We describe a class of the singular solutions to the multicomponent analogs of the Lamé equation, arising as equations of motion of the elliptic Calogero–Moser systems of particles carrying spin 1/2. At special value of the coupling constant we propose the ansatz which allows one to get meromorphic solutions with two arbitrary parameters. They are quantized upon the requirement of the regularity of the wave function on the hyperplanes at which particles meet and imposing periodic boundary conditions. We find also the extra integrals of motion for three-particle systems which commute with the Hamiltonian for arbitrary values of the coupling constant.

Keywords: Calogero–Moser systems; Elliptic functions; Integrability; Spin dynamical models

This letter is devoted to the problem of finding solutions to the matrix equation which arises naturally in the theory of quantum Calogero–Moser N -particle systems [\[1](#page-7-0), [2](#page-7-1)],

$$
H\psi = \left[-\frac{1}{2} \sum_{j=1}^{N} \left(\frac{\partial}{\partial x_j} \right)^2 + \sum_{j < k}^{N} a(a + S_{jk}) \wp(x_{jk}) \right] \psi = E\psi,\tag{1}
$$

where $\{x_j\}$ are coordinates of the particles, $x_{jk} \equiv x_j - x_k$, $\{s_j\}$ are their spins, ψ depends on ${x_j}$ and ${s_j}$, $a \in \mathbb{R}_+$, ${S_{jk}}$ permute s_j and s_k and form the $SU(n)$ spin representation of the permutation group S_N , and $\varphi(x)$ is the Weierstrass elliptic function with two arbitrary periods $2\omega_1$, $2\omega_2$ with only restriction $\text{Im}(\omega_2\omega_1^{-1}) \neq 0$. We shall suppose for definiteness that ω_1 is real. At $N = 2$, $\{S_{jk}\}\equiv 1$, one arrives at the usual Lamé equation, but the matrix problem is highly nontrivial even in the case of $N \geq 3$, $n = 2$ (particles carry spin 1/2) which we shall mainly discuss.

Various limits of the equation [\(1\)](#page-0-2) were extensively studied in a lot of papers [\[3](#page-7-2), [4,](#page-7-3) [5,](#page-7-4) [6,](#page-7-5) [7](#page-7-6), [8](#page-7-7), [9](#page-7-8), [10](#page-7-9), [11](#page-7-10), [12](#page-7-11), [13](#page-7-12), [15](#page-7-13), [16](#page-7-14)] and references therein. In [\[3](#page-7-2)], Olshanetsky and Perelomov found the

connection between [\(1\)](#page-0-2) and the roots of A_{N-1} algebra, and proved the integrability of quantum spinless Calogero–Moser systems (i.e. $\{S_{jk}\}\equiv 1$) but did not find any way of determining ψ . The first results for spinless particles were obtained in [\[4](#page-7-3)] where the explicit form of ψ was found for $a = 1, N = 3$, and algebraic structure of the manifold containing all ψ 's was described for all $a \in \mathbb{N}$, and all N. Later on, overcomplicated meromorphic solution for all $a \in \mathbb{N}$, N was found by Felder and Varchenko [\[5\]](#page-7-4). In [\[6](#page-7-5)], the author obtained explicit formulas for spinless case for all $a \in \mathbf{R}_+$ in the form of infinite series.

The trigonometric limit of [\(1\)](#page-0-2) ($|\omega_2| \to \infty$) has been also intensively studied [\[7,](#page-7-6) [8,](#page-7-7) [9](#page-7-8), [10](#page-7-9), [11](#page-7-10), [12,](#page-7-11) [13,](#page-7-12) [15\]](#page-7-13) for the case of particles carrying spin. In [\[7,](#page-7-6) [8](#page-7-7), [9](#page-7-8), [10,](#page-7-9) [11\]](#page-7-10), the solutions were found as the spin generalization of the Jack polynomials which provide adequate description in this limit of the eigenvalues problem for spinless case and arbitrary $a \in \mathbb{R}_{+}$. The corresponding symmetry responsible for these exact results was found to be the $\mathcal{Y}(SU(n))$ Yangian algebra [\[12,](#page-7-11) [13](#page-7-12), [14](#page-7-15)]. The authors of the paper [\[16](#page-7-14)] have considered elliptic spin case but they have found the effect of (quasi)exact solvability only for the case of the BC_N root systems, and [\(1\)](#page-0-2) does not fall into their classes. The quantum Lax pair, i.e. the solution to the equation $[H, L] = [L, M], L, M$ being $(N \times N)$ -matrices, was also mentioned in [\[15](#page-7-13)] for the elliptic case, but it was constructed without any dependence on a spectral parameter. Moreover, in the elliptic case even the existence of the Lax relation $[H, L] = [L, M]$ does not give the integrals of motion in the form of $I_j = \sum_{k,l}^{N} (L^j)_{kl}$ since the M matrix does not obey the "sum-to-zero" conditions $\sum_{j=1}^{N} M_{jk} = \sum_{k=1}^{N} M_{jk} = 0$.

