We find the three-dimensional gravity dual of a process in which two clouds of (1+1)dimensional conformal matter moving in opposite directions collide. This gives the most general conformally invariant holographic flow in the 1+1 dimensional boundary theory in terms of two arbitrary functions. With a suitable choice of the arbitrary functions the process can be interpreted as an opaque collision of two extended systems with central, fragmentation and interaction regions. Comparison with classical gluon field calculations relates the size of the system with the saturation scale.

1 Introduction

The final state of a heavy ion collision has been recently studied in gauge/gravity duality in a number of papers [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15]. The early stages of the collision process are more difficult to model and have so far received less attention [16]. In this paper, we consider both the final state and the onset of the collision in a simplified model in which the boundary theory is (1+1) dimensional and the bulk is locally AdS₃. We shall give explicitly the general bulk solution that is dual to two colliding clusters of conformal boundary matter. That such a general solution can be found is, of course, due to the simplicity of gravitational dynamics in three dimensions. The solution involves two arbitrary functions, each depending on only one of the light cone coordinates. With a suitable choice for these two functions, the boundary process can be described in the language of heavy ion collisions as having two incident extended systems, an interaction diamond and central and fragmentation regions in the final state. There is one important difference between our boundary matter and that of real (3+1)-dimensional heavy ion collisions though: our matter is extremely opaque and bounces off backwards in the collision.

As a special case, our bulk solution also provides the metric of two colliding shock waves in three dimensions. This metric describes a spacetime in which two massless point particles create a three-dimensional black hole [17, 18]. In four (or more) spacetime dimensions the metric of a single shock wave is known both with a vanishing [19, 20] and nonvanishing [21, 22, 23] cosmological constant, and an extension to colliding waves would have important applications in the study of black hole production at colliders [24], but finding such a solution has proved a formidable task [25, 26].

We use the three-dimensional coordinates (x^+, x^-, z) , (τ, η, z) and (t, x, z), referred to respectively as the light cone, Milne and Minkowski coordinates. The conformal boundary is at z = 0, the coordinates are at z = 0 related to each other by

$$x^{\pm} = \frac{t \pm x}{\sqrt{2}} = \frac{\tau}{\sqrt{2}} e^{\pm \eta}, \qquad t = \tau \cosh \eta, \ x = \tau \sinh \eta, \tag{1}$$

where $\tau > 0$, and the boundary Minkowski metric takes the form

$$ds^{2} = -2dx^{+}dx^{-} = -d\tau^{2} + \tau^{2}d\eta^{2} = -dt^{2} + dx^{2}.$$
(2)

2 Colliding conformal boundary matter

In three dimensions, the metric of a plane wave moving in the x^+ direction can be written in the light cone coordinates as

$$g_{MN}^{+} = \frac{\mathcal{L}^2}{z^2} \begin{pmatrix} 0 & -1 & 0\\ -1 & z^2 f(x^-) & 0\\ 0 & 0 & 1 \end{pmatrix},$$
(3)

where $f(x^{-})$ is an arbitrary function of x^{-} . This metric satisfies the AdS₃ Einstein equations

$$R_{MN} - \frac{1}{2} R g_{MN} - \frac{1}{\mathcal{L}^2} g_{MN} = 0, \qquad (4)$$

following from the action

$$S = \frac{1}{16\pi G_3} \int d^3x \sqrt{-g} \left(R + \frac{2}{\mathcal{L}^2} \right),\tag{5}$$

and must therefore be locally isometric to AdS₃. In the special case in which $f(x^{-})$ is proportional to $\delta(x^{-})$, we obtain the three-dimensional negative cosmological constant generalisation of the Aichelburg-Sexl (AS) shock wave [19].

By symmetry, the metric of a plane wave moving in the x^{-} direction can be written as

$$g_{MN}^{-} = \frac{\mathcal{L}^2}{z^2} \begin{pmatrix} z^2 g(x^+) & -1 & 0\\ -1 & 0 & 0\\ 0 & 0 & 1 \end{pmatrix},$$
 (6)

where $g(x^+)$ is an arbitrary function. Note that in each case the metric components are independent of the light cone coordinate in whose direction the wave is travelling.

While extensions of the above plane wave solutions to four and more dimensions are known [21, 22, 23], an extension that would describe two colliding waves in four or more dimensions has proved elusive. In three dimensions, however, we can find such a solution by making in the light cone coordinates (x^+, x^-, z) the ansatz

$$g_{MN} = \frac{\mathcal{L}^2}{z^2} \begin{pmatrix} g_{\mu\nu} & 0\\ 0 & 1 \end{pmatrix},\tag{7}$$

where the two-dimensional metric components $g_{\mu\nu}$ may a priori depend on any of the coordinates. If $g_{\mu\nu}$ is assumed to reduce at $z \to 0$ to the (1+1)-dimensional Minkowski metric (2), the general solution to Einstein's equations (4) may be shown to be

$$g_{MN} = \frac{\mathcal{L}^2}{z^2} \begin{pmatrix} z^2 g(x^+) & -1 - \frac{z^4}{4} g(x^+) f(x^-) & 0\\ -1 - \frac{z^4}{4} g(x^+) f(x^-) & z^2 f(x^-) & 0\\ 0 & 0 & 1 \end{pmatrix},$$
(8)

where g and f are arbitrary functions, each of dimension $1/(\text{distance})^2$. This solution can also be obtained by specialising that given in [27] to a flat boundary metric. It may be regarded as a superposition of the plane wave (3) moving in the x^+ direction and the plane wave (6) moving in the x^- direction, the only nonlinearity in the superposition being a correction in the component g_{+-} . The solution can thus be characterised as a collision of two plane waves. If f and g are each proportional to the delta-function, the solution describes the collision of two shock waves.

