \mathcal{M} \rightarrow \mathcal{H}$ and $\Delta: \mathcal{A} \rightarrow \mathbf{B}(\mathcal{H})$ be the corresponding inclusion maps. (At this point, \mathcal{A} is just a vector space, and Δ is a linear map.) Let us also consider the maps

$$\begin{aligned} C_{\mathcal{M}}: X &\mapsto J_{\mathcal{M}}^{\dagger} X J_{\mathcal{M}} : \mathbf{B}(\mathcal{H}) \rightarrow \mathbf{B}(\mathcal{M}), \\ \Lambda: X &\mapsto \Phi(J_{\mathcal{M}} X J_{\mathcal{M}}^{\dagger}) : \mathbf{B}(\mathcal{M}) \rightarrow \mathbf{B}(\mathcal{H}). \end{aligned}$$

It is evident that $C_{\mathcal{M}}$ is a UCP map and that Λ is completely positive; we will soon see that it is also unital. By construction, Λ factors through $\mathcal{A} = \text{Im } \Phi$, that is, $\Lambda = \Delta \Gamma$ for some map $\Gamma: \mathbf{B}(\mathcal{M}) \rightarrow \mathcal{A}$. We can use equation (10.12) to infer that for any $X \in \mathbf{B}(\mathcal{H})$,

$$\Phi(X) = \Phi(\Pi_{\mathcal{M}} X \Pi_{\mathcal{M}}) = \Phi(J_{\mathcal{M}} J_{\mathcal{M}}^{\dagger} X J_{\mathcal{M}} J_{\mathcal{M}}^{\dagger}) = \Lambda C_{\mathcal{M}}(X).$$

Thus, $\Phi = \Lambda C_{\mathcal{M}} = \Delta \Gamma C_{\mathcal{M}}$, which also implies that $\Lambda(1_{\mathcal{M}}) = \Lambda C_{\mathcal{M}}(1_{\mathcal{H}}) = \Phi(1_{\mathcal{H}}) = 1_{\mathcal{H}}$.

Since Φ is idempotent, $\Delta(A) = \Phi \Delta(A) = \Delta \Gamma C_{\mathcal{M}} \Delta(A)$ for all $A \in \mathcal{A}$; hence, $\Gamma C_{\mathcal{M}} \Delta = 1_{\mathcal{A}}$ due to the injectivity of Δ . This is a convenient summary:

$$\begin{array}{ccc} & \mathbf{B}(\mathcal{H}) & \\ \Delta \nearrow & \downarrow C_{\mathcal{M}} & \\ \mathcal{A} & \xleftarrow{\Gamma} \mathbf{B}(\mathcal{M}) & \end{array} \quad \Delta \Gamma = \Lambda, \quad \Lambda C_{\mathcal{M}} = \Phi, \quad \Gamma C_{\mathcal{M}} \Delta = 1_{\mathcal{A}}.$$

Let $w = C_{\mathcal{M}} \Delta$ so that $\Gamma w = 1_{\mathcal{A}}$. The last equation implies that w is injective, Γ is surjective, and the UCP map $\Psi = C_{\mathcal{M}} \Lambda = w \Gamma$ is idempotent. Therefore,

$$\text{Im } w = \text{Im } \Psi = \text{Ker}(1 - \Psi) \subseteq \mathbf{B}(\mathcal{M}).$$

This subspace of $\mathbf{B}(\mathcal{M})$ is closed, contains the unit operator, and is invariant under the involution $X \mapsto X^{\dagger}$. Furthermore, the second part of Lemma 10.4 says that w carries the Choi-Effros product on \mathcal{A} to the usual operator product on $\mathbf{B}(\mathcal{M})$, so $\text{Im } w$ is closed under the operator product. Thus, $\text{Im } w$ is a C^* subalgebra of $\mathbf{B}(\mathcal{M})$. We may identify it with \mathcal{A} , which makes the latter into a C^* algebra and w into an inclusion of C^* algebras. At the same time, Γ becomes a UCP map because $\Psi = w \Gamma$ is UCP map.

