ON NON-VANISHING OF COHOMOLOGIES OF GENERALIZED RAYNAUD POLARIZED SURFACES

YUKIHIDE TAKAYAMA

Abstract. We consider a family of slightly extended version of the Raynaud's surfaces X over the field of positive characteristic with Mumford-Szpiro type polarizations \mathcal{Z} , which have Kodaira non-vanishing $H^1(X, \mathcal{Z}^{-1}) \neq 0$. The surfaces are at least normal but smooth under a special condition. We compute the cohomologies $H^i(X, \mathcal{Z}^n)$ for $i, n \in \mathbb{Z}$ and study their (non-)vanishing. Finally, we give a fairly large family of non Mumford-Szpiro type polarizations $\mathcal{Z}_{a,b}$ with Kodaira non-vanishing.

MSC classification: (Primary: 14J25, 14J17; secondary: 13D99)

1. Introduction

Let X be a projective variety over an algebraically closed field k and $\mathcal Z$ an ample invertible sheaf on X. It is well known that Kodaira vanishing theorem does not hold if the characteristic of the field char(k) = p is positive. The first counter-example has been found by Raynaud [\[14\]](#page-18-0). He constructed a smooth polarized surface (X, \mathcal{Z}) with $H^1(X, \mathcal{Z}^{-1}) \neq 0$ using Tango-structure [\[22\]](#page-18-1). Mukai [\[10\]](#page-18-2) generalized Raynaud's construction to obtain polarized smooth projective varieties (X, \mathcal{Z}) of any dimension with $H^1(X, \mathcal{Z}^{-1}) \neq 0$. He also showed that, if a smooth projective surface X is a counter-example to Kodaira vanishing, then X must be either hyperelliptic with $p = 2, 3$ or of general type. The construction similar to Mukai's has been also studied by Takeda [\[18,](#page-18-3) [19,](#page-18-4) [20\]](#page-18-5) and Russel [\[15\]](#page-18-6). Mumford [\[13\]](#page-18-7) and Szpiro [\[16\]](#page-18-8) gave a sufficient condition for a polarized smooth projective surface to be a counterexample to Kodaira vanishing and pointed out that Raynaud's examples are its instances. Szpiro [\[17\]](#page-18-9) and Lauritzen-Rao [\[8\]](#page-18-10) also gave different counter-examples to Kodaira vanishing. Mumford [\[11\]](#page-18-11) constructed a normal polarized surface (X, \mathcal{Z}) with $H^1(X, \mathcal{Z}^{-1}) \neq 0$ but it is not known whether desingularizations of X satisfy Kodaira vanishing.

The aim of this paper is to study (non-)vanishing of $H^{i}(X, \mathcal{Z}^{n}), i, n \in \mathbb{Z}$, for a family of surfaces X with Mumford-Szpiro type polarizations \mathcal{Z} , which is an extension of Raynaud's counter-examples. Recall that Raynaud's examples are cyclic covers of ruled surfaces over smooth projective curves of genus $q \geq 2$. The degree ℓ of the cyclic covers is $\ell = 2$ for $p \geq 3$ and $\ell = 3$ for $p = 2$. Notice that Kodaira vanishing holds for ruled surfaces [\[23,](#page-19-0) [10\]](#page-18-2). The smooth curve must have a special kind of divisor called Tango-structure (Tango-Raynaud structure) and this gives a strong restriction to the genus q of the curve, i.e. p must divide $2q-2$. If we consider a weaker condition called pre-Tango, which is satisfied by any smooth curves with $g \geq p$ ([\[21\]](#page-18-12)), but in this case the obtained surface is singular.

As is implicitly described in [\[14\]](#page-18-0), we can choose the degree ℓ of cyclic cover more freely. In Mukai's construction [\[10\]](#page-18-2), ℓ can be any integer ≥ 2 with $(p, \ell) = 1$ (and a mild condition), but then we must take normalization to construct the cyclic cover. In this paper, we consider an additional condition $\ell \mid p+1$. This assures the normality of the cyclic cover without normalization and moreover the computation of cohomologies $H^{i}(X, \mathcal{Z}^{n})$ is much easier. Thus, we obtain a fairly large class of surfaces over the fields of positive characteristics containing many counter-examples to Kodaira vanishing, together with formulas for cohomologies $H^{i}(X, \mathcal{Z}^{n})$. These surfaces are normal if the base curve C has a pre-Tango structure and smooth if C has a Tango structure.

This family would be particularly interesting in the sense that this provides a class of finitely generated graded integral algebras (R, \mathfrak{m}) , over the fields of positive characteristics whose graded local cohomologies $H^i_{\mathfrak{m}}(R)$, $i < \dim R$, do not necessarily vanish at negative degrees. For a polarized variety (X, \mathcal{L}) , we consider the section ring $(R, \mathfrak{m}) := (\bigoplus_{n\geq 0} H^0(X, \mathcal{L}^n), \bigoplus_{n>0} H^0(X, \mathcal{L}^n)),$ which is a finitely generated graded algebra over $\overline{k} = H^0(X, \mathcal{O}_X)$ with natural N-grading. We have $X \cong \text{Proj}(R)$. Then by computing Čech complexes we know that $H_{\mathfrak{m}}^{0}(R) = 0$ and we have

$$
0 \longrightarrow R \longrightarrow \bigoplus_{n \in \mathbb{Z}} H^0(X, \mathcal{L}^n) \longrightarrow H^1_{\mathfrak{m}}(R) \longrightarrow 0
$$

and $H^{i+1}_{\mathfrak{m}}(R) \cong \bigoplus_{n \in \mathbb{Z}} H^i(X, \mathcal{L}^n)$ for $i \geq 1$. From this, we immediately know that we always have $[H_m^j(R)]_n = 0$ for $j = 0, 1$ and for all $n < 0$ and moreover, if Kodaira type vanishing holds, then we have $[H_m^i(R)]_n = 0$ for all $n < 0$ and $i < \dim R$ (see $[7]$. It is known that if X has at most F-rational singularities and X is obtained by generic mod p reduction from a variety with at most rational singularities, then we have Kodaira type vanishing (see [\[5,](#page-18-14) [4,](#page-18-15) [7\]](#page-18-13)). From our generalized Raynaud surfaces, we obtain examples of R with dim $R = 3$ different from this type, whose local cohomologies can be studied by analyzing cohomologies of vector bundles over smooth curves of genus ≥ 2 .

In section 2, we will present the construction of our generalized Raynaud surface X, which is the cyclic cover of degree ℓ of the ruled surface P over a curve C with pre-Tango structure. In section 3, we show that K_X is ample if $(p, \ell) = (3, 4)$ and $p \ge 5$ (Proposition [10\)](#page-8-0) and in this case we have Kodaira type vanishing $H^1(X, K_X^{-1}) = 0$ (Proposition [12\)](#page-9-0). Then we apply the Mumford-Szpiro type sufficient condition for Kodaira non-vanishing to obtain the polarization (X, \mathcal{Z}) with Kodaira non-vanishing (Proposition [16\)](#page-10-0). Then we will compute cohomologies $H^{i}(X, \mathcal{Z}^{n}), i, n \in \mathbb{Z}$, in section 4 (Propositions [19,](#page-11-0) [21](#page-13-0) and [25,](#page-15-0) Theorem [22,](#page-13-1) Corollary [4\)](#page-14-0) and show some (non-)vanishing results (Corollaries [20,](#page-12-0) [24](#page-15-1) and [26,](#page-16-0) Theorem [23\)](#page-14-1). Finally, we give a class of polarizations with Kodaira non-vanishing, which are not of Mumford-Szpiro type (Theorem [28\)](#page-17-0).

The author thanks Kei-ichi Watanabe, Masataka Tomari and Yushifumi Takeda for stimulating discussions.

2. Fibered surfaces on pre-Tango curves

In this section, we present the construction of our polarized surface, which is a cyclic cover of a ruled surface over a smooth projective curve. This is an extension of the Raynaud's counter-example [\[14\]](#page-18-0) allowing more variations of the degree of the cyclic cover and a weaker condition for the base curve. See [\[10,](#page-18-2) [18,](#page-18-3) [19,](#page-18-4) [20,](#page-18-5) [21,](#page-18-12) [24\]](#page-19-1) for similar constructions and detailed description. In the following, let k be an algebraically closed field of characteristic char(k) = $p > 0$.

2.1. **pre-Tango and Tango structure.** Let C be a smooth projective curve over k with genus $g \geq 2$. We denote by $K(C)$ the function field of C and we define $K(C)^p = \{f^p \mid f \in K(C)\}.$ Then the Tango-invariant $n(C)$ is defined by

$$
n(C) := \max \left\{ \deg \left[\frac{(df)}{p} \right] \mid f \in K(C) \backslash K(C)^p \right\},\
$$

where $[\cdot]$ denotes round down of coefficients, see [\[22\]](#page-18-1). We know that $0 \leq n(C) \leq$ $2(g-1)$ p and C is called a *pre-Tango curve* (or a *Tango curve*) if n(C) > 0 (or $n(C) = \frac{2(g-1)}{2}$ p). This means the existence of an ample divisor D on C such that $(df) \geq pD(\geq 0)$ (or $(df) = pD(\geq 0)$) with some $f \in K(C) \backslash K(C)^p$. We call the invertible sheaf $\mathcal{L} := \mathcal{O}_C(D)$ a *pre-Tango structure* (or a *Tango structure*) of C.

Pre-Tango structure can be described in other way around. Consider the relative Frobenius morphism $F: C' \longrightarrow C$ and let \mathcal{B}^1 be the image of the push forward $F_*d: F_*\mathcal{O}_{C'} \longrightarrow F_*\Omega^1_{C'}$ of the Kähler differential $d: \mathcal{O}_{C'} \longrightarrow \Omega^1_{C'}$. Then we have the following short exact sequence

(1)
$$
0 \longrightarrow \mathcal{O}_C \longrightarrow F_*\mathcal{O}_{C'} \longrightarrow \mathcal{B}^1 \longrightarrow 0.
$$

Now any ample invertible subsheaf $\mathcal{L} \subset \mathcal{B}^1$ is a pre-Tango structure of C and the existence of such subsheaves is assured if $g \ge p$ (see Cor. 1.5 [\[21\]](#page-18-12)), namely, curves with large genus are pre-Tango.

In the rest of this section, we consider a pre-Tango structure $\mathcal{L} = \mathcal{O}_C(D)$ of a pre-Tango curve C.