To analyze the bulk solution (8) from the boundary theory viewpoint, we compute the energy-momentum tensor on the conformal boundary at z = 0 [28]. The small z expansion of $g_{\mu\nu}$ reads

$$g_{\mu\nu}(x^{\pm},z) = g_{\mu\nu}^{(0)} + g_{\mu\nu}^{(2)} z^{2} + \dots$$

$$= \begin{pmatrix} 0 & -1 \\ -1 & 0 \end{pmatrix} + \begin{pmatrix} g(x^{+}) & 0 \\ 0 & f(x^{-}) \end{pmatrix} z^{2} - \begin{pmatrix} 0 & \frac{1}{4}g(x^{+})f(x^{-}) \\ \frac{1}{4}g(x^{+})f(x^{-}) & 0 \end{pmatrix} z^{4},$$
(9)

from which we obtain

$$T_{\mu\nu} = \frac{\mathcal{L}}{8\pi G_3} [g^{(2)}_{\mu\nu} - g^{(0)}_{\mu\nu} \text{Tr}(g^{(2)}_{\mu\nu})] = \frac{\mathcal{L}}{8\pi G_3} g^{(2)}_{\mu\nu} = \frac{\mathcal{L}}{8\pi G_3} \begin{pmatrix} g(x^+) & 0\\ 0 & f(x^-) \end{pmatrix}.$$
 (10)

 $T_{\mu\nu}$ is clearly conserved. A conserved total energy E can hence be defined as the integral of T^{tt} over a surface of constant t. From (10) we find that E decomposes as

$$E = E^{+} + E^{-},$$

$$E^{+} = \frac{\mathcal{L}}{8\pi G_{3}} \frac{1}{\sqrt{2}} \int_{-\infty}^{\infty} dx^{-} f(x^{-}),$$

$$E^{-} = \frac{\mathcal{L}}{8\pi G_{3}} \frac{1}{\sqrt{2}} \int_{-\infty}^{\infty} dx^{+} g(x^{+}),$$
(11)

where E^+ and E^- are respectively the energies of the components moving in the direction of x^+ and x^- .

When g = 0 but $f \neq 0$, the energy-momentum tensor can be written in terms of the null vector $n^{\mu} = (1,0)$ as

$$T_{\mu\nu} = \frac{\mathcal{L}}{8\pi G_3} f(x^-) n_\mu n_\nu, \qquad n_\mu = (0, -1), \tag{12}$$

which shows that the boundary matter is null dust moving in the x^+ direction. Similarly, when f = 0 but $g \neq 0$, the boundary matter is null dust moving in the x^- direction. When both f and g are nonvanishing, the energy-momentum tensor is the sum of the left-moving and right-moving parts, and as f and g are independent, it is possible to interpret the boundary matter as two null dust clouds that just pass through each other without interacting. In higher dimensions interactions are however present, and the boundary energy-momentum tensor after the collision is then usually interpreted as a single-component fluid with internal dynamics and thermodynamics [29]. As we are viewing the (1 + 1)-dimensional boundary as a simplified model for the (3 + 1)-dimensional boundary, we shall seek a single-component interpretation for the boundary matter.

Consider in particular the situation in which f and g are both non-zero and have the same sign. We can then write the energy-momentum tensor in the perfect fluid form $T_{\mu\nu} = (\epsilon + p)u_{\mu}u_{\nu} + pg^{(0)}_{\mu\nu}$, where the normalised future-pointing timelike velocity vector u^{μ} reads

$$u_{\mu} = \left(-\left(\frac{g(x^{+})}{4f(x^{-})}\right)^{1/4}, -\left(\frac{f(x^{-})}{4g(x^{+})}\right)^{1/4} \right)$$
(13)

and the energy density ϵ and the pressure p are given by

$$\epsilon = p = \pm \frac{\mathcal{L}}{8\pi G_3} \sqrt{g(x^+)f(x^-)}, \qquad (14)$$

with the sign in (14) being that of f and g. Note that the dimensions in these formulas are correct since \mathcal{L}/G_3 is dimensionless and f and g each have dimension $1/(\text{distance})^2$. To find

the trajectories of the comoving fluid elements, we have to integrate the equation $dx^{\mu}/d\tau = u^{\mu}(x^+, x^-)$. Using the normalisation condition $1 = -u^2 = 2u^+u^- = 2(dx^+/d\tau)^2(dx^-/dx^+)$, we find $u^{\mu} = (\sqrt{dx^+/2dx^-}, \sqrt{dx^-/2dx^+})$, and comparison with (13) then shows that the trajectories are obtained by integrating the separable differential equation

$$\frac{dx^{-}}{dx^{+}} = \sqrt{\frac{g(x^{+})}{f(x^{-})}} \,. \tag{15}$$

3 Special cases

While the general bulk solution (8) involves the two arbitrary functions f and g, Einstein's equations (4) imply that this solution must be locally isometric to AdS₃. The solution can therefore be brought at least locally to the standard Bañados-Teitelboim-Zanelli (BTZ) form [30, 31],

$$ds^{2} = -Fdt^{2} + \frac{dr^{2}}{F} + r^{2}(d\varphi + N^{\varphi}dt)^{2}, \qquad (16)$$

where

$$F = \frac{(r^2 - r_+^2)(r^2 - r_-^2)}{\mathcal{L}^2 r^2}, \qquad N^{\varphi} = -\frac{r_+ r_-}{\mathcal{L} r^2}, \tag{17}$$

and the the parameters r_{\pm} determine the mass parameter M and the angular momentum parameter J by

$$M = \frac{r_{+}^{2} + r_{-}^{2}}{\mathcal{L}^{2}}, \qquad J = \frac{2r_{+}r_{-}}{\mathcal{L}}.$$
(18)

We shall now write out this transformation for certain choices for f and g. These choices will emerge in section 4 as regions of special interest in a solution that describes a heavy ion collision process on the boundary.

