## Abstract

In a recent paper, a genuine four-partite entangled state is proposed [Y. Yeo and W. K. Chua, Phys. Rev. Lett. **96**, 060502 (2006)], which has been found to have many interesting entanglement properties. We show this state is locally equivalent to some graph states.

Quantum entanglement has many applications such as teleportation [1] and dense coding [2]. Recently Yeo and Chua found a genuine four-qubit entangled state  $|\chi^{00}\rangle$  that can be used to teleport an arbitrary two-qubit state [3]. The state  $|\chi^{00}\rangle$  proposed in Ref. [3] has the form

$$\left|\chi^{00}\right\rangle = \frac{1}{\sqrt{2}} \left(\left|\zeta^{0}\right\rangle + \left|\zeta^{1}\right\rangle\right)_{A_{3}A_{4}B_{1}B_{2}},\tag{1}$$

with

$$\left|\zeta^{0}\right\rangle = \frac{1}{2} \left(\left|0000\right\rangle - \left|0011\right\rangle - \left|0101\right\rangle + \left|0110\right\rangle\right),$$
 (2)

$$\left|\zeta^{1}\right\rangle = \frac{1}{2}\left(\left|1001\right\rangle + \left|1010\right\rangle + \left|1100\right\rangle + \left|1111\right\rangle\right).$$
 (3)

It has been found that  $|\chi^{00}\rangle$  has many interesting entanglement properties [3]. It has maximal entanglement between  $A_3A_4$  and  $B_1B_2$  or between  $A_3B_1$  and  $A_4B_2$ , while it is not reducible to a pair of Bell states. The amount of entanglement between  $A_3B_2$  and  $A_4B_1$  has the value 1 when we use von Neumann entropy as an entanglement measure. It has properties that differ from those of four-party GHZ and W states [3]. Due to its interesting entanglement properties, the state  $|\chi^{00}\rangle$  attracts much attention [4, 5, 6].

It is not clear why the state  $|\chi^{00}\rangle$  has so many interesting entanglement properties. We will show  $|\chi^{00}\rangle$  is locally equivalent to some graph states. First let us give a simple introduction to graph states [7]. Let G = (V, E) be a graph, in which V is the set of vertices and E is the set of edges. The graph state  $|G\rangle$  corresponding to the graph G is the pure state

$$|G\rangle = \prod_{\{a,b\}\in E} U_{ab} |+\rangle^V, \qquad (4)$$

where  $|+\rangle = (|0\rangle + |1\rangle) / \sqrt{2}$  and  $U_{ab}$  is the controlled-phase gate

$$U_{ab} = |0\rangle_a \langle 0|_a \otimes I^b + |1\rangle_a \langle 1|_a \otimes \sigma_z^b.$$
(5)

For an instance, the graph  $G_a$  in FIG. 1(a) corresponds to the graph state

$$|G_a\rangle = U_{A_3A_4}U_{B_1B_2}U_{A_3B_1}U_{A_4B_2}|+\rangle_{A_3}|+\rangle_{A_4}|+\rangle_{B_1}|+\rangle_{B_2}.$$
 (6)

Two graphs G = (V, E) and G' = (V, E') are locally equivalent, if there is a local unitary  $U \in U(2)^V$  such that their corresponding graph states

$$\left|G'\right\rangle = U\left|G\right\rangle.\tag{7}$$

Local equivalence of graphs is connected to a graph transformation called local complementation: suppose G = (V, E) is a graph and  $a \in V$ , the local complement of G at a, denoted by  $\tau_a(G)$ , is a new graph obtained by complementing the neighborhood of a and leaving the rest of the graph unchanged. It has been proved that two graphs G = (V, E)and G' = (V, E') will be locally equivalent if they are related by a sequence of local complementations, i.e.,  $G' = \tau_{a_1} \circ \ldots \circ \tau_{a_n}(G)$  for some  $a_1, \ldots, a_n \in V$  [7, 8]. It can be easily found that the graph  $G_a$  in FIG. 1(a) and the graph  $G_b$  in FIG. 1(b) are locally equivalent because they are connected by a local complementation:

$$G_b = \tau_{A_4} \left( G_a \right). \tag{8}$$

The local equivalence between  $G_a$  and  $G_b$  can be confirmed by the relation between their corresponding graph states:

$$|G_b\rangle = e^{i\frac{\pi}{4}} e^{-i\frac{\pi}{4}\sigma_z^{A_3}} e^{i\frac{\pi}{4}\sigma_x^{A_4}} e^{-i\frac{\pi}{4}\sigma_z^{B_2}} |G_a\rangle.$$
(9)

Actually all graphs in FIG. 1 are locally equivalent since they are connected by local complementations. For more about graph states we refer to Ref. [7] and the references therein.