In this situation, to our mind, every analytical results to the solutions of the elliptic matrix Schrödinger equation [\(1\)](#page-0-2) are of value, even for some restrictions for a, N and n. In what follows, we put $N = 3$ (three-particle case) and consider at first the question of the integrability of the problem defined by [\(1\)](#page-0-2) for arbitrary a and n. For the spinless case, it is known [\[3](#page-7-2)] that there is the operator

$$
\mathcal{J}_{scalar} = \frac{\partial^3}{\partial x_1 \partial x_2 \partial x_3} + a(a+1) \left[\left(\wp(x_{23}) - \wp(\alpha) \right) \frac{\partial}{\partial x_1} + \left(\wp(x_{31}) - \wp(\alpha) \right) \frac{\partial}{\partial x_2} + \left(\wp(x_{12}) - \wp(\alpha) \right) \frac{\partial}{\partial x_3} \right],\tag{2}
$$

commuting with H in this case, where α is an arbitrary "spectral" parameter which arises in the Lax-matrix approach. One can try to generalize this structure for the spin case as

$$
\widetilde{\mathcal{J}}_{scalar} = \frac{\partial^3}{\partial x_1 \partial x_2 \partial x_3} + \frac{1}{2} \sum_{j \neq k \neq l \neq j}^{3} a(a + S_{jk}) (\wp(x_{jk}) - \wp(\alpha)) \frac{\partial}{\partial x_l},\tag{3}
$$

but direct calculation shows that (3) does not commute with H and the term of higher order in permutations must be added. To gain some intuition for constructing the proper operator, we consider the "freezing trick" $(a \to \infty)$ by which the integrals of motion for quantum elliptic spin chain [\[17\]](#page-7-16) should be obtained, and try to add the analogs of these integrals to the ansatz [\(3\)](#page-1-0),

$$
\widetilde{\mathcal{J}}_{spin} = \frac{\partial^3}{\partial x_1 \partial x_2 \partial x_3} + \frac{1}{2} \sum_{\substack{j \neq k \neq l \neq j}}^3 a(a + S_{jk}) (\wp(x_{jk}) - \wp(\alpha)) \frac{\partial}{\partial x_l} + \lambda \sum_{\substack{j \neq k \neq l \neq j}}^3 f(x_{jk}) f(x_{kl}) f(x_{lj}) S_{jk} S_{kl},
$$
\n(4)

where the function $f(x_{jk})$ is analogous to the elements of the Lax matrix for quantum spin chain situation,

$$
f(x_{jk}) = \frac{\sigma(x_{jk} + \alpha)}{\sigma(x_{jk})\sigma(\alpha)}.
$$
\n(5)

Here $\sigma(x)$ is the Weierstrass sigma function, $\frac{d^2}{dx^2} \log \sigma(x) = -\wp(x)$, $\sigma(x) \sim x + O(x^5)$ as $x \to 0$, and λ is some parameter which should be determined by the commutativity condition,

$$
[H,\widetilde{\mathcal{J}}_{spin}]=0.
$$

Our computations shows that the ansatz [\(4\)](#page-2-0) is indeed correct and

$$
\lambda = a^2/3. \tag{6}
$$

Moreover, the function

$$
\Phi_{jkl} = f(x_{jk})f(x_{kl})f(x_{lj})\tag{7}
$$

is simplified drastically when being considered as the elliptic function of the spectral parameter α, having a pole of third order as $\alpha \to 0$ (and no other singularities on the torus C/Γ, Γ = $2\mathbf{Z}\omega_1 + 2\mathbf{Z}\omega_2$. It can be written as

$$
\Phi_{jkl} = -\frac{1}{2}\wp'(\alpha) + \psi_{jkl}\wp(\alpha) + \varphi_{jkl},\tag{8}
$$

where the functions ψ_{jkl} and φ_{jkl} do not depend on α and can be found by calculating the coeffi-cients of the Laurent series for [\(7\)](#page-2-1) at $\alpha \to 0$,

$$
\psi_{jkl} = \zeta(x_{jk}) + \zeta(x_{kl}) + \zeta(x_{lj}),\tag{9}
$$

$$
\varphi_{jkl} = -\frac{1}{6} \Big\{ \wp'(x_{jk}) + \wp'(x_{kl}) + \wp'(x_{lj}) + 2 \big[\zeta(x_{jk}) + \zeta(x_{kl}) + \zeta(x_{lj}) \big]^3 \Big\}.
$$
 (10)