3.1 Bjorken similarity flow

Consider the region in which $x^{\pm} > 0$, and let

$$g(x) = f(x) = \frac{M-1}{4x^2},$$
(19)

where M is a constant. For $M \neq 1$, we have from (13)

$$u_{\mu} = \left(-\sqrt{\frac{x^{-}}{2x^{+}}}, -\sqrt{\frac{x^{+}}{2x^{-}}}\right) = \frac{1}{\sqrt{2}}(-e^{-\eta}, -e^{\eta}), \quad u^{\mu} = \frac{x^{\mu}}{\tau} = \frac{1}{\sqrt{2}}(e^{\eta}, e^{-\eta}), \quad (20)$$

and (14) gives

$$\epsilon = \frac{\mathcal{L}}{8\pi G_3} \frac{M-1}{4x^+ x^-} = \frac{\mathcal{L}}{16\pi G_3} \frac{M-1}{\tau^2}.$$
 (21)

In the coordinates (t, x), (20) reads $u^{\mu} = (t/\tau, x/\tau)$. The boundary flow is thus Bjorken similarity flow [32].

In Milne coordinates (τ, η, z) , the bulk metric reads

$$ds^{2} = \frac{\mathcal{L}^{2}}{z^{2}} \left[-\left(1 - \frac{(M-1)z^{2}}{4\tau^{2}}\right)^{2} d\tau^{2} + \left(1 + \frac{(M-1)z^{2}}{4\tau^{2}}\right)^{2} \tau^{2} d\eta^{2} + dz^{2} \right].$$
 (22)

This bulk metric was analysed from the gauge/gravity duality viewpoint in [9]. The metric can be transformed to the BTZ form (16) with J = 0,

$$ds^{2} = -\left(\frac{r^{2}}{\mathcal{L}^{2}} - M\right)dt^{2} + \frac{dr^{2}}{r^{2}/\mathcal{L}^{2} - M} + r^{2}d\eta^{2}.$$
 (23)

For positive M, the Killing vector ∂_t has a Killing horizon at $r = \mathcal{L}\sqrt{M}$, and the temperature associated with this horizon is $T = \sqrt{M}/(2\pi\mathcal{L})$ and the Bekenstein-Hawking entropy ΔS_{BTZ} for an interval $\Delta \eta$ is given by $\Delta S_{\text{BTZ}}/(\mathcal{L}\Delta \eta) = \sqrt{M}/(4G_3)$. A time-dependent scaling argument from the boundary of (23) to the boundary of (22) then gives the flow (20)–(21) the time-dependent temperature and entropy density

$$T(\tau) = \frac{\sqrt{M}}{2\pi\tau}, \qquad s(\tau) = \frac{\sqrt{M}}{4G_3}\frac{\mathcal{L}}{\tau}.$$
(24)

The term -1 in the factor M-1 in (21) can be interpreted as a vacuum energy contribution, and once this contribution is subtracted, the fluid is a perfect fluid in adiabatic expansion for any positive value of M.

3.2 Angular momentum

Let f(x) and g(x) be again proportional to $1/x^2$, but with coefficients that are not necessarily equal. We write the coefficients as

$$g(x^{+}) = \frac{M - 1 - J/\mathcal{L}}{4(x^{+})^{2}}, \qquad f(x^{-}) = \frac{M - 1 + J/\mathcal{L}}{4(x^{-})^{2}}, \tag{25}$$

where M and J are constants. In the domain $x^{\pm} > 0$, going to Milne coordinates (τ, η, z) then puts the metric in the form investigated in section 5 of [9], and it follows from the analysis therein that the metric can be brought to the spinning BTZ form (16). If $J/\mathcal{L} = M - 1$, so that g vanishes and we have on the boundary a null dust (12) moving in the x^+ direction, this conclusion can be extended from the domain $x^{\pm} > 0$ to the half-space $x^- > 0$. Similarly, if $-J/\mathcal{L} = M - 1$, so that f vanishes and we have on the boundary a null dust (12) moving in the x^- direction, this conclusion holds in the half-space $x^+ > 0$.

3.3 Plateau: constant f and g

Let now both f and g be constants.

Suppose first that f and g either have the same sign or are both zero. By a boost in (x^+, x^-) it is then always possible to make f and g equal, so it suffices to consider this case. We set $f = g = \mu/(2\mathcal{L}^2)$, where μ is a dimensionless constant. The bulk metric reads

$$ds^{2} = \frac{\mathcal{L}^{2}}{z^{2}} \left\{ -2\left(1 + \frac{\mu^{2}z^{4}}{16\mathcal{L}^{2}}\right) dx^{+} dx^{-} + \frac{\mu z^{2}}{2\mathcal{L}^{2}} \left[\left(dx^{+}\right)^{2} + \left(dx^{-}\right)^{2} \right] + dz^{2} \right\},$$
(26)

and transforming to the coordinates (t, x, z), brings this metric to the form

$$ds^{2} = -\left(\frac{\mathcal{L}}{z} - \frac{\mu z}{4\mathcal{L}}\right)^{2} dt^{2} + \mathcal{L}^{2} \frac{dz^{2}}{z^{2}} + \left(\frac{\mathcal{L}}{z} + \frac{\mu z}{4\mathcal{L}}\right)^{2} dx^{2}.$$
 (27)

Writing finally

$$r = \mathcal{L}\left(\frac{\mathcal{L}}{z} + \frac{\mu z}{4\mathcal{L}}\right),\tag{28}$$

the metric is transformed to the spinless BTZ form (23) with $d\eta \to dx/\mathcal{L}$ and $M = \mu$. If $\mu > 0$, the temperature associated with the Killing vector ∂_t is

$$T = \frac{\sqrt{\mu}}{2\pi\mathcal{L}},\tag{29}$$

and the entropy ΔS_{BTZ} for an interval Δx is

$$\frac{\Delta S_{\rm BTZ}}{\Delta x} = \frac{\sqrt{\mu}}{4G_3}.$$
(30)

If f and g have opposite sign, a similar analysis can be given, but this case will not occur in section 4 below.