2.2. dividing (pre-)Tango structure . Consider the Jacobi variety $\mathcal J$ which consists of all the divisors of degree 0 on C. It is well known that if $(e, p) = 1, e \in \mathbb{N}$, the map $\varphi_e : \mathcal{J} \longrightarrow \mathcal{J}$ s.t. $\varphi_e(D_0) = eD_0$ is surjective (cf. page 42 [\[12\]](#page-18-16)), i.e. every $D_0 \in \mathcal{J}$ can be divided by e. Thus we know that, for every $\mathbb{N} \ni e \geq 2$ such that $(e, p) = 1$ and $e | \deg \mathcal{L}$, there exists an ample invertible sheaf N with $\mathcal{L} = \mathcal{N}^e$.

2.3. Construction of the ruled surface P and the divisor $E + C''$. Tensoring [\(1\)](#page-2-0) by \mathcal{L}^{-1} to take the global sections, we have

$$
0 \longrightarrow H^0(C, \mathcal{B}^1 \otimes \mathcal{L}^{-1}) \stackrel{\eta}{\longrightarrow} H^1(C, \mathcal{L}^{-1}) \stackrel{F^*}{\longrightarrow} H^1(C, \mathcal{L}^{-p}).
$$

On the other hand, we have the short exact sequence

(2)
$$
0 \longrightarrow \mathcal{B}^1 \longrightarrow F_*\Omega^1_{C'} \stackrel{c}{\longrightarrow} \Omega^1_C \longrightarrow 0
$$

where c is the Cartier operator [\[2\]](#page-18-17). By tensoring [\(2\)](#page-2-1) by \mathcal{L}^{-1} to take the global sections, we have

$$
0 \longrightarrow H^0(C, \mathcal{B}^1 \otimes \mathcal{L}^{-1}) \longrightarrow H^0(C, F_*(\Omega^1_{C'}(-pD))) \stackrel{c(-D)}{\longrightarrow} H^0(C, \Omega^1_C \otimes \mathcal{L}^{-1}).
$$

Then we know $\text{Ker } F^* \cong H^0(C, \mathcal{B}^1 \otimes \mathcal{L}^{-1}) = \text{Ker } c(-D) \cong \{df \mid f \in K(C), (df) \geq 0\}$ pD , which is non-trivial since C is pre-Tango (cf. Lemma 12 [\[22\]](#page-18-1)).

Now take any $0 \neq df_0 \in H^0(C, \mathcal{B}^1 \otimes \mathcal{L}^{-1})$. Then $\xi := \eta(df_0)$ is a non-trivial element in $H^1(C, \mathcal{L}^{-1}) \cong \text{Ext}^1_{\mathcal{O}_C}(\mathcal{L}, \mathcal{O}_C)$, so that we have a non-splitting extension

(3)
$$
0 \longrightarrow \mathcal{O}_C \longrightarrow \mathcal{E} \longrightarrow \mathcal{L} \longrightarrow 0
$$

where $\mathcal E$ is a locally free sheaf of rank 2.

Moreover, we have $0 = F^* \xi \in H^1(C, \mathcal{L}^{-p}) \cong Ext^1_{\mathcal{O}_C}(\mathcal{L}^p, \mathcal{O}_C)$ and the corresponding split extension

 $0 \longrightarrow \mathcal{O}_C \longrightarrow F^*\mathcal{E} \longrightarrow \mathcal{L}^p \longrightarrow 0$

is just the Frobenius pullback of the sequence [\(3\)](#page-3-0). Using the splitting maps and tensoring by \mathcal{L}^{-1} we obtain another exact sequence

(4)
$$
0 \longrightarrow \mathcal{O}_C \longrightarrow F^* \mathcal{E} \otimes \mathcal{L}^{-p} \longrightarrow \mathcal{L}^{-p} \longrightarrow 0.
$$

Now from the sequences [\(3\)](#page-3-0) and [\(4\)](#page-3-1) we obtain two ruled surfaces and their canonical cross sections σ and τ . Namely,

$$
\pi: P = \mathbb{P}(\mathcal{E}) \longrightarrow C, \quad E := \sigma(C) \subset P
$$

where E is determined, as a Cartier divisor, by the global section s that is the image of 1 by the inclusion $H^0(C, \mathcal{O}_C) \hookrightarrow H^0(C, \mathcal{E}) = H^0(P, \mathcal{O}_P(1))$ induced from [\(3\)](#page-3-0) and

$$
\pi': P' = \mathbb{P}(F^*\mathcal{E} \otimes \mathcal{L}^{-p}) \cong \mathbb{P}(F^*\mathcal{E}) \longrightarrow C \quad \tilde{C}'' := \tau(C)
$$

where \tilde{C}'' is determined, as a Cartier divisor, by the global section t'' that is the image of 1 by the inclusion $H^0(C, \mathcal{O}_C) \hookrightarrow H^0(C', F^*E \otimes \mathcal{L}^{-p}) \cong H^0(P', \mathcal{O}_{P'}(1))$ induced from [\(4\)](#page-3-1). Now we define the morphism $\varphi : P \longrightarrow P'$ over C by taking the pth power of the coordinates of $\pi^{-1}(x) \cong \mathbb{P}_k^1(\subset P)$ to obtain the coordinates of $(\pi')^{-1}(x) \cong \mathbb{P}^1_k(\subset P')$ for every $x \in C$. Then we set $C'' = \varphi^{-1}(\tilde{C}'')$. By construction, we have $\mathcal{O}_P(\mathcal{C}^n) \cong \mathcal{O}_P(p) \otimes \pi^* \mathcal{L}^{-p}$ and $\mathcal{C}^{\prime\prime}$ is a degree p curve in P. We know that $E \cap C'' = \emptyset$. E is smooth since $E \cong C$ via σ .

2.4. Purely inseparable cover $\pi |_{C''}: C'' \to C$. Now as a Cartier divisor we write $D = \{(U_i, g_i)\}_i$, where $C = \bigcup_i U_i$ is an open covering, $g_i \in K(C)$ is the local equation of D. By taking a finer covering, we can assume that $\mathcal{E}|_{U_i}$ are the free \mathcal{O}_{U_i} -modules. Then we can describe $(df) \geq pD$ by $f = \{ (U_i, g_i^p) \}$ ${p \choose i}i \in K(C)$ with $K(C)^p \not\supseteq c_i \in \mathcal{O}_{U_i}$, i.e. $(df) \mid_{U_i} = (g_i^p dc_i)$. Then,

Proposition 1. *We have*

 $C'' |_{U_i} = \text{Proj } \mathcal{O}_{U_i}[x, y]/(c_i x^p + y^p).$

In particular, C'' is an purely inseparable covering of C .

Proof. The sequence [\(3\)](#page-3-0) is locally as follows:

$$
0 \longrightarrow \mathcal{O}_{U_i} \longrightarrow \mathcal{O}_{U_i} \oplus \mathcal{O}_{U_i} g_i^{-1} \longrightarrow \mathcal{O}_{U_i} g_i^{-1} \longrightarrow 0
$$

so that we have $P|_{U_i} = \text{Proj}(S(\mathcal{O}_{U_i} \oplus \mathcal{O}_{U_i} g_i^{-1}))$ $\binom{-1}{i}$ = Proj $\mathcal{O}_{U_i}[x, y]$, where the indeterminates x and y represent the free basis 1 and g_i^{-1} i^{-1} . On the other hand, we know that the sequence [\(4\)](#page-3-1) is locally as follows:

$$
0\longrightarrow{\mathcal{O}}_{U_i}\stackrel{i}{\longrightarrow}({\mathcal{O}}_{U_i}\otimes{\mathcal{O}}_{U_i}g_i^{-p})\otimes{\mathcal{O}}_{U_i}g_i^p\stackrel{j}{\longrightarrow}{\mathcal{O}}_{U_i}g_i^p\longrightarrow0
$$

where we view

$$
\begin{array}{rcl}\n(\mathcal{O}_{U_i} \otimes \mathcal{O}_{U_i} \cdot g_i^{-p}) \otimes \mathcal{O}_{U_i} \cdot g_i^p \cong & \mathcal{O}_{U_i} \cdot g_i^p \oplus \mathcal{O}_{U_i} \cdot 1 \\
\cong & \mathcal{O}_{U_i}(c_i g_i^p, 1) \oplus \mathcal{O}_{U_i}(g_i^p, 0)\n\end{array}
$$

and we define $i(a) = a(c_i g_i^p)$ i ^p, 1) and $j(a(c_i g_i^p))$ $i^{(p)}(i, 1) + b(g_i^p)$ $\left(\begin{matrix} p \\ i \end{matrix} , 0 \right) = b g_i^p$ for $a, b \in \mathcal{O}_{U_i}$. Thus $P' |_{U_i} = \text{Proj}(S((\mathcal{O}_{U_i} g_i^p \oplus \mathcal{O}_{U_i}))) \cong \text{Proj} \mathcal{O}_i[x', y']$ where the indeterminates x' and y' represents the free basis g_i^p $\tilde{\ell}_i^p$ and 1. Also $\tilde{C}'' = \tau(C)$ is locally the zero locus of $t'' |_{U_i} = c_i g_i^p + 1$, so that we have

$$
\tilde{C}''\mid_{U_i}=\operatorname{Proj} \mathcal{O}_{U_i}[x',y']/(c_ix'+y')
$$

Since $\varphi: P = \text{Proj } \mathcal{O}_{U_i}[x, y] \longrightarrow P' = \text{Proj } \mathcal{O}_{U_i}[x', y']$ is induced by the Frobenius $\mathcal{O}_{U_i}[x', y'] \ni x', y' \mapsto x^p, y^p \in \mathcal{O}_{U_i}[x, y]$, we have

$$
C'' |_{U_i} = \text{Proj } \mathcal{O}_{U_i}[x, y]/(c_i x^p + y^p).
$$

Remark 1. By a similar discussion to the proof of Proposition [1](#page-3-2) we can show

 $E|_{U_i} = \text{Proj}(\mathcal{O}_{U_i}[x, y]/(x)) \cong \text{Spec} \mathcal{O}_{U_i}[y].$

Later we will construct cyclic covers of P ramified at $E+C''$ and the smoothness of the cyclic covers depends on the smoothness of E and C''. Since $E \cong C$ is smooth by definition, we have to see if C'' is smooth. To this end, we must prepare the following lemma.

Lemma 2. $\Omega_{C''/C} \cong \pi^* \mathcal{O}_C(D)$.