The last assertion in the theorem (that operators in the image of Δ are block-diagonal with respect to the decomposition $\mathcal{H} = \mathcal{M} \oplus \mathcal{M}^{\perp}$) is just the first part of Lemma 10.4. □

Now, we determine the specific form of the maps involved. Since $w: \mathcal{A} \rightarrow \mathbf{B}(\mathcal{M})$ is an inclusion of C^* algebras and $\dim \mathcal{M} < \infty$, the structure of w is described by Proposition 1.1:

$$w(A_1, \dots, A_m) = \sum_{j=1}^m W_j^{\dagger} (A_j \otimes 1_{\mathcal{E}_j}) W_j \quad \text{for } (A_1, \dots, A_m) \in \mathcal{A} = \bigoplus_{j=1}^m \mathbf{B}(\mathcal{L}_j). \quad (10.16)$$

Let us also use the fact that for each $A \in \mathcal{A}$, the operator $\Delta(A)$ is the direct sum of $\Delta(A)|_{\mathcal{M}} = w(A)$ and $\Delta(A)|_{\mathcal{M}^\perp}$. The latter can be obtained from A by some UCP map $\Sigma: \mathcal{A} \rightarrow \mathbf{B}(\mathcal{M}^\perp)$. Thus,

$$\Delta(A) = \sum_{j=1}^m J_{\mathcal{M}} W_j^\dagger (A_j \otimes 1_{\mathcal{E}_j}) W_j J_{\mathcal{M}}^\dagger + J_{\mathcal{M}^\perp} \Sigma(A) J_{\mathcal{M}^\perp}^\dagger \quad (A \in \mathcal{A}). \quad (10.17)$$

Proposition 10.5. *Let $w: \mathcal{A} \rightarrow \mathbf{B}(\mathcal{M})$ have the form (10.16), where (W_1, \dots, W_m) are the components of a unitary map $W: \bigoplus_{j=1}^m \mathcal{L}_j \otimes \mathcal{E}_j \rightarrow \mathcal{M}$. Then any UCP map $\Gamma: \mathbf{B}(\mathcal{M}) \rightarrow \mathcal{A}$ satisfying the equation $\Gamma w = 1_{\mathcal{A}}$ admits the component-wise representation*

$$\Gamma_j: \mathbf{B}(\mathcal{M}) \rightarrow \mathbf{B}(\mathcal{L}_j), \quad \Gamma_j(X) = \text{Tr}_{\mathcal{E}_j} (W_j X W_j^\dagger (1_{\mathcal{L}_j} \otimes \gamma_j)) \quad (10.18)$$

for some density matrices γ_j on \mathcal{E}_j .

Proof. Each component $\Gamma_j: \mathbf{B}(\mathcal{M}) \rightarrow \mathbf{B}(\mathcal{L}_j)$ can be written in the Choi form,

$$\Gamma_j(X) = L_j^\dagger (X \otimes 1_{\mathcal{F}_j}) L_j, \quad \text{where } L_j: \mathcal{L}_j \rightarrow \mathcal{M} \otimes \mathcal{F}_j, \quad L_j^\dagger L_j = 1_{\mathcal{L}_j}.$$

Thus, the equation $\Gamma w = 1_{\mathcal{A}}$ becomes $L_j^\dagger ((W_k^\dagger (A_k \otimes 1_{\mathcal{E}_k}) W_k) \otimes 1_{\mathcal{F}_j}) L_j = A_j$ for all (A_1, \dots, A_m) . It follows that

$$(W_k \otimes 1_{\mathcal{F}_j}) L_j = \begin{array}{c} \mathcal{F}_j \\ \text{---} \end{array} \begin{array}{c} \mathcal{E}_k \\ \text{---} \end{array} \boxed{W_k} \xrightarrow{\mathcal{M}} \boxed{L_j} \text{---} \mathcal{L}_j = \delta_{kj} (1_{\mathcal{L}_j} \otimes \xi_j),$$

where the diagram illustrates the tensor structure of the first expression and $\xi_j \in \mathcal{E}_j \otimes \mathcal{F}_j$ is some unit vector. Multiplying the above equation by $W_k^\dagger \otimes 1_{\mathcal{F}_j}$ on the left and summing over k , we get

$$L_j = (W_j^\dagger \otimes 1_{\mathcal{F}_j}) (1_{\mathcal{L}_j} \otimes \xi_j).$$