Suppose then that g = 0 but $f \neq 0$, so that on the boundary we have the null dust (12) moving in the x^+ direction. We now write $f = \mu/\mathcal{L}^2$, where μ is a nonvanishing constant. The bulk metric is

$$ds^{2} = \frac{\mathcal{L}^{2}}{z^{2}} \left[-2dx^{+} dx^{-} + \frac{\mu z^{2}}{\mathcal{L}^{2}} (dx^{-})^{2} + dz^{2} \right]$$

$$= -\frac{(\mathcal{L}^{4}/z^{4})}{\mathcal{L}^{2}/z^{2} + \mu/2} dt^{2} + \mathcal{L}^{2} \frac{dz^{2}}{z^{2}} + \left(\frac{\mathcal{L}^{2}}{z^{2}} + \frac{\mu}{2}\right) \left(dx - \frac{(\mu/2)dt}{\mathcal{L}^{2}/z^{2} + \mu/2}\right)^{2}$$
(31)

and can, by introducing the coordinates (t, r, x) with

$$r = \mathcal{L}\sqrt{\frac{\mathcal{L}^2}{z^2} + \frac{\mu}{2}},\tag{32}$$

be written in the form

$$ds^{2} = -\frac{\left(r^{2} - \mu \mathcal{L}^{2}/2\right)^{2}}{\mathcal{L}^{2}r^{2}}dt^{2} + \frac{\mathcal{L}^{2}r^{2}dr^{2}}{\left(r^{2} - \mu \mathcal{L}^{2}/2\right)^{2}} + r^{2}\left(\frac{dx}{\mathcal{L}} - \frac{(\mathcal{L}\mu/2)dt}{r^{2}}\right)^{2}.$$
 (33)

This metric is of the BTZ form (16) with $d\varphi \to dx/\mathcal{L}$, $M = \mu$ and $J = \mu \mathcal{L}$. For $\mu > 0$ the metric is hence an extremal rotating BTZ hole, with the angular dimension unwrapped.

A similar analysis applies to the case in which f = 0 but $g \neq 0$, with M and J now having opposite signs.

3.4 Interpolation

Finally, we set

$$f(x^{-}) = \frac{1}{v^2 a^2}, \qquad g(x^{+}) = \frac{1}{v^2 (x^{+})^2},$$
(34)

where a is a positive constant of dimension length, v is a positive dimensionless constant and we assume $x^+ > 0$. This case can be regarded as being half-way between the Bjorken similarity flow case (19) and the plateau case of subsection 3.3. Note that ∂_{x^-} is a spacelike Killing vector in the bulk, and the boundary flow (13) is invariant under the corresponding null Killing vector ∂_{x^-} on the boundary.

We first transform from (x^+, x^-, z) to (w^+, w^-, α) by

$$x^{-} = vaw^{-},$$

$$\log\left(\frac{2av^{2}x^{+}}{\mathcal{L}^{2}}\right) = \frac{v}{\sqrt{1+(v/2)^{2}}}w^{+},$$

$$\log\left(\frac{z}{\mathcal{L}}\right) = -\alpha + \frac{(v/2)}{\sqrt{1+(v/2)^{2}}}w^{+}.$$
(35)

The conformal boundary is then at $\alpha \to \infty$ with fixed w^{\pm} . These coordinates are adapted to the commuting bulk Killing vectors $\partial_{w^-} = av \partial_{x^-}$ and ∂_{w^+} . To eliminate from the metric a cross term proportional to $d\alpha dw^+$, we transform to (y^+, y^-, ρ) , where

$$\cosh 2\alpha = \rho \sqrt{1 + (v/2)^2},$$

$$dw^+ = dy^+ - \frac{(v/4) d\rho}{(\rho^2 - 1) \sqrt{\left[1 + (v/2)^2\right] \rho^2 - 1}},$$

$$dw^- = dy^- - \frac{(v/4) \rho d\rho}{(\rho^2 - 1) \sqrt{\left[1 + (v/2)^2\right] \rho^2 - 1}},$$
(36)

and $\rho > 1$. The metric becomes

$$ds^{2} = \mathcal{L}^{2} \left[\left(dy^{+} \right)^{2} + \left(dy^{-} \right)^{2} - 2\rho \, dy^{+} dy^{-} + \frac{d\rho^{2}}{4\left(\rho^{2} - 1\right)} \right].$$
(37)

Note that both a and v have now disappeared. Transforming further to $(\theta^1, \theta^2, \chi)$ by

$$y^{\pm} = \frac{1}{2}(\theta^1 \pm \theta^2),$$

$$\rho = \cosh 2\chi,$$
(38)

where $\chi > 0$, we have

$$ds^{2} = \mathcal{L}^{2} \left[-(\sinh \chi)^{2} (d\theta^{1})^{2} + (\cosh \chi)^{2} (d\theta^{2})^{2} + d\chi^{2} \right].$$
(39)

The metric (39) is recognised as part of the AdS₃ hyperboloid in coordinates in which the Killing vectors ∂_{θ^1} and ∂_{θ^2} generate two commuting boosts [30, 31]: writing the hyperboloid in embedding coordinates (T^1, T^2, X^1, X^2) as

$$\mathcal{L}^{2} = (T^{1})^{2} + (T^{2})^{2} - (X^{1})^{2} - (X^{2})^{2},$$

$$ds^{2} = -(dT^{1})^{2} - (dT^{2})^{2} + (dX^{1})^{2} + (dX^{2})^{2},$$
(40)

we can choose the transformation to (39) so that $\partial_{\theta^1} = T^1 \partial_{X^1} + X^1 \partial_{T^1}$ and $\partial_{\theta^2} = T^2 \partial_{X^2} + X^2 \partial_{T^2}$. As $\partial_{x^-} = (va)^{-1} \partial_{y^-} = (va)^{-1} (\partial_{\theta^1} - \partial_{\theta^2})$, it finally follows that

$$\partial_{x^{-}} = \frac{1}{va} \left(T^{1} \partial_{X^{1}} + X^{1} \partial_{T^{1}} - T^{2} \partial_{X^{2}} - X^{2} \partial_{T^{2}} \right).$$
(41)