Proof. By Proposition [1,](#page-3-2) we have $\mathcal{O}_{C''}|_{U_i} = \mathcal{O}_{U_i}[x_i, y_i]/(c_i x_i^p + y_i^p)$ $\binom{p}{i}$ and $(df) \geq pD$ with $f = \{ (U_i, g_i^p) \}$ $\{e_i^p c_i\}$ _i $\in K(C)$. Thus on $U_i \cap U_j$ we have g_i^p $\overset{p}{i}c_{i}=\overset{\rightharpoonup}{g_{j}^{p}}$ $_{j}^{p}c_{j}$ so that

$$
(g_j^p c_j)(g_i^{-1} x_i)^p + y_i^p = c_i x_i^p + y_i^p = c_j x_j^p + y_j^p = (g_j^p c_j)(g_j^{-1} x_j)^p + y_j^p
$$

Thus we have $g_i^{-1}x_i = g_j^{-1}x_j$ and $y_i = y_j$, and then

$$
g_i^{-1} dx_i = d(g_i^{-1} x_i) = d(g_j^{-1} x_j) = g_j^{-1} dx_j
$$

for $d := d_{C''/C}$. Now on $\tilde{U}_i = U_i \cap \{y_i \neq 0\}$, we have $\mathcal{O}_{C''} \mid_{\tilde{U}_i} = \mathcal{O}_{\tilde{U}_i}[X_i]/(c_i X_i^p + 1)$ with $X_i := x_i/y_i$ and then

$$
\Omega_{C''/C} |_{\tilde{U}_i} = \mathcal{O}_{C''} |_{\tilde{U}_i} \cdot g_i^{-1} dX_i = \pi^* \mathcal{O}_C(D) |_{\tilde{U}_i}
$$

Notice that we have g_i^{-1} $i^{-1}dX_i = g_i^{-1}$ $\tilde{U}_j^{-1}dX_j$ on $\tilde{U}_i\cap\tilde{U}_j$.

On the other hand, on $\hat{U}_i = U_i \cap \{x_i \neq 0\}$ we can write

$$
\mathcal{O}_{C''} |_{\hat{U}_i} = \mathcal{O}_C[Y_i]/(c_i + Y_i^p) \quad \text{with } Y_i = x_i^{-1}
$$

and then

$$
\Omega_{C''/C}\mid_{\hat{U}_i}=\mathcal{O}_{C''}\mid_{\hat{U}_i}dY_i=\mathcal{O}_{C''}\mid_{\hat{U}_i}\cdot x_i^{-2}dx_i.
$$

By setting $t = g_i^{-1}x_i = g_j^{-1}x_j$ on $U_i \cap U_j$, we have

$$
x_i^{-2} dx_i = x_i^{-2} g_i dt = g_i^{-1} t^{-2} dt
$$

and so that we have $\Omega_{C''/C}$ $|_{\hat{U}_i} \cong \pi^* \mathcal{O}_C(D)$ $|_{\hat{U}_i}$. Consequently, we have $\Omega_{C''/C} \cong$ $\pi^*{\cal O}_C(D)$, locally free of rank 1, as required.

The following result first appeared in Mukai's paper in Japanese([\[10\]](#page-18-2) Prop. 5) with a brief outline of the proof and his result is for varieties of arbitrary dimensions. We give here a detailed proof in the case of curves for the readers convenience.

Theorem 3. Let C be a pre-Tango curve. Then C'' is smooth if and only if C is *Tango.*

Proof. In the following we will denote the restriction of $\pi : P \longrightarrow C$ to $C'' \subset P$ also by π . Now we consider the sequence

(5)
$$
0 \longrightarrow \pi^* \mathcal{O}_C(pD) \xrightarrow{df} \pi^* \Omega_C \xrightarrow{\psi} \Omega_{C''} \xrightarrow{\rho} \Omega_{C''/C} \longrightarrow 0
$$

where df is the multiplication by $df = \{(g_i^p)$ ${}_{i}^{p}dc_{i}$ }, The exactness of $\pi^*\Omega_C \longrightarrow$ $\Omega_{C''} \longrightarrow \Omega_{C''/C} \longrightarrow 0$ is well known. The multiplication by df is injective since $dc_i \neq 0$ and C is smooth. Moreover we have Ker $\psi \supset$ Im df. To see this we have only to show that $\psi(dc_i)$, which is by definition the Kähler differential of the image of c_i by $\pi^{\sharp}: \mathcal{O}_C \longrightarrow \mathcal{O}_{C''}$, is trivial. But this is immediate since, by Proposition [1,](#page-3-2) $\pi^{\sharp}: \mathcal{O}_C \longrightarrow \mathcal{O}_{C''}$ is locally the canonical inclusion $\mathcal{O}_C \hookrightarrow \mathcal{O}_C[x,y]/(c_ix^p+y^p)$. Thus [\(5\)](#page-5-0) is exact if and only if Ker $\psi \subset \text{Im } df$.

Now Ω_C is locally free of rank 1 since C is smooth. Then we know by NAK that C being Tango, i.e. $(dc_i) = 0$ is equivalent with Coker $(df) = 0$. This implies that [\(5\)](#page-5-0) is exact, and then we have $\Omega_{C''} \cong \Omega_{C''/C}$, which is locally free of rank 1 by Lemma [2,](#page-4-0) and C'' is smooth. Conversely, assume that C'' is smooth. Then since $\Omega_{C''/C}$ and $\Omega_{\mathcal{C}''}$ are locally free module of rank 1, we must have Ker $\rho = \text{Im } \psi = 0$ so that we have $\text{Coker}(df) = 0$, i.e., C is Tango.

2.5. Construction of cyclic cover of P ramified at $E + C''$. In this section, we will construct a cyclic cover X of P of suitable degree ramified at $E + C''$. We choose $\ell \geq 2$ such that $\ell \mid p+1$ and $\ell \mid e$, and set

$$
\mathcal{M} := \mathcal{O}_P\left(-\frac{p+1}{\ell}\right) \otimes \pi^* \mathcal{N}^{\frac{pe}{\ell}}.
$$

Then we have $\mathcal{M}^{-\ell} = \mathcal{O}_P(E + C'')$. Now we define an \mathcal{O}_P -algebra structure in $\bigoplus_{i=0}^{\ell-1} \mathcal{M}^i$ with the multiplication defined by

$$
\begin{array}{rcl}\mathcal{M}^{i}\times \mathcal{M}^{j}&\longrightarrow &\mathcal{M}^{i+j}\\ (a,b)&\mapsto&a\otimes b\\ &\overset{c}{\longmapsto} &a\otimes b\end{array}
$$

if $i + j \leq \ell - 1$ and

$$
\begin{array}{rcl}\mathcal{M}^{i}\times \mathcal{M}^{j}&\longrightarrow &\mathcal{M}^{i+j-\ell}\\ (a,b)&\mapsto&a\otimes b\otimes \zeta\end{array}
$$

if $i + j > \ell$, with $\zeta = s \otimes t''$ where s and t'' are the global sections defining E and C'' . Then we obtain

$$
\psi: X := \mathcal{S}pec\left(\bigoplus_{i=0}^{\ell-1} \mathcal{M}^i\right) \longrightarrow P,
$$

which is the cyclic cover of the ruled surface P ramified at $E + C''$ of degree ℓ , where Spec denotes the affine morphism. Now we will define $\phi = \pi \circ \psi : X \to C$.

Remark 2. $\phi: X \to C$ is an extension of Raynaud's original counter-example to Kodaira vanishing. Namely, let C be a Tango curve and let $e = \ell = 3$ if $p = 2$ and $e = \ell = 2$ if $p \geq 3$, then we obtain the example as given in [\[14\]](#page-18-0).

We define $\tilde{E} = \psi^{-1}(E)$ and $\tilde{C}'' = \psi^{-1}(C'')$, then we have

(6)
$$
\ell \tilde{E} = \psi^* E \quad \text{and} \quad \ell \tilde{C}'' = \psi^* C''
$$

and

(7)
$$
\psi_* \mathcal{O}_X = \bigoplus_{i=0}^{\ell-1} \mathcal{M}^i.
$$

Moreover, we have the following, which will be used later.

Lemma 4. *For* $k \geq 1$, we have $\psi_*\mathcal{O}_X(-k\tilde{E}) \cong \mathcal{O}_P(-kE) \oplus \bigoplus$ $_{\ell-1}$ $\frac{i=1}{i}$ \mathcal{M}^i .

Proof. From the exact sequence

$$
0 \longrightarrow \mathcal{O}_X(-k\tilde{E}) \longrightarrow \mathcal{O}_X \longrightarrow \mathcal{O}_{k\tilde{E}} \longrightarrow 0,
$$

we obtain by [\(7\)](#page-6-0)

$$
0 \longrightarrow \psi_* \mathcal{O}_X(-k\tilde{E}) \longrightarrow \bigoplus_{i=0}^{\ell-1} \mathcal{M}^i \longrightarrow \psi_* \mathcal{O}_{k\tilde{E}} \longrightarrow R^1 \psi_* \mathcal{O}_X(-k\tilde{E}),
$$

where $R^1 \psi_* \mathcal{O}_X(-\tilde{E}) = 0$ since $\psi : X \to P$ is an affine morphism. Also since ψ : $\tilde{E} \cong E$, we have $\psi_* \mathcal{O}_{k\tilde{E}} \cong \mathcal{O}_{kE} = \mathcal{O}_P / \mathcal{O}_P(-kE)$. Then we obtain the following diagram:

$$
\begin{array}{ccccccc}\n0 & \longrightarrow & \psi_* \mathcal{O}_X(-k\tilde{E}) & \longrightarrow & \mathcal{O}_P \oplus \bigoplus_{i=1}^{\ell-1} \mathcal{M}^i & \longrightarrow & \psi_* \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 \\
\parallel & & & & \parallel & & \parallel & & \parallel \\
 & & & & \mathcal{O}_{\ell} \oplus \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 & \parallel \\
 & & & & & \mathcal{O}_{\ell} \oplus \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 & \parallel \\
 & & & & & \mathcal{O}_{\ell} \oplus \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 & \parallel \\
 & & & & & \mathcal{O}_{\ell} \oplus \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 & \parallel \\
 & & & & & \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 & \parallel \\
 & & & & & \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 & \parallel \\
 & & & & & \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 & \parallel \\
 & & & & & \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 & \parallel \\
 & & & & & \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 & \parallel \\
 & & & & & & \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 & \parallel \\
 & & & & & \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 & \parallel \\
 & & & & & \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 & \parallel \\
 & & & & & \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 & \parallel \\
 & & & & & \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 & \parallel \\
 & & & & & \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 & \parallel \\
 & & & & & \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 & \parallel \\
 & & & & & \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 & \parallel \\
 & & & & & \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 & \parallel \\
 & & & & & \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 & \parallel \\
 & & & & & \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 & \parallel \\
 & & & & & \mathcal{O}_{k\tilde{E}} & \longrightarrow & 0 & \parallel \\
 & & & & & \mathcal{O}_{
$$

$$
0 \longrightarrow \mathcal{O}_P(-kE) \oplus \bigoplus_{i=1}^{\ell-1} \mathcal{M}^i \longrightarrow \mathcal{O}_P \oplus \bigoplus_{i=1}^{\ell-1} \mathcal{M}^i \longrightarrow \mathcal{O}_P/\mathcal{O}_P(-kE) \longrightarrow 0
$$

from which we have $\psi_* \mathcal{O}_X(-k\tilde{E}) \cong \mathcal{O}_P(-kE) \oplus \bigoplus_{i=1}^{\ell-1} \mathcal{M}^i$ by 5-lemma.