The formula [\(10\)](#page-2-2) is obtained with the use of the well-known relation

$$
\wp(x_{jk}) + \wp(x_{kl}) + \wp(x_{lj}) = \left[\zeta(x_{jk}) + \zeta(x_{kl}) + \zeta(x_{lj})\right]^2,
$$

where $\zeta(x)$ is the usual Weierstrass zeta function, $\zeta'(x) = -\wp(x)$. Hence we found two independent integrals of motion from [\(4](#page-2-0)[–10\)](#page-2-2) due to the arbitrariness of a spectral parameter α ,

$$
\mathcal{J}_1 = \sum_{j < k < l} \frac{\partial^3}{\partial x_j \partial x_k \partial x_l} + \frac{1}{2} \sum_{j \neq k \neq l \neq j}^3 a(a + S_{jk}) \wp(x_{jk}) \frac{\partial}{\partial x_l} + \frac{a^2}{3} \sum_{j \neq k \neq l \neq j}^3 \varphi_{jkl} S_{jk} S_{kl},\tag{11}
$$

$$
\mathcal{J}_2 = \frac{1}{2} \sum_{j \neq k \neq l \neq j}^{3} S_{jk} \frac{\partial}{\partial x_l} - \frac{a}{3} \sum_{j \neq k \neq l \neq j}^{3} \psi_{jkl} S_{jk} S_{kl}.\tag{12}
$$

The formula for \mathcal{J}_2 is especially simple: it resembles the total momentum (and coincides with it as $\{S_{jk}\}=1$). In the trigonometric limit, it can be expressed through the scalar product of the Yangian generator and total spin which (in this limit only!) both commute with H . We confirmed also, by direct computation of $[\mathcal{J}_1,\mathcal{J}_2]$, that these operators mutually commute and form with H and total momentum the commutative ring for all values of the parameter a.

Let us now construct the explicit solutions of [\(1\)](#page-0-2) for the simplest nontrivial case of three particles carrying spin 1/2. When all spins aligned up or down, we have the situation analogous to the spinless case [\[4\]](#page-7-3). The nontrivial form of the wave function ψ arising for the states with total spin $S = 1/2$ is as follows

$$
\psi(x_1, x_2, x_3) = A(\mathbf{x})|\uparrow\uparrow\downarrow\rangle + B(\mathbf{x})|\uparrow\downarrow\uparrow\rangle + C(\mathbf{x})|\downarrow\uparrow\uparrow\rangle, \quad A + B + C = 0. \tag{13}
$$

The operators $\{a(a + S_{jk})\}$ act on the spin pairs in the states $(\uparrow \uparrow), (\uparrow \downarrow + \downarrow \uparrow)$ as $a(a + 1)$ and for $(\uparrow\downarrow - \downarrow\uparrow)$ as $a(a-1)$. If a is chosen as positive integer, there are singularities in the spinless case in the form of poles, $(x_j - x_k)^{-a}$ as $x_{jk} \to 0$. It is natural to expect that in the case of particles with spin at least some solutions to (1) have the similar structure, i.e. A, B, C have singular behavior as $x_{jk} \to 0$ in the form of poles. The equation [\(1\)](#page-0-2) reads in the component form after substituting [\(13\)](#page-3-0) as

$$
\left(\frac{1}{2}\sum_{j=1}^{3}\frac{\partial^{2}}{\partial x_{j}^{2}} + E\right)A - \sum_{j>k}^{3}\wp(x_{jk})A - \left[\wp(x_{12})A + \wp(x_{31})C + \wp(x_{23})B\right] = 0,
$$
\n(14)

$$
\left(\frac{1}{2}\sum_{j=1}^{3}\frac{\partial^{2}}{\partial x_{j}^{2}} + E\right)B - \sum_{j>k}^{3}\wp(x_{jk})B - \left[\wp(x_{12})C + \wp(x_{31})B + \wp(x_{23})A\right] = 0,
$$
\n(15)

$$
\left(\frac{1}{2}\sum_{j=1}^{3}\frac{\partial^{2}}{\partial x_{j}^{2}}+E\right)C-\sum_{j>k}^{3}\wp(x_{jk})C-\left[\wp(x_{12})B+\wp(x_{31})A+\wp(x_{23})C\right]=0.\tag{16}
$$

