2000 Mathematics Subject Classification: Primary 32A15, Secondary 42A75, 32A50

Keywords: entire function of exponential type, Besicovitch's almost periodic function

Abstract

Suppose that an almost periodic in Besicovitch's sense function $f(x)$ of several variables is the restriction to the real hyperplane of an entire function of exponential type b . Then its spectrum is contained in the ball of radius b with the center in the origin.

In his paper [3] H. Bohr showed that the spectrum of an almost periodic function $f(x)$ on the real axis \mathbb{R} is a subset of $[-\sigma, \sigma]$, as long as f is the restriction to \mathbb{R} of an entire function of an exponential type σ . R. Boas [2] extended the assertion to almost periodic functions on \mathbb{R} in Besicovitch's metric (for brevity, B-almost periodic functions). In the general case, these functions are unbounded on \mathbb{R} , hence the proof of the latter assertion is more difficult.

H. Bohr's result was generalized to almost periodic functions in a finite dimensional space by S.Yu. Favorov and O.I. Udodova [8]. But the case of B-almost periodicity is more complicated, because restrictions to straight lines of B-almost periodic functions in \mathbb{R}^p are not necessary almost periodic.

It should be mentioned that B-almost periodic functions of several variables were considered earlier in [4], [6], [7]. But in [6], [7] the spectrum of functions was not under consideration, and in [4] the author studied only B-almost periodic functions with bounded Besicovitch's norm in a tube domain with a cone in the base.

Our proof differs from ones in [2], [3], [8] and is based on estimates of entire functions and Logvinenko's theorem [9] on the growth of entire functions of several variables on the hyperplane \mathbb{R}^p .

We will use the following notations.

By $z = x + iy$, $z = (z_1, \dots, z_p)$, $x = (x_1, \dots, x_p)$, $y = (y_1, \dots, y_p)$ we denote the vectors in \mathbb{C}^p (or, respectively, in \mathbb{R}^p , $'x$ means the vector $(x_2, \dots, x_p) \in \mathbb{R}^{p-1}$, $\langle x, y \rangle$ is the inner product in \mathbb{R}^p . Next, $|z|$, $|x|$, $|'x|$ are the Euclidean norms in the spaces \mathbb{C}^p , \mathbb{R}^p , and \mathbb{R}^{p-1} , respectively. By dx , $d'x$, and dx_1 we denote the Lebesgue measure in \mathbb{R}^p , \mathbb{R}^{p-1} , and \mathbb{R} , respectively. Furthermore, $B(x, \delta)$ means the open ball in \mathbb{R}^p of radius δ with the center in x , C with lower indexes are constants, depending only on f .

Besicovitch's norm of a locally integrable function $f(x)$ in \mathbb{R}^p is the limit

$$\|f\|_B = \overline{\lim}_{T \rightarrow \infty} \left(\frac{1}{2T} \right)^p \int_{[-T, T]^p} |f(x)| dx.$$

The function $f(x)$ is called *B-almost periodic* in \mathbb{R}^p , if for any $\varepsilon > 0$ there is a (generalized) trigonometric polynomial

$$P(x) = \sum c_n e^{i\langle x, \lambda^{(n)} \rangle}, \quad c_n \in \mathbf{C}, \lambda^{(n)} \in \mathbf{R}^p, \quad (1)$$

such that

$$\|f - P\|_B < \varepsilon.$$

The *Fourier coefficient* of f is the limit

$$a(\lambda, f) = \lim_{T \rightarrow \infty} \left(\frac{1}{2T} \right)^p \int_{[-T, T]^p} f(x) e^{-i\langle x, \lambda \rangle} dx. \quad (2)$$

The *spectrum* spf of $f(x)$ is the set

$$\{\lambda \in \mathbf{R}^p : a(\lambda, f) \neq 0\}.$$

Note that the existence the limit (2) and countability of the spectrum follow easily from the definition of B-almost periodicity, and the equality

$$a(\lambda, P) = \begin{cases} c_n, & \lambda = \lambda^{(n)} \\ 0, & \lambda \neq \lambda^{(n)}, \end{cases} \quad (3)$$

which holds for any n and any polynomial (1).

By [7], for any B -almost periodic function there exists a sequence of polynomial (1) (the so-called Bochner-Fejer sums) with $\lambda^n \in \text{spf}$, which approximate f .

The main result of our paper is the following theorem.

Theorem 1. *Let a B -almost periodic function $f(x)$ in \mathbb{R}^p extends to \mathbb{C}^p as an entire function with the bound*

$$|f(z)| \leq C_0 e^{\sigma|z|}. \quad (4)$$

Then we have $\text{spf} \subset B(0, \sigma)$.

