#### Abstract

We study the leading term of the holonomy map of a perturbed plane polynomial Hamiltonian foliation. The non-vanishing of this term implies the non-persistence of the corresponding Hamiltonian identity cycle. We prove that this does happen for generic perturbations and cycles, as well for cycles which are commutators in Hamiltonian foliations of degree two. Our approach relies on the Chen's theory of iterated path integrals which we briefly resume.

## 1 Introduction

Let $\mathcal{F}^{n}$ be a degree $n$ polynomial foliation on the plane $\mathbb{C}^{2}$. A cycle on a leaf is a non-zero free homotopy class of closed loops on this leaf. Let $\delta$ be a closed non-contractible loop on a leaf and denote the holonomy map associated to $\delta$ by $h_{\delta}$. The cycle represented by $\delta$ is said to be an identity cycle provided that $h_{\delta}$ is the identity map, and Hamiltonian identity cycle, provided that $\mathcal{F}^{n}=\{d f=0\}$. The present paper is motivated by the following:

Conjecture 1. A generic polynomial foliation on $\mathbb{C}^{2}$ can not have identity cycles.
which follows on its turn from the following more general:
Conjecture 2. [13, p.4], (D.V. Anosov, early 1960s) For a generic polynomial foliation by analytic curves on $\mathbb{C}^{k}$, all leaves are topological discs except for a countable number of topological cylinders.

Conjecture 1 has its origin in the the famous Petrovskii-Landis paper [19], see the comments of Ilyashenko in [12. We consider a restricted version of Conjecture 1 ,

Conjecture 3. Let $\delta$ be a Hamiltonian identity cycle. There is a sufficiently small degree $n$ perturbation of $\mathcal{F}^{n}$ which either destroys $\delta$, or makes it a limit cycle.

For $n>2$ Conjecture 3is a Theorem as proved by Ilyashenko and Pyartli [11, Theorem 2]. In the present paper we propose a different approach to Conjecture 3 based on a
well known integral formula for the dominant term of the asymptotic expansion of the perturbed holonomy map. Namely, let

$$
h_{\delta}^{\varepsilon}(t)=t+\varepsilon^{k} M_{k}(t)+o\left(\varepsilon^{k}\right)
$$

be the asymptotic expansion of the holonomy map $h_{\delta}^{\varepsilon}$ associated to the perturbed foliation

$$
d f+\varepsilon \omega=0
$$

and to a cycle of the non-perturbed foliation $\{d f=0\}$ (here $\omega$ is a polynomial form). Clearly Conjecture 3 would follow from $h_{\delta}^{\varepsilon} \neq i d$ which on its turn is a consequence of $M_{k} \neq 0$. The function $M_{k}$, the so called Poincaré-Pontryagin-Melnikov function, has an integral representation in terms of iterated path integrals of length at most $k$, see [4]. Let $\left(F_{t}^{n}\right)_{n \geq 1}$ be the lower central series of the fundamental group $F_{t}$ of the fiber $f^{-1}(t)$. The properties of iterated integrals imply that if $\delta \in F_{t}^{k}$ then $M_{i}=0$ for $i=1,2, \ldots, k-1$. The Poincaré-Pontryagin-Melnikov function $M_{k}$ is therefore a kind of "linearization" of the holonomy map with respect to the deformation parameter $\varepsilon$. We might expect that, at least for generic $\omega$, the function $M_{k}$ is non zero. This claim, if true, would be stronger than the claim of Conjecture 3. We shall show, however, that for $k \geq 5$ there exist cycles $\delta \in F_{t}^{k}$ such that for every polynomial one-form $\omega$ of degree at most $n$, holds $M_{k}=0$ (Example 3).

The present paper is devoted to the study of the Poincaré-Pontryagin-Melnikov function $M_{k}$. Our first result is that for generic $f, \omega$ and for almost all identity cycles $\delta \in F_{t}^{k} / F_{t}^{k+1}$, the function $M_{k}$ is not identically zero (Theorem 6). We investigate then in more details the case $n=2$ (the fibers $f^{-1}(t)$ are elliptic curves). We prove that if $\delta \in F_{t}^{2} / F_{t}^{3}$ (e.g. $\delta=a b a^{-1} b^{-1}$ is a commutator), then $M_{2} \neq 0$ for almost all degree $n$ one-forms $\omega$ (Theorem 7). In particular the identity cycle $\delta$ is destroyed.

The proof of the above results relies in an essential way on the Chen's theory of interated path integral. We formulate and prove the relevant results in 43 , which can be read independently. The main results here are Theorem 1 and Theorem 2 (the so called $\pi_{1}$ de Rham theorem). These results are not completely new, see the paper of R. Hain [6]. Our presentation, as well the proofs are different, and we hope simpler, as based on a classical combinatorial theorem of Ree [21]. To the end of this Introduction we resume 83 .

Let $\Gamma=\bar{\Gamma} \backslash S$, where $\bar{\Gamma}$ is a compact Riemann surface and $S \subset \bar{\Gamma}$ a non-empty finite set of points. Each holomorphic one-form $\omega$ in $\Gamma$ defines a linear map $\int \omega \in \operatorname{Hom}_{\mathbb{Z}}\left(H_{1}(\Gamma, \mathbb{Z}), \mathbb{C}\right)$ by integration:

$$
\int \omega: H_{1}(\Gamma, \mathbb{Z}) \rightarrow \mathbb{C}: \delta \mapsto \int_{\delta} \omega
$$

and he classical de Rham theorem stipulates that $\operatorname{Hom}_{\mathbb{Z}}\left(H_{1}(\Gamma, \mathbb{Z}), \mathbb{C}\right)$ is generated by such linear maps. In the context of the present paper $\Gamma=f^{-1}(t)$ is a leaf of the non-perturbed foliation $\{d f=0\}$ and $\int_{\delta} \omega$ is the first Poincaré-Pontryagin-Melnikov function $M_{1}$.

