Abstract

We consistently formalize the probabilistic description of multipartite joint measurements performed on systems of any nature. This allows us: (1) to specify in probabilistic terms the difference between nonsignaling, the Einstein-Podolsky-Rosen (EPR) locality and Bell's locality; (2) to introduce the notion of an LHV model for an $S_1 \times \ldots \times S_N$ -setting N-partite correlation experiment with outcomes of any spectral type, discrete or continuous, and to prove both general and specifically "quantum" statements on an LHV simulation in an arbitrary multipartite case; (3) to classify LHV models for a multipartite quantum state, in particular, to show that any N-partite quantum state, pure or mixed, admits an $S_1 \times 1 \times \ldots \times 1$ -setting LHV description; (4) to evaluate a threshold visibility for an arbitrary bipartite noisy quantum state to admit an $S_1 \times S_2$ -setting LHV description under any generalized quantum measurements of two parties.

1 Introduction

The probabilistic description of quantum measurements performed by several parties has been discussed in the literature ever since the seminal publication [1] of Einstein, Podolsky and Rosen (EPR) in 1935. In that paper, the authors argued that *locality*¹ of measurements performed by different parties on perfectly correlated quantum events implies the "simultaneous reality - and thus definite values"² of physical quantities described by noncommuting quantum observables. This EPR argument, contradicting the quantum formalism [2] and referred to as the EPR paradox, seemed to imply a possibility of a *hidden variable* account of quantum measurements. However, the von Neumann "no-go" theorem [2], published in 1932, was considered wholly to exclude this possibility.

Analysing this problem in 1965 - 1966, Bell showed [3] that the setting of von Neumann "no-go" theorem contains the linearity assumption, inconsistent, in general, with the quantum formalism, and explicitly constructed [3] the hidden variable (HV) model reproducing the statistical properties of all quantum observables of qubit. Considering, however, spin measurements of two parties on the two-qubit quantum system in the singlet state, Bell proved [4] that any local hidden variable (LHV) description of these bipartite measurements on perfectly correlated quantum events disagrees with the statistical predictions of quantum theory. Based on his observations in [3,4], Bell concluded [3] that the EPR paradox should be resolved specifically due to the violation of locality under multipartite quantum measurements and that "...non-locality is deeply rooted in quantum mechanics itself and will persist in any completion"³.

In 1967, Kochen and Specker corrected [6] the setting of von Neumann "no-go" theorem according to Bell's remark in [3] and proved [6] that, for a quantum system described by a Hilbert space of a dimension $d \geq 3$, there does not exist a non-contextual hidden variable (HV) model that reproduces the statistical properties of all quantum observables and conserves the functional subordination between them. Specified for a tensor-product Hilbert space, the Kochen-Specker theorem excludes the existence of the non-contextual HV model for *all* projective measurements on a multipartite quantum state. For *multipartite* projective measurements, this HV model takes the LHV form.

Thus, on one hand, Bell's analysis⁴ in [4] does not exclude a possibility for multipartite measurements on an *arbitrary* nonseparable quantum state to admit an LHV model. On the other hand, the Kochen-Specker "no-go" theorem [6] *does not disprove* the existence for a multipartite quantum state of an LHV model of a *general* type. Therefore, Bell's analysis [4] plus the Kochen-Specker theorem [6] do not disprove that multipartite measurements on an *arbitrary* nonseparable quantum state may admit an LHV model of a *general* type.

In 1982, Fine [7] formalized the notion of an LHV model for a bipartite correlation experiment (not necessarily quantum), with two settings and two outcomes per site, and proved the main statements on an LHV simulation of this bipartite case.

In 1989, Werner presented [8] the nonseparable bipartite quantum state on $\mathbb{C}^d \otimes \mathbb{C}^d$, $d \geq 2$, that admits the LHV model under any bipartite projective measurements performed on this state.

 $^{^{1}}$ In [1], the Einstein-Podolsky-Rosen locality of parties' measurements is otherwise expressed as "without in any way disturbing" systems observed by other parties.

 $^{^{2}}$ See [1], page 778.

³See [5], page 171.

⁴In the physical literature, Bell's analysis in [4] is referred to as *Bell's theorem*.

Ever since these seminal publications, the conceptual and mathematical aspects of the LHV description of multipartite quantum measurements have been analysed in a plenty of papers, see, for example, [9-13] and references therein. The so-called Bell-type inequalities⁵, specifying multipartite measurement situations (correlation experiments) admitting an LHV description, are now widely used in many quantum information tasks.

Nevertheless, as it has been recently noted by Gisin [13], in this field, there are still "many questions, a few answers".

In our opinion, there is even still a lack in a consistent view on *locality* under multipartite measurements on spatially separated physical systems. For example, Werner and Wolf [10] identify *locality* with *nonsignaling* while Masanes, Acin and Gisin [12] specify quantum multipartite correlations as, in general, *nonlocal* and satisfying "the no-signaling principle". In [11], we argue that, in contrast to the opinion of Bell [4,5], under quantum multipartite joint measurements, locality meant by Einstein, Podolsky and Rosen in [1], the EPR locality, is never violated.

Furthermore, the notion of an LHV model is also understood differently by different authors. For example, for a bipartite quantum state, Werner's notion [8] of an LHV model is not equivalent to that of Fine [7] for bipartite measurements performed on this state.

It should be also stressed that, for an arbitrary multipartite case, there does not still exist either a consistent analysis of a possibility of an LHV simulation or a concise analytical approach to the derivation of extreme Bell-type inequalities for more than two outcomes per site. However, *generalized* bipartite quantum measurements on even two qubits may have infinitely many outcomes.

From the mathematical point of view, the necessity to analyse a possibility of an LHV simulation arises for any multipartite correlation experiment (not necessarily quantum), specified not in terms of a single probability space. The latter is one of the main notions of Kolmogorov's measure-theoretical formulation [14] of probability theory.

The aim of the present paper is to introduce a consistent frame for the probabilistic description of a multipartite correlation experiment on systems of *any* nature and to analyse a possibility of a simulation of such an experiment in LHV terms. The paper is organized as follows.

In sections 2, 3, we consistently formalize the probabilistic description of multipartite joint measurements with outcomes of any spectral type, discrete or continuous, and specify in probabilistic terms the difference between *nonsignaling*, the EPR locality [1] and Bell's locality [3-5]. We, in particular, show (proposition 1) that nonsignaling does not necessarily imply the EPR locality. The details of the probabilistic models for the description of multipartite joint measurements on physical systems, classical or quantum, are considered in section 3.1.

In section 4, we introduce the notion of an LHV model for an $S_1 \times ... \times S_N$ -setting N-partite correlation experiment, with outcomes of any spectral type, discrete or continuous, and prove the general statements (theorem 1, proposition 2) on an LHV simulation. We stress that the same family of multipartite joint measurements may admit several LHV models and that a family of multipartite joint measurements admitting an LHV model satisfies the nonsignaling condition but does not need to exhibit either Bell's locality or the EPR locality. The special statements on an LHV simulation in a general bipartite case and in a dichotomic multipartite

 $^{{}^{5}}$ A Bell-type inequality represents a linear probabilistic constraint (on either correlation functions or joint probabilities) that holds under any multipartite correlation experiment admitting an LHV description and may be violated otherwise.

case are introduced by theorems 2 and 3, respectively.

In section 5, we classify LHV models arising under EPR local multipartite joint measurements on a quantum state. We introduce the notion of an $S_1 \times ... \times S_N$ -setting LHV description of an *N*-partite quantum state and prove several statements (propositions 3 - 6) on an LHV description of a multipartite quantum state.

In a sequel to this paper, we shall introduce a single general representation incorporating in a unique manner all Bell-type inequalities for either joint probabilities or correlation functions that have been introduced or will be introduced in the literature.

2 Multipartite joint measurements

Consider a measurement situation where each *n*-th of *N* parties (players) performs a measurement, specified by a setting s_n , and Λ_n is a set of outcomes λ_n , not necessarily real numbers, observed by *n*-th party (equivalently, at *n*-th site).

This measurement situation defines the joint⁶ measurement with outcomes in $\Lambda_1 \times ... \times \Lambda_N$. We call this joint measurement N-partite and specify it by an N-tuple $(s_1, ..., s_N)$ of measurement settings where n-th argument refers to a setting at n-th site.

For an N-partite joint measurement $(s_1, ..., s_N)$, denote by

$$P_{(s_1,\dots,s_N)}(D_1 \times \dots \times D_N): = \operatorname{Prob}\{\lambda_1 \in D_1, \dots, \lambda_N \in D_N\}$$
(1)

the joint probability of events $D_1 \subseteq \Lambda_1, ..., D_N \subseteq \Lambda_N$, observed by the corresponding parties and by⁷

$$\langle \Psi(\lambda_1, ..., \lambda_N) \rangle := \int \Psi(\lambda_1, ..., \lambda_N) P_{(s_1, ..., s_N)}(\mathrm{d}\lambda_1 \times ... \times \mathrm{d}\lambda_N)$$
(2)

the expected value of a bounded measurable real-valued function $\Psi(\lambda_1, ..., \lambda_N)$. Specified for a function Ψ of the product form, notation (2) takes the form

$$\langle \varphi_1(\lambda_1) \cdot \dots \cdot \varphi_N(\lambda_N) \rangle = \int \varphi_1(\lambda_1) \cdot \dots \cdot \varphi_N(\lambda_N) \ P_{(s_1,\dots,s_N)}(d\lambda_1 \times \dots \times d\lambda_N)$$
(3)

and may refer either to the joint probability⁸:

$$\langle \chi_{D_1}(\lambda_1) \cdot \ldots \cdot \chi_{D_N}(\lambda_N) \rangle$$

$$= \int \chi_{D_1}(\lambda_1) \cdot \ldots \cdot \chi_{D_N}(\lambda_N) P_{(s_1,\ldots,s_N)}(d\lambda_1 \times \ldots \times d\lambda_N)$$

$$= P_{(s_1,\ldots,s_N)}(D_1 \times \ldots \times D_N),$$

$$(4)$$

or, if outcomes are real-valued and bounded, to the mean value:

$$\left\langle \lambda_{n_1} \cdot \ldots \cdot \lambda_{n_M} \right\rangle = \int \lambda_{n_1} \cdot \ldots \cdot \lambda_{n_M} P_{(s_1, \ldots, s_N)}(\mathrm{d}\lambda_1 \times \ldots \times \mathrm{d}\lambda_N), \tag{5}$$

of the product of outcomes observed at $M \leq N$ sites: $1 \leq n_1 < ... < n_M \leq N$.

⁶Any measurement with outcomes in a direct product set is called *joint*.

⁷For an integral over all values of variables, the domain of integration is not usually specified.

⁸Here, $\chi_D(\lambda)$, $\lambda \in \Lambda$, is an indicator function of a subset $D \subseteq \Lambda$. That is: $\chi_D(\lambda) = 1$ if $\lambda \in D$ and $\chi_D(\lambda) = 0$ if $\lambda \notin D$.

For $M \ge 2$, the mean value (5) is referred to as the correlation function. A correlation function for an N-partite joint measurement is called *full* whenever M = N.