Plugging this formula in the equation $\Gamma_j(X) = L_j^\dagger (X \otimes 1_{\mathcal{F}_j}) L_j$ gives the required representation with $\gamma_j = \text{Tr}_{\mathcal{F}_j} (\xi_j \xi_j^\dagger)$. \square

In conclusion, let us consider the dual maps. It follows from Proposition 10.5 that $\text{Enc} = (\Gamma C_{\mathcal{M}})^*$ has the form (1.3). Similarly, equation (10.17) implies that $\text{Dec} = \Delta^*$ has the form (1.4). Finally, $\text{Dec Enc} = (\Gamma C_{\mathcal{M}} \Delta)^* = 1_{\mathcal{A}^*}$ and $\text{Enc Dec} = (\Delta \Gamma C_{\mathcal{M}})^* = \Phi^*$.

10.4 From almost-idempotent UCP maps to ε - C^* algebras

Let \mathcal{H} be an arbitrary nonzero Hilbert space, and let us consider a UCP map $\Phi: \mathbf{B}(\mathcal{H}) \rightarrow \mathbf{B}(\mathcal{H})$ such that

$$\|\Phi^2 - \Phi\|_{\text{cb}} \leq \eta, \quad (10.19)$$

where η is a sufficiently small nonnegative number. First, we recall some constructions from Section 1.2. This definition is based on Proposition 3.1 and equation (3.4):

$$\tilde{\Phi} = \theta(2\Phi - 1) = \frac{1}{2} \left(1 + \text{sgn}(2\Phi - 1) \right) = \frac{1}{2} \left(1 + (2\Phi - 1)(1 - 4(\Phi - \Phi^2))^{-1/2} \right). \quad (10.20)$$

The right-hand side involves a Taylor expansion in $4(\Phi - \Phi^2)$, which converges if $\eta < 1/4$. The map $\tilde{\Phi}$ has the properties

$$\tilde{\Phi}^2 = \tilde{\Phi}, \quad \|\tilde{\Phi} - \Phi\|_{\text{cb}} \leq O(\eta), \quad \tilde{\Phi}(1) = 1, \quad \tilde{\Phi}(X^\dagger) = \tilde{\Phi}(X)^\dagger \text{ for all } X \in \mathbf{B}(\mathcal{H}), \quad (10.21)$$

which allow for the definition of \mathcal{A} :

$$\mathcal{A} = \text{Im } \tilde{\Phi} = \text{Ker}(1 - \tilde{\Phi}) \subseteq \mathbf{B}(\mathcal{H}). \quad (10.22)$$

As such, \mathcal{A} is a closed subspace of $\mathbf{B}(\mathcal{H})$; it contains the unit operator $I = 1_{\mathcal{H}}$ and is invariant under the involution $X \mapsto X^\dagger$. We define the multiplication (approximate Choi-Effros product) on \mathcal{A} by the equation

$$X \star Y = \tilde{\Phi}(XY) \quad (X, Y \in \mathcal{A}). \quad (10.23)$$

Theorem 10.6. *The space \mathcal{A} with the norm, involution, and unit inherited from $\mathbf{B}(\mathcal{H})$ and the multiplication $(X, Y) \mapsto X \star Y$ is an $O(\eta)$ - C^* algebra.*

The nontrivial part of the proof is concerned with the following equations,

$$\Phi\left(\Phi(\Phi(X)\Phi(Y))\Phi(Z)\right) = \Phi(\Phi(X)\Phi(Y)\Phi(Z)) + O(\eta)\|X\|\|Y\|\|Z\|, \quad (10.24)$$

$$\Phi\left(\Phi(X)\Phi(\Phi(Y)\Phi(Z))\right) = \Phi(\Phi(X)\Phi(Y)\Phi(Z)) + O(\eta)\|X\|\|Y\|\|Z\|, \quad (10.25)$$

but we will begin with the easy part.

Proof of Theorem 10.6 using equations (10.24) and (10.25). The axioms of an ε - C^* algebra not involving the multiplication are clearly satisfied, and it is also evident that $X \star I = X = I \star X$ and $(X \star Y)^\dagger = Y^\dagger \star X^\dagger$ for all $X, Y \in \mathcal{A}$.