Let us introduce the notation

$$
Y(\mathbf{x}) = A(\mathbf{x}) - B(\mathbf{x}), \quad Z(\mathbf{x}) = A(\mathbf{x}) - C(\mathbf{x}) \tag{17}
$$

and deduct (15) and (16) from (14) . Under the condition (13) , it is easy to see that the system $(14-16)$ $(14-16)$ is equivalent to two coupled equations for $Y(\mathbf{x})$ and $Z(\mathbf{x})$,

$$
\left(\frac{1}{2}\sum_{j=1}^{3}\frac{\partial^{2}}{\partial x_{j}^{2}} + E\right)Y - \wp(x_{12})(Y+Z) - (2Y-Z)\wp(x_{31}) = 0,
$$
\n(18)

$$
\left(\frac{1}{2}\sum_{j=1}^{3}\frac{\partial^{2}}{\partial x_{j}^{2}} + E\right)Z - \wp(x_{12})(Y+Z) - (2Z-Y)\wp(x_{23}) = 0.
$$
\n(19)

Since the "potentials" here are double periodic, it might be expected that the solutions to [\(18](#page-4-0)[,19\)](#page-4-1) are quasiperiodic, acquiring the same Bloch factors under the shifts of the arguments by the periods $2\omega_1$, $2\omega_2$ of the Weierstrass functions. According to [\(18\)](#page-4-0), $Y(\mathbf{x})$ has a simple pole at $x_{31} \to 0$, the same is for $Z(\mathbf{x})$ as $x_{23} \to 0$. The analysis of limits $x_{23} \to 0$ for [\(18\)](#page-4-0) and $x_{31} \to 0$ for [\(19\)](#page-4-1) shows that the left-hand sides of [\(18\)](#page-4-0) and [\(19\)](#page-4-1) are regular at these conditions. And finally, if $Y(\mathbf{x}) \to Z(\mathbf{x})$ as $x_{12} \to 0$, there should be a simple pole singularity of these functions in this limit. Combining all these properties, we come to the ansatz for Y and Z in the form

$$
Y(\mathbf{x}) = b \frac{\sigma(\mu_{12})\sigma(x_{12} + \lambda_{12})\sigma(x_{31} + \lambda_{31})}{\sigma(x_{12})\sigma(x_{31})} \exp(k_1 x_1 + k_2 x_2 + k_3 x_3), \tag{20}
$$

$$
Z(\mathbf{x}) = b \frac{\sigma(\lambda_{12})\sigma(x_{12} + \mu_{12})\sigma(x_{23} + \mu_{23})}{\sigma(x_{12})\sigma(x_{23})} \exp(k_1 x_1 + k_2 x_2 + k_3 x_3),
$$
\n(21)

where $\sigma(x)$ is the sigma Weierstrass function defined above, b, $\{k_j\}, \lambda_{12}, \lambda_{31}, \mu_{12}, \mu_{23}$ are some parameters. The Bloch factors for [\(20\)](#page-4-2) and [\(21\)](#page-4-3) are equal if and only if

$$
\mu_{12} = \lambda_{12} - \lambda_{31}, \quad \mu_{23} = -\lambda_{31}.\tag{22}
$$

These expressions look rather asymmetric in $\{A, B, C\}$, but the symmetry becomes evident with the use of the remarkable identity

$$
Y(\mathbf{x}) - Z(\mathbf{x}) = C(\mathbf{x}) - B(\mathbf{x})
$$

=
$$
-b \frac{\sigma(\lambda_{31})\sigma(x_{23} - \lambda_{12})\sigma(x_{31} - \lambda_{12} + \lambda_{31})}{\sigma(x_{23})\sigma(x_{31})} \exp(k_1 x_1 + k_2 x_2 + k_3 x_3),
$$
 (23)