Our goal is to show  $|\chi^{00}\rangle$  is locally equivalent to graph states depicted by graphs in FIG. 1. It can be easily checked that  $|\chi^{00}\rangle$  is locally equivalent to  $|G_b\rangle$ :

$$\left|\chi^{00}\right\rangle = \sigma_z^{A_3} \sigma_z^{B_2} H^{B_2} \left|G_b\right\rangle,\tag{10}$$

where  $H^{B_2}$  is the Hadamard gate acting on qubit  $B_2$ . Because graph states depicted in FIG. 1 are locally equivalent, the state  $|\chi^{00}\rangle$  is locally equivalent to all these graph states. Since locally equivalent states have the same entanglement properties, the entanglement properties of  $|\chi^{00}\rangle$  can be obtained by studying the graph state  $|G_a\rangle$  or other locally equivalent graph states depicted in FIG. 1. It is not hard to find that  $|G_a\rangle$  has all the above mentioned properties of  $|\chi^{00}\rangle$ .

Now we give two more properties about  $|\chi^{00}\rangle$ . It is known that graph states are also stabilizer states [7], and the graph state  $|G_b\rangle$  is stabilized by the following four independent

commuting observables:

$$K_1 = \sigma_x^{A_3} \sigma_z^{A_4} \sigma_z^{B_1} \sigma_z^{B_2},\tag{11}$$

$$K_2 = \sigma_z^{A_3} \sigma_x^{A_4} \sigma_z^{B_2},\tag{12}$$

$$K_3 = \sigma_z^{A_3} \sigma_x^{B_1} \sigma_z^{B_2},\tag{13}$$

$$K_4 = \sigma_z^{A_3} \sigma_z^{A_4} \sigma_z^{B_1} \sigma_x^{B_2}. \tag{14}$$

From Eq. (10) we know  $|\chi^{00}\rangle$  is also a stabilizer state and it is stabilized by

$$\bar{K}_1 = \sigma_z^{A_3} \sigma_z^{B_2} H^{B_2} K_1 \sigma_z^{A_3} H^{B_2} \sigma_z^{B_2} = \sigma_x^{A_3} \sigma_z^{A_4} \sigma_z^{B_1} \sigma_x^{B_2}, \tag{15}$$

$$\bar{K}_2 = \sigma_z^{A_3} \sigma_z^{B_2} H^{B_2} K_2 \sigma_z^{A_3} H^{B_2} \sigma_z^{B_2} = -\sigma_z^{A_3} \sigma_x^{A_4} \sigma_x^{B_2},$$
(16)

$$\bar{K}_3 = \sigma_z^{A_3} \sigma_z^{B_2} H^{B_2} K_3 \sigma_z^{A_3} H^{B_2} \sigma_z^{B_2} = -\sigma_z^{A_3} \sigma_x^{B_1} \sigma_x^{B_2}, \tag{17}$$

$$\bar{K}_4 = \sigma_z^{A_3} \sigma_z^{B_2} H^{B_2} K_4 \sigma_z^{A_3} H^{B_2} \sigma_z^{B_2} = \sigma_z^{A_3} \sigma_z^{A_4} \sigma_z^{B_1} \sigma_z^{B_2}, \tag{18}$$

that is to say

$$\bar{K}_i \left| \chi^{00} \right\rangle = \left| \chi^{00} \right\rangle, i = 1, \dots, 4.$$
(19)

Eq. (19) can be directly checked from the expressions of  $|\chi^{00}\rangle$  and  $\bar{K}_i$ .

Another property about  $|\chi^{00}\rangle$  is that it also admits a GHZ-argument [9]. According to observables  $\bar{K}_1$ ,  $\bar{K}_2$ ,  $\bar{K}_4$  and

$$\bar{K}_1 \bar{K}_2 \bar{K}_4 = \sigma_x^{A_3} \sigma_x^{A_4} \sigma_z^{B_2}, \tag{20}$$

we can design four different measurement settings. In each measurement setting, the measurement results on different qubits will have a correlation. The observables  $\bar{K}_1$ ,  $\bar{K}_2$ ,  $\bar{K}_4$  and  $\bar{K}_1\bar{K}_2\bar{K}_4$  lead to the following correlations respectively

$$m_x^{A_3} m_z^{A_4} m_z^{B_1} m_x^{B_2} = 1, (21)$$

$$-m_z^{A_3}m_x^{A_4}m_x^{B_2} = 1, (22)$$

$$m_z^{A_3} m_z^{A_4} m_z^{B_1} m_z^{B_2} = 1, (23)$$

$$m_x^{A_3} m_x^{A_4} m_z^{B_2} = 1, (24)$$

where  $m_x^{A_3} = \pm 1$  and  $m_z^{A_3} = \pm 1$  denote measurement outcomes if the qubit  $A_3$  is measured in spin-*x* or spin-*z* direction. In local hidden variable theories all these four Eqs. (21-24) should be satisfied at the same time. However the product of Eq. (21), (22) and (23) gives

$$m_x^{A_3} m_x^{A_4} m_z^{B_2} = -1, (25)$$

which contradict with Eq. (24), so local hidden variable theories cannot be used to explain the measurement results on state  $|\chi^{00}\rangle$ .

In conclusion we have shown that the interesting four-partite genuine entangled state  $|\chi^{00}\rangle$  proposed in [3] is locally equivalent to graph states depicted by graphs in FIG. 1. This finding uncovers the mysteries of the state  $|\chi^{00}\rangle$  and gives an explanation why it has so many interesting entanglement properties. We have also shown  $|\chi^{00}\rangle$  is a stabilizer state and there is a GHZ-argument for  $|\chi^{00}\rangle$ .