Lemma 5. *For* $k \geq 0$ *and* $1 \leq r \leq \ell - 1$ *, we have*

$$
(i) \ \psi_* \mathcal{O}_X(k\ell \tilde{E}) = \bigoplus_{i=0}^{\ell-1} \mathcal{M}^i(kE),
$$

$$
(ii) \ \psi_*({\mathcal O}_X((k\ell+r)\tilde{E})) = {\mathcal O}_P(r+1+k-\ell) \oplus \bigoplus_{i=1}^{\ell-1} {\mathcal M}^i((k+1)E).
$$

Proof. Using [\(6\)](#page-6-1) and [\(7\)](#page-6-0), we have $\psi_* \mathcal{O}_X(k\ell E) = \psi_* \psi^* \mathcal{O}_P(kE) = \psi_* \mathcal{O}_X \otimes \mathcal{O}_P(kE) =$ $\bigoplus_{i=0}^{\ell-1} \mathcal{M}^i(kE)$, which proves (i). Now for $1 \leq r \leq \ell-1$, we compute by [\(6\)](#page-6-1) and Lemma [4](#page-6-2)

$$
\psi_* \mathcal{O}_X(r\tilde{E})
$$
\n
$$
= \psi_* (\mathcal{O}_X(-(\ell - r)\tilde{E} \otimes \ell \tilde{E})) = \psi_* (\mathcal{O}_X(-(\ell - r)\tilde{E}) \otimes \psi^* \mathcal{O}_P(E))
$$
\n
$$
= \psi_* \mathcal{O}_X(-(\ell - r)\tilde{E}) \otimes \mathcal{O}_P(E) = \mathcal{O}_P((r + 1 - \ell)E) \oplus \bigoplus_{i=1}^{\ell-1} \mathcal{M}^i(E),
$$

from which we immediately obtain (ii) .

Our surface X is at least normal even if $E + C''$ is singular, namely in the case that C is pre-Tango but not Tango (see Theorem [3\)](#page-5-1). To prove this fact we use a result by Esnault-Viehweg. Let Y be a variety, $\mathcal H$ an invertible sheaf over Y and $E = \sum_{j=1}^{r} \alpha_j E_j$ an effective divisor such that $\mathcal{H}^{\ell} = \mathcal{O}_X(E)$ for some integer $\ell \geq 2$. We define $\mathcal{H}^{(i)} := \mathcal{H}^i \otimes \mathcal{O}_X(-[\frac{i}{\ell}E])$ and set $\mathcal{A} := \bigoplus_{i=0}^{\ell-1} \mathcal{H}^{(i)^{-1}}$. Then we have

Proposition 6 (cf. Claim 3.12 of [\[3\]](#page-18-18)). *The canonical morphism* $\mathcal{S}pec(A) \longrightarrow Y$ *is finite and* Spec(A) *is normal.*

Corollary 7. *For every pre-Tango curve* C*, the above constructed surface* X *is normal. In particular,* X *is Cohen-Macaulay. Moreover,* X *is smooth if* C *is a Tango curve.*

Proof. We apply Prop. [6](#page-7-0) in the case of $(X, \mathcal{H}, \ell, E) := (P, \mathcal{M}^{-1}, \ell, E + C'')$. Since C'' and E are reduced curves, we have $\mathcal{O}_P([\frac{i}{\ell}(E+C'')]) = \mathcal{O}_P$ for $0 \leq i \leq \ell - 1$. Thus $Spec(A)$ is nothing but our surface X and normal. Since dim $X = 2$, we know that X is Cohen-Macaulay by Serre's (S_2) condition. The final statement follows from Theorem [3.](#page-5-1)

Remark 3. The cyclic cover constructed by Mukai [\[10\]](#page-18-2) is more general than ours. Let $\mathcal{L}, D, \mathcal{N}, e$ be as in [2.5.](#page-5-2) Choose $\ell \geq 2$ such that $\ell \mid e$ and $(\ell, p) = 1$. Notice that the last condition is weaker than our condition $\ell \mid (p+1)$. Mukai's construction is as follows. For any $\alpha \in \mathbb{N}$ such that $\ell \mid (p + \alpha)$ we write

$$
0 \sim C'' - pE + p\pi^*(D) = C'' + \alpha E + \ell K \quad \text{with} \quad K := -\frac{p+\alpha}{\ell}E + \frac{p}{\ell}\pi^* D
$$

and set

$$
\mathcal{M}_{\alpha} := \mathcal{O}_P(K) = \mathcal{O}_P\left(-\frac{p+\alpha}{\ell}\right) \otimes \pi^* \mathcal{N}^{\frac{pe}{\ell}}.
$$

Then, we have $\mathcal{M}_{\alpha}^{-\ell} = \mathcal{O}_P(C'' + \alpha E)$. Now we consider

$$
\psi': X':=\mathcal S pec \bigoplus_{\circ i=0}^{\ell-1} \mathcal M_{\alpha}^i \longrightarrow P,
$$

which is normal if and only if $\alpha = 1$. Thus we take the normalization X of X' to obtain the cyclic cover $\phi: X \to P$. Corollary [7](#page-7-1) also holds for this construction. But the normalization $f: X \to X'$ makes it difficult to compute the cohomologies $H^i(X, \mathcal{Z}^n) = H^i(X', f_*\mathcal{Z}^n)$ for a polarization (X, \mathcal{Z}) .

3. Basic properties of the surfaces

We will show some basic properties of our surface X . Also we will define the Mumford-Szpiro type polarization (X, \mathcal{Z}) in the end of this section.

The cross section $E \subset X$ has a positive self-intersection number.

Proposition 8. The self-intersection number of \tilde{E} is $\tilde{E}^2 = \frac{1}{\epsilon}$ ℓ \cdot deg D (> 0).

Proof. We compute
$$
\tilde{E}^2 = \left(\frac{\psi^*(E)}{\ell}, \frac{\psi^*(E)}{\ell}\right) = \frac{\deg \psi}{\ell^2} \cdot E^2 = \frac{1}{\ell} \cdot E^2 = \frac{1}{\ell} \cdot \deg D.
$$
 \Box

Now we consider the canonical divisor K_X .

Proposition 9.
$$
K_X \sim \phi^* \left(K_C - \frac{p\ell - p - \ell}{\ell} \cdot D \right) + (p\ell - p - \ell - 1)\tilde{E}.
$$

Proof. We have $K_X \sim \psi^* K_P + (\ell - 1)\tilde{E} + (\ell - 1)\tilde{C}''$ by the branch formula. Applying ψ^* to $C'' \sim pE - p\pi^* D$ to obtain $\tilde{C}'' \sim p\tilde{E} - \frac{p}{\rho}$ $\frac{p}{\ell} \cdot \phi^*(D)$. Then a direct computation, together with the well known formula $K_P = -2E + \pi^*K_C + \pi^*(D)$, shows the required result. \Box

Proposition 10. K_X *is ample if* $(p, \ell) = (3, 4)$ *or* $p \ge 5$ *.*

Proof. We have $K_X = \phi^* A + B$, where $A = K_C - (p\ell - p - \ell)D/\ell$, $B = (p\ell - p - \ell - 1)\tilde{E}$ by Proposition [9.](#page-8-1) Since $0 < \deg D \leq \frac{2(g-1)}{n}$ $\frac{p-1}{p}$ and $g \geq 2$, we see deg $A > 0$. Also we see that deg $B \le 0$ if and only if $(p, \ell) = (2, 2), (2, 3), (3, 2)$. Thus, since $\ell \mid (p + 1)$, we have deg $B > 0$ if and only if $(p, \ell) = (3, 4)$ and $p \ge 5$. In these cases, we have $K_X^2 > 0$ and $K_X.H > 0$ for every irreducible curve $H \in Pic(P)$ in P by Proposition [8](#page-8-2) (cf. Prop. V.2.3 [\[6\]](#page-18-19)). Thus K_X is ample by Nakai-Moishezon criterion.

Now we are interested in whether $H^1(X, K_X^{-1}) = 0$ holds if K_X is ample.

Lemma 11. *We have*

$$
H^{1}(X, K_{X}^{-1}) = \bigoplus_{i=0}^{\ell-1} H^{1}(P, K_{P}^{-1} - \frac{(p+1)(\ell-1+i)}{\ell}E + \frac{p(\ell-1+i)}{\ell}\pi^{*}D)
$$

Proof. Since $\psi : X \to P$ is an affine morphism, we have $H^1(X, K_X^{-1}) = H^1(P, \psi_*(K_X^{-1}))$. By branch formula and $C'' \sim pE - p\pi^*D$, we have

$$
K_X^{-1} = \psi^* \left(K_P^{-1} - \frac{(p+1)(\ell-1)}{\ell} E + \frac{p(\ell-1)}{\ell} \pi^* D \right)
$$

so that

$$
\psi_*(\mathcal{O}_X(K_X^{-1})) = \psi_* \mathcal{O}_X \otimes_{\mathcal{O}_X} \mathcal{O}_P\left(K_P^{-1} - \frac{(p+1)(\ell-1)}{\ell}E + \frac{p(\ell-1)}{\ell}\pi^*D\right)
$$

where $\psi_* \mathcal{O}_X = \bigoplus_{i=0}^{\ell-1} \mathcal{M}^i$. Then we obtain the above stated result.

Since Kodaira vanishing holds for P (see [\[10,](#page-18-2) [23\]](#page-19-0)), to show that $H^1(X, K_X^{-1}) = 0$ we have only to show that

$$
L_i := K_P + \frac{(p+1)(\ell - 1 + i)}{\ell} E - \frac{p(\ell - 1 + i)}{\ell} \pi^* D
$$

are ample for $i = 0, \ldots, \ell - 1$.

Proposition 12. $H^1(X, K_X^{-1}) = 0$ *holds for* $p \ge 5$ *or* $p = 3$ *and* $\ell = e = 4$ *.*

Proof. Let **f** be any fiber of π : $P \to C$. Then we have $\pi^*D = \deg D \cdot \mathbf{f}$ and the numerical equivalence $K_P \equiv -2E + 2(g - 1) \cdot \mathbf{f} + \deg D \cdot \mathbf{f}$. Thus we have $L_i \equiv u_i \cdot E + v_i \cdot \mathbf{f}$ where

$$
u_i := \frac{(p+1)(\ell-1+i)}{\ell} - 2
$$
, $v_i := 2g - 2 - \frac{p\ell - p - \ell + pi}{\ell} \cdot \deg D$.