If only outcomes of M < N parties: $1 \le n_1 < ... < n_M \le N$, are taken into account while outcomes of all other parties are ignored then the joint probability distribution of outcomes observed at these M sites is given by the following marginal of $P_{(s_1,...,s_N)}$:

$$P_{(s_1,\ldots,s_N)}(\Lambda_1\times\ldots\times\Lambda_{n_1-1}\times d\lambda_{n_1}\times\Lambda_{n_1+1}\times\ldots\times\Lambda_{n_M-1}\times d\lambda_{n_M}\times\Lambda_{n_M+1}\times\ldots\times\Lambda_N).$$
(6)

In particular, the marginal

$$P_{(s_1,\dots,s_N)}(\Lambda_1 \times \dots \times \Lambda_{n-1} \times d\lambda_n \times \Lambda_{n+1} \times \dots \times \Lambda_N)$$
(7)

represents the probability distribution of outcomes observed at n-th site.

Recall that events $D_1, ..., D_N$ observed by N parties are probabilistically independent [15] iff

$$P_{(s_1,\dots,s_N)}(D_1 \times \dots \times D_N) = \prod_n P_{(s_1,\dots,s_N)}(\Lambda_1 \times \dots \times \Lambda_{n-1} \times D_n \times \Lambda_{n+1} \times \dots \times \Lambda_N).$$
(8)

3 Nonsignaling, the EPR locality and Bell's locality

Consider now an N-partite measurement situation where any n-th party performs $S_n \geq 1$ measurements, each specified by a positive integer $s_n \in \{1, ..., S_n\}$. Let $\Lambda_n^{(s_n)}$ be a set of outcomes $\lambda_n^{(s_n)}$, observed under s_n -th measurement at n-th site.

This measurement situation (N-partite correlation experiment) is described by the whole family

$$\{(s_1, ..., s_N) \mid s_1 = 1, ..., S_1, ..., s_N = 1, ..., S_N\},\tag{9}$$

consisting of $S_1 \times \ldots \times S_N$ joint measurements.

Let, for any joint measurements $(s_1, ..., s_N)$ and $(s'_1, ..., s'_N)$ in (9) with M < N common settings at arbitrary sites $1 \le n_1 < ... < n_M \le N$:

$$\{s_{n_1}, \dots, s_{n_M}\} = \{s_1, \dots, s_N\} \cap \{s'_1, \dots, s'_N\},\tag{10}$$

marginals (6) coincide:

=

$$P_{(s_{1},..,s_{N})}(\Lambda_{1}^{(s_{1})} \times ... \times \Lambda_{n_{1}-1}^{(s_{n_{1}-1})} \times d\lambda_{n_{1}}^{(s_{n_{1}})} \times ... \times d\lambda_{n_{M}}^{(s_{n_{M}})} \times \Lambda_{n_{M}+1}^{(s_{n_{M}+1})} \times ... \times \Lambda_{N}^{(s_{N})})$$
(11)
$$P_{(s_{1}',..,s_{N}')}(\Lambda_{1}^{(s_{1}')} \times ... \times \Lambda_{n_{1}-1}^{(s_{n_{1}-1}')} \times d\lambda_{n_{1}}^{(s_{n_{1}})} \times ... \times d\lambda_{n_{M}}^{(s_{n_{M}})} \times \Lambda_{n_{M}+1}^{(s_{n_{M}+1}')} \times ... \times \Lambda_{N}^{(s_{N}')}).$$

If parties' measurements are performed on *spatially separated physical systems* then condition (11) corresponds to *nonsignaling* in the sense that: (i) a measurement device of each party does not directly affect physical systems and measurement devices at other sites; (ii) spatially separated physical systems either do not interact with each other or interact *locally*⁹

⁹In the sense that the physical principle of local action [16] is not violated.

with interaction signals¹⁰ coming from one system to another already after measurements upon them. If observed physical systems interact during measurements nonlocally then the nonsignaling condition (11) is, in general, violated.

For a general multipartite correlation experiment, we use a similar terminology.

Definition 1 For a family (9) of N-partite joint measurements, we refer to (11) as the nonsignaling condition.

Let further a measurement of each party be *local* in the Einstein, Podolsky and Rosen (EPR) sense [1]. As specified in footnote 1, the latter means that results of this measurement are not *in any way disturbed* by measurements performed by other parties.

In probabilistic terms, the EPR locality of all parties' measurements under a joint measurement $(s_1, ..., s_N)$ is expressed¹¹ by the relation:

$$P_{(s_1,\dots,s_N)}(\Lambda_1^{(s_1)} \times \dots \times \Lambda_{n_1-1}^{(s_{n_1-1})} \times d\lambda_{n_1}^{(s_{n_1})} \times \dots \times d\lambda_{n_M}^{(s_{n_M})} \times \Lambda_{n_M+1}^{(s_{n_M}+1)} \times \dots \times \Lambda_N^{(s_N)})$$

= $P_{(s_{n_1},\dots,s_{n_M})}(d\lambda_{n_1}^{(s_{n_1})} \times \dots \times d\lambda_{n_M}^{(s_{n_M})}),$ (12)

holding for any $M \leq N$ parties $1 \leq n_1 < ... < n_M \leq N$. With respect to an N-partite joint measurement, relation (12) induces the following notion.

Definition 2 An N-partite joint measurement $(s_1, ..., s_N)$ is EPR local if each marginal of its joint probability distribution $P_{(s_1,...,s_N)}$ satisfies condition (12).

For an EPR local N-partite joint measurement $(s_1, ..., s_N)$, the probability distribution of outcomes observed at *n*-th site depends only on a measurement setting at this site and we further denote it by

$$P_{(s_1,\dots,s_N)}(\Lambda_1^{(s_1)} \times \dots \times \Lambda_{n-1}^{(s_{n-1})} \times d\lambda_n^{(s_n)} \times \Lambda_{n+1}^{(s_{n+1})} \times \dots \times \Lambda_N^{(s_N)})$$
(13)
= $P_n^{(s_n)}(d\lambda_n^{(s_n)})$

Note that condition (12) does not imply the product form of distribution $P_{(s_1,\ldots,s_N)}$. Therefore, under an EPR local multipartite joint measurement, events observed at different sites *do not need* to be probabilistically independent.

From (12) it follows that any family of EPR local N-partite joint measurements satisfies the nonsignaling condition (11). However, the converse of this statement is not true¹².

Proposition 1 For a family (9) of N-partite joint measurements satisfying the nonsignaling condition (11), each of joint measurements does not need to be EPR local.

Proof. Consider, for example, the family of bipartite¹³ joint measurements, with two settings at each site and the joint probability distrubutions¹⁴

¹⁰Interaction signals between physical systems cannot propagate faster than light.

¹¹For a bipartite case, this definition was introduced in [11].

¹²In some publications (for example, in [12]), conditions (11), (12) are misleadingly viewed as equivalent.

¹³In quantum information litearture, two parties are traditionally named as Alice and Bob and their measurements are usually labeled by a_i and b_k .

¹⁴This family of bipartite joint measurements was introduced in [11].

$$P_{(a_i,b_k)}(\mathrm{d}\lambda_1^{(a_i)} \times \mathrm{d}\lambda_2^{(b_k)}) = \int_{\Omega} P_1^{(a_i)}(\mathrm{d}\lambda_1^{(a_i)}|\omega) \ P_2^{(b_k)}(\mathrm{d}\lambda_2^{(b_k)}|\omega) \ \tau_{a_1,a_2}^{(b_1,b_2)}(\mathrm{d}\omega), \quad i,k = 1,2,$$
(14)

where measure $\tau_{a_1,a_2}^{(b_1,b_2)}$ depends on all measurements at both parties. From relations

$$P_{(a_i,b_1)}(d\lambda_1^{(a_i)} \times \Lambda_2^{(b_1)}) = P_{(a_i,b_2)}(d\lambda_1^{(a_i)} \times \Lambda_2^{(b_2)})$$

$$= \int_{\Omega} P_1^{(a_i)}(d\lambda_1^{(a_i)}|\omega) \ \tau_{a_1,a_2}^{(b_1,b_2)}(d\omega), \quad \forall i = 1, 2,$$
(15)

and

$$P_{(a_1,b_k)}(\Lambda_1^{(a_1)} \times d\lambda_2^{(b_k)}) = P_{(a_2,b_k)}(\Lambda_1^{(a_2)} \times d\lambda_2^{(b_k)})$$

$$= \int_{\Omega} P_2^{(b_k)}(d\lambda_2^{(b_k)}|\omega) \ \tau_{a_1,a_2}^{(b_1,b_2)}(d\omega), \quad \forall k = 1, 2,$$
(16)

it follows that marginals of $P_{(a_i,b_k)}$, i, k = 1, 2, satisfy the nonsignaling condition (11), though do not, in general, satisfy the EPR locality condition (12).

For an N-partite joint measurement $(s_1, ..., s_N)$ performed on spatially separated physical systems, the EPR locality corresponds to nonsignaling plus no-feedback of performed measurements on a state of a composite physical system before all of parties' measurements.

Along with the nonsignaling condition and the EPR locality, consider also the concept of *Bell's locality*, introduced in [3-5] for multipartite measurements on spatially separated physical systems. This type of locality corresponds to *nonsignaling plus no-feedback plus the existence of variables* $\omega \in \Omega$ of a composite system such that whenever this system is initially characterized by a variable $\omega \in \Omega$ with certainty, then any events observed at different sites are *probabilistically independent:*

$$P_{(s_1,\dots,s_N)}(\mathrm{d}\lambda_1^{(s_1)}\times\dots\times\mathrm{d}\lambda_N^{(s_N)}\mid\omega) = P_1^{(s_1)}(\mathrm{d}\lambda_1^{(s_1)}\mid\omega)\cdot\dots\cdot P_N^{(s_N)}(\mathrm{d}\lambda_N^{(s_N)}\mid\omega), \quad \forall\omega\in\Omega.$$
(17)

If a composite system is initially specified by a probability distribution ν of variables $\omega \in \Omega$ then (17) and the law of total probability¹⁵ imply:

$$P_{(s_1,\dots,s_N)}(d\lambda_1^{(s_1)} \times \dots \times d\lambda_N^{(s_N)}) = \int_{\Omega} P_1^{(s_1)}(d\lambda_1^{(s_1)}|\omega) \cdot \dots \cdot P_N^{(s_N)}(d\lambda_N^{(s_N)}|\omega) \ \nu(d\omega).$$
(18)

For a general N-partite joint measurement, this relation induces the following notion.

Definition 3 An N-partite joint measurement $(s_1, ..., s_N)$ is Bell local if its joint probability distribution $P_{(s_1,...,s_N)}$ admits representation (18) where variables $\omega \in \Omega$ and a probability distribution ν do not depend on performed measurements.

From (11), (12), (18) and proposition 1 it follows that, for an N-partite correlation experiment,

$$Bell's \ locality \ \Rightarrow \ EPR \ locality \ \Rightarrow \ Nonsignaling.$$
(19)

The converse implications are not, in general, true.

 $^{^{15}}$ See, for example, in [15].

3.1 EPR local physical models

Consider the details of the probabilistic models describing *EPR local N*-partite joint measurements, performed on a composite *physical* system, classical or quantum.