The Chen's de Rham theorem generalizes the de Rham theorem as follows. The fundamental group $F=\pi_{1}(\Gamma, *)$ is free finitely generated. For $A, B \subset F$ we denote by $(A, B)$ the subgroup of $F$ generated by commutators $(a, b)=a b a^{-1} b^{-1}, a \in A, b \in B$. Define by induction the free abelian subgroups $F^{k}=\left(F, F^{k-1}\right), F^{1}=F$. The Chen's de Rham theorem, e.g. [8], claims that for each $k$ the vector space $\operatorname{Hom}_{\mathbb{Z}}\left(F^{k} / F^{k+1}, \mathbb{C}\right)$ is generated by iterated integrals of length $k$. As $F^{1} / F^{2}=H_{1}(\Gamma, \mathbb{Z})$ then in the case $k=1$ we get the usual de Rham theorem. In the context of the present paper, the Poincaré-Pontryagin-Melnikov function $M_{k}$ defines an element of $\operatorname{Hom}_{\mathbb{Z}}\left(F^{k} / F^{k+1}, \mathbb{C}\right)$.

The purpose of 93 is to prove a more precise version of this " $\pi_{1}$ de Rham theorem" by constructing explicitly the space $\operatorname{Hom}_{\mathbb{Z}}\left(F^{k} / F^{k+1}, \mathbb{C}\right)$ in terms of iterated integrals along Lie elements of length $k$ (see Theorem (1). The construction is purely combinatorial, the only analytic ingredient in the proof being the usual de Rham theorem. Therefore we can formulate the result in algebraic terms as follows:

Let $X=\left\{x_{1}, x_{2}, \ldots, x_{m}\right\}$ be a set (which does not represent necessarily loops and one-forms) and $\mathrm{k} \subset \mathrm{K}$ two fields of characteristic zero. Denote by $\mathrm{Ass}_{X}$ the graded k algebra of associative but non-commutative polynomials in variables $x_{1}, x_{2}, \ldots, x_{m}$ and by $L_{X} \subset$ Ass $_{X}$ the graded Lie algebra generated by $x_{1}, \ldots, x_{m}$. Let also $F_{X}$ be a free group generated by the elements of $X$. By an iterated integral we mean any map

$$
\begin{array}{rll}
\int: F_{X} \times \operatorname{Ass}_{X} & \rightarrow \mathrm{~K} \\
(\delta, \omega) & \mapsto \int_{\delta} \omega
\end{array}
$$

which is k -linear in $\operatorname{Ass}_{X}$ and satisfies the four axioms given in the next section. It will follow from these axioms that $\int$ induces a well-defined map:

$$
\begin{equation*}
F_{X}^{k} / F_{X}^{k+1} \times \operatorname{Ass}_{X}^{k} \rightarrow \mathrm{~K}, \quad k=1,2, \ldots \tag{1}
\end{equation*}
$$

which is $\mathbb{Z}$-linear in the first coordinate and $k$-linear in the second coordinate. Of course an example of such a map is the usual path integrals of Chen mentioned above. The $\pi_{1}$ de Rham theorem can be formulated as follows: If the vector space of $\mathbb{Z}$-linear maps

$$
\begin{aligned}
\int \omega: F_{X} / F_{X}^{2} & \rightarrow \mathrm{~K}, \text { where } \omega \in L_{X}^{1} \\
\delta & \mapsto \int_{\delta} \omega
\end{aligned}
$$

is isomorphic to $\operatorname{Hom}_{\mathbb{Z}}\left(F_{X} / F_{X}^{2}, \mathrm{~K}\right)$, then the vector space of $\mathbb{Z}$-linear maps

$$
\begin{aligned}
\int \omega: F_{X}^{k} / F_{X}^{k+1} & \rightarrow \text { K, where } \omega \in L_{X}^{k} \\
\delta & \mapsto \int_{\delta} \omega
\end{aligned}
$$

is isomorphic to $\operatorname{Hom}_{\mathbb{Z}}\left(F_{X}^{k} / F_{X}^{k+1}, \mathrm{~K}\right)$ for all $k=1,2, \ldots$ We also prove that $\int \omega, \omega \in \operatorname{Ass}_{X}^{k}$ is identically zero if and only if $\omega$ is a linear combination of shuffle elements.

Acknowledgments. Part of this paper was written while the authors were visiting subsequently IMPA of Rio de Janeiro (Brasil), the Ochanomizu University, Tokyo (Japan) and the University of Toulouse (France). They are obliged for the hospitality.

## 2 Iterated path integrals

Let k be a field. All modules and algebras are taken over k, unless stated otherwise. For a set $X=\left\{x_{1}, x_{2}, \ldots, x_{m}\right\}$, let $\mathrm{Ass}_{X}$ be the graded free associative algebra on $X$. Its elements are the non-commutative polynomials in $x_{i}$ with coefficients in k. Define a Lie bracket in $\operatorname{Ass}_{X}$ by $[x, y]=x y-y x$, and let $L_{X} \subset \operatorname{Ass}_{X}$ be the graded free Lie algebra on $X$. Thus, for instance, $x_{1},\left[x_{1}, x_{2}\right],\left[\left[x_{1}, x_{2}\right], x_{3}\right]$ belong to $L_{X}$ but not $1, x_{1} x_{2}, x_{1} x_{2} x_{3}$. $\mathrm{Ass}_{X}$ is the universal algebra of the Lie algebra $L_{X}$, see [22]. The graded piece $L_{X}^{1}$ is just the k -vector space generated by $x_{1}, x_{2}, \ldots, x_{m}, L_{X}^{2}$ is the k -vector space generated by $\left[x_{i}, x_{j}\right]$ etc. Each element of $L_{X}$ is called a Lie element. We denote by Ass $_{X}^{k}$ (resp. $L_{X}^{k}$ ) the homogeneous component of degree $k$ of Ass $_{X}$ (resp. $L_{X}$ ).