Let us check the approximate submultiplicativity of the norm. If $X, Y \in \mathcal{A}$, then

$$\|X \star Y\| = \|\tilde{\Phi}(XY)\| \leq \|\Phi(XY)\| + O(\eta)\|XY\| \leq (1 + O(\eta))\|X\|\|Y\|, \quad (10.26)$$

where we have used the inequalities $\|\tilde{\Phi} - \Phi\|_{\text{cb}} \leq O(\eta)$ and $\|\Phi\|_{\text{cb}} \leq 1$.

Using the same inequalities, one may safely replace Φ with $\tilde{\Phi}$ in (10.24) and (10.25). Subtracting the resulting equations, we get

$$\left\| \tilde{\Phi}\left(\tilde{\Phi}(\tilde{\Phi}(X)\tilde{\Phi}(Y))\tilde{\Phi}(Z)\right) - \tilde{\Phi}\left(\tilde{\Phi}(X)\tilde{\Phi}(\tilde{\Phi}(Y)\tilde{\Phi}(Z))\right) \right\| \leq O(\eta)\|X\|\|Y\|\|Z\|.$$

If $X, Y, Z \in \mathcal{A}$, then $\tilde{\Phi}(X) = X$, $\tilde{\Phi}(Y) = Y$, and $\tilde{\Phi}(Z) = Z$, so that the previous equation becomes the ε -associativity axiom for $\varepsilon = O(\eta)$:

$$\|(X \star Y) \star Z - X \star (Y \star Z)\| \leq O(\eta)\|X\|\|Y\|\|Z\|. \quad (10.27)$$

Finally, the operator inequality $\Phi(X^\dagger)\Phi(X) \leq \Phi(X^\dagger X)$ (see (10.10)) implies that $\|\Phi(X^\dagger X)\| \geq \|\Phi(X)\|^2$. Replacing Φ with $\tilde{\Phi}$ and assuming that $X \in \mathcal{A}$, we get

$$\|X^\dagger \star X\| \geq (1 - O(\eta))\|X\|^2. \quad (10.28)$$

□

Proof of (10.24) and (10.25) in the finite-dimensional case. Let (\mathcal{F}, V) be the Choi representation of Φ , and let us introduce the notation

$$\Pi = VV^\dagger = \begin{array}{c} \mathcal{F} \\ \text{---} \bullet \text{---} \bullet \text{---} \mathcal{H} \end{array}, \quad \begin{array}{c} \mathcal{F} \\ \text{---} \text{---} \text{---} \mathcal{H} \end{array} = 1 - \Pi. \quad (10.29)$$

First, we show that

$$\begin{array}{c} \text{---} \text{---} \text{---} \text{---} \text{---} \\ \text{---} \text{---} \text{---} \text{---} \text{---} \end{array} \begin{array}{c} \text{---} \bullet \text{---} \bullet \text{---} \text{---} \\ \text{---} \bullet \text{---} \bullet \text{---} \text{---} \end{array} \begin{array}{c} \mathcal{F} \\ \text{---} \bullet \text{---} \bullet \text{---} \mathcal{H} \end{array} = O(\sqrt{\eta}) \|X\|. \quad (10.30)$$

Indeed,

$$\begin{aligned} & \begin{array}{c} \text{---} \text{---} \text{---} \text{---} \text{---} \\ \text{---} \text{---} \text{---} \text{---} \text{---} \end{array} \begin{array}{c} \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \\ \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \end{array} \begin{array}{c} \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \\ \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \end{array} \begin{array}{c} \mathcal{F} \\ \text{---} \bullet \text{---} \bullet \text{---} \mathcal{H} \end{array} \\ &= \begin{array}{c} \text{---} \text{---} \text{---} \text{---} \text{---} \\ \text{---} \text{---} \text{---} \text{---} \text{---} \end{array} \begin{array}{c} \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \\ \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \end{array} \begin{array}{c} \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \\ \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \end{array} \begin{array}{c} \mathcal{F} \\ \text{---} \bullet \text{---} \bullet \text{---} \mathcal{H} \end{array} \\ &= \Phi^2(\Phi(X^\dagger) \Phi(X)) - \Phi(\Phi^2(X^\dagger) \Phi^2(X)) = O(\eta) \|X\|^2. \end{aligned}$$