The proof of this theorem is based on the following statement.

Theorem 2. *Let $f(x), x \in \mathbb{R}^p$ be a function with a finite norm $\|f\|_B$. If f can be extended to \mathbb{C}^p as an entire function with estimate (4), then*

$$|f(x)| \leq C_1 \prod_{j=1}^p (1 + |x_j|)^p \quad \forall x \in \mathbb{R}^p. \quad (5)$$

We get the proof of theorem 2, using the following auxiliary results.

Theorem A ([9]). *Let $f(z)$ be an entire function on \mathbb{C}^p , which satisfies (4), and E be a δ -net in \mathbb{R}^p . If $\sigma\delta < K(p)$, then*

$$\sup_{x \in \mathbb{R}^p} |f(x)| \leq (1 - \sigma\delta)^{-1} \sup_{x \in E} |f(x)|.$$

Theorem B (see, for example, [5], p. 311). *Let a function $g(w)$ be a holomorphic in $\mathbb{C}^+ = \{w \in \mathbb{C}, \text{Im } w > 0\}$, continuous in the closure of \mathbb{C}^+ , and satisfy the estimate*

$$|g(w)| \leq ce^{a|w|}, \quad w \in \mathbb{C}^+. \quad (6)$$

If

$$\int_{-\infty}^{+\infty} \frac{\log^+ |g(t)|}{1+t^2} dt < \infty, \quad (7)$$

then

$$\log |g(w)| \leq \frac{\text{Im } w}{\pi} \int_{-\infty}^{+\infty} \frac{\log |g(\text{Re } w + t)|}{t^2 + (\text{Im } w)^2} dt + h \text{Im } w, \quad w \in \mathbb{C}^+,$$

where $h = \overline{\lim}_{t \rightarrow +\infty} \frac{\log |g(it)|}{t}$.

In the case $\sup_{\mathbb{R}} |g(w)| < \infty$ theorem B yields the well known version of Fragment–Lindelöf Principle

$$|g(w)| \leq \sup_{\operatorname{Im} w=0} |g(w)| e^{h \operatorname{Im} w}, \quad w \in \mathbb{C}^+. \quad (8)$$

Proof of Theorem 2. Since $\|f\|_B < \infty$, we get for any $\delta \in (0, 1)$ and $\tilde{x} \in \mathbb{R}^p$

$$\int_{B(\tilde{x}, \delta)} |f(x)| dx \leq \int_{[-\tilde{x}-\delta, \tilde{x}+\delta]^p} |f(x)| dx \leq C_2 (1 + |\tilde{x}|)^p.$$

Therefore there is a constant $C_3 < \infty$ such that for any ball of radius δ there exists a point x' in the ball with

$$|f(x')| \leq C_3 \delta^{-p} (1 + |x'|)^p.$$

Put

$$g(z) = f(z) \prod_{j=1}^p \left(\frac{\sin z_j}{z_j} \right)^p.$$

We have

$$|g(z)| \leq C_0 e^{(\sigma+p^2)|z|}, \quad z \in \mathbb{C}^p.$$

Since $|g(x)| \leq C_4 \delta^{-p}$ at the points of the δ -net, we see that theorem A with a suitable δ implies the bound

$$\sup_{x \in \mathbb{R}^p} |g(x)| \leq C_5. \quad (9)$$

Using (9), we apply inequality (8) first in the domain $\operatorname{Im} z_1 > 0$, and then in the domain $\operatorname{Im} z_1 < 0$. We get

$$|g(z_1, 'x)| \leq C_5 e^{(\sigma+p^2)|y_1|} \quad (10)$$

for all $z_1 = x_1 + iy_1 \in \mathbb{C}$, $'x \in \mathbb{R}^{p-1}$. Apply (8) to the function $g(z_1, \dots, z_p)$ as a function in the variable z_2 and use (10) instead of (9). Repeating these arguments by the variables z_3, \dots, z_p , we get

$$|g(z)| \leq c_5 e^{(\sigma+p^2)(|y_1|+\dots+|y_p|)}.$$

Therefore,

$$\left| f(z) \cdot \prod_{j=1}^p \left(\frac{\sin z_j}{z_j} \right)^p \right| \leq C_6$$

on the set $A = \{z \in \mathbf{C}^p : |y_1| \leq 1, \dots, |y_p| \leq 1\}$. Hence,

$$\left| f(z) \cdot \prod_{j=2}^p \left(\frac{\sin z_j}{z_j} \right)^p \right| \leq C_7(1 + |z_1|)^p$$

on the set $\{z : z \in A, z \notin \bigcup_n B(n\pi, \frac{1}{2})\}$. By the Maximum Principle, we get the same inequality with the constant $2^p C_7$ instead of C_7 at every point of A . Repeating these arguments $p - 1$ times, we obtain (5). Theorem is proved.