EPR local classical model. Let, under an EPR local *N*-partite joint measurement, each party perform a measurement on a *classical* subsystem In this case, there always exist variables $\theta \in \Theta$ and a probability distribution π (a classical state) of these variables, characterizing a composite classical system before measurements and such that, for any EPR local *N*-partite joint measurement $(s_1, ..., s_N)$ on this classical system in a state π , the joint probability distribution $P_{(s_1,...,s_N)}(\cdot | \pi)$ has the form:

$$P_{(s_1,\dots,s_N)}(\mathrm{d}\lambda_1^{(s_1)}\times\dots\times\mathrm{d}\lambda_N^{(s_N)}\mid\pi) = \int\limits_{\Theta} P_1^{(s_1)}(\mathrm{d}\lambda_1^{(s_1)}\mid\theta)\cdot\dots\cdot P_N^{(s_N)}(\mathrm{d}\lambda_N^{(s_N)}\mid\theta)\ \pi(\mathrm{d}\theta), \quad (20)$$

where, for a variable $\theta \in \Theta$ defined initially with certainty, $P_n^{(s_n)}(\cdot|\theta)$ represents the probability distribution of outcomes observed under s_n -th classical measurement at *n*-th site. In (20), the *EPR locality* follows from the independence (no-feedback) of variables θ and a state π on performed measurements plus the independence (nonsignaling) of each conditional distribution $P_n^{(s_n)}(\cdot|\theta)$ on measurements of other parties.

From (18), (20) it follows that any classical EPR local multipartite joint measurement is also Bell local.

Let a classical measurement s_n at *n*-th site is *ideal*, that is, describes without an error a property of a composite classical system existed before this measurement. On a measurable space¹⁶ ($\Theta, \mathcal{F}_{\Theta}$), representing a classical composite system before measurements, any of its observed properties is described by a measurable function $f_{n,s_n} : \Theta \to \Lambda_n^{(s_n)}$. In the ideal case, distribution $P_n^{(s_n, \text{ ideal})}(\cdot|\theta)$, standing (20), takes the form:

$$P_n^{(s_n, \text{ ideal})}(D_n^{(s_n)}|\theta) = \chi_{f_{n,s_n}^{-1}(D_n^{(s_n)})}(\theta),$$
(21)

where

$$f_{n,s_n}^{-1}(D_n^{(s_n)}) = \left\{ \theta \in \Theta \mid f_{n,s_n}(\theta) \in D_n^{(s_n)} \right\} \in \mathcal{F}_{\Theta}$$
(22)

is the preimage of a subset $D_n^{(s_n)} \subseteq \Lambda_n^{(s_n)}$ in \mathcal{F}_{Θ} under mapping f_{n,s_n} . If classical measurements of all parties are ideal, then substituting (21) into (20), we derive that, under an *ideal classical EPR local N*-partite joint measurement $(s_1, ..., s_N)$, the joint probability distribution $P_{(s_1,...,s_N)}^{(\text{ideal})}$ has the image form:

$$P_{(s_1,\dots,s_N)}^{(\text{ideal})}(D_1^{(s_1)} \times \dots \times D_N^{(s_N)} \mid \pi) = \pi \left(f_{1,s_1}^{-1}(D_1^{(s_1)}) \cap \dots \cap f_{N,s_N}^{-1}(D_N^{(s_N)}) \right).$$
(23)

EPR local quantum model. If an EPR local *N*-partite joint measurement is performed on a *quantum N*-partite system, then this system is initially specified by a density operator ρ (a quantum state) on a complex separable Hilbert space $\mathcal{H}_1 \otimes ... \otimes \mathcal{H}_N$ and, for any EPR

¹⁶In this pair, \mathcal{F}_{Θ} is a sigma algebra of subsets of a set Θ .

local *N*-partite joint measurement performed on this system in a state ρ , the joint probability distribution $P_{(s_1,\ldots,s_N)}(\cdot|\rho)$ is given by:

$$P_{(s_1,\dots,s_N)}(\mathrm{d}\lambda_1^{(s_1)} \times \dots \times \mathrm{d}\lambda_N^{(s_N)} \mid \rho) = \mathrm{tr}[\rho\{\mathrm{M}_1^{(s_1)}(\mathrm{d}\lambda_1^{(s_1)}) \otimes \dots \otimes \mathrm{M}_N^{(s_N)}(\mathrm{d}\lambda_N^{(s_N)})\}],$$
(24)

where $M_n^{(s_n)}(d\lambda_n^{(s_n)})$, $n \in \{1, ..., N\}$, is a positive operator-valued *(POV)* measure¹⁷, describing s_n -th quantum measurement at *n*-th site. In (24), the *EPR locality* is expressed by the independence *(no-feedback)* of state ρ on performed measurements plus the independence *(nonsignaling)* of each $M_n^{(s_n)}$ on measurements at other sites.

If s_n -th measurement of *n*-th party is *ideal*, that is, reproduces without an error a realvalued quantum property described on \mathcal{H}_n by a quantum observable W_{s_n} , then the POV measure $\mathcal{M}_n^{(s_n)}$ is projection-valued and is given by the spectral measure $\mathcal{E}_{W_{s_n}}$ of observable W_{s_n} .

4 LHV simulation

Consider a possibility of a local hidden variable (LHV) simulation of an N-partite correlation experiment, described by the $S_1 \times ... \times S_N$ -setting family of N-partite joint measurements:

$$\{(s_1, ..., s_N) \mid s_1 = 1, ..., S_1, ..., s_N = 1, ..., S_N\},$$
(25)

with joint probability distributions

$$\{P_{(s_1,\dots,s_N)}, \quad s_1 = 1,\dots,S_1, \ \dots, \ s_N = 1,\dots,S_N\}.$$
(26)

The following notion corresponds to the description of *randomized* measurements in probability theory and generalizes to an arbitrary multipartite case the concept of a stochastic hidden variable model, formulated by Fine [7] for a bipartite case with two settings and two outcomes per site.

Definition 4 An $S_1 \times ... \times S_N$ -setting family (25) of N-partite joint measurements admits a local hidden variable (LHV) model if all its joint probability distributions (26) admit the factorizable representation of the form:

$$P_{(s_1,\ldots,s_N)}(\mathrm{d}\lambda_1^{(s_1)}\times\ldots\times\mathrm{d}\lambda_N^{(s_N)}) = \int_{\Omega} P_1^{(s_1)}(\mathrm{d}\lambda_1^{(s_1)}|\omega)\cdot\ldots\cdot P_N^{(s_N)}(\mathrm{d}\lambda_N^{(s_N)}|\omega) \ \nu(\mathrm{d}\omega), \qquad (27)$$

in terms of a single probability space¹⁸ $(\Omega, \mathcal{F}_{\Omega}, \nu)$ and conditional probability distributions¹⁹ $P_1^{(s_1)}(\cdot|\omega), \ldots, P_N^{(s_N)}(\cdot|\omega),$ defined ν -almost everywhere on Ω and such that each $P_n^{(s_n)}(\cdot|\omega)$ depends only on a setting of the corresponding measurement at n-th site.

If, in addition to (27), some distributions $P_n^{(s_n)}(\cdot|\omega)$ corresponding to different sites are correlated then we refer to such an LHV model as conditional.

 $^{^{17}}M_n^{(s_n)}(d\lambda_n^{(s_n)})$ is a normalized measure with values $M_n^{(s_n)}(D_n^{(s_n)})$, $\forall D_n^{(s_n)} \subseteq \Lambda_n^{(s_n)}$, that are positive operators on a complex separable Hilbert space \mathcal{H}_n . On the notion of a POV measure, see, for example, the review section in [17].

¹⁸In this triple, ν is a probability distribution on a measurable space $(\Omega, \mathcal{F}_{\Omega})$ (see footnote 16). In measure theory, triple $(\Omega, \mathcal{F}_{\Omega}, \nu)$ is referred to as a measure space.

¹⁹For any subset $D \subseteq \Lambda$, function $P(D|\cdot) : \Omega \to [0,1]$ is measurable.

If every party observes a finite number of outcomes, for example, each $\Lambda_n^{(s_n)} = \Lambda = \{\lambda_1, ..., \lambda_K\}$, then it suffices to verify the validity of representation (27) only for all one-point subsets $\{\lambda_{k_1}\} \times ... \times \{\lambda_{k_N}\} = \{(\lambda_{k_1}, ..., \lambda_{k_N})\} \subset \Lambda^N$.

From the LHV representation (27) it follows that any $S_1 \times ... \times S_N$ -setting family (25) of N-partite joint measurements admitting an LHV model satisfies the *nonsignaling* condition (11). We stress that, in a general LHV model, variables $\omega \in \Omega$ and a probability distribution ν have a purely simulation character and may depend on measurement settings of all (or some) parties. Therefore, in a family of N-partite joint measurements admitting an LHV model, each of joint measurements *does not need* to be either EPR local or Bell local (see section 3).

In view of representations (20), (27), any $S_1 \times ... \times S_N$ -setting family of EPR local *N*-partite joint measurements performed on a classical state π on $(\Theta, \mathcal{F}_{\Theta})$ admits the LHV model where the probability space is defined as $(\Theta, \mathcal{F}_{\Theta}, \pi)$ and does not depend on either numbers or settings of parties' measurements. This LHV model is of the special, *classical*, type.

Definition 5 An LHV model (27), conditional or unconditional, is called deterministic if there exist measurable functions $f_{n,s_n}: \Omega \to \Lambda_n^{(s_n)}$ such that, in (27)²⁰:

$$P_n^{(s_n)}(D_n^{(s_n)}|\omega) = \chi_{f_{n,s_n}^{-1}(D_n^{(s_n)})}(\omega), \quad \forall D_n^{(s_n)} \subseteq \Lambda_n^{(s_n)},$$
(28)

 ν -almost everywhere on Ω .

In a deterministic LHV model, specified by a probability space $(\Omega, \mathcal{F}_{\Omega}, \nu)$, each joint probability distribution $P_{(s_1,...,s_N)}$ has the image form:

$$P_{(s_1,\dots,s_N)}(D_1^{(s_1)} \times \dots \times D_N^{(s_N)}) = \nu \left(f_{1,s_1}^{-1}(D_1^{(s_1)}) \cap \dots \cap f_{N,s_N}^{-1}(D_N^{(s_N)}) \right),$$
(29)

for any outcome events $D_1^{(s_1)} \subseteq \Lambda_1^{(s_1)}, \, ..., \, D_N^{(s_N)} \subseteq \Lambda_N^{(s_N)}.$

Let an $S_1 \times ... \times S_N$ -setting family (25) of N-partite joint measurements admit an LHV model, specified by a probability space $(\Omega, \mathcal{F}_{\Omega}, \nu)$. From the structure of representation (27) and formula (3) it follows:

1. the same LHV model holds for any its $K_1 \times ... \times K_N$ -setting subfamily of N-partite joint measurements, where $K_1 \leq S_1, ..., K_N \leq S_N$, and for any $S_{n_1} \times ... \times S_{n_M}$ -setting family

$$\{(s_{n_1}, ..., s_{n_M}) \mid s_{n_1} = 1, ..., S_{n_1}, ..., s_{n_M} = 1, ..., S_{n_M}\}$$
(30)

of *M*-partite joint measurements: $1 \le n_1 < ... < n_M \le N$, $1 \le M < N$, induced by family (25);

2. for any measurable bounded real-valued functions $\varphi_n^{(s_n)}(\lambda_n^{(s_n)}), n = 1, ..., N$, the expected value of their product admits the factorizable representation:

$$\left\langle \varphi_1^{(s_1)}(\lambda_1^{(s_1)}) \cdot \dots \cdot \varphi_N^{(s_N)}(\lambda_N^{(s_N)}) \right\rangle = \int \Phi_1^{(s_1)}(\omega) \cdot \dots \cdot \Phi_N^{(s_N)}(\omega) \ \nu(\mathrm{d}\omega), \tag{31}$$

²⁰Here, $\chi_{f_{n,s_n}^{-1}(D_n^{(s_n)})}(\omega)$ is an indicator function of preimage $f_{n,s_n}^{-1}(D_n^{(s_n)})$, see (22).

with ν -measurable functions $\Phi_n^{(s_n)}(\omega) = \int \varphi_n^{(s_n)}(\lambda_n^{(s_n)}) P_n^{(s_n)}(\mathrm{d}\lambda_n^{(s_n)}|\omega)$. In a deterministic LHV model, $\Phi_n^{(s_n)}(\omega) = (\varphi_n^{(s_n)} \circ f_{n,s_n})(\omega)$.