Let $F_{X}$ be the free group on $X$, its elements are the words in the letters $x_{i}$ and their formal inverses $x_{i}^{-1}$. For $x, y \in F_{X}$ we define the commutator $(x, y)=x y x^{-1} y^{-1}$.

For $A, B \subset F_{X}$ we denote by $(A, B)$ the subgroup of $F_{X}$ generated by commutators $(a, b), a \in A, b \in B$. Consider the lower central series $F_{X}^{n}$ of $F_{X}$, where $F_{X}^{n}=\left(F_{X}, F_{X}^{n-1}\right)$, $F_{X}^{1}=F_{X}$. The associated graded $\mathbb{Z}$-Lie algebra is given by

$$
\begin{gather*}
\operatorname{gr} F_{X}=\sum_{n=1}^{\infty} \operatorname{gr}^{n} F_{X}, \quad \operatorname{gr}^{n} F_{X}=F_{X}^{n} / F_{X}^{n+1}  \tag{2}\\
{\left[x F_{X}^{i+1}, y F_{X}^{j+1}\right]=(x, y) F_{X}^{i+j+1}}
\end{gather*}
$$

The canonical map $X \rightarrow \operatorname{gr}^{1} F_{X}$ which send $x_{i}$ to $x_{i}$ induces an isomorphism of Lie algebras

$$
\begin{equation*}
\phi: L_{X} \rightarrow\left(\operatorname{gr} F_{X}\right) \otimes_{\mathbb{Z}} \mathrm{k} \tag{3}
\end{equation*}
$$

(e.g. [22] Theorem 6.1). For two words $\omega_{1} \cdots \omega_{r}, \omega_{r+1} \cdots \omega_{r+s}$ define the shuffle product $\omega_{1} \cdots \omega_{r} * \omega_{r+1} \cdots \omega_{r+s}$ to be the sum of all words of length $r+s$ that are permutations of $\omega_{1} \cdots \omega_{r} \omega_{r+1} \cdots \omega_{r+s}$ such that both $\omega_{1} \cdots \omega_{r}$ and $\omega_{r+1} \cdots \omega_{r+s}$ appear in their original order, e.g.

$$
\omega_{1} \omega_{2} * \omega_{3}=\omega_{1} \omega_{2} \omega_{3}+\omega_{1} \omega_{3} \omega_{2}+\omega_{3} \omega_{1} \omega_{2} .
$$

Let K be a field extension of the field k .
Definition 1. An iterated integral is a map

$$
\begin{align*}
\int: F_{X} \times \operatorname{Ass}_{X} & \rightarrow \mathrm{~K}  \tag{4}\\
(\delta, \omega) & \mapsto \int_{\delta} \omega
\end{align*}
$$

which is $k$-linear in the second variable and satisfies the four axioms:
A1 For every non-commutative polynomial $\omega \in \operatorname{Ass}_{X}$ and $\delta \in F_{X}, \int_{1} \omega \in \mathrm{k}$ is the constant term of $\omega$ and $\int_{\delta} 1=1$ for all $\delta \in F_{X}$. We use the convention $\omega_{1} \omega_{2} \cdots \omega_{r}=1$ for $r=0$.

A2 For $\alpha, \beta \in F_{X}$ and $\omega_{1}, \omega_{2}, \ldots \omega_{r} \in \operatorname{Ass}_{X}^{1}$

$$
\int_{\alpha \beta} \omega_{1} \cdots \omega_{r}=\sum_{i=0}^{r} \int_{\alpha} \omega_{1} \cdots \omega_{i} \int_{\beta} \omega_{i+1} \cdots \omega_{r} .
$$

A3 For $\alpha \in F_{X}$ and $\omega_{1}, \omega_{2}, \ldots \omega_{r} \in \operatorname{Ass}_{X}^{1}$

$$
\int_{\alpha^{-1}} \omega_{1} \omega_{2} \cdots \omega_{r}=(-1)^{r} \int_{\alpha} \omega_{r} \cdots \omega_{1}
$$

A4 For $\alpha \in F_{X}$ and $\omega_{1}, \omega_{2}, \ldots \omega_{r+s} \in \operatorname{Ass}_{X}^{1}$ we have

$$
\begin{equation*}
\int_{\alpha} \omega_{1} \cdots \omega_{r} \int_{\alpha} \omega_{r+1} \cdots \omega_{r+s}=\int_{\alpha} \omega_{1} \cdots \omega_{r} * \omega_{r+1} \cdots \omega_{r+s} \tag{5}
\end{equation*}
$$

where

$$
\omega_{1} \cdots \omega_{r} * \omega_{r+1} \cdots \omega_{r+s}=\sum \omega_{k_{1}} \omega_{k_{2}} \cdots \omega_{k_{r+s}}
$$

is the shuffle product of $\omega_{1} \cdots \omega_{r}$ and $\omega_{r+1} \cdots \omega_{r+s}$.

Let $\left\{\delta_{1}, \delta_{2}, \ldots, \delta_{m}\right\}$ be a set which generates $F_{X}$ freely and $\left\{\omega_{1}, \omega_{2}, \ldots, \omega_{m}\right\}$ be a basis of the k -vector space $\mathrm{Ass}_{X}^{1}$. A1, A2, A3 imply that every iterated integral can be written as a polynomial in

$$
\begin{equation*}
\int_{\delta_{j}} \omega_{i_{1}} \omega_{i_{1}} \cdots \omega_{i_{r}}, j=1,2, \ldots, m, i_{1}, i_{2}, \ldots, i_{r} \in\{1,2, \ldots, m\} \tag{6}
\end{equation*}
$$

Therefore by A4 the map (4) defines an iterated integral if and only if the numbers

$$
\int_{\delta_{j}} \omega_{i_{1}} \omega_{i_{2}} \cdots \omega_{i_{r}}=a^{j}\left(i_{1}, \ldots, i_{r}\right) \in \mathrm{k}
$$

satisfy the "shuffle relations"

$$
\begin{equation*}
a^{j}\left(i_{1}, \ldots, i_{r}\right) a^{j}\left(i_{r+1}, \ldots, i_{r+s}\right)=\sum a^{j}\left(k_{1}, \ldots, k_{r+s}\right), \tag{7}
\end{equation*}
$$

where $\left(k_{1}, \ldots, k_{r+s}\right)$ runs through all shuffles of $\left(i_{1}, \ldots, i_{r}\right)$ and $\left(i_{r+1}, \ldots, i_{r+s}\right)$. The existence of such numbers $a^{j}\left(i_{1}, \ldots, i_{r}\right)$ is, however, not obvious.