Then, using the condition $\ell \mid (p+1)$, we can show that $L_i.E > 0$ and $L_i.f > 0$ if $p \geq 5$ or $p = 3$ and $\ell = e = 4$. Also a straightforward computation shows that $L_i^2 > 0$. Then by Nakai-Moishezon's criteria, L_i , $i = 0, \ldots, \ell - 1$, are ample. \Box

Next we consider the fibers $X_y := \phi^{-1}(y)$ ($\subset X$) for $y \in C$.

Proposition 13. Every X_y has a singularity at the intersection with the curve \tilde{C}'' , which is the cusp of the form $Z^{\ell} = W^p$.

Proof. The fiber X_y may have singularities at the intersection with $\tilde{E} + \tilde{C}''$, which are the inverse image of $\mathbb{P}^1 \cap (E + C'') \ (\subset P)$ by ψ . By Proposition [1,](#page-3-2) $C'' \subset P$ is locally defined by the equations $c_i X^p + Y^p \in \mathcal{O}_{U_i}[X,Y]$ with $y \in U_i$. Thus $Z = (c_i X^p + Y^p)^{1/\ell}$ is a local coordinate of $\phi^{-1}(U_i) \subset X$. Setting the new coordinate $W = c_i^{1/p} X + Y$ we have $Z^{\ell} = W^p$ as required. Moreover, a similar argument shows that $\phi^{-1} \cap E$ is not singular (cf. Remark [1\)](#page-4-1).

Although X_y is birational with \mathbb{P}^1 , it has a positive geometric genus.

Proposition 14. The geometric genus of
$$
X_y
$$
 is $\frac{(\ell-1)(p-1)}{2}$ (> 0).

Proof. By normalization, we can assume that X_y is smooth and $\psi_y = \psi |_{X_y}$. $\phi^{-1}(y) \longrightarrow \mathbb{P}^1 \cong \pi^{-1}(y), y \in C$, is a finite separated morphism. By taking the normalization, we can assume from the beginning that $X_y := \phi^{-1}(y)$ is a smooth curve and the degree deg $\psi_y(=\ell)$ is preserved. Also the ramification divisor for ψ_y is $(\ell-1)(\tilde{E}\cap X_y)+(\ell-1)(\tilde{C}''\cap X_y)$, whose degree is $(\ell-1)(p+1)$. Thus by Hurwitz formula we obtain the required result.

Mumford and Szpiro generalized Raynaud's examples and obtained the following result.

Theorem 15 (Mumford and Szpiro [\[13,](#page-18-7) [16\]](#page-18-8)). Let $\phi: X \to C$ be a fibration from *a smooth projective surface to a smooth projective curve and assume that each fiber is reduced and irreducible with positive geometric genus. Then if there exists a*

cross section $\Gamma \subset X$ *of* ϕ *with positive self intersection number, we have* (i) $\mathcal{Z} =$ $\mathcal{O}_X(\Gamma) \otimes \phi^*(\phi_* \mathcal{O}_X(\Gamma)|_{\Gamma})$ *is ample, and (ii)* $H^1(X, \mathcal{Z}^{-1}) \neq 0$.

By Proposition [8](#page-8-2) and Proposition [14,](#page-9-1) we know that our surface X is an instance of this theorem when $\Gamma = E$. Moreover,

Proposition 16. In this case, we have $\mathcal{Z} = \mathcal{O}_X(\tilde{E}) \otimes \phi^* \mathcal{N}^{e/\ell} = \mathcal{O}_X(\tilde{D})$ where $\tilde{D} = \psi^{-1}(E) + \phi^{-1}D'$ with $D' = \frac{1}{\ell}D$.

Proof. We have $\phi_*\mathcal{O}_X(\tilde{E}) |_{\tilde{E}} = \phi_*(\mathcal{O}_X(\tilde{E}) \otimes \mathcal{O}_{\tilde{E}}) = (\pi_* \circ \psi_*)(\psi^*\mathcal{O}_P(\frac{1}{\ell}E) \otimes \mathcal{O}_{\tilde{E}}) =$ $\pi_*(\psi_*\mathcal{O}_{\tilde{E}} \otimes \mathcal{O}_P(\frac{1}{\ell}E)).$ Now from the short exact sequence

$$
0 \longrightarrow \mathcal{O}_X(-\tilde{E}) \longrightarrow \mathcal{O}_X \longrightarrow \mathcal{O}_{\tilde{E}} \longrightarrow 0
$$

we obtain,

$$
0 \longrightarrow \psi_* \mathcal{O}_X(-\tilde{E}) \longrightarrow \psi_* \mathcal{O}_X \longrightarrow \psi_* \mathcal{O}_{\tilde{E}} \longrightarrow R^1 \psi_* \mathcal{O}_X(-\tilde{E})
$$

and $R^1\psi_*\mathcal{O}_X(-\tilde{E})=0$ since ψ is an affine morphism. Thus by Lemma [4](#page-6-2) we have

$$
\psi_*\mathcal{O}_{\tilde{E}} \cong \psi_*\mathcal{O}_X/\psi_*\mathcal{O}_X(-\tilde{E}) \cong \frac{\bigoplus_{i=0}^{\ell-1} \mathcal{M}^i}{\mathcal{O}_P(-E) \oplus \bigoplus_{i=1}^{\ell-1} \mathcal{M}^i} \cong \mathcal{O}_E,
$$

and then

$$
\phi_*\mathcal{O}_X(\tilde{E})\mid_{\tilde{E}} = \pi_*\left(\mathcal{O}_E \otimes \mathcal{O}_P(\frac{1}{\ell}E)\right) = \mathcal{O}_C(\frac{1}{\ell}D)(=\mathcal{N}^{e/\ell}).
$$

since E is the canonical section of $\pi : P \to C$.

Notice that if $e = \ell = 2$ when char $k \geq 3$ and $e = \ell = 3$ when char $k = 2$ then $\mathcal Z$ in Proposition [16](#page-10-0) is the same as the ample invertible sheaf of Raynaud's counter-example to Kodaira vanishing.

4. Cohomologies for Mumford-Szpiro type polarization

In this section, we will compute the cohomologies $H^{i}(X, \mathcal{Z}^{n})$ for the Mumford-Szpiro type polarization (X, \mathcal{Z}) given in Proposition [16,](#page-10-0) namely $\mathcal{Z} = \mathcal{O}_X(\tilde{E}) \otimes \phi^* \mathcal{N}_{\ell}$ where we set $\mathcal{N}_{\ell} = \mathcal{N}^{\frac{e}{\ell}}$.

First of all, we summarize the well-known facts about ruled surfaces, which are necessary in our computation of cohomologies.

Lemma 17. For the ruled surface π : $P = \mathbb{P}(\mathcal{E}) \longrightarrow C$, we have

- (i) $\pi_*\mathcal{O}_P(k) = S^k(\mathcal{E})$, which is the kth component of the symmetric algebra $S(\mathcal{E})$. We will understand $S^k(\mathcal{E}) = 0$ for $k < 0$.
- (ii) for a locally free sheaf \mathcal{F} on P, $H^i(P, \mathcal{O}_P(n) \otimes \pi^* \mathcal{F}) \cong H^i(C, S^n(\mathcal{E}) \otimes \mathcal{F})$ for $n \geq 0$ *and* $i \in \mathbb{Z}$.

$$
(iii)
$$

$$
R^1 \pi_* \mathcal{O}_P(n) = \begin{cases} 0 & \text{if } n \ge -1 \\ S^{-n-2}(\mathcal{E})^\vee \otimes \mathcal{L}^\vee & \text{if } n \le -2 \end{cases}
$$

For an extension of (ii) with $\mathcal F$ any coherent sheaf, see Proposition 7.10.13 [\[1\]](#page-18-20).

Proof. (i) is Proposition II.7.11(a) [\[6\]](#page-18-19). Now we have $R^1\pi_*\mathcal{O}_P(n) = \pi_*\mathcal{O}_P(-n +$ 2))^{$\vee \otimes \mathcal{L}^{\vee}$ by Exer. III.8.4(c) [\[6\]](#page-18-19). Then applying (i) we obtain (iii), cf. Appen-} dix A [\[9\]](#page-18-21). Finally, we have $S^n(\mathcal{E}) \otimes \mathcal{F} \cong \pi_*(\mathcal{O}_P(n) \otimes \pi^* \mathcal{F})$ by (*i*) and $R^i \pi_*(\mathcal{O}_P(n) \otimes$ $\pi^* \mathcal{F} = R^i \pi_* \mathcal{O}_P(n) \otimes \mathcal{F} = 0$ for $n \geq 0$ and $i \geq 0$ by *(iii)*. Thus we obtain *(ii)* by Leray spectral sequence.

The following vanishing result will also be used.

Proposition 18. For any $1 \leq m$ and $k < e$, we have $H^0(C, S^m(\mathcal{E})^{\vee} \otimes \mathcal{N}^k) = 0$.

Proof. Since rank $\mathcal{E} = 2$ and \mathcal{L} is the surjective image of \mathcal{E} , we have rank $S^m(\mathcal{E}) =$ $m + 1$ and there exists a filtration

$$
0 = \mathcal{F}_0 \subset \mathcal{F}_1 \subset \cdots \subset \mathcal{F}_m \subset \mathcal{F}_{m+1} = S^m(\mathcal{E})
$$

such that \mathcal{F}_j is a locally free sheaf of rank $\mathcal{F}_j = j$ and

$$
0 \longrightarrow \mathcal{F}_{j-1} \longrightarrow \mathcal{F}_j \longrightarrow \mathcal{L}^j \longrightarrow 0
$$

for $j = 1, \ldots, m + 1$. Now taking the dual, tensoring by \mathcal{N}^k and taking the global sections, we have for $j = 2, \ldots, m + 1$

$$
0 \longrightarrow H^0(C, \mathcal{L}^{-j} \otimes \mathcal{N}^k) \longrightarrow H^0(C, \mathcal{F}_j^{\vee} \otimes \mathcal{N}^k) \stackrel{\psi_j}{\longrightarrow} H^0(C, \mathcal{F}_{j-1}^{\vee} \otimes \mathcal{N}^k).
$$

If $\deg \mathcal{L}^j \otimes \mathcal{N}^{-k} = (ej - k) \cdot \deg \mathcal{N} > 0$, i.e. $ej > k$, we have $H^0(C, \mathcal{L}^{-j} \otimes \mathcal{N}^k) = 0$ so that ψ_j is an inclusion. Thus we have

$$
\psi_2 \circ \cdots \circ \psi_{m+1} : H^0(C, S^m(\mathcal{E})^{\vee} \otimes \mathcal{N}^k) \subset H^0(C, \mathcal{F}_1^{\vee} \otimes \mathcal{N}^k) = H^0(C, \mathcal{L}^{-1} \otimes \mathcal{N}^k)
$$

if $ej > k$ for all $j = 2, ..., m + 1$, i.e. if $2e > k$. Now $H^0(C, \mathcal{L}^{-1} \otimes \mathcal{N}^k) = 0$ and thus $H^0(C, S^m(\mathcal{E})^{\vee} \otimes \mathcal{N}^k) = 0$, if $\deg \mathcal{L}^{-1} \otimes \mathcal{N}^k = (k - e) \cdot \deg \mathcal{N} < 0$, i.e. if $e > k$.