The following theorem establishes the mutual equivalence of *four* different statements on an LHV simulation of a multipartite correlation experiment. Statements (a) - (c) generalize to an arbitrary multipartite case, with any numbers of settings and outcomes at each site, the corresponding propositions of Fine [7] for a bipartite case with two settings and two outcomes per site. Statement (d) establishes the relation between the existence of an LHV model (27) and the existence of the LHV-form representation (31) for the product expected values.

Theorem 1 For an $S_1 \times ... \times S_N$ -setting family (25) of N-partite joint measurements, the following statements are equivalent:

(a) there exists an LHV model, formulated by definition 4;

(b) there exists a deterministic LHV model, specified by definition 5;

(c) there exists a joint probability distribution

$$\mu(\mathrm{d}\lambda_1^{(1)} \times \dots \times \mathrm{d}\lambda_1^{(S_1)} \times \dots \times \mathrm{d}\lambda_N^{(1)} \times \dots \times \mathrm{d}\lambda_N^{(S_N)})$$
(32)

that returns all $P_{(s_1,\ldots,s_N)}$ of family (25) as marginals;

(d) there exists a probability space $(\Omega, \mathcal{F}_{\Omega}, \nu)$ and ν -measurable real-valued functions $\Psi_n^{(s_n)}$: $\Omega \to [-1, 1]$ on $(\Omega, \mathcal{F}_{\Omega})$ such that, for any ± 1 -valued functions $\psi_n^{(s_n)} : \Lambda_n^{(s_n)} \to \{-1, 1\}$, the LHV-form representation:

$$\left\langle \psi_{n_1}^{(s_{n_1})}(\lambda_{n_1}^{(s_{n_1})}) \cdot \dots \cdot \psi_{n_M}^{(s_{n_M})}(\lambda_{n_M}^{(s_{n_M})}) \right\rangle = \int \Psi_{n_1}^{(s_{n_1})}(\omega) \cdot \dots \cdot \Psi_{n_M}^{(s_{n_M})}(\omega) \ \nu(\mathrm{d}\omega), \tag{33}$$

holds for any

$$1 \le n_1 < \dots < n_M \le N, \quad 1 \le M \le N.$$
 (34)

Proof. Implication (b) \Rightarrow (a) is obvious. Let (a) hold and each $P_{(s_1,\ldots,s_N)}$ admit representation (27), specified by a probability space $(\Omega', \mathcal{F}_{\Omega'}, \nu')$ and conditional distributions $P_n^{(s_n)}(\cdot|\omega')$. The joint probability measure

$$\int_{\Omega'} \prod_{s_n,n} P_n^{(s_n)}(\mathrm{d}\lambda_n^{(s_n)}|\omega') \ \nu'(\mathrm{d}\omega')$$
(35)

on $\Lambda_1 \times \ldots \times \Lambda_N$ returns all distributions $P_{(s_1,\ldots,s_N)}$ of family (25) as marginals. Hence, (a) \Rightarrow (c).

Suppose that (c) holds. Then each $P_{(s_1,\ldots,s_N)}$ represents the corresponding marginal of μ and this means that, for any events $D_n^{(s_n)} \subseteq \Lambda_n^{(s_n)}$,

$$P_{(s_1,...,s_N)}(D_1^{(s_1)} \times ... \times D_N^{(s_N)})$$

$$= \int \chi_{D_1^{(s_1)}}(\lambda_1^{(s_1)}) \cdot ... \cdot \chi_{D_N^{(s_N)}}(\lambda_N^{(s_N)}) \ \mu(d\lambda_1 \times ... \times d\lambda_N),$$
(36)

where

$$\lambda_n = (\lambda_n^{(1)}, \dots, \lambda_n^{(S_n)}), \qquad \Lambda_n = \Lambda_n^{(1)} \times \dots \times \Lambda_n^{(S_n)}.$$
(37)

Representation (36) constitutes a particular case of the LHV representation (27), specified by

$$\omega = (\lambda_1, ..., \lambda_N), \qquad \Omega = \Lambda_1 \times ... \times \Lambda_N, \qquad (38)$$
$$\nu = \mu, \qquad P_n^{(s_n)}(D_n^{(s_n)}|\omega) = \chi_{D_n^{(s_n)}}(\lambda_n^{(s_n)}).$$

Introducing further measurable functions $f_{n,s_n}: \Omega \to \Lambda_n^{(s_n)}$, defined by the relation $f_{n,s_n}(\omega) := \lambda_n^{(s_n)}$, and noting that²¹

$$\chi_{D_n^{(s_n)}}(\lambda_n^{(s_n)}) = \chi_{f_{n,s_n}^{-1}(D_n^{(s_n)})}(\omega)$$
(39)

and (36) reads

$$P_{(s_1,\dots,s_N)}(D_1^{(s_1)} \times \dots \times D_N^{(s_N)}) = \int_{\Omega} \chi_{f_{1,s_1}^{-1}(D_1^{(s_1)})}(\omega) \cdot \dots \cdot \chi_{f_{N,s_N}^{-1}(D_N^{(s_N)})}(\omega) \nu(\mathrm{d}\omega) \quad (40)$$
$$= \nu \left(f_{1,s_1}^{-1}(D_1^{(s_1)}) \cap \dots \cap f_{N,s_N}^{-1}(D_N^{(s_N)}) \right).$$

This representation and definition 5 mean that $(c) \Rightarrow (b)$. Thus, we have proved

$$(a) \Leftrightarrow (b) \Leftrightarrow (c) \tag{41}$$

and it remains only to show that (d) implies (a).

Consider ±1-valued functions $\psi_n^{(s_n)}(\lambda_n^{(s_n)}) \in \{-1,1\}$. Let $D_n^{(s_n)} \subseteq \Lambda_n^{(s_n)}$ be a subset where a function $\psi_n^{(s_n)}$ admits the value (+1). The relation

$$\psi_n^{(s_n)}(\lambda_n^{(s_n)}) = 2\chi_{D_n^{(s_n)}}(\lambda_n^{(s_n)}) - 1$$
(42)

establishes the one-to-one correspondence between ±1-valued functions $\psi_n^{(s_n)}$ on $\Lambda_n^{(s_n)}$ and subsets $D_n^{(s_n)} \subseteq \Lambda_n^{(s_n)}$. Due to (42), each ±1-valued function $\psi_n^{(s_n)}$ on $\Lambda_n^{(s_n)}$ is uniquely specified by a subset $D_n^{(s_n)} \subseteq \Lambda_n^{(s_n)}$ and we replace notation $\psi_n^{(s_n)} \to \psi_{D_n^{(s_n)}}$. Taking (42) into account in representation (4), we derive:

$$P_{(s_1,\dots,s_N)}(D_1^{(s_1)} \times \dots \times D_N^{(s_N)}) = \frac{1}{2^N} \left\langle \{1 + \psi_{D_1^{(s_1)}}(\lambda_1^{(s_1)})\} \cdot \dots \cdot \{1 + \psi_{D_N^{(s_N)}}(\lambda_N^{(s_N)})\} \right\rangle.$$
(43)

Suppose that (d) holds. Then, for each n and each s_n , representation (33) defines the mapping $\psi_{D_n^{(s_n)}} \to \Psi_n^{(s_n)}$ from the set of all subsets $D_n^{(s_n)}$ of $\Lambda_n^{(s_n)}$ into the set of ν -measurable real-valued functions on $(\Omega, \mathcal{F}_{\Omega})$. This mapping is such that: $(\Psi_n^{(s_n)}(\Lambda_n^{(s_n)}))(\omega) = 1$ and $(\Psi_n^{(s_n)}(\emptyset))(\omega) = -1$, ν -almost everywhere on Ω .

Substituting (33) into (43), we derive that any joint distribution $P_{(s_1,\ldots,s_N)}$ admits the LHV representation:

²¹For notation $f_{n,s_n}^{-1}(D_n^{(s_n)})$, see (18).

$$P_{(s_1,\dots,s_N)}(D_1^{(s_1)} \times \dots \times D_N^{(s_N)}) = \int_{\Omega} P_1^{(s_1)}(D_1^{(s_1)}|\omega) \cdot \dots \cdot P_N^{(s_N)}(D_N^{(s_N)}|\omega)\nu(\mathrm{d}\omega),$$
(44)

where

$$P_n^{(s_n)}(D_n^{(s_n)}|\omega) = \frac{1}{2} \{ 1 + (\Psi_n^{(s_n)}(D_n^{(s_n)}))(\omega) \}.$$
(45)

Thus, $(d) \Rightarrow (a)$. In view of (41), this proves the mutual equivalence of all statements of theorem 1. \blacksquare

Since different joint probability measures may have the same marginals, in view of statement (c) of theorem 1, the same multipartite correlation experiment may admit a few LHV models not reducible to each other.

Consider a particular N-partite case where, say, n-th party performs $S_n \ge 2$ measurements while all other parties perform only one measurement: $S_k = 1, k \neq n$. Due to reindexing of sites, any of such cases can be reduced to the $S_1 \times 1... \times 1$ -setting case.

Proposition 2 Any $S_1 \times 1... \times 1$ -setting family of N-partite joint measurements, satisfying the nonsignaling condition (11), admits an LHV model.

Proof. For an $S_1 \times 1... \times 1$ -setting family of N-partite joint measurements, each joint distribution $P_{(s_1,1,\ldots,1)}$, $s_1 \in \{1,\ldots,S_1\}$, satisfies the relation:

$$P_{(s_1,1,\dots,1)}(\Lambda_1^{(s_1)} \times D') = 0, \quad \Rightarrow \quad P_{(s_1,1,\dots,1)}(D_1^{(s_1)} \times D') = 0, \tag{46}$$

for any subsets $D_1^{(s_1)} \subseteq \Lambda_1^{(s_1)}$ and $D' \subseteq \Lambda' := \Lambda_2^{(1)} \times \dots \times \Lambda_N^{(1)}$. Implication (46) means that, for any subset $D_1^{(s_1)} \subseteq \Lambda_1^{(s_1)}$, the probability distribution $P_{(s_1,1,\dots,1)}(D_1^{(s_1)} \times d\lambda')$ of outcomes $\lambda' = (\lambda_2^{(1)}, \dots, \lambda_N^{(1)})$ in Λ' is absolutely continuous²² with respect to the marginal $P_{(s_1,1,\dots,1)}(\Lambda_1^{(s_1)} \times d\lambda')$. Therefore, from the Radon-Nikodym theorem it follows:

$$P_{(s_1,1,\dots,1)}(d\lambda_1^{(s_1)} \times d\lambda_2^{(1)} \times \dots \times d\lambda_N^{(1)})$$

$$= \alpha_{s_1}(d\lambda_1^{(s_1)} | \lambda_2^{(1)}, \dots, \lambda_N^{(1)}) P_{(s_1,1,\dots,1)}(\Lambda_1^{(s_1)} \times d\lambda_2^{(1)} \times \dots \times d\lambda_N^{(1)}),$$
(47)

where $\alpha_{s_1}(d\lambda_1^{(s_1)}|\lambda')$ is a conditional probability distribution of outcomes in $\Lambda_1^{(s_1)}$, given a certain λ' .