Example 1. Let $\left\{\delta_{1}, \delta_{2}, \ldots, \delta_{m}\right\}$ be a set which generates $F_{X}$ freely and $\left\{\omega_{1}, \omega_{2}, \ldots, \omega_{m}\right\}$ be a basis of the k -vector space $\mathrm{Ass}_{X}^{1}$. We set

$$
\begin{gather*}
a^{j}\left(i_{1}, \ldots, i_{n}\right)=\int_{\delta_{j}} \omega_{i_{1}} \omega_{i_{2}} \cdots \omega_{i_{n}}=0 \text { if at least one of } \omega_{i_{s}} \text { is not } \omega_{j}  \tag{8}\\
a^{j}(j, \ldots, j)=\int_{\delta_{j}} \omega_{j}^{n}=\frac{1}{n!}
\end{gather*}
$$

The verification that the numbers $a^{j}\left(i_{1}, \ldots, i_{n}\right)$ define an iterated integral is straightforward. This iterated integral can be interpreted as Chen's iterated integral in the following way: We take the Ceyley diagrams (see [18]) which is the topological space $Y:=\cup_{i=0}^{m-1} \mathbb{Z}^{i} \times \mathbb{R} \times \mathbb{Z}^{m-i-1} \subset \mathbb{R}^{m}$. Each element $\delta$ of the free group $F_{X}$ is represented by a path $\tilde{\delta}$ in $Y$ with the starting point $0 \in \mathbb{R}^{n}$ and the end point in some element of $\mathbb{Z}^{m}$. Each element $\omega$ of $\operatorname{Ass}_{X}$ can be interpreted as a differential form $\tilde{\omega}$ substituting $d y_{i}$ by $x_{i}$, where $\left(y_{1}, y_{2}, \ldots, y_{m}\right)$ is the coordinate system in $\mathbb{R}^{m}$. Now, $\int_{\delta} \omega$ is the classical Chen's iterated integral $\int_{\delta} \tilde{\omega}$.

Example 2. As in the Introduction, let $\Gamma$ be a punctured Riemann surface with free finitely generated fundamental group $F_{X}=\pi_{1}(\Gamma, *)$. Let $\left\{\omega_{1}, \omega_{2}, \ldots, \omega_{m}\right\}$ be a collection of holomorphic one-forms on $\Gamma$ such that their classes in the de Rham cohomology of $\Gamma$ form a basis. The Chen's iterated integral

$$
a^{j}\left(i_{1}, \ldots, i_{n}\right)=\int_{\delta_{j}} \omega_{i_{1}} \omega_{i_{2}} \cdots \omega_{i_{n}}
$$

where $\delta_{1}, \delta_{2}, \ldots, \delta_{m}$ generates $F_{X}$ freely, satisfies the shuffle relations (77), see [7, 8], and hence defines an iterated integral in the sense of Definition 1 (in order to follow the terminology used in this text we may identify $\omega_{i}$ with $x_{i}$ ).

## 3 The $\pi_{1}$ de Rham theorem

Let $\alpha, \beta \in F_{X}$ and $\omega \in \operatorname{Ass}_{X}^{1}=L_{X}^{1}$. Then $\mathbf{A 3}$ implies that every iterated integral (1) satisfies

$$
\int_{\alpha \beta} \omega=\int_{\alpha} \omega+\int_{\beta} \omega, \int_{\alpha \beta \alpha^{-1}} \omega=\int_{\alpha} \omega, \int_{(\alpha, \beta)} \omega=0 .
$$

More generally,

$$
\begin{equation*}
\forall \alpha \in F_{X}^{n+1}, \omega \in \mathrm{Ass}_{X}^{m} \text {, such that } m \leq n \text { holds true } \int_{\alpha} \omega=0 \tag{9}
\end{equation*}
$$

Therefore the iterated integral $\int$ induces a map

$$
\begin{align*}
\int: \operatorname{gr}^{k} F_{X} \times \operatorname{Ass}_{X}^{k} & \rightarrow \mathbb{C}  \tag{10}\\
(\delta, \omega) & \mapsto \int_{\delta} \omega
\end{align*}
$$

which is $\mathbb{Z}$-linear in the first argument and $k$-linear in the second argument. Suppose that $\omega \in \operatorname{Ass}_{X}^{k}$ is a shuffle product of $\omega_{1}, \omega_{2}$ :

$$
\omega=\omega_{1} * \omega_{2}, \omega_{1} \in \operatorname{Ass}_{X}^{k_{1}}, \omega_{2} \in \operatorname{Ass}_{X}^{k_{2}}, k_{1}+k_{2}=k
$$

and $\alpha \in \operatorname{gr}^{k} F_{X}$. Then A4 and (9) imply

$$
\int_{\alpha} \omega=0
$$

Thus the vector space $S_{X}^{k}$ generated by shuffle products

$$
S_{X}^{k}=\operatorname{Span}\left\{\omega_{1} * \omega_{2}: \omega_{1} \in \operatorname{Ass}_{X}^{k_{1}}, \omega_{2} \in \operatorname{Ass}_{X}^{k_{2}}, k_{1}+k_{2}=k\right\}
$$

is in the kernel of the bilinear map (101). We are ready to formulate the $\pi_{1}$ de Rham theorem:

Theorem 1. Let $\int$ be an iterated integral in the sense of Definition 1 .
(a) If the induced bilinear map

$$
\begin{align*}
\int: \operatorname{gr}^{k} F_{X} \times L_{X}^{k} & \rightarrow \mathrm{~K}  \tag{11}\\
(\delta, \omega) & \mapsto \int_{\delta} \omega
\end{align*}
$$

is non-degenerate for $k=1$, then then it is non-degenerate for all $k \in \mathbb{N}$.
(b) Let $\omega \in \operatorname{Ass}_{X}^{k}$. The linear map

$$
\begin{align*}
\int \omega: \operatorname{gr}^{k} F_{X} & \rightarrow \mathrm{~K}  \tag{12}\\
\delta & \mapsto \int_{\delta} \omega
\end{align*}
$$

is the zero map, if and only if $\omega \in S_{X}^{k}$.
In $\operatorname{Ass}_{X}$ we consider the canonical $k$-bilinear symmetric product given by

$$
\left\langle x_{i_{1}} x_{i_{2}} \cdots x_{i_{r}}, x_{j_{1}} x_{j_{2}} \cdots x_{j_{s}}\right\rangle=\left\{\begin{array}{cc}
1 & i_{1}=j_{1}, \ldots, i_{r}=j_{r}, r=s \\
0 & \text { otherwise }
\end{array}\right.
$$

Before proving Theorem 1 we shall need the following auxiliary result:

Theorem 2. $S_{X}^{k}$ and $L_{X}^{k}$ are orthogonal vector subspaces of $\mathrm{Ass}_{X}^{k}$ and for all $k \in \mathbb{N}$

$$
\operatorname{Ass}_{X}^{k}=L_{X}^{k} \oplus S_{X}^{k}
$$

This is a geometric reformulation of the following classical result of Ree 21, Theorem 2.2].

Theorem 3. A polynomial

$$
\begin{equation*}
\omega=\sum_{n>0} \sum a\left(i_{1}, i_{2}, \ldots, i_{n}\right) x_{i_{1}} x_{i_{2}} \cdots x_{i_{n}} \in \operatorname{Ass}_{X} \tag{13}
\end{equation*}
$$

is a Lie element (i.e. belongs to $L_{X}$ ) if and only if for all $\left(i_{1}, \ldots, i_{r}\right)$ and $\left(j_{1}, \ldots, j_{s}\right)$ we have:

$$
\begin{equation*}
\sum a\left(k_{1}, k_{2}, \ldots, k_{r+s}\right)=0 \tag{14}
\end{equation*}
$$

where $\left(k_{1}, \ldots, k_{r+s}\right)$ runs through all shuffles of $\left(i_{1}, \ldots, i_{r}\right)$ and $\left(j_{1}, \ldots, j_{s}\right)$.
Proof of the equivalence of Theorem 2 and Theorem [3. Without loss of generality we can assume that $\omega$ in (13) is homogeneous of degree $n$. The proof follows from the equality:

$$
\left\langle\omega, x_{i_{1}} x_{i_{2}} \cdots x_{i_{r}} * x_{j_{1}} x_{j_{2}} \cdots x_{j_{s}}\right\rangle=\sum a\left(k_{1}, k_{2}, \ldots, k_{r+s}\right)
$$

where $x_{i_{1}} x_{i_{2}} \cdots x_{i_{r}} * x_{j_{1}} x_{j_{2}} \cdots x_{j_{s}}, r+s=n$ is a shuffle element and $\left(k_{1}, \ldots, k_{r+s}\right)$ runs through all shuffles of $\left(i_{1}, \ldots, i_{r}\right)$ and $\left(j_{1}, \ldots, j_{s}\right)$. Note that we can formulate Theorem 2 in the following way: The polynomial $\omega$ is a Lie element if and only if it is orthogonal to all shuffles $x_{i_{1}} x_{i_{2}} \cdots x_{i_{r}} * x_{j_{1}} x_{j_{2}} \cdots x_{j_{s}}, r+s=n$.

To prove Theorem 1 we note that as the map (11) is non-degenerate for $k=1$, then it can be "diagonalized" as follows: We fix a set of generators $\left\{\delta_{1}, \delta_{2}, \ldots, \delta_{m}\right\}$ for $F_{X}$ and find $\Omega=\left\{\omega_{1}, \ldots, \omega_{m}\right\} \subset \operatorname{Ass}_{X}^{1}$ such that $\int_{\delta_{i}} \omega_{j}=1$ if $i=j$ and $=0$ otherwise. Now, Ass $X$ is freely generated by $\Omega$. Therefore we shall suppose, without loss of generality, that

$$
\begin{equation*}
\int_{x_{i}} x_{j}=\left\langle x_{i}, x_{j}\right\rangle=0 \text { if } i \neq j \text { and } 0 \text { otherwise. } \tag{15}
\end{equation*}
$$