4.1. Computation of $H^2(X, \mathcal{Z}^n)$. Now we compute $H^2(X, \mathcal{Z}^n)$.

Proposition 19. *For* $k \geq 0$ *and* $1 \leq r \leq \ell - 1$ *,*

$$
H^{2}(X, \mathcal{Z}^{n})
$$
\n
$$
\begin{cases}\n\bigoplus_{i=\left[\frac{n}{p+1}+1\right]}^{l-1} H^{2}(P, \mathcal{O}_{P}\left(-\frac{i(p+1)}{\ell}+k\right) \otimes \pi^{*}\mathcal{N}_{\ell}^{ip+n}) & \text{if } n=k\ell \geq 0 \\
H^{2}(P, \mathcal{O}_{P}(r+1+k-\ell)) \otimes \pi^{*}\mathcal{N}_{\ell}^{n}) \\
\oplus \bigoplus_{i=\left[\frac{n+\ell-r}{p+1}+1\right]}^{l-1} H^{2}(P, \mathcal{O}_{P}\left(-\frac{i(p+1)}{\ell}+k+1\right) \otimes \pi^{*}\mathcal{N}_{\ell}^{ip+n}) & \text{if } n=k\ell+r > 0 \\
H^{2}(P, \mathcal{O}_{P}(n) \otimes f^{*}\mathcal{N}_{\ell}^{n}) \\
\oplus \bigoplus_{i=1}^{l-1} H^{2}(P, \mathcal{O}_{P}\left(-\frac{i(p+1)}{\ell}\right) \otimes \pi^{*}\mathcal{N}_{\ell}^{ip+n}) & \text{if } n < 0.\n\end{cases}
$$

Proof. Since $\psi: X \to P$ is an affine morphism, the Leray spectral sequence degenerates so that we have $H^2(X, \mathcal{Z}^n) = H^2(P, \psi_*(\mathcal{O}_X(n\tilde{E}) \otimes (\psi^* \circ \pi^*)\mathcal{N}_{\ell}^n)) =$ $H^2(P, \psi_*\mathcal{O}_X(n\tilde{E}) \otimes \pi^* \mathcal{N}_{\ell}^n)$. Then by Lemma [4](#page-6-2) and Lemma [5,](#page-6-3) we compute

$$
H^{2}(X, \mathcal{Z}^{n})
$$
\n
$$
\begin{cases}\nH^{2}(P, \mathcal{O}_{P}(k) \otimes \pi^{*}\mathcal{N}_{\ell}^{n}) \\
\oplus \bigoplus_{i=1}^{\ell-1} H^{2}(P, \mathcal{O}_{P}\left(-\frac{i(p+1)}{\ell} + k\right) \otimes \pi^{*}\mathcal{N}_{\ell}^{ip+n}) & \text{if } n = k\ell \ge 0\n\end{cases}
$$
\n
$$
= \begin{cases}\nH^{2}(P, \mathcal{O}_{P}(r+1+k-\ell)) \otimes \pi^{*}\mathcal{N}_{\ell}^{n} \\
\oplus \bigoplus_{i=1}^{\ell-1} H^{2}(P, \mathcal{O}_{P}\left(-\frac{i(p+1)}{\ell} + k + 1\right) \otimes \pi^{*}\mathcal{N}_{\ell}^{ip+n}) & \text{if } n = k\ell + r > 0\n\end{cases}
$$
\n
$$
H^{2}(P, \mathcal{O}_{P}(n) \otimes \pi^{*}\mathcal{N}_{\ell}^{n})
$$
\n
$$
\oplus \bigoplus_{i=1}^{\ell-1} H^{2}(P, \mathcal{O}_{P}\left(-\frac{i(p+1)}{\ell}\right) \otimes \pi^{*}\mathcal{N}_{\ell}^{ip+n}) \quad \text{if } n < 0.
$$

Moreover, in the case of $n = k\ell \geq 0$, we have $-\frac{i(p+1)}{\ell} + k \geq 0$ if $i \leq \frac{n}{p+1}$. Also in the case of $n = k\ell + r > 0$, we have $-\frac{i(p+1)}{\ell} + k + 1 \geq 0$ if $i \leq \frac{n+\ell-r}{p+1}$. Now by Lemma [17\(](#page-10-1)ii), we have $H^2(P, \mathcal{O}_P(j) \otimes \pi^* \mathcal{N}^n) = H^2(C, S^j(\mathcal{E}) \otimes \mathcal{N}^n) = 0$ for $j \geq 0$. Thus we do not have to consider the direct summands with the indices i in the above specified ranges. \Box

As an immediate consequence, we have the following vanishing result.

Corollary 20. We have $H^2(X, \mathcal{Z}^n) = 0$ (i) if $\ell \mid n$ and $n \geq (\ell - 1)(p + 1)$ *, in particular* $n \geq p(p+1)$ *, or* (ii) if $\ell \nmid n$ *and* $n \geq p(p+1) - 1$ *. In particular,* $H²(X, \mathcal{Z}ⁿ) = 0$ for all $n \geq p(p+1)$.

Proof. By Proposition [19](#page-11-0) and Lemma [17\(](#page-10-1)*ii*), we know that, for $n \geq 0$, $H^2(X, \mathcal{Z}^n) =$ 0 if (i) $n = k\ell \ge 0$ and $\ell - 1 < \left[\frac{n}{p+1} + 1\right]$, or (ii) $n = k\ell + r > 0$, $\ell - 1 < \left[\frac{n+\ell-r}{p+1} + 1\right]$ and $r+1+k-\ell \geq 0$. The second condition of (i) is equivalent to $\frac{n}{p+1}+1-(\ell-1) \geq 1$, i.e., $n \ge (p+1)(\ell-1)$. Since $\ell \mid (p+1)$, we have $\ell-1 \le p$ so that $n \ge p(p+1)$ implies in particular $n \geq (p+1)(\ell-1)$. Similarly, the second condition of (ii) is equivalent to $n \ge (p+1)(\ell-1) - (\ell-r)$. Since $\ell \mid (p+1)$ and $1 \le r \le \ell-1$, We have $(p+1)(\ell-1)-(\ell-r) \leq p(p+1)-1$. Thus in particular the second condition of (ii) is satisfied for $n \geq p(p+1)-1$. Moreover, by the first and the third condition of (ii), we have $n \geq (\ell - r)(\ell - 1)$. Since $1 \leq r$ and $\ell \mid (p + 1)$, we have $(\ell - r)(\ell - 1) \leq (\ell - 1)^2 \leq p^2 < p(p + 1) - 1$. Thus, in this case, $n \geq p(p + 1) - 1$ suffices for the vanishing. \Box

4.2. **computation of** $H^1(X, \mathcal{Z}^n)$. The case of $n \geq 0$ can be computed by the same method as in Proposition [19](#page-11-0) except the difference in the dimension of cohomologies. **Proposition 21.** Let $n \geq 0$. For $k \geq 0$, $1 \leq r \leq \ell - 1$, we have

$$
H^{1}(X, \mathcal{Z}^{n})
$$
\n
$$
= \begin{cases}\nH^{1}(C, S^{k}(\mathcal{E}) \otimes \mathcal{N}_{\ell}^{n}) \\
\oplus \bigoplus_{i=1}^{\left[\frac{n}{p+1}\right]} H^{1}(C, S^{-\frac{i(p+1)}{\ell}+k}(\mathcal{E}) \otimes \mathcal{N}_{\ell}^{ip+n}) \\
\oplus \bigoplus_{i=\left[\frac{n}{p+1}+1\right]}^{\ell-1} H^{1}(P, \mathcal{O}_{P}\left(-\frac{i(p+1)}{\ell}+k\right) \otimes \pi^{*} \mathcal{N}_{\ell}^{ip+n}) & \text{if } n = k\ell \ge 0 \\
H^{1}(P, \mathcal{O}_{P}(r+1+k-\ell)) \otimes \pi^{*} \mathcal{N}_{\ell}^{n}) \\
\oplus \bigoplus_{i=1}^{\left[\frac{n+\ell-r}{p+1}\right]} H^{1}(C, S^{-\frac{i(p+1)}{\ell}+k+1}(\mathcal{E}) \otimes \mathcal{N}_{\ell}^{ip+n}) \\
\oplus \bigoplus_{i=\left[\frac{n+\ell-r}{p+1}+1\right]}^{\ell-1} H^{1}(P, \mathcal{O}_{P}\left(-\frac{i(p+1)}{\ell}+k+1\right) \otimes \pi^{*} \mathcal{N}_{\ell}^{ip+n}) & \text{if } n = k\ell + r > 0\n\end{cases}
$$

Moreover, by Lemma [17](#page-10-1)(ii), the first term in the case of $n = k\ell + r > 0$ *is* $H^1(P, \mathcal{O}_P(r+1+k-\ell)) \otimes \pi^* \mathcal{N}_{\ell}^{n}) \cong H^1(C, S^{r+1+k-\ell}(\mathcal{E}) \otimes \mathcal{N}_{\ell}^{n}) \text{ if } r+k \geq \ell-1.$

Now we consider the case of $n < 0$.