Since all N-partite joint measurements $(s_1, 1, ..., 1)$ satisfy the nonsignaling condition (12), we have:

$$P_{(s_{1},1,...,1)}(\Lambda_{1}^{(s_{1})} \times d\lambda_{2}^{(1)} \times ... \times d\lambda_{N}^{(1)})$$

$$= P_{(s_{1}',1,...,1)}(\Lambda_{1}^{(s_{1}')} \times d\lambda_{2}^{(1)} \times ... \times d\lambda_{N}^{(1)})$$

$$= \tau(d\lambda_{2}^{(1)} \times ... \times d\lambda_{N}^{(1)}), \quad \forall s_{1}, s_{1}' \in \{1,...,S_{1}\}.$$
(48)

The joint probability distribution

$$\left(\alpha_{1}(\mathrm{d}\lambda_{1}^{(1)}|\lambda_{2}^{(1)},...,\lambda_{N}^{(1)})\cdot...\cdot\alpha_{S_{1}}(\mathrm{d}\lambda_{1}^{(S_{1})}|\lambda_{2}^{(1)},...,\lambda_{N}^{(1)})\right)\tau(\mathrm{d}\lambda_{2}^{(1)}\times...\times\mathrm{d}\lambda_{N}^{(1)})$$
(49)

 $^{^{22}}$ On this notion, see, for example, [15, 18].

returns all distributions $P_{(s_1,1,\ldots,1)}$ as the corresponding marginals. In view of implication $(c) \Rightarrow (a)$ in theorem 1, this proves the statement.

Consider now an LHV simulation of a bipartite correlation experiment.

Due to proposition 2, any $(S_1 \times 1)$ -setting (or $(1 \times S_2)$ -setting) family of bipartite joint measurements, satisfying the nonsignaling condition (11), admits an LHV model. The existence of an LHV model for an arbitrary $S_1 \times S_2$ -setting family of bipartite joint measurements is specified by the following theorem²³

Theorem 2 Necessary and sufficient condition for an $S_1 \times S_2$ -setting family of bipartite joint measurements, with outcomes of any spectral type, to admit an LHV model is the existence of joint probability distributions:

$$\mu_{\blacktriangleright}^{(s_1)}(\mathrm{d}\lambda_1^{(s_1)} \times \mathrm{d}\lambda_2^{(1)} \times ... \times \mathrm{d}\lambda_2^{(S_2)}), \quad s_1 = 1, ..., S_1,$$
(50)

such that each $\mu_{\blacktriangleright}^{(s_1)}$ returns all $P_{(s_1,s_2)}$, $s_2 = 1, ..., S_2$, as marginals and all $\mu_{\blacktriangleright}^{(s_1)}$, $s_1 = 1, ..., S_1$, are compatible in the sense that the relation:

$$\mu_{\blacktriangleright}^{(s_1)}(\Lambda_1^{(s_1)} \times d\lambda_2^{(1)} \times \dots \times d\lambda_2^{(S_2)}) = \mu_{\blacktriangleright}^{(s_1')}(\Lambda_1^{(s_1')} \times d\lambda_2^{(1)} \times \dots \times d\lambda_2^{(S_2)}),$$
(51)

holds for any $s_1, s'_1 \in \{1, ..., S_1\}$. The same concerns the existence of joint probability distributions:

$$\mu_{\blacktriangleleft}^{(s_2)}(\mathrm{d}\lambda_1^{(1)} \times ... \times \mathrm{d}\lambda_1^{(S_1)} \times \mathrm{d}\lambda_2^{(s_2)}), \quad s_2 = 1, ..., S_2, \tag{52}$$

such that each $\mu_{\blacktriangleleft}^{(s_2)}$ returns all $P_{(s_1,s_2)}$, $s_1 = 1, ..., S_1$, as marginals and all $\mu_{\blacktriangleleft}^{(s_2)}$, $s_2 = 1, ..., S_2$, satisfy the relation:

$$\mu^{(s_2)}_{\blacktriangleleft}(\mathrm{d}\lambda_1^{(1)} \times \dots \times \mathrm{d}\lambda_1^{(S_1)} \times \mathrm{d}\lambda_2^{(s_2)}) = \mu^{(s_2')}_{\blacktriangleleft}(\mathrm{d}\lambda_1^{(1)} \times \dots \times \mathrm{d}\lambda_1^{(S_1)} \times \mathrm{d}\lambda_2^{(s_2')}), \tag{53}$$

for any $s_2, s'_2 \in \{1, ..., S_2\}$.

Proof. Denote

$$\lambda_2 := (\lambda_2^{(1)}, \dots, \lambda_2^{(S_2)}), \quad \Lambda_2 := \Lambda_2^{(1)} \times \dots \times \Lambda_2^{(S_2)}, \tag{54}$$

for short. For each distribution $\mu_{\blacktriangleright}^{(s_1)}(d\lambda_1^{(s_1)} \times d\lambda_2)$ in (50), the relation

$$\mu_{\blacktriangleright}^{(s_1)}(\Lambda_1^{(s_1)} \times D_2) = 0 \quad \Rightarrow \quad \mu_{\blacktriangleright}^{(s_1)}(D_1^{(s_1)} \times D_2) = 0 \tag{55}$$

holds for any subsets $D_1^{(s_1)} \subseteq \Lambda_1^{(s_1)}$ and $D_2 \subseteq \Lambda_2$. This means that, for any $D_1^{(s_1)} \subseteq \Lambda_1^{(s_1)}$, the probability measure $\mu_{\blacktriangleright}^{(s_1)}(D_1^{(s_1)} \times d\lambda_2)$ of outcomes in Λ_2 is absolutely continuous²⁴ with respect to the marginal probability distribution $\mu_{\blacktriangleright}^{(s_1)}(\Lambda_1^{(s_1)} \times d\lambda_2)$. Therefore, each $\mu_{\blacktriangleright}^{(s_1)}$ admits the Radon-Nikodym representation:

$$\mu_{\blacktriangleright}^{(s_1)}(\mathrm{d}\lambda_1^{(s_1)} \times \mathrm{d}\lambda_2) = \alpha_1^{(s_1)}(\mathrm{d}\lambda_1^{(s_1)}|\lambda_2)\mu_{\blacktriangleright}^{(s_1)}(\Lambda_1^{(s_1)} \times \mathrm{d}\lambda_2), \tag{56}$$

 $^{^{23}}$ This theorem generalizes to an arbitrary bipartite case Fine's proposition 1 [7, page 292] for the 2×2-setting case with two outcomes per site.

²⁴See reference in footnote 22.

where $\alpha_1^{(s_1)}(\cdot|\lambda_2)$ is a conditional probability distribution of outcomes $\lambda_1^{(s_1)} \in \Lambda_1^{(s_1)}$. In view of (51), we denote

$$\mu_{\blacktriangleright}^{(s_1)}(\Lambda_1^{(s_1)} \times d\lambda_2) = \mu_{\blacktriangleright}^{(s_1')}(\Lambda_1^{(s_1')} \times d\lambda_2)$$

= $\tau_2(d\lambda_2), \quad s_1, \ s_1' \in \{1, ..., S_1\}.$ (57)

The joint probability measure

$$\left(\alpha_1^{(1)}(\mathrm{d}\lambda_1^{(1)}|\lambda_2)\cdot\ldots\cdot\alpha_1^{(S_1)}(\mathrm{d}\lambda_1^{(S_1)}|\lambda_2)\right)\tau_2(\mathrm{d}\lambda_2) \tag{58}$$

returns all $P_{(s_1,s_2)}$ as marginals. In view of theorem 1, this proves the sufficiency part of theorem 2.

In order to prove the necessity part, let an $S_1 \times S_2$ -setting family admit a LHV model. Then, by theorem 1, there exists a joint probability distribution $\mu(d\lambda_1^{(1)} \times ... \times d\lambda_1^{(S_1)} \times d\lambda_2^{(1)} \times ... \times d\lambda_2^{(S_2)})$ of all outcomes observed by two parties. The marginals

$$\mu(\Lambda_1^{(1)} \times .. \times \Lambda_1^{(s_1-1)} \times d\lambda_1^{(s_1)} \times \Lambda_1^{(s_1+1)} ... \times \Lambda_1^{(S_1)} \times d\lambda_2^{(1)} \times ... \times d\lambda_2^{(S_2)}), \quad (59)$$

$$s_1 = 1, ..., S_1,$$

constitute the probability distributions $\mu_{\blacktriangleright}^{(s_1)}$, specified by (50), (51). For measures $\mu_{\blacktriangleleft}^{(s_2)}$, the necessity and sufficiency parts are proved quite similarly.

Proposition 2 and theorems 1, 2 refer to an arbitrary multipartite case with outcomes of any spectral type. Below, we consider peculiarities of an LHV simulation in a multipartite case with only two outcomes per site.

4.1A dichotomic multipartite case

Let, under an N-partite joint measurement $(s_1, ..., s_N)$, each party perform a measurement with only two outcomes, a *dichotomic* measurement. These two outcomes do not need to be numbers, however, due to possible mappings $\lambda_n^{(s_n)} \mapsto \varphi_n^{(s_n)}(\lambda_n^{(s_n)}) \in \{-1,1\}$, it suffices to analyse only a dichotomic case with outcomes: $\lambda_n^{(s_n)} = \pm 1$. Since the direct product $\{\lambda_1^{(s_1)}\} \times \ldots \times \{\lambda_N^{(s_N)}\}$ of one-point subsets constitutes the one-point subset $\{(\lambda_1^{(s_1)}, \ldots, \lambda_N^{(s_N)})\} \subset \Lambda_1^{(s_1)} \times \ldots \times \Lambda_N^{(s_N)}$, for a discrete case, we further omit brackets $\{\cdot\}$ and denote:

brackets $\{\cdot\}$ and denote:

$$P_{(s_1,\dots,s_N)}(\{\lambda_1^{(s_1)}\} \times \dots \times \{\lambda_N^{(s_N)}\}) = P_{(s_1,\dots,s_N)}(\lambda_1^{(s_1)},\dots,\lambda_N^{(s_N)}).$$
(60)

Lemma 1 For an arbitrary N-partite joint measurement $(s_1, ..., s_N)$, with ± 1 -valued outcomes at each site,

$$2^{N} P_{(s_{1},...,s_{N})}(\lambda_{1}^{(s_{1})},...,\lambda_{N}^{(s_{N})})$$

$$= 1 + \sum_{\substack{1 \le n_{1} < ... < n_{N-k} \le N, \\ k=0,...,N-1}} \xi(\lambda_{n_{1}}^{(s_{n_{1}})}) \cdot ... \cdot \xi(\lambda_{n_{N-k}}^{(s_{n_{N-k}})}) \left\langle \lambda_{n_{1}}^{(s_{n_{1}})} \cdot ... \cdot \lambda_{n_{N-k}}^{(s_{n_{N-k}})} \right\rangle,$$
(61)

where $\xi(\pm 1) = \pm 1$.