Now, consider a diagram that has two parts similar to the left-hand side of (10.30), one containing X and the other containing Z :

$$W = \begin{array}{c} \text{---} \text{---} \text{---} \text{---} \text{---} \\ \text{---} \text{---} \text{---} \text{---} \text{---} \end{array} \begin{array}{c} \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \\ \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \end{array} \begin{array}{c} \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \\ \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \end{array} \begin{array}{c} \mathcal{F} \\ \text{---} \bullet \text{---} \bullet \text{---} \mathcal{H} \end{array} = O(\eta) \|X\| \|Y\| \|Z\|. \quad (10.31)$$

Expanding both rectangles as $1 - VV^\dagger$, we get

$$\begin{aligned} W &= \begin{array}{c} \text{---} \text{---} \text{---} \text{---} \text{---} \\ \text{---} \text{---} \text{---} \text{---} \text{---} \end{array} \begin{array}{c} \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \\ \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \end{array} \begin{array}{c} \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \\ \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \end{array} \begin{array}{c} \mathcal{F} \\ \text{---} \bullet \text{---} \bullet \text{---} \mathcal{H} \end{array} \\ &- \begin{array}{c} \text{---} \text{---} \text{---} \text{---} \text{---} \\ \text{---} \text{---} \text{---} \text{---} \text{---} \end{array} \begin{array}{c} \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \\ \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \end{array} \begin{array}{c} \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \\ \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \end{array} \begin{array}{c} \mathcal{F} \\ \text{---} \bullet \text{---} \bullet \text{---} \mathcal{H} \end{array} \\ &- \begin{array}{c} \text{---} \text{---} \text{---} \text{---} \text{---} \\ \text{---} \text{---} \text{---} \text{---} \text{---} \end{array} \begin{array}{c} \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \\ \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \end{array} \begin{array}{c} \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \\ \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \end{array} \begin{array}{c} \mathcal{F} \\ \text{---} \bullet \text{---} \bullet \text{---} \mathcal{H} \end{array} \\ &+ \begin{array}{c} \text{---} \text{---} \text{---} \text{---} \text{---} \\ \text{---} \text{---} \text{---} \text{---} \text{---} \end{array} \begin{array}{c} \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \\ \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \end{array} \begin{array}{c} \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \\ \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \bullet \text{---} \end{array} \begin{array}{c} \mathcal{F} \\ \text{---} \bullet \text{---} \bullet \text{---} \mathcal{H} \end{array} \\ &= \Phi^2(\Phi(\Phi(X) \Phi(Y)) \Phi(Z)) - \Phi(\Phi^2(\Phi(X) \Phi(Y)) \Phi^2(Z)) \\ &- \Phi^2(\Phi^2(X) \Phi^2(Y) \Phi(Z)) + \Phi(\Phi(\Phi^2(X) \Phi^2(Y)) \Phi^2(Z)) \\ &= \Phi(\Phi(\Phi(X) \Phi(Y)) \Phi(Z)) - \Phi(\Phi(X) \Phi(Y) \Phi(Z)) + O(\eta) \|X\| \|Y\| \|Z\|. \end{aligned}$$

The combination of this result and equation (10.31) gives (10.24). Equation (10.25) is obtained similarly. \square

To prove the result in full generality (in finite or infinite dimensions), we need to replace the Choi representation with the Stinespring representation and find suitable generalizations of the Hilbert spaces $\mathcal{H}_n = \mathcal{H} \otimes \mathcal{F}^{\otimes n}$, isometries $V_n = V \otimes 1_{\mathcal{F}}^{\otimes(n-1)}: \mathcal{H}_{n-1} \rightarrow \mathcal{H}_n$, and $*$ -homomorphisms $u_n: X \mapsto X \otimes 1_{\mathcal{F}}: \mathbf{B}(\mathcal{H}_{n-1}) \rightarrow \mathbf{B}(\mathcal{H}_n)$. Such a “Stinespring stack”

$$\mathcal{H}_0 \xrightarrow{V_1} \mathcal{H}_1 \xrightarrow{V_2} \mathcal{H}_2 \xrightarrow{V_3} \cdots, \quad \mathbf{B}(\mathcal{H}_0) \xrightarrow{u_1} \mathbf{B}(\mathcal{H}_1) \xrightarrow{u_2} \mathbf{B}(\mathcal{H}_2) \xrightarrow{u_3} \cdots \quad (10.32)$$