To summarise, the invariant geometric characterisation of the bulk Killing vector ∂_{x^-} can be read off from (41). As ∂_{x^-} is the bulk continuation of the boundary Killing vector under which the fluid flow is invariant, one is tempted to seek thermodynamics for the boundary flow from thermodynamics of bulk phenomena that are invariant under ∂_{x^-} . This strategy works for Bjorken similarity flow, as outlined in subsection 3.1 [9], and for the plateau flow, as outlined in subsection 3.3, since in both cases the Killing vector in question is a spacelike boost and the Killing horizon of the commuting orthogonal boost has a Hawking temperature. With the Killing vector (41), however, a thermodynamical bulk interpretation appears not to be known, and there is evidence that one may not exist [33]. It is certainly possible to transform the bulk metric to the BTZ form: given any M and J satisfying $M > |J/\mathcal{L}|$, the transformation

$$y^{\pm} = \frac{1}{2}\sqrt{M \mp (J/\mathcal{L})} \left(\frac{t}{\mathcal{L}} \pm \varphi\right),$$

$$\rho = \frac{2(r/\mathcal{L})^2 - M}{\sqrt{M^2 - (J/\mathcal{L})^2}},$$
(42)

takes the metric (37) to the BTZ metric (16). However, we then have

$$\partial_{y^{\pm}} = \frac{\mathcal{L}\partial_t \pm \partial_{\varphi}}{\sqrt{M \mp (J/\mathcal{L})}},\tag{43}$$

and consideration of the Killing vector $\partial_{x^-} = (va)^{-1} \partial_{y^-}$ does not appear to single out specific values of M and J for which the Killing horizon of ∂_t could be argued to provide a temperature for the boundary flow.

4 Collision

We now turn to situations in which a collision of two null dust flows evolves into Bjorken similarity flow at late times. We hence assume both f and g to vanish at negative argument, be nonzero and have the same sign for positive argument and approach Bjorken similarity flow form (19) at large positive argument.

Figure 1: Structure of the conformally invariant boundary flow following from the solution (8), assuming that f and g are vanishing at negative argument and are nonvanishing and have the same sign for positive argument. Within the past light cone of the origin the energy-momentum tensor vanishes. The left wedge $x^+ < 0 < x^-$ contains null dust moving to the right, and the right wedge $x^- < 0 < x^+$ contains null dust moving to the left. The future light cone of the origin contains expanding matter with the flow given by (13) and energy density given by (14). The special solution (44) that gives rise to unregulated Bjorken similarity flow (20)–(21) within the future light cone of the origin is also indicated; for this solution the energy density (21) diverges as $\tau \to 0$.

The general structure of the boundary flow is shown in Figure 1. Within the past light cone of the origin we have vacuum, the left wedge $x^+ < 0 < x^-$ contains null dust moving to the right, and the right wedge $x^- < 0 < x^+$ contains null dust moving to the left. Within the future light cone of the origin the null dusts have collided and formed the flow given by (13) and (14), which at late times tends to Bjorken similarity flow, (20) and (21).

The key point is now that a suitable choice of the null dust profiles resolves the initial singularity of Bjorken similarity flow. We look at unregulated Bjorken similarity flow in subsection 4.1 analyse two regulated versions in subsections 4.2 and 4.3.

4.1 Unregulated Bjorken similarity flow

Consider first the choice

$$g(x) = f(x) = \frac{M-1}{4x^2} \Theta(x),$$
 (44)

where M is a constant. Within the future light cone of the origin we then have Bjorken similarity flow (20)–(21). As reviewed in subsection 3.1, for positive M this flow can be

understood to describe a perfect fluid in adiabatic expansion with $\epsilon(\tau) \sim 1/\tau^2$ and $T(\tau) \sim 1/\tau$.

The problem with this scenario is however that the energy density diverges at $\tau \to 0$, and the energies E^{\pm} (11) of the initial null dust components also diverge. While for a (3+1)dimensional boundary the bulk dynamics may provide criteria for regulating the initial singularity [8, 13], we are not aware of similar criteria for (1+1)-dimensional boundary. We shall therefore regulate the singularity by a bottom-up phenomenological approach, introducing in the functions f and g and new scale that corresponds to the initial conditions.

4.2 Smooth profile

As a first alternative, we modify Bjorken similarity flow functions (44) to

$$f(x) = g(x) = \frac{M-1}{4(x^2 + a^2)}\Theta(x),$$
(45)

where a is a positive constant of dimension length. As the only other length scale in the problem is \mathcal{L} , one may expect on phenomenological grounds a to be proportional to \mathcal{L} by a dimensionless constant of order unity. For $x^{\pm} > 0$, we then obtain from (14)

$$\epsilon = p = \frac{\mathcal{L}}{8\pi G_3} \frac{\frac{1}{4} (M-1)}{\sqrt{(x^{+2} + a^2)(x^{-2} + a^2)}} = \frac{\mathcal{L}(M-1)}{16\pi G_3} \frac{1}{\sqrt{\tau^4 + 2a^2 \cosh(2\eta) + 4a^4}}.$$
 (46)

The energy density thus remains finite at $\tau \to 0$, has some η dependence at intermediate τ and approaches the similarity solution (21) as $\tau \to \infty$ at fixed η .