Proof. Due to relations

$$2\chi_{\{1\}}(\lambda_n^{(s_n)}) - 1 = \lambda_n^{(s_n)}, \qquad 2\chi_{\{-1\}}(\lambda_n^{(s_n)}) - 1 = -\lambda_n^{(s_n)}, \tag{62}$$

holding for each $\lambda_n^{(s_n)} \in \{-1, 1\}$, we have:

$$\chi_{D_n^{(s_n)}}(\lambda_n^{(s_n)}) = \frac{1 + \lambda_n^{(s_n)}\xi(D_n^{(s_n)})}{2}, \quad \xi(\{1\}) = 1, \quad \xi(\{-1\}) = -1, \tag{63}$$

for each of one-point subsets $\{-1\}$ or $\{1\}$.

Substituting (63) into (4), for any direct product combination $D_1^{(s_1)} \times ... \times D_N^{(s_N)}$ of one-point subsets $\{-1\}$ and $\{1\}$, we derive:

$$P_{(s_{1},...,s_{N})}(D_{1}^{(s_{1})} \times ... \times D_{N}^{(s_{N})})$$

$$= \frac{1}{2^{N}} \left\langle (1 + \lambda_{1}^{(s_{1})} \xi(D_{1}^{(s_{1})})) \cdot ... \cdot (1 + \lambda_{N}^{(s_{N})} \xi(D_{N}^{(s_{N})})) \right\rangle$$

$$= \frac{1}{2^{N}} + \frac{1}{2^{N}} \sum_{\substack{1 \le n_{1} < ... < n_{N-k} \le N, \\ k = 0, ..., N-1}} \xi(D_{n_{1}}^{(s_{n_{1}})}) \cdot ... \cdot \xi(D_{n_{N-k}}^{(s_{n_{N-k}})}) \left\langle \lambda_{n_{1}}^{(s_{n_{1}})} \cdot ... \cdot \lambda_{n_{N-k}}^{(s_{n_{N-k}})} \right\rangle,$$
(64)

Using in (64) notation (60) and renaming $\xi(\{1\}) \to \xi(1), \, \xi(\{-1\}) \to \xi(-1)$, we prove (61).

From (61) it, in particular, follows:

$$2^{N} P_{(s_{1},...,s_{N})}(1,...,1) = 1 + \sum_{\substack{1 \le n_{1} < ... < n_{N-k} \le N, \\ k=0,...,N-1}} \left\langle \lambda_{n_{1}}^{(s_{n_{1}})} \cdot ... \cdot \lambda_{n_{N-k}}^{(s_{n_{N-k}})} \right\rangle.$$
(65)

In view of lemma 1, the mutual equivalence of statements (a) and (d) of theorem 1 takes the following form.

Theorem 3 An $S_1 \times ... \times S_N$ -setting family (25) of N-partite joint measurements, with ± 1 -valued outcomes at each site, admits an LHV model, formulated by definition 4, iff there exist a probability space $(\Omega, \mathcal{F}_{\Omega}, \nu)$ and ν -measurable real-valued functions

$$f_{n,s_n}: \Omega \to [-1,1], \quad \forall s_n, \forall n, \tag{66}$$

on $(\Omega, \mathcal{F}_{\Omega})$ such that any of the mean values:

$$\left\langle \lambda_{n_1}^{(s_{n_1})} \cdot \ldots \cdot \lambda_{n_M}^{(s_{n_M})} \right\rangle, \quad 1 \le n_1 < \ldots < n_M \le N, \qquad 1 \le M \le N, \tag{67}$$

admits the representation

$$\left\langle \lambda_{n_1}^{(s_{n_1})} \cdot \dots \cdot \lambda_{n_M}^{(s_{n_M})} \right\rangle = \int f_{n_1, s_{n_1}}(\omega) \cdot \dots \cdot f_{n_M, s_{n_M}}(\omega) \ \nu(\mathrm{d}\omega) \tag{68}$$

of the LHV-form.

Proof. The necessity follows from property 2 (see formula (31)). In order to prove the sufficiency part, let us substitute (68) into formula (61), in the form (64). For any direct product combination $D_1^{(s_1)} \times ... \times D_N^{(s_N)}$ of one-point subsets $\{-1\}$ and $\{1\}$, we derive:

$$P_{(s_1,\dots,s_N)}(D_1^{(s_1)} \times \dots \times D_N^{(s_N)})$$

$$= \frac{1}{2^N} \int [1 + \xi(D_1^{(s_1)}) f_{1,s_1}(\omega)] \cdot \dots \cdot [1 + \xi(D_N^{(s_N)}) f_{N,s_N}(\omega)] \nu(\mathrm{d}\omega).$$
(69)

Extending (69) to all subsets of set $\{-1, 1\}$, we have:

$$P_{(s_1,\dots,s_N)}(D_1^{(s_1)} \times \dots \times D_N^{(s_N)}) = \int P_1^{(s_1)}(D_1^{(s_1)} \mid \omega) \cdot \dots \cdot P_N^{(s_N)}(D_N^{(s_N)} \mid \omega) \ \nu(\mathrm{d}\omega), \tag{70}$$

where

$$P_n^{(s_n)}(\{1\} \mid \omega) = \frac{1}{2}[1 + f_{n,s_n}(\omega)], \quad P_n^{(s_n)}(\{-1\} \mid \omega) = \frac{1}{2}[1 - f_{n,s_n}(\omega)], \quad (71)$$
$$P_n^{(s_n)}(\emptyset \mid \omega) = 0, \quad P_n^{(s_n)}(\{-1,1\} \mid \omega) = 1.$$

This proves the statement. \blacksquare

From theorem 3 it follows that, for an arbitrary $S_1 \times ... \times S_N$ -setting family of N-partite joint measurements with two outcomes per site, the existence of the LHV-form representation (68) for only full correlation functions *does not*, in general, imply the existence of an LHV model (27) for joint probability distributions.

All statements of section 4 refer to an LHV simulation of a general correlation experiment. In the following section, we specify an LHV simulation of a quantum multipartite correlation experiment.

5 Quantum LHV models

We start by analysing an LHV simulation of an $S_1 \times S_2$ -setting bipartite correlation experiment performed upon a bipartite quantum system in a separable state:

$$\rho_{sep} = \sum_{m} \gamma_m \rho_1^{(m)} \otimes \rho_2^{(m)}, \quad \gamma_m \ge 0, \qquad \sum_{m} \gamma_m = 1, \tag{72}$$

on a complex separable Hilbert space $\mathcal{H} \otimes \mathcal{H}$, possibly infinite dimensional.

Let at each site quantum measurements be described by POV measures $M_1^{(s_1)}(d\lambda_1^{(s_1)})$, $s_1 = 1, ..., S_1$, and $M_2^{(s_2)}(d\lambda_2^{(s_2)})$, $s_2 = 1, ..., S_2$. From (24) and (72) it follows that, in the case considered, the joint probability distributions $P_{(s_1,s_2)}(\cdot|\rho_{sep})$ have the form:

$$P_{(s_1,s_2)}(\mathrm{d}\lambda_1^{(s_1)} \times \mathrm{d}\lambda_2^{(s_2)} \mid \rho_{sep})$$

$$= \sum_m \gamma_m \mathrm{tr}[\rho_1^{(m)} \mathrm{M}_1^{(s_1)}(\mathrm{d}\lambda_1^{(s_1)})] \, \mathrm{tr}[\rho_2^{(m)} \mathrm{M}_2^{(s_2)}(\mathrm{d}\lambda_2^{(s_2)})].$$
(73)

This form constitutes a particular case of the LHV representation (27), specified by the probability space

$$\Omega' = \{1, 2,\}, \qquad \nu'_{m} = \gamma_{m}, \quad \forall m,$$
(74)

and conditional distributions $P_n^{(s_n)}(\cdot | m) = \operatorname{tr}[\rho_n^{(m)} \mathcal{M}_n^{(s_n)}(\cdot)], s_n = 1, ..., S_n, n = 1, 2$, for any $m \in \Omega'$.

Thus, any $S_1 \times S_2$ -setting bipartite correlation experiment performed on a separable state ρ_{sep} admits the LHV model where the probability space is determined only by this separable state and does not depend either on numbers or on settings of parties' measurements.

Furthermore, all $P_{(s_1,s_2)}(\cdot | \rho_{sep})$, $s_1 = 1, ..., S_1$, $s_2 = 1, ..., S_2$, defined by (73), are marginals of the joint probability measure

$$\mu_{\rho_{sep}}^{(1)}(\mathrm{d}\lambda_{1}^{(1)} \times ... \times \mathrm{d}\lambda_{1}^{(S_{1})} \times \mathrm{d}\lambda_{2}^{(1)} \times ... \times \mathrm{d}\lambda_{2}^{(S_{2})})$$

$$= \sum_{m} \gamma_{m} \prod_{s_{1}, s_{2}} \mathrm{tr}[\rho_{1}^{(m)} \mathrm{M}_{1}^{(s_{1})}(\mathrm{d}\lambda_{1}^{(s_{1})})] \, \mathrm{tr}[\rho_{2}^{(m)} \mathrm{M}_{2}^{(s_{2})}(\mathrm{d}\lambda_{2}^{(s_{2})})].$$
(75)

Therefore, from representation (36) (in the proof of theorem 1) it follows that the considered correlation experiment admits also the LHV model, specified in (27) by the probability space $(\Omega, \mathcal{F}_{\Omega}, \mu_{\rho_{sep}}^{(1)})$, where

$$\omega = (\lambda_1^{(1)}, ..., \lambda_1^{(S_1)}, \lambda_2^{(1)}, ..., \lambda_2^{(S_2)}),$$

$$\Omega = \Lambda_1^{(1)} \times ... \times \Lambda_1^{(S_1)} \times \Lambda_2^{(1)} \times ... \times \Lambda_2^{(S_2)},$$
(76)

and conditional distributions $P_n^{(s_n)}(D_n^{(s_n)}|\omega) = \chi_{D_n^{(s_n)}}(\omega)$. This LHV model is, however, induced by the LHV model (74).