Theorem 22. For $n < 0$, we have

$$
H^1(X, \mathcal{Z}^n) = \bigoplus_{i=1}^{\ell-1} H^0(C, S^{\frac{i(p+1)}{\ell}-2}(\mathcal{E})^{\vee} \otimes \mathcal{N}_{\ell}^{ip-\ell+n}).
$$

Proof. Consider a part of the five-term exact sequence

 $0 \longrightarrow H^1(C, \phi_* \mathcal{Z}^n) \longrightarrow H^1(X, \mathcal{Z}^n) \longrightarrow H^0(C, R^1 \phi_* \mathcal{Z}^n) \longrightarrow H^2(C, \phi_* \mathcal{Z}^n)$

for the Leray spectral sequence $E_2^{p,q} = H^p(C, R^q \phi_* \mathcal{Z}^n) \Rightarrow H^{p+q}(X, \mathcal{Z}^n)$. We have $H^2(C, \phi_* \mathcal{Z}^n) = 0$ since dim $C = 1$, and moreover an easy calculation using Lemma [4](#page-6-2) shows

$$
H^1(C, \phi_* \mathcal{Z}^n) = H^1(C, \pi_* \mathcal{O}_P(n) \otimes \mathcal{N}_{\ell}^n) \oplus \bigoplus_{i=1}^{\ell-1} H^1(C, \pi_* \mathcal{O}_P(-\frac{i(p+1)}{\ell}) \otimes \mathcal{N}_{\ell}^{ip+n})
$$

and this is $= 0$ by Lemma [17\(](#page-10-1)i). Thus, we have

(8)
$$
H^{1}(X, \mathcal{Z}^{n}) = H^{0}(C, R^{1}\phi_{*}\mathcal{Z}^{n}) \quad (n < 0).
$$

On the other hand, in a part of the five-term exact sequence

$$
0 \longrightarrow R^1 \pi_*(\psi_* \mathcal{Z}^n) \longrightarrow R^1 \phi_* \mathcal{Z}^n \longrightarrow \pi_*(R^1 \psi_* \mathcal{Z}^n)
$$

for $\psi: X \to P$ and $\pi: P \to C$, we have $R^1 \psi_* \mathcal{Z}^n = 0$ since ψ is an affine morphism. Thus we have

(9)
$$
R^1 \phi_* \mathcal{Z}^n = R^1 \pi_* (\psi_* \mathcal{Z}^n) \quad (n \in \mathbb{Z}).
$$

Now an easy calculation using Lemma [4](#page-6-2) and Lemma [17\(](#page-10-1)iii) shows

$$
R^1 \pi_*(\psi_* \mathcal{Z}^n) = \begin{cases} \bigoplus_{i=1}^{\ell-1} R^1 \pi_* \mathcal{M}^i \otimes \mathcal{N}_{\ell}^{-1} & \text{if } n = -1 \\ S^{-n-2}(\mathcal{E})^{\vee} \otimes \mathcal{N}_{\ell}^{n-\ell} \oplus \bigoplus_{i=1}^{\ell-1} R^1 \pi_* \mathcal{M}^i \otimes \mathcal{N}_{\ell}^{n} & \text{if } n \le -2 \end{cases}
$$

But by Proposition [18](#page-11-1) and deg $\mathcal{N}_{\ell} > 0$, we have

$$
H^0(C, S^{-n-2}(\mathcal{E})^{\vee} \otimes \mathcal{N}_{\ell}^{n-\ell}) = 0 \text{ for } n \le -2.
$$

Thus by [\(8\)](#page-13-2) and [\(9\)](#page-13-3) we have

(10)
$$
H^1(X, \mathcal{Z}^n) = \bigoplus_{i=1}^{\ell-1} H^0(C, R^1 \pi_* \mathcal{M}^i \otimes \mathcal{N}_\ell^n).
$$

By relative Serre duality, the well-known formula $\omega_{P/C} = \mathcal{O}_P(-2) \otimes \pi^* \mathcal{L}$ and Lemma $17(i)$, we compute

$$
R^1\pi_*\mathcal{M}^i\cong \pi_*(\mathcal{M}^{-i}\otimes \omega_{P/C})^{\vee}=S^{\frac{i(p+1)}{\ell}-2}(\mathcal{E})^{\vee}\otimes \mathcal{N}_{\ell}^{ip-\ell}.
$$

and we obtain the above stated result.

We give here some specific instances of Theorem [22.](#page-13-1)

Example 4. Let $n < 0$. Then,

• *if* $\ell = p + 1$ *:* $H^1(X,\mathcal{Z}^n)=H^0(C,\mathcal{N}_{\ell}^{p-1+n})\oplus\bigoplus$ p $i=3$ $H^0(C, S^{i-2}(\mathcal{E})^{\vee} \otimes \mathcal{N}_{\ell}{}^{ip-p-1-n})$

where the first term vanishes for $n < -(p-1)$ *. In particular, if* $p = 2$ *(and*) *then* $\ell = 3$), we have $H^1(X, \mathcal{Z}^n) = 0$ for $n \leq -2$ and moreover $H^1(X, \mathcal{Z}^{-1}) \neq 0$ 0 *since this is exactly the Raynaud's counter-example.*

• *if* $2\ell = p + 1$ *:*

$$
H^{1}(X, \mathcal{Z}^{n}) = H^{0}(C, \mathcal{N}_{\ell}^{\frac{p-1}{2}+n}) \oplus \bigoplus_{i=2}^{\frac{p-1}{2}} H^{0}(C, S^{2i-2}(\mathcal{E})^{\vee} \otimes \mathcal{N}_{\ell}^{\frac{ip-\frac{p+1}{2}+n}{2}})
$$

where the first term vanishes for $n < -\frac{p-1}{2}$ $\frac{-1}{2}$. In particular, if $p = 3$ (and then $\ell = 2$, we have $H^1(X, \mathcal{Z}^n) = 0$ for $n \leq -2$ and moreover $H^1(X, \mathcal{Z}^{-1}) \neq 0$ *since this is exactly the Raynaud's counter-example.*

Now we show some non-vanishing results.

Theorem 23. $H^1(X, \mathcal{Z}^n) \neq 0$ for every n such that $-(\ell - \lceil \frac{2\ell}{p+1} \rceil) \leq n \leq -1$, where $\lceil \cdots \rceil$ *denotes the round up.*

Proof. Since $\mathcal{L} = \mathcal{N}^e = \mathcal{N}_\ell^{\ell}$ is the surjective image of \mathcal{E} (cf. [\(3\)](#page-3-0), we have the short exact sequence

$$
S^{\frac{k}{\ell}}(\mathcal{E}) \longrightarrow \mathcal{N}_{\ell}^{k} \longrightarrow 0
$$

for any $k \in \mathbb{N}$ such that $\ell \mid k$. Taking the dual and tensoring by \mathcal{N}_{ℓ}^k , we obtain

$$
0 \longrightarrow \mathcal{O}_C \longrightarrow S^{\frac{k}{\ell}}(\mathcal{E})^{\vee} \otimes \mathcal{N}_{\ell}^k.
$$

Then we have

$$
k = H^0(C, \mathcal{O}_C) \subset H^0(C, S^{\frac{k}{\ell}}(\mathcal{E})^{\vee} \otimes \mathcal{N}_{\ell}^k).
$$

Applying this result, we know that the term $H^0(C, S^{\frac{i(p+1)}{\ell}-2}(\mathcal{E})^{\vee} \otimes \mathcal{N}_{\ell}{}^{ip-\ell+n}), 1 \leq$ $i \leq \ell - 1$, in Theorem [22](#page-13-1) is non-trivial if

$$
\frac{i(p+1)}{\ell} - 2 \ge 0 \quad \text{and} \quad \ell\left(\frac{i(p+1)}{\ell} - 2\right) = ip - \ell + n,
$$

namely $n = -(\ell - i)$, with $\lceil \frac{2\ell}{p+1} \rceil \leq i \leq \ell - 1$.

For small characteristics, the evaluation of the non-vanishing degrees in Theorem [22](#page-13-1) is best possible.

Corollary 24. If $p = 2$ or 3, we have $H^1(X, \mathcal{Z}^n) = 0$ for every $n < -(\ell - \lceil \frac{2\ell}{p+1} \rceil)$. *Proof.* Since $\ell \mid p+1$, we have only to consider the cases $(p, \ell) = (2, 3), (3, 2), (3, 4)$ and

$$
-\left(\ell - \lceil \frac{2\ell}{p+1} \rceil\right) = \begin{cases} -1 & \text{if } (p,\ell) = (2,3) \\ -1 & \text{if } (p,\ell) = (3,2) \\ -2 & \text{if } (p,\ell) = (3,4). \end{cases}
$$

The first two cases are already shown in Example [4.](#page-14-0) Then we assume $(p, \ell) = (3, 4)$ in the following. We have

$$
H^1(X, \mathcal{Z}^n) = \bigoplus_{i=1}^3 H^0(C, S^{i-2}(\mathcal{E})^\vee \otimes \mathcal{N}_\ell^{3i-4+n})
$$

=
$$
H^0(X, \mathcal{N}_\ell^{2+n}) \oplus H^0(C, S^1(\mathcal{E})^\vee \otimes \mathcal{N}_\ell^{5+n}) \quad (n < 0)
$$

by Theorem [22.](#page-13-1) Since $\deg \mathcal{N}_{\ell} > 0$, we have $H^0(X, \mathcal{N}_{\ell}^{2+n}) = 0$ for $n < -2$. Moreover, since $\mathcal{N}_{\ell}^{5+n} = \mathcal{N}_{\ell}^{\frac{e(5+n)}{4}}$ by definition and since $\frac{e(5+n)}{4} < e$ for $n < -2$, we have $H^0(C, S^1(\mathcal{E})^{\vee} \otimes \mathcal{N}_{\ell}^{5+n}) = 0$ for $n < -2$ by Proposition [18.](#page-11-1) Thus, in this case we have $H^1(X, \mathcal{Z}^n)$ $) = 0$ for $n < -2$.

4.3. computation of $H^0(X, \mathcal{Z}^n)$. Since $\mathcal Z$ is ample, we have $H^0(X, \mathcal{Z}^n) = 0$ for $n < 0$. For $n \geq 0$, we have

Proposition 25. *For* $n, k \geq 0$ *and* $1 \leq r \leq \ell - 1$ *, we have*

$$
H^{0}(X, \mathcal{Z}^{n})
$$
\n
$$
= \begin{cases} \bigoplus_{i=0}^{\ell-1} H^{0}(C, S^{-\frac{i(p+1)}{\ell}+k}(\mathcal{E}) \otimes \mathcal{N}_{\ell}^{ip+n}) & \text{if } n = k\ell \ge 0 \\ H^{0}(C, S^{r+1-k-\ell}(\mathcal{E}) \otimes \mathcal{N}_{\ell}^{n}) & \text{if } n = k\ell + r > 0. \\ \bigoplus_{i=1}^{\ell-1} H^{0}(C, S^{-\frac{i(p+1)}{\ell}+k+1}(\mathcal{E}) \otimes \mathcal{N}_{\ell}^{ip+n}) & \text{if } n = k\ell + r > 0. \end{cases}
$$

Proof. By Lemma [5,](#page-6-3) we compute

$$
H^{0}(X, \mathcal{Z}^{n}) = H^{0}(P, \psi_{*}\mathcal{O}_{X}(n\tilde{E}) \otimes \pi^{*}\mathcal{N}_{\ell}^{n})
$$

=
$$
\begin{cases} \bigoplus_{i=0}^{\ell-1} H^{0}(C, \pi_{*}\mathcal{M}^{i}(kE) \otimes \mathcal{N}_{\ell}^{n}) & \text{if } n = k\ell \ge 0 \\ H^{0}(C, \pi_{*}\mathcal{O}_{P}(r+1+k-\ell) \otimes \mathcal{N}_{\ell}^{n}) \\ \oplus \bigoplus_{i=1}^{\ell-1} H^{0}(C, \pi_{*}\mathcal{M}^{i}((k+1)E) \otimes \mathcal{N}_{\ell}^{n}) & \text{if } n = k\ell + r > 0 \end{cases}
$$

Then apply Lemma [17\(](#page-10-1)i). \square

Remark 5. According to Proposition [25,](#page-15-0) we know that the lower bound B such that $H^0(X, \mathcal{Z}^n) = 0$ for $n \geq B$, depends on the vanishing of cohomologies of type $H^0(C, S^m(\mathcal{E}) \otimes \mathcal{N}_{\ell}^n)$ for $m, n \gg 0$. Hence it seems to be difficult to give a general estimation of B.