which is valid for all values of the parameters λ_{12} and λ_{31} and coordinates $\{x_{jk}\}$. Some long but not too tedious calculations show that [\(20\)](#page-4-2) and [\(21\)](#page-4-3) under the condition [\(22\)](#page-4-4) indeed give the solutions to the system [\(18](#page-4-0)[,19\)](#page-4-1) if the following restrictions to the parameters $\{\lambda\}$, $\{k\}$ take place,

$$
k_1 - k_2 = \zeta(\lambda_{31} - \lambda_{12}) - \zeta(\lambda_{12}),
$$
\n(24)

$$
k_2 - k_3 = \zeta(\lambda_{31}) + \zeta(\lambda_{12}),\tag{25}
$$

$(\tilde{k}_1,\tilde{k}_2,\tilde{k}_3)$	λ_{12}	λ_{31}	$\psi(\mathbf{x}, \mathbf{s}, \tilde{\mathbf{k}}, \tilde{\lambda}_{12}, \tilde{\lambda}_{31})$
(k_1, k_2, k_3)	λ_{12}	λ_{31}	$\psi(\mathbf{x}, \mathbf{s}, \mathbf{k}, \lambda_{12}, \lambda_{31})$
(k_2, k_1, k_3)	$-(\lambda_{12}-\lambda_{31})$	λ_{31}	$-\Pi_{12}\psi(\mathbf{x},\mathbf{s},\mathbf{k},\lambda_{12},\lambda_{31})$
(k_1, k_3, k_2)	$-\lambda_{31}$	$-\lambda_{12}$	$-\Pi_{23}\psi(\mathbf{x},\mathbf{s},\mathbf{k},\lambda_{12},\lambda_{31})$
(k_3, k_2, k_1)	λ_{12}	$\lambda_{12} - \lambda_{31}$	$-\Pi_{31}\psi({\bf x},{\bf s},{\bf k},\lambda_{12},\lambda_{31})$
(k_2, k_3, k_1)	$-\lambda_{31}$	$\lambda_{12} - \lambda_{31}$	$\Pi_{12}\Pi_{23}\psi(\mathbf{x},\mathbf{s},\mathbf{k},\lambda_{12},\lambda_{31})$
(k_3, k_1, k_2)	$-(\lambda_{12}-\lambda_{31})$	$-\lambda_{12}$	$\Pi_{13}\Pi_{32}\psi({\bf x},{\bf s},{\bf k},\lambda_{12},\lambda_{31})$

TABLE I: Relation of the transformations of the parameters $\{k\}$ and $\{\lambda\}$ of the eigenfunction ψ that obey [\(24–](#page-4-5)[26\)](#page-5-0) and the action of permutation operators of particles $\{\Pi_{ij}\}\$ on ψ .

where $\zeta(x)$ is the zeta Weierstrass function defined above. To get [\(24,](#page-4-5)[25\)](#page-4-6), we used the formula

$$
\zeta(x) + \zeta(y) + \zeta(z) - \zeta(x + y + z) = \frac{\sigma(x + y)\sigma(y + z)\sigma(z + x)}{\sigma(x)\sigma(y)\sigma(z)\sigma(x + y + z)}.
$$

As for the corresponding eigenvalue, it can be written in very symmetric form,

$$
E = -\frac{1}{6}(k_1 + k_2 + k_3)^2 - \frac{1}{3}(\wp(\lambda_{12}) + \wp(\lambda_{31}) + \wp(\lambda_{12} - \lambda_{31})),
$$
\n(26)

with two still unspecified parameters λ_{12} , λ_{31} . Note that [\(20,](#page-4-2)[21,](#page-4-3)[26\)](#page-5-0) look very similar to the solution of the usual Lamé equation,

$$
-\frac{d^2\psi(x)}{dx^2} + a(a+1)\psi(x) = E\psi(x),
$$

in the case of $a = 1$, where $\psi(x) \sim \exp(-x\zeta(\alpha))\sigma(x+\alpha)[\sigma(x)]^{-1}$ (the Hermite (1872) solution), and $E = -\wp(\alpha)$. We also found by some long calculation that [\(20,](#page-4-2)[21\)](#page-4-3) form also the eigenfunctions of the operators \mathcal{J}_1 , \mathcal{J}_2 [\(11](#page-3-4)[,12\)](#page-3-5) at $a = 1$, with the eigenvalues

$$
j_1 = \frac{1}{27}(k_1 + k_2 + k_3)^3 - \frac{k_1 + k_2 + k_3}{9} (\zeta(\lambda_{12}) - \zeta(\lambda_{31}) - \zeta(\lambda_{12} - \lambda_{31}))
$$