The formula (15) generalizes as follows:
Proposition 1. We have

$$
\begin{equation*}
\int_{\delta} \omega=\left\langle\omega, \phi^{-1} \delta\right\rangle, \quad \forall \omega \in \operatorname{Ass}_{X}^{k}, \quad \delta \in \operatorname{gr}^{k} F_{X} \tag{16}
\end{equation*}
$$

where $\phi$ is the isomorphism (3).
Proof. The proof is by induction on $k$. For $k=1$ it follows from (15). If $\delta=(a, b)$, where
$a \in F_{X}^{p}, b \in F_{X}^{q}, p+q=k>1$, then A2 implies

$$
\begin{aligned}
\int_{(a, b)} x_{j_{1}} x_{j_{2}} \cdots x_{j_{k}}= & \int_{a} x_{j_{1}} \cdots x_{j_{p}} \int_{b} x_{j_{p+1}} \cdots x_{j_{k}} \\
& -\int_{b} x_{j_{1}} \cdots x_{j_{q}} \int_{a} x_{j_{q+1}} \cdots x_{j_{k}} \\
= & \left\langle\phi^{-1}(a), x_{j_{1}} \cdots x_{j_{p}}\right\rangle\left\langle\phi^{-1}(b), x_{j_{p+1}} \cdots x_{j_{k}}\right\rangle \\
& -\left\langle\phi^{-1}(b), x_{j_{1}} \cdots x_{j_{q}}\right\rangle\left\langle\phi^{-1}(a) x_{j_{q+1}} \cdots x_{j_{k}}\right\rangle \\
= & \left\langle\phi^{-1}(a) \phi^{-1}(b), x_{j_{1}} \cdots x_{j_{p}} x_{j_{p+1}} \cdots x_{j_{k}}\right\rangle \\
& -\left\langle\phi^{-1}(b) \phi^{-1}(a), x_{j_{1}} \cdots x_{j_{q}} x_{j_{q+1}} \cdots x_{j_{k}}\right\rangle \\
= & \left\langle\phi^{-1}(a) \phi^{-1}(b)-\phi^{-1}(b) \phi^{-1}(a), x_{j_{1}} x_{j_{2}} \cdots x_{j_{k}}\right\rangle \\
== & \left\langle\phi^{-1}((a, b)), x_{j_{1}} x_{j_{2}} \cdots x_{j_{k}}\right\rangle .
\end{aligned}
$$

Remark 1. For an arbitrary iterated integral map, the same proof implies that for every $\delta \in \operatorname{gr}^{k} F_{X}$ such that

$$
\phi^{-1}(\delta)=\sum a\left(i_{1}, i_{2}, \ldots, i_{k}\right) x_{i_{1}} x_{i_{2}} \cdots x_{i_{k}} \in \operatorname{gr}^{k} L_{X}
$$

holds

$$
\begin{equation*}
\int_{\delta} \omega_{j_{1}} \omega_{j_{2}} \cdots \omega_{j_{k}}=\sum_{i_{1}, i_{2}, \ldots, i_{k}} a\left(i_{1}, i_{2}, \ldots, i_{k}\right) \int_{x_{i_{1}}} \omega_{j_{1}} \int_{x_{i_{2}}} \omega_{j_{2}} \ldots \int_{x_{i_{k}}} \omega_{j_{k}} \tag{17}
\end{equation*}
$$

Proof of Theorem 1. The part (b) follows from Theorem 2 and Proposition 1. Let $\delta \in$ $\operatorname{gr}^{k} F_{X}$ and

$$
\phi^{-1}(\delta)=\sum a\left(i_{1}, i_{2}, \ldots, i_{k}\right) x_{i_{1}} x_{i_{2}} \cdots x_{i_{k}} \in \operatorname{gr}^{k} L_{X}
$$

where in the above sum each non-commutative monomial $x_{i_{1}} x_{i_{2}} \cdots x_{i_{k}}$ is repeated only once. Then $\delta \neq 0$ if and only if

$$
\left\langle\phi^{-1}(\delta), \phi^{-1}(\delta)\right\rangle=\sum\left|a\left(i_{1}, i_{2}, \ldots, i_{k}\right)\right|^{2} \neq 0
$$

Therefore for every $\delta \in \operatorname{gr}^{k} F_{X}$ there exists $\omega \in L_{X}^{k}$, namely $\omega=\phi^{-1}(\delta)$, such that

$$
\int_{\delta} \omega \neq 0 .
$$

Here we have used strongly the fact that the characteristic of $k$ is zero.
Remark 2. A canonical basis of the k-vector spaces $L_{X}^{k} \cong \operatorname{gr}^{k} F_{X}$ is given by basic commutators (see for instance [9, 22]). By definition of $\langle\cdot, \cdot\rangle$ if the number of some $x_{i}, i=$ $1,2, \ldots, m$ used in two basic commutators $\omega_{1}$ and $\omega_{2}$ are different then $\left\langle\omega_{1}, \omega_{2}\right\rangle=0$. The basic commutators of weight 1 and 2 are dual to each other with respect to the bilinear map $\langle\cdot, \cdot\rangle$. However, this is not the case for weight 3 and the number of generators $m$ bigger than 2. For instance, we have

$$
\langle[y,[x, z]],[z,[x, y]]\rangle=2
$$

For $m=2$ the basic commutators of weight 3 (resp. 4) are orthogonal to each other. In $m=2$ and $r=5$ the orthogonality fails. There are two couples in which the number of $x$ is equal to 2 (resp. 3). In fact we have

$$
\langle[y,[x,[x,[x, y]]]],[[x, y],[x,[x, y]]]\rangle=-28,\langle[y,[y,[x,[x, y]]]],[[x, y],[y,[x, y]]]\rangle=-14
$$

The computation of basic commutators and scalar products in the free Lie algebra $L_{X}$ are implemented in the symbolic algebra system Axıom, see [15] and the webpage of the second name author