To see how the singularity at $\tau \to 0$ is opened up, we may compute the flow lines. Now all the particles do not emanate from the origin $x^+ = x^- = 0$. When the initial point is on the right-hand-side branch of the light cone, at $x^- = 0$ and $x^+ = x_i > 0$, equation (15) implies

$$\int_0^{x^-} \frac{dx^-}{\sqrt{(x^-)^2 + a^2}} = \int_{x_i}^{x^+} \frac{dx^+}{\sqrt{(x^+)^2 + a^2}},\tag{47}$$

which can be integrated to

$$x^{-}(x^{+}) = \frac{\left(x^{+} + \sqrt{(x^{+})^{2} + a^{2}}\right)^{2} - \left(x_{i} + \sqrt{x_{i}^{2} + a^{2}}\right)^{2}}{2\left(x^{+} + \sqrt{(x^{+})^{2} + a^{2}}\right)\left(x_{i} + \sqrt{x_{i}^{2} + a^{2}}\right)}.$$
(48)

Note that these paths stay in the region $x^+ > x^-$. When the initial point is on the left-handside branch of the light cone, the situation is similar with x^+ and x^- interchanged. The only path that starts from the origin is $x^+ = x^-$, obtained from (48) with $x_i = 0$. A selection of flow lines is shown in Figure 2. In the limit $a \to 0$, we obtain Bjorken similarity flow (20).

What this regularisation seems to lack, however, is a way to associate a temperature to the early stages of the flow. With Bjorken similarity flow, the temperature arose by noting that the flow is invariant under longitudinal boosts generated by the Killing vector ∂_{η} , the

Figure 2: Flow lines (48) for a = 1 and $x_i = 1/4$, 1/3, 1/2, 1, 2, 3, 4 and 5, and the corresponding flow lines with x^+ and x^- interchanged.

bulk solution (22) extends this Killing vector from the boundary to the bulk, and in the bulk metric (23) there is a commuting timelike Killing vector ∂_t whose horizon has a Hawking temperature [9]. We have not found a similar isometry argument that would apply to the flow with the particle paths (48).

4.3 Hard core profile

As a second alternative, we modify Bjorken similarity flow functions (44) to

$$f(x) = g(x) = \frac{M-1}{4} \left[\frac{1}{x^2} \Theta(x-a) + \frac{1}{a^2} \Theta(x) \Theta(a-x) \right],$$
(49)

where a is again a positive constant of dimension length. Phenomenologically, we might call the second term in (49) a hard core "nucleus", of characteristic size a, and the first term its longitudinal "tail". We shall assume M > 1.

Figure 3: The boundary flow with the regularisation (49). The various regions are described in the text. A curve of constant τ at $\tau > a\sqrt{2}$ is shown in the region $x^{\pm} > 0$.

The different regions on the boundary are shown in Figure 3. From (11) we find that the "incident beam energies" in the left and right wedges are given by

$$E^{\pm} = \frac{\mathcal{L}(M-1)}{32\pi G_3} \frac{\sqrt{2}}{a},$$
(50)

and for each null dust component this energy is distributed equally between the nucleus and its tail. As shown in subsection 3.3, the bulk metric in each null dust nucleus region can be thought of an extremal BTZ black hole, with the angular dimension unwrapped, and has therefore vanishing temperature. We thus regard the incident null dust beams as completely unthermalised, both in the nucleus and in the tail.

The region $x^{\pm} > 0$, in which the beams have collided, is divided into the central region in which the null dust tails overlap, two fragmentation regions in which one nucleus overlaps the other's tail, and the interaction diamond in which the two nuclei overlap. In the light

cone coordinates, the velocity field is given by

$$u^{\mu} = \begin{cases} \left(\sqrt{\frac{x^{+}}{2x^{-}}}, \sqrt{\frac{x^{-}}{2x^{+}}}\right) = \frac{x^{\mu}}{\tau}, \quad \text{central}; \\ \left(\sqrt{\frac{x^{+}}{2a}}, \sqrt{\frac{a}{2x^{+}}}\right), \quad \text{fragmentation at } x^{-} < a; \\ \left(\sqrt{\frac{a}{2x^{-}}}, \sqrt{\frac{x^{-}}{2a}}\right), \quad \text{fragmentation at } x^{+} < a; \\ \left(\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right), \quad \text{diamond.} \end{cases}$$
(51)

Note that in the interaction diamond the fluid is thus at rest in the Minkowski coordinates (t, x). For the energy density, (14) and (49) give

$$\epsilon(x^{+}, x^{-}) = \frac{\mathcal{L}(M-1)}{32\pi G_{3}} \left[\frac{1}{x^{+}x^{-}} \Theta(x^{+}-a)\Theta(x^{-}-a) + \frac{1}{ax^{+}} \Theta(x^{+}-a)\Theta(x^{-})\Theta(a-x^{-}) + (x^{+}\leftrightarrow x^{-}) + \frac{1}{a^{2}} \Theta(a-x^{+})\Theta(x^{+})\Theta(x^{-})\Theta(a-x^{-}) \right], \quad (52)$$

or, in Milne coordinates,

$$\epsilon(\tau,\eta) = \frac{\mathcal{L}(M-1)}{32\pi G_3} \left\{ \Theta\left(\tau - a\sqrt{2}\right) \left[\frac{2}{\tau^2} \Theta\left(\log\frac{\tau}{a\sqrt{2}} - |\eta|\right) + \frac{\sqrt{2}e^{-|\eta|}}{a\tau} \Theta\left(|\eta| - \log\frac{\tau}{a\sqrt{2}}\right) \right] + \Theta\left(a\sqrt{2} - \tau\right) \left[\frac{1}{a^2} \Theta\left(\log\frac{a\sqrt{2}}{\tau} - |\eta|\right) + \frac{\sqrt{2}e^{-|\eta|}}{a\tau} \Theta\left(|\eta| - \log\frac{a\sqrt{2}}{\tau}\right) \right] \right\}.$$
(53)