$$
-\frac{1}{54} \Big[14(\zeta(\lambda_{12}) - \zeta(\lambda_{31}) - \zeta(\lambda_{12} - \lambda_{31}))^3 + 9(\wp'(\lambda_{12}) - \wp'(\lambda_{31}) - \wp'(\lambda_{12} - \lambda_{31})) \Big], \qquad (27)
$$

$$
j_2 = \zeta(\lambda_{12}) - \zeta(\lambda_{31}) - \zeta(\lambda_{12} - \lambda_{31}),
$$
\n(28)

also with arbitrary values of the parameters $\{\lambda\}$.

Since the relation [\(26\)](#page-5-0) is invariant under all the permutations of the indices of $\{k\}$, the complete symmetrization of (13) on permutations of particles also gives an eigenfunction of H , we named it $\psi_0(\mathbf{x}, \mathbf{s}, \mathbf{k}, \lambda_{12}, \lambda_{31})$, if $\{k\}$ and $\{\lambda\}$ obey [\(24](#page-4-5)[–26\)](#page-5-0). The complete set of transformations of the parameters and its relation to permutation operators of particles is contained in Table [I.](#page-5-1) This eigenfunction $\psi_0(\mathbf{x}, \mathbf{s}, \mathbf{k}, \lambda_{12}, \lambda_{31})$ is regular as $x_j - x_k \to 0$. Furthermore, Eq. [\(26\)](#page-5-0) is invariant under global sign reversals of $\{k\}$ and $\{\lambda\}$ so we have another eigenfunction $\psi_1(\mathbf{x}, \mathbf{s}, \mathbf{k}, \lambda_{12}, \lambda_{31})$ also symmetric under permutations of particles and regular as $x_j - x_k \to 0$ and linearly independent of $\psi_0(\mathbf{x}, \mathbf{s}, \mathbf{k}, \lambda_{12}, \lambda_{31})$, that verifies

$$
\psi_1(\mathbf{x}, \mathbf{s}, \mathbf{k}, \lambda_{12}, \lambda_{31}) = \psi_0(\mathbf{x}, \mathbf{s}, -\mathbf{k}, -\lambda_{12}, -\lambda_{31}) = -\psi_0(-\mathbf{x}, \mathbf{s}, \mathbf{k}, \lambda_{12}, \lambda_{31}).
$$
\n(29)

The discrete spectrum of the corresponding three-particle system on the real circle $x_{1,2,3} \in$ **R** mod $2\omega_1$ can be obtained by imposing the periodic boundary conditions

$$
(k_1 - k_2)\omega_1 - \zeta(\omega_1)(\lambda_{12} - 2\lambda_{31}) = i\pi l_1
$$

\n
$$
(k_2 - k_3)\omega_1 - \zeta(\omega_1)(\lambda_{12} + \lambda_{31}) = i\pi l_2
$$

\n(30)

There is a degeneration in the energy, but ψ_0 and ψ_1 have distinct and opposite eigenvalues through the action of \mathcal{J}_1 and \mathcal{J}_2 . Due to the relation satisfied by the total spin

$$
\frac{1}{2} \otimes \frac{1}{2} \otimes \frac{1}{2} = \frac{3}{2} \oplus \frac{1}{2} \oplus \frac{1}{2},
$$

there exists an intrinsic degeneration of functions with total spin 1/2. That is the reason why we have such a degeneration on the energy level (26) .

To conclude, we obtained for the first time the extra integrals of motion for the elliptic Calogero– Moser system of three particles with spin [\(11,](#page-3-4)[12\)](#page-3-5). Thus we proved its complet integrability. It can be shown by direct computation with the use of the Liouville theorem that, replacing 3 by 4 in [\(11](#page-3-4)[,12\)](#page-3-5), \mathcal{J}_1 and \mathcal{J}_2 are also two mutually commuting integrals of motion for the $N = 4$ case. We found two non-trivial meromorphic eigenfunctions, depending on two parameters, for the spin 1/2 case and coupling constant $a = 1$ [\(20,](#page-4-2)[21\)](#page-4-3).

We can conjecture that the regular eigenfunctions of [\(1\)](#page-0-2) will be totally symmetric functions under permutation of particles for all values of N and a as it has been shown for some of its limits [\[13\]](#page-7-12) and for other unrelated spin dynamical models [\[18\]](#page-7-17).