is constructed inductively, starting from $\mathcal{H}_0 = \mathcal{H}$ and $\Phi_0 = \Phi$. For each $n = 1, 2, \dots$, we define $(\mathcal{H}_n, u_n, V_n)$ to be the canonical Stinespring representation of Φ_{n-1} ; then $\Phi_n: X \mapsto u_n(V_n^\dagger X V_n)$. Thus,

$$u_n(V_n^\dagger X V_n) = \Phi_n(X) = V_{n+1}^\dagger u_{n+1}(X) V_{n+1} \quad (X \in \mathcal{H}_n). \quad (10.33)$$

This corresponds to the first diagram in Proposition 10.1 for $\mathcal{L} = \mathcal{H}_{n-1}$, $\mathcal{K} = \mathcal{H} = \mathcal{H}_n$, and $\mathcal{G} = \mathcal{H}_{n+1}$. The commutativity of the second diagram (not needed for the task at hand) is expressed by the equation

$$u_{n+1}(V_n Y V_n^\dagger) = V_{n+1} u_n(Y) V_{n+1}^\dagger \quad (Y \in \mathcal{H}_{n-1}). \quad (10.34)$$

Equations (10.33) and (10.34) can be applied iteratively. Let

$$V_{n,m} = V_n \cdots V_{m+1}: \mathcal{H}_m \rightarrow \mathcal{H}_n, \quad u_{n,m} = u_n \cdots u_{m+1}: \mathbf{B}(\mathcal{H}_m) \rightarrow \mathbf{B}(\mathcal{H}_n) \quad (n \geq m); \quad (10.35)$$

in particular, $V_{n,n-1} = V_n$ and $u_{n,n-1} = u_n$. Then

$$u_{m+k,m}(V_{n,m}^\dagger X V_{n,m}) = V_{n+k,m+k}^\dagger u_{n+k,n}(X) V_{n+k,m+k} \quad (X \in \mathcal{H}_n), \quad (10.36)$$

$$u_{n+k,n}(V_{n,m} Y V_{n,m}^\dagger) = V_{n+k,m+k} u_{m+k,m}(Y) V_{n+k,m+k}^\dagger \quad (Y \in \mathcal{H}_m). \quad (10.37)$$

Remark 10.7. Since V_1, V_2, \dots are isometries, one may regard them as inclusions and define

$$\mathcal{H}_\infty = \overline{\bigcup_n \mathcal{H}_n}, \quad u_\infty: X \mapsto \lim_{n \rightarrow \infty} J_{n+1} u_{n+1}(J_n^\dagger X J_n) J_{n+1}: \mathbf{B}(\mathcal{H}_\infty) \rightarrow \mathbf{B}(\mathcal{H}_\infty), \quad (10.38)$$

where the bar denotes the completion, and $J_n: \mathcal{H}_n \rightarrow \mathcal{H}_\infty$ are the inclusion maps.

General proof of equations (10.24) and (10.25). First, we construct an analogue of the left-hand side of (10.30) covered by k additional layers:

$$R_k(X) = u_{2+k,1} \left((I_1 - V_1 V_1^\dagger) u_1(\Phi(X)) \right) V_{2+k} V_{1+k}, \quad (10.39)$$

where $I_n = 1_{\mathcal{H}_n}$. The norm of $R_k(X)$ is estimated as follows,

$$\begin{aligned} R_k(X)^\dagger R_k(X) &= V_{1+k}^\dagger V_{2+k}^\dagger u_{2+k,1} \left(u_1(\Phi(X^\dagger)) (I_1 - V_1 V_1^\dagger) u_1(\Phi(X)) \right) V_{2+k} V_{1+k} \\ &= u_{k,0} \left(V_1^\dagger u_1(V_1^\dagger u_1(\Phi(X^\dagger)) (I_1 - V_1 V_1^\dagger) u_1(\Phi(X)) V_1) V_1 \right) \\ &= u_{k,0} \left(\Phi^2(\Phi(X^\dagger) \Phi(X)) - \Phi(\Phi^2(X^\dagger) \Phi^2(X)) \right) = O(\eta) \|X\|^2, \end{aligned}$$

where the second line was obtained using (10.36) and the equation $u_{1+k,0} = u_{1+k,1} u_1$:

$$V_{1+k}^\dagger V_{2+k}^\dagger u_{2+k,1}(Z) V_{2+k} V_{1+k} = V_{1+k}^\dagger u_{1+k,0}(V_1^\dagger Z V_1) V_1 = u_{k,0}(V_1^\dagger u_1(V_1^\dagger Z V_1) V_1).$$