Consider further an $S_1 \times S_2$ -setting bipartite correlation experiment, performed on the *specific* bipartite separable state

$$\widetilde{\rho}_{sep} = \sum_{m} \gamma_{m} |e_{m}\rangle \langle e_{m}| \otimes |e_{m}\rangle \langle e_{m}|, \qquad (77)$$

where $\{e_m\}$ is an orthonormal basis in \mathcal{H} . Since state $\tilde{\rho}_{sep}$ is reduced from the nonseparable pure state

$$T = |\sum_{m} \sqrt{\gamma_m} e_m^{\otimes(S_1 + S_2)} \rangle \langle \sum_{m} \sqrt{\gamma_m} e_m^{\otimes(S_1 + S_2)} |$$
(78)

on $\mathcal{H}^{\otimes(S_1+S_2)}$, all distributions $P_{(s_1,s_2)}(\cdot \mid \tilde{\rho}_{sep})$ represent marginals of the joint measure

$$\mu_{\widetilde{\rho}_{sep}}^{(2)}(d\lambda_{1}^{(1)} \times ... \times d\lambda_{1}^{(S_{1})} \times d\lambda_{2}^{(1)} \times ... \times d\lambda_{2}^{(S_{2})})$$

$$= tr[T\{M_{1}^{(1)}(d\lambda_{1}^{(1)}) \otimes ... \otimes M_{1}^{(S_{1})}(d\lambda_{1}^{(S_{1})}) \otimes M_{2}^{(1)}(d\lambda_{2}^{(1)}) \otimes ... \otimes M_{2}^{(S_{2})}(d\lambda_{2}^{(S_{2})})\}]$$

$$= \sum_{m,l} \sqrt{\gamma_{m}} \sqrt{\gamma_{l}} \prod_{s_{1},s_{2}} \langle e_{m} | M_{1}^{(s_{1})}(d\lambda_{1}^{(s_{1})}) | e_{l} \rangle \langle e_{m} | M_{2}^{(s_{2})}(d\lambda_{2}^{(s_{2})}) | e_{l} \rangle.$$
(79)

Quite similarly as above, in view of representation (36) of theorem 1, this implies that any $S_1 \times S_2$ -setting family of bipartite joint measurements performed on $\tilde{\rho}_{sep}$ admits the LHV model, specified by the probability space $(\Omega, \mathcal{F}_{\Omega}, \mu_{\tilde{\rho}_{sep}}^{(2)})$, where variables $\omega \in \Omega$ are defined in (76) while distribution $\mu_{\tilde{\rho}_{sep}}^{(2)} \neq \mu_{\tilde{\rho}_{sep}}^{(1)}$. The latter LHV model is not reducible to the LHV model (74).

Thus, any $S_1 \times S_2$ -setting bipartite correlation experiment, performed on state $\tilde{\rho}_{sep}$, admits at least two LHV models not reducible to each other. The first LHV model, with the probability space (74) depending only on state $\tilde{\rho}_{sep}$, holds for any setting $S_1 \times S_2$. The second LHV model, with the probability space $(\Omega, \mathcal{F}_{\Omega}, \mu_{\tilde{\rho}_{sep}}^{(2)})$, is constructed specifically for a given setting $S_1 \times S_2$ and does not need to hold for a setting $S'_1 \times S'_2$ with $S'_1 + S'_2 > S_1 + S_2$.

In view of this analysis, we introduce the following notions.

Definition 6 An N-partite quantum state ρ admits an $S_1 \times ... \times S_N$ -setting LHV description if any $S_1 \times ... \times S_N$ -setting N-partite correlation experiment performed on this quantum state admits an LHV model formulated by definition 4.

This definition and the LHV property 1 (specified in section 3 after definition 5) imply the following statements on a LHV description of an arbitrary N-partite quatum state.

Proposition 3 Let an N-partite quatum state ρ on $\mathcal{H}_1 \otimes ... \otimes \mathcal{H}_N$ admits an $S_1 \times ... \times S_N$ -setting LHV description. Then:

(i) ρ admits any $K_1 \times ... \times K_N$ -setting LHV description where $K_1 \leq S_1, ..., K_N \leq S_N$;

(ii) for any sites $1 \le n_1 < ... < n_M \le N$, where $1 \le M < N$, the reduced M-partite state $\rho_{(n_1,...,n_M)}$ on $\mathcal{H}_{n_1} \otimes ... \otimes \mathcal{H}_{n_M}$ admits the $S_{n_1} \times ... \times S_{n_M}$ -setting LHV description.

We stress that an N-partite quatum state ρ , admitting the $K_1 \times ... \times K_N$ -setting LHV description, does not need to admit an $S_1 \times ... \times S_N$ -setting LHV description if $S_1 + ... + S_N > K_1 + ... + K_N$.

Definition 7 An N-partite quantum state ρ is said to admit an LHV model of Werner's type if any setting N-partite correlation experiment performed on this state admits one and the same LHV model formulated by definition 4.

Any separable state admits an LHV model of Werner's type. For a bipartite case, this model is specified by (74). The nonseparable Werner state [8] $W_{d,\Phi}$ on $\mathbb{C}^d \otimes \mathbb{C}^d$, with parameter $\Phi \geq -1 + \frac{d+1}{d^2}$, admits [8] an LHV model of Werner's type under any projective measurements of two parties.

From definitions 6, 7 it follows that if an N-partite quantum state ρ admits an LHV model of Werner's type then it admits a LHV description for any setting $S_1 \times \ldots \times S_N$. However, the converse of this statement is not true and even if an N-partite quantum state ρ admits an LHV description for any setting $S_1 \times \ldots \times S_N$, this does not imply that this ρ admits an LHV model of Werner's type - since for each concrete setting $S_1 \times \ldots \times S_N$, a probability space may depend not only a state ρ but also on performed measurements.

Due to definition 6 and proposition 2 in section 3, we have the following statement.

Proposition 4 An arbitrary N-partite quantum state ρ admits an $S_1 \times \underbrace{1 \times \ldots \times 1}_{N-1}$ -setting

LHV description for any $S_1 \ge 2$.

Consider a convex combination of N-partite quantum states admitting an LHV description.

Proposition 5 Let each of quantum states $\rho_1, ..., \rho_M$ on $\mathcal{H}_1 \otimes ... \otimes \mathcal{H}_N$ admit an $S_1 \times ... \times S_N$ -setting LHV description. Then any their convex combination:

$$\sum_{m} \gamma_m \rho_m, \quad \gamma_m \ge 0, \qquad \sum_{m} \gamma_m = 1, \tag{80}$$

also admits the $S_1 \times ... \times S_N$ -setting LHV description.

Proof. Suppose that every state ρ_m on $\mathcal{H}_1 \otimes ... \otimes \mathcal{H}_N$ admits an $S_1 \times ... \times S_N$ -setting LHV description. Then, by definition 6 and theorem 1, for any $S_1 \times ... \times S_N$ -setting family of N-partite joint measurements (24), performed on ρ_m and specified by POV measures $M_n^{(s_n)}$, $\forall s_n, \forall n$, there exists a joint probability distribution

$$\mu_m(\mathrm{d}\lambda_1^{(1)} \times \dots \times \mathrm{d}\lambda_1^{(S_1)} \times \dots \times \mathrm{d}\lambda_N^{(1)} \times \dots \times \mathrm{d}\lambda_N^{(S_N)}),\tag{81}$$

returning all

$$P_{(s_1,...,s_N)}(d\lambda_1^{(s_1)} \times ... \times d\lambda_N^{(s_N)} | \rho_m)$$

$$= tr[\rho_m \{ M_1^{(s_1)}(d\lambda_1^{(s_1)}) \otimes ... \otimes M_N^{(s_N)}(d\lambda_N^{(s_N)}) \}],$$

$$s_1 = 1,...,S_1,...,s_N = 1,...,S_N,$$
(82)

as marginals. This implies that, for a mixture $\eta = \sum_{m} \gamma_m \rho_m$, every

$$P_{(s_1,\ldots,s_N)}(\mathrm{d}\lambda_1^{(s_1)} \times \ldots \times \mathrm{d}\lambda_N^{(s_N)} \mid \eta)$$

$$= \sum_m \gamma_m \mathrm{tr}[\rho_m\{\mathrm{M}_1^{(s_1)}(\mathrm{d}\lambda_1^{(s_1)}) \otimes \ldots \otimes \mathrm{M}_N^{(s_N)}(\mathrm{d}\lambda_N^{(s_N)})\}]$$
(83)

constitutes the marginal of distribution $\sum_m \gamma_m \mu_m$. Therefore, by theorem 1, any $S_1 \times \ldots \times S_N$ -setting family of N-partite joint measurements on state $\sum_m \gamma_m \rho_m$ admits an LHV model. By definition 6, the latter means that state η_β admits the $S_1 \times \ldots \times S_N$ -setting LHV description.

In the following statement, proved in appendix, we establish a threshold bound for an arbitrary noisy bipartite state to admit an $S_1 \times S_2$ -setting LHV description. For any $1 \times S_2$ -setting (or $S_1 \times 1$ -setting) family, this bound is consistent with the statement of proposition 4.

Proposition 6 Let a bipartite quantum state ρ on $\mathbb{C}^{d_1} \otimes \mathbb{C}^{d_2}$, $d_1, d_2 \geq 2$, do not admit the LHV description for a given setting $S_1 \times S_2$. The noisy state

$$\eta_{\rho}(\gamma) = (1-\gamma) \frac{I_{\mathbb{C}^{d_1} \otimes \mathbb{C}^{d_2}}}{d_1 d_2} + \gamma \rho, \qquad 0 \le \gamma \le (1+\beta_{\rho})^{-1}, \tag{84}$$

admits the $S_1 \times S_2$ -setting LHV description under any generalized quantum measurements of two parties. In (84),

$$\beta_{\rho} = \min\left\{ d_1(S_2 - 1) ||\tau_{\rho}^{(1)}||; \ d_2(S_1 - 1) ||\tau_{\rho}^{(2)}|| \right\}$$
(85)

and $||\tau_{\rho}^{(1)}||$, $||\tau_{\rho}^{(2)}||$ are operator norms of the reduced states $\tau_{\rho}^{(1)} = \operatorname{tr}_{\mathbb{C}^{d_2}}[\rho]$ and $\tau_{\rho}^{(2)} = \operatorname{tr}_{\mathbb{C}^{d_1}}[\rho]$ on \mathbb{C}^{d_1} and \mathbb{C}^{d_2} , respectively.

As an example, let us specify bound (84) for the noisy state

$$\eta_{\psi}^{(d)}(\gamma) = (1-\gamma) \frac{I_{\mathbb{C}^d \otimes \mathbb{C}^d}}{d^2} + \gamma |\psi\rangle \langle \psi|, \qquad (86)$$

on $\mathbb{C}^d \otimes \mathbb{C}^d$, $d \geq 2$, induced by the maximally entangled pure state $\psi = \frac{1}{\sqrt{d}} \sum_{m=1}^d e_m \otimes e_m$, where $\{e_m\}$ is an orthonormal basis in \mathbb{C}^d .

In this case, $||\tau_{|\psi\rangle\langle\psi|}^{(n)}|| = \frac{1}{d}$, n = 1, 2, and substituting this into (84), we conclude that state $\eta_{|\psi\rangle\langle\psi|}^{(d)}(\gamma)$ admits an $S_1 \times S_2$ -setting LHV description under any generalized quantum measurements of two parties whenever

$$0 \le \gamma \le \frac{1}{1 + \min_{n=1,2}(S_n - 1)}.$$
(87)

Note that the partial transpose of $\eta_{|\psi\rangle\langle\psi|}^{(d)}(\gamma)$ has the eigenvalue $\frac{1-\gamma(d+1)}{d^2}$, which is negative for any $\gamma > \frac{1}{d+1}$. Therefore, due to the Peres separability criterion [22], state $\eta_{|\psi\rangle\langle\psi|}^{(d)}(\gamma)$ is nonseparable for any $\gamma \in (\frac{1}{d+1}, 1]$. Thus, for state (86), bound (87) is nontrivial whenever $\min_{n=1,2}(S_n-1) < d$.