For the proof of Theorem 1 we need the following Lemma.

Lemma. *Suppose that $f(z)$ is an entire function in \mathbf{C}^p , which satisfies (4), and its restriction to \mathbb{R}^p satisfies the condition $\|f\|_B \leq \infty$. Then for any $s_0 \in (0, \infty)$, $T \geq T(s_0)$, and $s \in (0, s_0)$ we get*

$$\int_{[-T, T]^p} |f(x_1 + is, 'x)| e^{-s\sigma} dx \leq C_8 T^p,$$

with $C_8 = 2^{p+1}(1 + 2 \cdot 3^p \|f\|_B)$.

Proof of the Lemma. By theorem 2, the function $f(z_1, 'x)$ satisfies (7) in the variable z_1 for any fixed $'x \in \mathbb{R}^{p-1}$. Taking into account (4), we get

$$\overline{\lim}_{t \rightarrow \infty} \frac{\log |f(iy_1, 'x)|}{y_1} \leq \sigma.$$

Hence Theorem B implies for any $s > 0$

$$\log |f(x_1 + is, 'x)| \leq \frac{s}{\pi} \int_{-\infty}^{+\infty} \frac{\log |f(t + x_1, 'x)| dt}{t^2 + s^2} + \sigma s.$$

Since the measure $\frac{s}{\pi} \cdot \frac{dt}{t^2 + s^2}$ is a probability one on \mathbb{R} , we get for any locally integrable function $h(t)$ on \mathbb{R}

$$\exp \left(\frac{s}{\pi} \int_{|t| \leq 2T} \frac{h(t) dt}{t^2 + s^2} \right) \leq \frac{s}{\pi} \int_{|t| \leq 2T} \frac{e^{h(t)} dt}{t^2 + s^2} + \frac{s}{\pi} \int_{|t| > 2T} \frac{dt}{t^2 + s^2}.$$

Next,

$$\begin{aligned}
\int_{[-T, T]^p} |f(x_1 + is, 'x)| e^{-\sigma s} dx &\leq \int_{[-T, T]^p} \exp \left\{ \frac{s}{\pi} \int_{-\infty}^{+\infty} \frac{\log |f(t + x_1, 'x)|}{t^2 + s^2} dt \right\} dx \\
&\leq \int_{[-T, T]^p} \exp \left\{ \frac{s}{\pi} \int_{|t| \leq 2T} \frac{\log |f(t + x_1, 'x)|}{t^2 + s^2} dt \right\} \times \\
&\quad \exp \left\{ \frac{s}{\pi} \int_{|t| > 2T} \frac{\log |f(t + x_1, 'x)|}{t^2 + s^2} dt \right\} dx \leq \\
&\int_{[-T, T]^p} \left(\frac{s}{\pi} \int_{|t| \leq 2T} \frac{|f(t + x_1, 'x)|}{t^2 + s^2} dt + 1 \right) \exp \left\{ \frac{s}{\pi} \int_{|t| > 2T} \frac{\log |f(t + x_1, 'x)|}{t^2 + s^2} dt \right\} dx.
\end{aligned}$$

By (5) we have for $x \in [-T, T]^p$

$$\begin{aligned}
\frac{s}{\pi} \int_{|t| \geq 2T} \frac{\log |f(t + x_1, 'x)|}{t^2 + s^2} dt &\leq \frac{s}{\pi} \int_{|t| \geq 2T} \frac{C_3 \left(\sum_{j=1}^p p \log^+(1 + |x_j|) + p \log^+ t \right)}{t^2 + s^2} dt \\
&\leq C_3 \left[p^2 \log(1 + T) \frac{s}{\pi} \int_{|t| \geq 2T} \frac{dt}{t^2 + s^2} + \frac{ps}{\pi} \int_{|t| \geq 2T} \frac{\log^+ t dt}{t^2 + s^2} \right].
\end{aligned}$$

Note that the latter expression bounds from above by $\log 2$ for $s \leq s_0$ and $T \geq T(s_0)$.