By the similar argument as in the proofs of Proposition [19](#page-11-0) and [21,](#page-13-0) we know that we have only to consider fewer direct summands than Proposition [25](#page-15-0) in some cases. Namely,

• if
$$
n = k\ell
$$
 and $0 \le n < (p + 1)(\ell - 1)$, we have
\n
$$
\begin{aligned}\n\frac{\binom{n}{p+1}}{p+1} \\
H^0(X, \mathcal{Z}^n) &= \bigoplus_{i=0}^{n} H^0(C, S^{-\frac{i(p+1)}{\ell} + k}(\mathcal{E}) \otimes \mathcal{N}_{\ell}^{ip+n}) \\
\bullet \text{ if } n = k\ell + r, \ 0 < r \le \ell - 1, \text{ and } 0 < n < p(\ell - 1) + r - 1, \text{ we have} \\
H^0(X, \mathcal{Z}^n) \\
&= H^0(C, S^{r+1+k-\ell}(\mathcal{E}) \otimes \mathcal{N}_{\ell}^{n}) \oplus \bigoplus_{i=1}^{\left[\frac{n+\ell-r}{p+1}\right]} H^0(C, S^{-\frac{i(p+1)}{\ell} + k + 1}(\mathcal{E}) \otimes \mathcal{N}_{\ell}^{ip+n})\n\end{aligned}
$$

Then we have

Corollary 26. $H^0(X, \mathcal{Z}^n) = 0$ *if* $n = k\ell + r > 0$ *with* 0 < $r \leq \ell - 1$ *and* 0 ≤ k ≤ $\min\{\ell-r-2, \frac{p+1}{\ell}-2\}.$

Proof. By the above formula for $n = k\ell + r, 0 < r \leq \ell - 1$, we know that $H^0(X, \mathcal{Z}^n) =$ 0 if $r + 1 + k - \ell < 0$ and $n + \ell - r < p + 1$. From the latter inequation, we have

 $n = k\ell + r < \min\{p + 1 - \ell + r, p(\ell - 1) + r - 1\}$

and then together with the former inequation we have

$$
k < \min\left\{\ell - r - 1, \ \frac{p+1}{\ell} - 1, \ p - \frac{p+1}{\ell}\right\} = \min\{\ell - r - 1, \ \frac{p+1}{\ell} - 1\}
$$

where the last equation is by $\ell \geq 2$.

5. Families of non-vanishing polarizations

We have considered the Mumford-Szpiro type polarization given in Proposition [16.](#page-10-0) Raynaud's example is also of this kind. We show that much more varieties of polarizations can serve as counter-examples to Kodaira vanishing. We fist consider

$$
\mathcal{Z}_{a,b} := \mathcal{O}_X(a\tilde{E}) \otimes \phi^* \mathcal{N}_{\ell}{}^b \quad (a,b \ge 1).
$$

Proposition 27. $\mathcal{Z}_{a,b}$ *is ample.*

Proof. We have $E^2 = \deg D > 0$ and also $E.C > 0$ for every irreducible curve $C \in P$ (see Prop. V.2.3 [\[6\]](#page-18-19)). Thus $\mathcal{O}_P(nE)$, $n > 0$, is ample by Nakai-Moishezon criteria and, since $\psi: X \to P$ is a finite morphism, $\psi^* \mathcal{O}_P(nE) = \mathcal{O}_X(\ell n\tilde{E}), n > 0$, is also ample. In particular, $\mathcal{O}_X(a\tilde{E}), a \geq 1$, is ample. On the other hand, $\mathcal{N}_{\ell}^b =$ $\mathcal{N}^{be/\ell}, b \geq 1$, is ample so that in particular $\pi^* \mathcal{N}_{\ell}^b$ is semi-ample (i.e., its sufficiently large powers are generated by global sections). Consequently, $\mathcal{O}_X(a\tilde{E})\otimes \phi^*\mathcal{N}_{\ell}^b$ is \Box ample. \Box

Then, by carrying out a similar argument as the proofs of Theorem [22](#page-13-1) and Theorem [23,](#page-14-1) we have

Theorem 28. $H^1(X, \mathcal{Z}_{a,b}^{-1}) \neq 0$ for all $a \geq 1$ and $1 \leq b \leq \ell - 1$.

Proof. Let Q be an invertible sheaf on C and set $\mathcal{Z} = \mathcal{O}_X(a\tilde{E}) \otimes \phi^* \mathcal{Q}$. Now consider the following Leray spectral sequence of $\phi: X \longrightarrow C$

$$
E_2^{p,q} = H^p(C, R^q \phi_* \mathcal{Z}^{-1}) \Rightarrow H^{p+q}(X, \mathcal{Z}^{-1}) \quad (p \ge 0).
$$

We have $E_2^{2,0} = 0$ since dim $C = 1$. Then by the 5-term exact sequence we have

$$
H^1(X, \mathcal{Z}^{-1}) \longrightarrow H^0(C, R^1 \phi_* \mathcal{Z}^{-1}) \longrightarrow 0.
$$

Thus we have only to show $H^0(C, R^1\phi_*\mathcal{Z}^{-1}) = H^0(C, R^1\phi_*\mathcal{O}_X(-a\tilde{E}) \otimes \mathcal{Q}^{-1}) \neq 0$. Considering the 5-term exact sequence

$$
0 \longrightarrow R^{1}\pi_{*}(\psi_{*}\mathcal{O}_{X}(-a\tilde{E})) \longrightarrow R^{1}(\pi \circ \psi)_{*}\mathcal{O}_{X}(-a\tilde{E}) \longrightarrow \pi^{*}(R^{1}\psi_{*}\mathcal{O}_{X}(-a\tilde{E})),
$$

where $R^1 \psi_* \mathcal{O}_X(-a\tilde{E}) = 0$ since $\psi : X \to P$ is an affine morphism, we have

$$
R^1 \phi_* \mathcal{O}_X(-a\tilde{E}) = R^1(\pi \circ \psi)_* \mathcal{O}_X(-a\tilde{E}) \cong R^1 \pi_* (\psi_* \mathcal{O}_X(-a\tilde{E})).
$$

Thus by Lemma [4](#page-6-2) we obtain

$$
R^{1}\phi_{*}\mathcal{O}_{X}(-a\tilde{E}) = R^{1}\pi_{*}\mathcal{O}_{P}(-aE) \oplus \bigoplus_{i=1}^{\ell-1} (R^{1}\pi_{*}\mathcal{M}^{i})
$$

= $R^{1}\pi_{*}\mathcal{O}_{P}(-aE) \oplus \bigoplus_{i=1}^{\ell-1} (S^{(ip+i-2\ell)/\ell}(\mathcal{E}) \otimes \mathcal{N}^{(\ell-ip)e/\ell})^{\vee}.$

We note that the last equation is shown in the end of the proof of Theorem [22.](#page-13-1) Thus we have

$$
H^0(C, R^1\phi_*\mathcal{O}_X(-a\tilde{E})\otimes \mathcal{Q}^{-1})\supseteq \bigoplus_{i=1}^{\ell-1} H^0(C, (S^{(ip+i-2\ell)/\ell}(\mathcal{E})\otimes \mathcal{N}^{(\ell-ip)e/\ell})^{\vee}\otimes \mathcal{Q}^{-1}).
$$

(Actually we can show that this inclusion is really an equation.)

On the other hand, from $\mathcal{E} \longrightarrow \mathcal{L} \longrightarrow 0$ we have

$$
S^{(ip+i-2\ell)/\ell}(\mathcal{E})\otimes \mathcal{N}^{(\ell-ip)e/\ell}\longrightarrow \mathcal{L}^{(ip+i-2\ell)/\ell}\otimes \mathcal{N}^{(\ell-ip)e/\ell}\longrightarrow 0.
$$

Taking the dual and tensoring by \mathcal{Q}^{-1} , we have

$$
0 \longrightarrow (\mathcal{L}^{(ip+i-2\ell)/\ell} \otimes \mathcal{N}^{(\ell-ip)e/\ell})^{\vee} \otimes \mathcal{Q}^{-1} \longrightarrow (S^{(ip+i-2\ell)/\ell}(\mathcal{E}) \otimes \mathcal{N}^{(\ell-ip)e/\ell})^{\vee} \otimes \mathcal{Q}^{-1}
$$

and

$$
(\mathcal{L}^{(ip+i-2\ell)/\ell} \otimes \mathcal{N}^{(\ell-ip)e/\ell})^{\vee} = (\mathcal{N}^{(ip+i-2\ell)e/\ell} \otimes \mathcal{N}^{(\ell-ip)e/\ell})^{\vee} = \mathcal{N}^{(\ell-i)e/\ell}.
$$

Thus we have for $i = 1, \ldots, \ell - 1$

$$
H^0(C, \mathcal{N}^{(\ell-i)e/\ell} \otimes \mathcal{Q}^{-1}) \subset H^0(C, R^1\phi_*\mathcal{O}_X(-a\tilde{E}) \otimes \mathcal{Q}^{-1}).
$$

In particular, taking $\mathcal{Q} = \mathcal{N}^{\frac{(\ell-i)e}{\ell}} = \mathcal{N}_{\ell}^{\ell-i}$ with $i = 1, \ldots, \ell - 1$, we have $k \subset$ $H^0(C, R^1\phi_*\mathcal{O}_X(-a\tilde{E})\otimes \mathcal{Q}^{-1})$ as required and in this case $\mathcal Z$ is exactly what we \Box

The cohomologies $H^i(X, \mathcal{Z}_{a,b}^n), i, n \in \mathbb{Z}$, can also be computed by a similar method to what we have described.