6 Appendix

Consider the proof of proposition 6 in section 4. For the 2×2 -setting case, this proof is similar to our proof of theorem 1 in [19].

According to definition 6, in order to prove that state $\eta_{\rho}(\gamma)$ admits an $S_1 \times S_2$ -setting LHV description, we need to show that any $S_1 \times S_2$ -setting family of bipartite joint quantum measurements performed on $\eta_{\rho}(\gamma)$ admits an LHV model.

Let, at each site, quantum measurements be described by POV measures $M_1^{(s_1)}(d\lambda_1^{(s_1)})$, $s_1 = 1, ..., S_1$, and $M_2^{(s_2)}(d\lambda_2^{(s_2)})$, $s_2 = 1, ..., S_2$. From formula (24) it follows that distributions $P_{(s_1,.s_2)}(\cdot | \eta_{\rho})$ have the form

$$P_{(s_1,.s_2)}(\mathrm{d}\lambda_1^{(s_1)} \times \mathrm{d}\lambda_2^{(s_2)} \mid \eta_{\rho}) = \mathrm{tr}[\eta_{\rho}\{\mathrm{M}_1^{(s_1)}(\mathrm{d}\lambda_1^{(s_1)}) \otimes \mathrm{M}_2^{(s_2)}(\mathrm{d}\lambda_2^{(s_2)})\}], \qquad (A1)$$
$$s_1 = 1, ..., S_1, \quad s_2 = 1, ..., S_2.$$

For state η_{ρ} , introduce self-adjoint operators $T^{(1,S_2)}_{\blacktriangleright}$ on $\mathbb{C}^{d_1} \otimes (\mathbb{C}^{d_2})^{\otimes S_2}$ and $T^{(S_1,1)}_{\blacktriangleleft}$ on $(\mathbb{C}^{d_1})^{\otimes S_1} \otimes \mathbb{C}^{d_2}$, satisfying the relations:

$$\operatorname{tr}_{\mathbb{C}^{d_2}}^{(k_1,\dots,k_{S_2-1})}[T^{(1,S_2)}_{\blacktriangleright}] = \eta_{\rho}, \qquad 2 \le k_1 < \dots < k_{S_2-1} \le 1 + S_2, \tag{A2}$$

$$\operatorname{tr}_{\mathbb{C}^{d_1}}^{(l_1,\dots,l_{S_1-1})}[T^{(S_1,1)}_{\blacktriangleleft}] = \eta_{\rho}, \qquad 1 \le l_1 < \dots < l_{S_1-1} \le S_1.$$
(A3)

Here: (i) the below symbols at T_{\blacktriangleright} and T_{\blacktriangleleft} point to a direction of an extension of the Hilbert space $\mathbb{C}^{d_1} \otimes \mathbb{C}^{d_2}$; (ii) $\operatorname{tr}_{\mathbb{C}^{d_2}}^{(k_1,\ldots,k_{S_2-1})}[\cdot]$ denotes the partial trace over elements of \mathbb{C}^{d_2} , standing in k_1 -th, ..., k_{S_2-1} -th places in tensor products in $\mathbb{C}^{d_1} \otimes (\mathbb{C}^{d_2})^{\otimes S_2}$. Similarly, for the partial trace $\operatorname{tr}_{\mathbb{C}^{d_1}}^{(l_1,\ldots,l_{S_1-1})}[\cdot]$.

As we prove in [20], for any bipartite quantum state, dilations $T_{\blacktriangleright}^{(1,S_2)}$ and $T_{\blacktriangleleft}^{(S_1,1)}$ exist. In [20, 21], we refer to them as source operators for a bipartite state. Note that any positive source operator is a density operator.

If, for state η_{ρ} , there exist *density source operators* $T_{\blacktriangleright}^{(1,S_2)}$ and $T_{\blacktriangleleft}^{(S_1,1)}$, then the probability measures

$$\operatorname{tr}[T^{(1,S_2)}_{\blacktriangleright}\{\mathrm{M}^{(s_1)}_1(\mathrm{d}\lambda^{(s_1)}_1) \otimes \mathrm{M}^{(1)}_2(\mathrm{d}\lambda^{(1)}_2) \otimes \dots \otimes \mathrm{M}^{(S_2)}_2(\mathrm{d}\lambda^{(S_2)}_2)\}], \quad s_1 = 1, \dots, S_1,$$
(A4)

and

$$\operatorname{tr}[T_{\blacktriangleleft}^{(S_1,1)}\{\mathrm{M}_1^{(1)}(\mathrm{d}\lambda_1^{(1)}) \otimes \dots \otimes \mathrm{M}_1^{(S_1)}(\mathrm{d}\lambda_1^{(S_1)}) \otimes \mathrm{M}_2^{(s_2)}(\mathrm{d}\lambda_2^{(s_2)})\}], \quad s_2 = 1, \dots, S_2,$$
(A5)

constitute, correspondingly, distributions

$$\mu_{\blacktriangleright}^{(s_1)}(\mathrm{d}\lambda_1^{(s_1)} \times \mathrm{d}\lambda_2^{(1)} \times \dots \times \mathrm{d}\lambda_2^{(S_2)}), \quad s_1 = 1, \dots S_1,$$
(A6)

and

$$\mu^{(s_2)}_{\blacktriangleleft}(\mathrm{d}\lambda_1^{(1)} \times \dots \times \mathrm{d}\lambda_1^{(S_1)} \times \mathrm{d}\lambda_2^{(s_2)}), \quad s_2 = 1, \dots S_2, \tag{A7}$$

specified in theorem 2 of section 4.

Therefore, finding for state $\eta_{\rho}(\gamma)$ of a density source operator $T_{\blacktriangleright}^{(1,S_2)}$ (or $T_{\blacktriangleleft}^{(S_1,1)}$) will prove the existence for this state of an $S_1 \times S_2$ -setting LHV description.

Consider the spectral decomposition of state

$$\rho = \sum_{i} \alpha_{i} |\Psi_{i}\rangle \langle \Psi_{i}|, \quad \langle \Psi_{i}, \Psi_{j}\rangle = \delta_{ij}, \quad \forall \alpha_{i} > 0, \qquad \sum_{i} \alpha_{i} = 1.$$
(A8)

Let

$$\Psi_i = \sum_k \Phi_k^{(i)} \otimes f_k, \qquad \sum_k \langle \Phi_k^{(i)}, \Phi_k^{(j)} \rangle = \delta_{ij}, \tag{A9}$$

be the Schmidt decomposition of eigenvector Ψ_i with respect to an orthonormal basis $\{f_k\}$ in \mathbb{C}^{d_2} . Substituting this into (A8), we derive

$$\rho = \sum_{k,l=1}^{d_2} \rho_{kl} \otimes |f_k\rangle \langle f_l|, \qquad \rho_{kl} = \sum_i \alpha_i |\Phi_k^{(i)}\rangle \langle \Phi_l^{(i)}|. \tag{A10}$$

Operators ρ_{kk} are positive with $\sum_k \operatorname{tr}[\rho_{kk}] = 1$. Note that $\tau_{\rho}^{(1)} = \sum_k \rho_{kk}$ is the state on \mathbb{C}^{d_1} reduced from ρ .

Introduce on $\mathbb{C}^{d_1} \otimes (\mathbb{C}^{d_2})^{\otimes S_2}$ the self-adjoint operator

$$T^{(1,S_2)}_{\blacktriangleright}(\gamma) = (1-\gamma) \frac{I_{\mathbb{C}^{d_1}} \otimes I_{\mathbb{C}^{d_2}} \otimes I_{\mathbb{X}}}{d_1 d_2^{S_2}} + \frac{\gamma}{d_2^{S_2-1}} \sum_{k,l} \rho_{kl} \otimes |\{|f_k\rangle \langle f_l| \otimes I_{\mathbb{X}})\}_{sym}$$
(A11)
$$-\gamma (S_2 - 1) \tau^{(1)}_{\rho} \otimes \frac{I_{\mathbb{C}^{d_2}} \otimes I_{\mathbb{X}}}{d_2^{S_2}},$$

where $\mathbb{X} := (\mathbb{C}^{d_2})^{\otimes (S_2-1)}$ and operator $\{|f_k\rangle \langle f_l| \otimes I_{\mathbb{X}}\}_{sym}$ on $(\mathbb{C}^{d_2})^{\otimes S_2}$ represents the sym-

metrization of $|f_k\rangle\langle f_l| \otimes I_x$. It is easy to verify that $T^{(1,S_2)}_{\blacktriangleright}(\gamma)$ satisfies condition (A2) and, therefore, constitutes a source operator for state $\eta_{\rho}(\gamma)$. In order to find γ for which $T^{(1,S_2)}_{\blacktriangleright}(\gamma)$ is positive, let us

evaluate the sum of the first and the third terms standing in (A11). Taking into account the relation

$$- \|Y\| I_{\mathcal{K}} \le Y \le \|Y\| I_{\mathcal{K}}, \tag{A12}$$

holding for any bounded quantum observable Y on a Hilbert space \mathcal{K} , we derive:

$$(1-\gamma)\frac{I_{\mathbb{C}^{d_{1}}}\otimes I_{\mathbb{C}^{d_{2}}}\otimes I_{\mathbb{X}}}{d_{1}d_{2}^{S_{2}}} - \gamma(S_{2}-1)\tau_{\rho}^{(1)}\otimes \frac{I_{\mathbb{C}^{d_{2}}}\otimes I_{\mathbb{X}}}{d_{2}^{S_{2}}}$$

$$\geq \left[1-\gamma(1+d_{1}(S_{2}-1)||\tau_{\rho}^{(1)}||)\right] \frac{I_{\mathbb{C}^{d_{1}}}\otimes I_{\mathbb{C}^{d_{2}}}\otimes I_{\mathbb{X}}}{d_{1}d_{2}^{S_{2}}}.$$
(A13)

Therefore, $T^{(1,S_2)}_{\blacktriangleright}(\gamma)$ is positive (a density source operator) for any visibility

$$0 \le \gamma \le \left(1 + d_1(S_2 - 1) ||\tau_{\rho}^{(1)}||\right)^{-1}.$$
 (A14)

Quite similarly, state $\eta_{\rho}(\gamma)$ has a density source operator $T^{(S_1,1)}_{\blacktriangleleft}(\gamma)$ for any

$$0 \le \gamma \le \left(1 + d_2(S_1 - 1)||\tau_{\rho}^{(2)}||\right)^{-1}.$$
(A15)

From (A14) and (A15) it follows that state $\eta_{\rho}(\gamma)$ admits an $S_1 \times S_2$ -setting LHV description for any

$$0 \le \gamma \le \left(1 + \min\left\{d_1(S_2 - 1)||\tau_{\rho}^{(1)}||; \ d_2(S_1 - 1)||\tau_{\rho}^{(1)}||\right\}\right).$$
(A16)

Note that $||\tau_{\rho}^{(1)}|| \ge \frac{1}{d_1}$ and $||\tau_{\rho}^{(2)}|| \ge \frac{1}{d_2}$.