## 4 Picard-Fuchs equations and iterated path integrals

Let $f$ be a polynomial of degree $d$ in two variables $x, y$ and suppose, for simplicity, that the highest order homogeneous piece $g$ of $f$ is non-degenerate (has an isolated critical point). Let also $C \subset \mathbb{C}$ be the set of the critical values of $f$. The cohomology fiber bundle $\cup_{t \in \mathbb{C} \backslash C} H^{1}(\{f=t\}, \mathbb{C})$ and the corresponding Gauss-Manin connection, for which flat sections are generated by sections with images in $\cup_{t \in \mathbb{C} \backslash C} H^{1}(\{f=t\}, \mathbb{Z})$, is encoded in the global Brieskorn module $H=\frac{\Omega^{1}}{d f \wedge \Omega^{0}+d \Omega^{0}}$, where $\Omega^{i}$ is the set of polynomial $i$-forms in $\mathbb{C}^{2}$ as follows. We note first that $H$ is a $\mathbb{C}[t]$-module $(t .[\omega]=[f \omega])$ generated freely by

$$
\begin{equation*}
\omega_{i}:=x^{i_{1}} y^{i_{2}}(x d y-y d x), i=\left(i_{1}, i_{2}\right) \in I \tag{18}
\end{equation*}
$$

where $\left\{x^{i_{1}} y^{i_{2}}, i \in I\right\}$ is a basis of monomials for the $\mathbb{C}$-vector space $\frac{\mathbb{C}[x, y]}{\left\langle f_{x}, f_{y}\right\rangle}$, see [1, 17]. In particular the rank of $H$ equals the dimension of $H^{1}(\{f=t\}, \mathbb{Z})$ for generic $t$. The GaussManin connection of the family of curves $f(x, y)=t, t \in \mathbb{C}$ with respect to the parameter $t$ becomes an operator ' $: H \rightarrow \frac{1}{\Delta} H$ which satisfies the Leibniz rule, where $\Delta=\Delta(t)$ is the discriminant of the polynomial $f(x, y)-t$. In the basis $\omega=\left(\omega_{i}\right)_{i \in I}$ (written in a column) it is of the form

$$
\begin{equation*}
\omega^{\prime}=\frac{1}{\Delta} A \omega, \tag{19}
\end{equation*}
$$

where $A$ is a $m \times m$ matrix with entries in $\mathbb{C}[t]$ and $m=\# I$.
The above construction has a natural generalization based on the $\pi_{1}$ de Rham theorem (Theorem [1), which we discuss briefly. Let

$$
F_{t}=\pi_{1}(\{f=t\}, *), t \in \mathbb{C} \backslash C
$$

be the fundamental group of the fiber $\{f=t\}$ (it was denoted $F_{X}$ in $\{33$ ). Consider the trivial fiber bundle $\cup_{t \in \mathbb{C} \backslash C} \mathrm{gr}^{k} F_{t} \otimes_{\mathbb{Z}} \mathbb{C}$ and its dual $\cup_{t \in \mathbb{C} \backslash C \mathrm{gr}^{k}} F_{t} \otimes_{\mathbb{Z}} \mathbb{C}$. Both of them have a canonical flat connexion defined as follows:

Let $X=\left\{\omega_{i}\right\}_{i \in I}, \mathrm{k}=\mathbb{C}(t)$ and K the field of locally analytic multi-valued functions on $\mathbb{C} \backslash C$. The Gauss-Manin connection on Asss $_{X}^{1}$ extends canonically to a derivation operator

$$
\frac{\partial}{\partial t}=^{\prime}: \operatorname{Ass}_{X} \rightarrow \frac{1}{\Delta} \operatorname{Ass}_{X}
$$

which respects both the graduation of $\operatorname{Ass}_{X}$, the direct sum decomposition $\operatorname{Ass}_{X}=L_{X} \oplus$ $S_{X}$, and satisfies the Leibniz rule $(a b)^{\prime}=a^{\prime} b+a b^{\prime}, a, b \in$ Ass $_{X}$. In particular for monomials in $\operatorname{Ass}_{X}$ it is given by:

$$
\omega_{i_{1}} \omega_{i_{2}} \cdots \omega_{i_{r}} \rightarrow \sum_{j=1}^{r} \omega_{i_{1}} \omega_{i_{2}} \cdots \omega_{i_{j-1}} \omega_{i_{j}}^{\prime} \omega_{i_{j+1}} \cdots \omega_{r} .
$$

The main property of the map ' is the following:

$$
\begin{equation*}
\frac{\partial}{\partial t} \int_{\delta(t)} \omega=\int_{\delta(t)} \omega^{\prime} \tag{20}
\end{equation*}
$$

for all $\omega \in$ Ass $_{X}^{k}$ and continuous family of closed loops $\delta(t) \in F_{t}^{k}$. The induced map ${ }^{\prime}: L_{X} \rightarrow \frac{1}{\Delta} L_{X}$, where $L_{X}$ is the k -vector space $L_{X} \cong \frac{\operatorname{Ass} X}{S_{X}}$, is the desired generalization of the usual (algebraic) Gauss-Manin connexion.

## 5 Non-persistence of Hamiltonian identity cycles

Let $\mathcal{F}$ be a holomorphic foliation with singularities on the plane $\mathbb{C}^{2}$. A cycle on a leaf of $\mathcal{F}$ is a non-zero free homotopy class of closed loops on this leaf. Let $\delta$ be a closed noncontractible loop contained in a leaf and denote the holonomy map associated to $\delta$ by $h_{\delta}$. The cycle represented by $\delta$ is said to be an identity cycle provided that $h_{\delta}$ is the identity map, and Hamiltonian identity cycle provided that $\mathcal{F}=\{d f=0\}$ for some polynomial $f$. It is called a limit cycle provided that $\delta$ corresponds to an isolated fixed point of $h_{\delta}$. Let $\mathcal{F}^{n}$ be a polynomial foliation as above of degree $n$, and let $\delta$ be an identity cycle.

Question: Is there a sufficiently small degree $n$ perturbation of $\mathcal{F}^{n}$ which either destroys the cycle $\delta$, or makes it a limit cycle?

In the case when $\mathcal{F}^{n}$ is a plane Hamiltonian foliation the following theorem has been proved by Ilyashenko and Pyartli:

Theorem 4. ( [11, Theorem 2]) For any Hamiltonian identity cycle $\delta$ in a given leaf of $\mathcal{F}^{n}=\{d f=0\}, \operatorname{deg}(f)=n+1>3$, there exists a perturbation of this foliation in the class of polynomial foliations of degree $n$ which destroys the identity cycle .