In Eq. (52) the first line describes the central region, the second line the two fragmentation regions and the last line the interaction diamond. In Eq. (53), plotted in Figure 4, the first line gives the energy density for $\tau > a\sqrt{2}$, where the interaction diamond does not contribute, and the second line gives the energy density for $\tau < a\sqrt{2}$, where the central region does not contribute. At $\eta = 0$, (53) reduces to

$$\epsilon(\tau,\eta=0) = \frac{\mathcal{L}(M-1)}{32\pi G_3} \left[\frac{2\Theta(\tau-a\sqrt{2})}{\tau^2} + \frac{\Theta(a\sqrt{2}-\tau)}{a^2} \right].$$
 (54)

We may again obtain a concrete view of how the singularity is opened up by computing the flow lines. For concreteness, consider the flow lines approaching from the right. In the

Figure 4: The energy density (53) divided by $\mathcal{L}(M-1)/(32\pi G_3)$ as a function of η at constant τ in the regularisation (49). The left panel shows the case $\tau > a\sqrt{2}$ and the right panel the case $\tau < a\sqrt{2}$. The parameter b equals $a\sqrt{2}$.

null dust region these lines are the null lines $x^+ = x_i^+$, where x_i^+ is a positive constant. The lines continue into the other regions for $x_i^+ < a$ as

$$x^{-} = \begin{cases} x^{+} - x_{i}^{+}, \text{ or } x = x_{i}^{+}/\sqrt{2}, & \text{diamond}; \\ a - x_{i}^{+} + a \log \frac{x^{+}}{a}, & \text{fragmentation region}; \\ x^{+} e^{x_{i}^{+}/a}, & \text{central region}, \end{cases}$$
(55)

and for $x_i^+ > a$ as

$$x^{-} = \begin{cases} a \log \frac{x^{+}}{x_{i}^{+}}, & \text{fragmentation region;} \\ x^{+} \frac{a}{ex_{i}^{+}}, & \text{central region.} \end{cases}$$
(56)

The lines are plotted in Figure 5. What is most striking here is that the fluid is brought momentarily to rest on the light cone of the origin, and in the fragmentation region it then accelerates in the direction opposite to where it came from. The conformal matter is thus extremely opaque. This seems superficially to be in complete disagreement with what one knows about heavy ion collisions, where nuclei are extremely transparent. However, this transparency is due to the valence quarks which represent non-conformal degrees of freedom in nuclei. By contrast, the conformal degrees of freedom are those built in the classical gluon fields (see Section 5) computed from the valence currents as sources [34].

For further insight into the dynamics, we may consider the conserved energy (11) on a surface of constant t. For t < 0, all of the energy is in the incident null dust flows, while at $t = a/\sqrt{2}$ exactly half of the energy is in the interaction diamond and the other half is still in the null dust flows. As t increases, more and more of the energy moves into the central region: for $t > a\sqrt{2}$, the energy in the central region reads

$$E_{\text{central}}(t) = \frac{\mathcal{L}(M-1)}{32\pi G_3} \frac{\sqrt{2}}{a} \left(1 - \frac{1}{t\sqrt{2}/a - 1}\right).$$
 (57)

Figure 5: Paths (55) and (56) of the fluid elements moving initially to the left with $x^+ = x_i^+$. In the Minkowski coordinates (t, x), the fluid comes momentarily to rest on the light cone of the origin, and it stays at rest everywhere within the interaction diamond.

Note that as $T_{\mu\nu}$ is conserved, $E_{\text{central}}(t)$ can be alternatively calculated as the integral of $\cosh \eta$ times the comoving energy density $\epsilon(\tau, \eta)$ (53) over the constant τ surface that meets the constant t surface on the boundary of the central region, $t\sqrt{2}/a - 1 = \tau^2/(2a^2)$:

$$E_{\text{central}}(\tau) = 2 \int_{0}^{\log(\tau/a\sqrt{2})} d\eta \cosh\eta \ \tau \epsilon(\tau > a\sqrt{2}, \eta) = \frac{\mathcal{L}(M-1)}{32\pi G_3} \frac{\sqrt{2}}{a} \left(1 - \frac{2a^2}{\tau^2}\right).$$
(58)

The factor $\cosh \eta$ here comes from the relative velocity of the flow lines, orthogonal to the constant τ surfaces, and the vector ∂_t , with respect to which the conserved energy was defined.

Now, to what extent can we recover time-dependent thermodynamics for the fluid flow after the beams have collided? The energy density is given by (52), or equivalently (53), and the equation of state is $\epsilon = p$, as is expected of a (1+1)-dimensional situation. The crucial step to thermodynamics is to find a reasonable notion of temperature. In the fragmentation regions the situation is unclear, for reasons discussed in subsection 3.4. In the central region, however, the flow is Bjorken similarity flow. If boundary effects can be neglected, the arguments of subsection 3.1 give this flow the τ -dependent temperature and entropy density

$$T_{\text{central}} = \frac{\sqrt{M}}{2\pi\tau}, \qquad s_{\text{central}} = \frac{\sqrt{M}}{4G_3}\frac{\mathcal{L}}{\tau}.$$
 (59)

Neglecting the boundary effects is likely to be justified provided the proper length $\tau \Delta \eta$ of a constant τ curve through the central region is much larger than the length scale T_{central}^{-1} associated with the temperature, and for values of $|\eta|$ that are not close to the boundary of the central region. These conditions read

$$\frac{\pi}{\sqrt{M}} \ll \log \frac{\tau}{a\sqrt{2}}, \qquad |\eta| \ll \log \frac{\tau}{a\sqrt{2}}, \tag{60}$$

or equivalently

$$a e^{\pi/\sqrt{M}} \ll \sqrt{x^+ x^-}, \qquad a \ll x^{\pm}.$$
 (61)