By analogy with equation (10.31), we have

$$W = V_1^\dagger R_1(X^\dagger)^\dagger u_{3,0}(\Phi(Y)) V_3 R_0(Z) = O(\eta) \|X\| \|Y\| \|Z\|. \quad (10.40)$$

The expression for W is transformed as follows:

$$\begin{aligned} W &= V_1^\dagger V_2^\dagger V_3^\dagger u_{3,1} \left(u_1(\Phi(X)) (I_1 - V_1 V_1^\dagger) \right) u_{3,0}(\Phi(Y)) V_3 u_2 \left((I_1 - V_1 V_1^\dagger) u_1(\Phi(Z)) \right) V_2 V_1 \\ &= V_1^\dagger V_2^\dagger u_{2,0} \left(V_1^\dagger u_1(\Phi(X)) (I_1 - V_1 V_1^\dagger) u_1(\Phi(Y)) V_1 \right) u_2 \left((I_1 - V_1 V_1^\dagger) u_1(\Phi(Z)) \right) V_2 V_1 \\ &= V_1^\dagger V_2^\dagger u_2 \left(u_1 \left(V_1^\dagger u_1(\Phi(X)) (I_1 - V_1 V_1^\dagger) u_1(\Phi(Y)) V_1 \right) (I_1 - V_1 V_1^\dagger) u_1(\Phi(Z)) \right) V_2 V_1 = \Phi(Q), \end{aligned}$$

where

$$\begin{aligned} Q &= V_1^\dagger u_1 \left(V_1^\dagger u_1(\Phi(X)) (I_1 - V_1 V_1^\dagger) u_1(\Phi(Y)) V_1 \right) (I_1 - V_1 V_1^\dagger) u_1(\Phi(Z)) V_1 \\ &= V_1^\dagger u_1(\Phi(\Phi(X) \Phi(Y))) u_1(\Phi(Z)) V_1 - V_1^\dagger u_1(\Phi(\Phi(X) \Phi(Y))) V_1 V_1^\dagger u_1(\Phi(Z)) V_1 \\ &\quad - V_1^\dagger u_1(\Phi^2(X) \Phi^2(Y)) u_1(\Phi(Z)) V_1 + V_1^\dagger u_1(\Phi^2(X) \Phi^2(Y)) V_1 V_1^\dagger u_1(\Phi(Z)) V_1 \\ &= \Phi(\Phi(\Phi(X) \Phi(Y)) \Phi(Z)) - \Phi^2(\Phi(X) \Phi(Y)) \Phi^2(Z) \\ &\quad - \Phi(\Phi^2(X) \Phi^2(Y) \Phi(Z)) + \Phi(\Phi^2(X) \Phi^2(Y)) \Phi^2(Z) \\ &= \Phi(\Phi(\Phi(X) \Phi(Y)) \Phi(Z)) - \Phi(\Phi(X) \Phi(Y) \Phi(Z)) + O(\eta) \|X\| \|Y\| \|Z\|. \end{aligned}$$

Thus, $W = \Phi(\Phi(\Phi(X) \Phi(Y)) \Phi(Z)) - \Phi(\Phi(X) \Phi(Y) \Phi(Z)) + O(\eta) \|X\| \|Y\| \|Z\|$. This equation together with (10.40) implies (10.24). Equation (10.25) is obtained in the same way. \square

Acknowledgments

I thank Daniel Ranard for the motivation and challenge to work on the almost-idempotent channel problem as well as for multiple discussions and comments, Michael Freedman for nice discussions and comments, and Isaac Kim for pointing to related results [3, 4]. This work was supported by the Simons Foundation under grant 376205 and by the Institute of Quantum Information and Matter, a NSF Physics Frontiers Center.