Therefore, taking into account the inequality

$$\int_{[-T, T]^p} |f(x)| dx \leq 2 \|f\|_B (2T)^p, \quad T \geq C_9$$

we obtain

$$\int_{[-T, T]^p} |f(x_1 + is, 'x)| e^{-\sigma s} dx \leq 2 \left(\frac{s}{\pi} \int_{|t| \leq 2T} \frac{dt}{t^2 + s^2} \int_{[-T, T]^p} |f(x_1 + t, 'x)| dx + (2T)^p \right)$$

$$\leq 2^{p+1}T^p + 2\frac{s}{\pi} \int_{|t|\leq 2T} \frac{dt}{t^2 + s^2} \left[\int_{[-3T, 3T]} |f(x)| dx \right] \leq 2^{p+1}(1 + 2 \cdot 3^p \|f\|_B) T^p.$$

Lemma is proved.

Proof of Theorem 2

Let A be an orthogonal matrix in \mathbb{R}^p . It is easy to check the equality

$$a(\lambda, f) = a(A^{-1}\lambda, f_A), \quad (11)$$

where $f_A(x) = f(Ax)$ and λ is an arbitrary vector in \mathbb{R}^p .

Indeed, it follows from (3) that this equality is true for any polynomial P (1). To prove it for an arbitrary B-almost periodic function, we can approximate it by polynomial P such that $\|f - P\|_B < \varepsilon$. Therefore, $\|f_A - P_A\|_B < K^p \varepsilon$, where $K = \max_j |Ae_j|$, e_j is the natural basis in \mathbb{R}^p .

Hence, we obtain (11).

Take $\lambda \in \mathbb{R}^p$, $|\lambda| > \sigma$. Since bound (4) is the same for f_A , we may suppose that $\lambda = (-\sigma - \eta, 0, \dots, 0)$, $\eta > 0$. In this case we have

$$a(\lambda, f) = \lim_{T \rightarrow \infty} \left(\frac{1}{2T} \right)^p \int_{[-T, T]^p} f(x_1, 'x) e^{ix_1(\sigma+\eta)} dx. \quad (12)$$

The function $f(z_1, x')$ is holomorphic in z_1 , therefore for any $y_1 > 0$ we have

$$\begin{aligned} & \int_{[-T, T]^p} f(x_1, 'x) e^{ix_1(\sigma+\eta)} dx = \\ & i \int_0^{y_1} \int_{[-T, T]^{p-1}} f(-T + is, 'x) e^{-iT(\sigma+\eta) - s(\sigma+\eta)} d'x ds + \\ & \int_{[-T, T]^p} f(x_1 + iy_1, 'x) e^{ix_1(\sigma+\eta) - y_1(\sigma+\eta)} dx - \\ & i \int_0^{y_1} \int_{[-T, T]^{p-1}} f(T + is, 'x) e^{iT(\sigma+\eta) - s(\sigma+\eta)} d'x ds \\ & = I_1(T, y_1) + I_2(T, y_1) - I_3(T, y_1). \end{aligned}$$

By Lemma, we get

$$|I_2(T, y_1)| \leq C_8 T^p e^{-\eta y_1},$$

hence for a given $\varepsilon > 0$ and sufficiently large y_1

$$\overline{\lim}_{T \rightarrow \infty} |(2T)^{-p} I_2(T, y_1)| \leq \varepsilon. \quad (13)$$

Next, $|I_1 - I_3| \leq G(T)$, where

$$G(x_1) = \int_0^{y_1} \int_{[-T, T]^{p-1}} e^{-s\sigma} (|f(x_1 + is, 'x)| + |f(-x_1 + is, 'x)|) ds d'x.$$

By Lemma, the Lebesgue measure of the set

$$E = \left\{ x_1 : \frac{T}{2} < |x_1| < T, G(x_1) > 3C_8 T^{p-1} |y_1| \right\}$$

is at most

$$\frac{1}{2C_8 |y_1| T^{p-1}} \int_E G(x_1) dx_1 \leq \frac{1}{3C_8 |y_1| T^{p-1}} \int_0^{y_1} \int_{[-T, T]^p} e^{-s\sigma} (|f(x_1 + is, 'x)| + |f(-x_1 + is, 'x)|) dx ds < \frac{2T}{3}.$$

Hence for some $T' \in [\frac{T}{2}, T] \setminus E$ we get $G(T') \leq 3C_8 |y_1| T^{p-1}$. Therefore we have

$$\overline{\lim}_{T' \rightarrow \infty} (2T')^{-p} |(I_1(T', y_1) - I_3(T', y_1))| = 0.$$

Thus, the latter bound and (13) yield $a(\lambda, f) = 0$. Theorem is proved.