Similarly, if the boundary effects in the interaction diamond are neglected, the arguments of subsection 3.3 give the static flow therein the constant temperature and entropy density

$$T_{\text{diamond}} = \frac{\sqrt{M-1}}{2\sqrt{2}\pi a}, \qquad s_{\text{diamond}} = \frac{\sqrt{M-1}}{4G_3} \frac{\mathcal{L}}{a\sqrt{2}}, \tag{62}$$

and neglecting the boundary effects is likely to be justified provided the diamond is much larger than the length scale T_{diamond}^{-1} associated with the temperature and we are not close to the boundaries of the diamond, which conditions read

$$1 \ll M, \qquad |x^{\pm} - \frac{1}{2}a| \ll a.$$
 (63)

The formulas (59) and (62) for the temperature and the entropy density are thus likely to be reliable whenever $M \gg 1$, which can be regarded as the condition that the bulk is semiclassical [35], and we are not close to the boundary of respectively the central region and the interaction diamond. Note that these conditions do not depend on how *a* compares with the other length scales of the problem, \mathcal{L} and $\mathcal{L}\sqrt{M}$. As a consistency check, we note that in the limit of large M we have $\sqrt{M-1} \approx \sqrt{M}$, and formulas (59) and (62) for the temperature and the entropy density then agree at the point $(\tau, \eta) = (a\sqrt{2}, 0)$, at which the central region and the interaction diamond meet.

The model provides thus a consistent thermodynamical picture both in the hard core interaction region immediately after the collision, where the temperature and entropy density are approximately constant, and at late times, where the temperature falls off as $1/\tau$ and the fluid is a perfect fluid in adiabatic expansion [9]. In Section 5 we shall compare this (1+1)-dimensional thermodynamics with what would be expected in 3+1 dimensions in the classical gluon field model with currents of nuclei as sources.

5 Ensemble of classical gluon fields

Contrast now the above with the modeling of heavy ion collisions using ensembles of classical color fields [34]. One solves the color fields $A^a_{\mu}(t, \mathbf{x})$ in suitably chosen gauges from the Yang-Mills equations

$$[D_{\mu}, F^{\mu\nu}] = J^{\nu}, \tag{64}$$

where the source current represents the two nuclei moving along the light cone,

$$J^{\mu} = \delta^{\mu +} \delta(x^{-}) \rho_{(1)}(\mathbf{x}_{T}) + \delta^{\mu -} \delta(x^{+}) \rho_{(2)}(\mathbf{x}_{T}).$$
(65)

This current exists for all x^{\pm} and has the nuclear transparency built in it. The two color charge densities $\rho_{(m)}(\mathbf{x}_T)$ are, independently for the two nuclei, drawn from a Gaussian (in the simplest version of the model) random ensemble,

$$\langle \rho^a_{(m)}(\mathbf{x}_T) \rho^b_{(m)}(\mathbf{y}_T) \rangle = g^2 \mu^2_{(m)} \delta^{ab} \delta^2(\mathbf{x}_T - \mathbf{y}_T), \quad m = 1, 2,$$
(66)

where $g^2 \mu$ is a parameter describing the transverse density of color charges related [36] to the saturation scale by $Q_s^2 \approx 0.36(g^2\mu)^2 \approx 0.05 \text{GeV}^2 A^{1/3} (\sqrt{s}/Q_s)^{0.3}$. All information on the size of the nucleus and collision energy is built in Q_s . The computed expectation values $\langle A^a_{\mu} A^b_{\nu} \rangle$ can be converted to multiplicities and initial energy densities.

Numerical results are reported, for example, in [37]. One finds the initial energy density $\epsilon(\tau, \eta = 0) \sim Q_s^4$ for $\tau \leq 1/Q_s$; thermalisation takes place at later times. In view of the different dimensionalities the comparison is only qualitative, but with the identification $a \sim 1/Q_s$ the behavior is similar to that in Eq. (54). We thus suggest this interpretation for the parameter a introduced above. The gravity/CFT duality picture has also thermalisation built in.

6 Conclusions

We have in this paper presented an exact AdS_3 gravity solution which represents in the bulk a collision of two plane waves and on the conformal boundary a collision of two (1+1)dimensional extended objects. We chose the incoming wave profiles to consist of a hard core "nucleus", of boundary length scale *a* that can (but need not) be comparable to the AdS length scale \mathcal{L} in the bulk, and a "tail" with a $1/x^2$ falloff. In the region after the collision we then identified an interaction diamond where the hard core nuclei overlap, a central region where the tails overlap, and two interpolating fragmentation regions.

We saw that the boundary matter *recoils* in the collision: the conformal matter is thus extremely opaque. The interaction diamond corresponds, qualitatively, to the part of collision dynamics described by classical Yang-Mills field models with the indentification $a \sim 1/Q_s$, where Q_s is the saturation scale. There is also some qualitative similarity to Landau's hydrodynamic model [29, 38].

We identified the bulk duals of the central region and the interaction diamond as parts of a spinless BTZ black hole spacetime, with the angular dimension unwrapped, and in each case the local invariance of the boundary flow under a spacelike Killing vector was used to identify a horizon and its Hawking temperature in the bulk. When the colliding matter is sufficiently energetic, these bulk black holes are semiclassical $(M \gg 1)$, and we used the bulk-boundary flow. We argued that in the limit $M \gg 1$ the transition effects between the regions are negligible provided one is not close to the boundary of the region. In this approximation the flow in the interaction diamond the is static with constant temperature and entropy density, and the flow in the central region is Bjorken similarity flow of a perfect fluid in adiabatic expansion, with temperature inversely proportional to the proper time [9].

There are clearly many open issues to be studied. Within our colliding plane wave solution in the AdS_3 bulk, one question is how to introduce thermodynamics even when the boundary flow is not invariant under a spacelike Killing vector. The answer would open an avenue for investigating various phenomenologically-motivated thermalisation scenarios by suitable choices of the incoming wave profiles. The main issue of interest would clearly be to extend the work to more spatial dimensions, where gravitational bulk dynamics can be expected to give more structure to the boundary theory.