Our approach to the above problem of destroying the Hamiltonian identity cycles is as follows. Let $f$ be a degree $n+1$ polynomial and let $\omega=P d x+Q d y$ be a polynomial one-form in $\mathbb{C}^{2}$ of degree at most $n, \operatorname{deg} P, \operatorname{deg} Q \leq n$. Consider the holomorphic foliation on $\mathbb{C}^{2}$ defined by

$$
\begin{equation*}
d f+\epsilon \omega=0, \epsilon \sim 0 . \tag{21}
\end{equation*}
$$

Let $t$ be a regular value of $f$ and $\delta_{t} \subset f^{-1}(t)$ be a continuous family of non-contractible closed loops. As in the preceding sections we denote by $F_{t}$ the fundamental group of the fiber $\left\{f^{-1}(t)\right\}$. There is an integer $k \geq 1$ such that $\delta(t)$ represents a not zero element in $\mathrm{gr}^{k} F_{t}$. We consider the holonomy map $h_{\delta}^{\epsilon}$ along the path $\delta(t)$

$$
\begin{equation*}
h_{\delta}^{\epsilon}(t)=t+\sum_{i=1}^{\infty} \epsilon^{i} M_{i}(t) \tag{22}
\end{equation*}
$$

It is known [4, 16] that $M_{1}=\cdots=M_{k-1}=0$ and $M_{k}$ is an iterated path integral

$$
\begin{equation*}
M_{k}(t)=\int_{\delta(t)} \omega(\underbrace{\omega\left(\cdots \left(\omega(\omega)^{\prime}\right.\right.}_{k-1 \text { times }})^{\prime} \cdots)^{\prime})^{\prime} \tag{23}
\end{equation*}
$$

where $\omega^{\prime}$ is defined by (19). It follows from 82 that the iterated integral in (23) is well defined, as it depends only on the classes of $\omega^{(i)}, i=1,2, \ldots, k-1$ in the global Brieskorn module $H$.

If the function $M_{k}$ is not identically zero then its zeros correspond to limit cycles of the deformed foliation. In particular the deformation $d f+\epsilon \omega$ " destroys" the family of identity cycles $\delta(t)$ in the sense that the holonomy map $h_{\epsilon}, \epsilon \neq 0$, is not the identity map. This leads to the following:

Question: Let $\delta(t)$ be a continuous family of closed loops representing a non-trivial element of $\mathrm{gr}^{k} F_{t}$. Is there a sufficiently small degree $n$ perturbation of $\{d f=0\}$, such that the corresponding Poincaré-Pontryagin function $M_{k}$ is not zero?

A positive answer to this question implies that the holonomy map (22) is not the identity map. We shall prove that:
(i) The answer to the above question is, in general, negative (Example 3).
(ii) If the loop $\delta(t)$ is generic, then the answer is positive (Theorem (6).
(iii) If the loop is a commutator, $\delta(t) \in \operatorname{gr}^{2} F_{t}$, and the polynomial $f$ is of degree three (case not covered by [11), then the answer is positive (Theorem [7).

For completeness we consider first the seemingly trivial case $k=1$ (this is well known to the specialists). We have:

Proposition 2. Let $f$ be a degree $n+1>1$ polynomial, whose degree $n+1$ homogeneous part is non-degenerate (has an isolated critical point). For every fixed non-critical value $t \in \mathbb{C}$ and for every closed loop $\delta \subset f^{-1}(t)$ representing a non-zero homology class in $H_{0}\left(f^{-1}(t), \mathbb{Z}\right)$, there is a polynomial one-form $\omega=P d x+Q d y$ of degree at most $n$, $\operatorname{deg} P, \operatorname{deg} Q \leq n$, such that

$$
M_{1}^{\prime}(t)=\int_{\delta} \omega^{\prime} \neq 0
$$

The above proposition implies that $M_{1}(t)$ is not identically zero and hence the cycle $\delta$ is destroyed by the perturbation (21). This also follows (with a Morse-plus condition on $f$ ) from the following theorem, proved by Ilyashenko:

Theorem 5 ([10]). Let $f$ be a Morse-plus bi-variate polynomial, $\delta(t) \subset H_{1}\left(f^{-1}(t), \mathbb{Z}\right)$ a continuous family of vanishing cycles, and $\omega$ a polynomial one-form of degree at most $n$ as above. Then $M_{1}(t)=\int_{\delta(t)} \omega$ is identically zero, if and only if $\omega$ is exact.

The condition that $f$ must be Morse-plus (has $n^{2}$ distinct critical values) can not be removed from Ilyashenko's theorem.

Proof of Proposition 园. Consider the one-forms $\omega_{i}^{\prime}=\frac{d \omega_{i}}{d f}$ defined by (18). It is well known (and easy to check) that when $|i|=i_{1}+i_{2}<n-1$, the $n(n-1) / 2$ forms $\omega_{i}^{\prime}$ generate the space of holomorphic differential one-forms on the compact Riemann surface $\Gamma=\overline{f^{-1}(t)}$

$$
H^{0}\left(\Gamma, \Omega^{1}\right)=\operatorname{Span}\left\{\omega_{i}^{\prime}:|i|=i_{1}+i_{2}<n-1\right\}
$$

while the $n(n+1) / 2$ one-forms $\omega_{i}^{\prime},|i|=i_{1}+i_{2} \leq n-1$, generate the space of meromorphic one-forms with at most a simple pole at infinity:

$$
\begin{equation*}
H^{0}\left(\Gamma, \Omega^{1}\left(\infty_{1}+\infty_{2}+\ldots \infty_{n+1}\right)\right)=\operatorname{Span}\left\{\omega_{i}^{\prime}:|i|=i_{1}+i_{2} \leq n-1\right\} \tag{24}
\end{equation*}
$$

where $\infty_{i}$ are the $n+1$ distinct intersection points of $\Gamma$ with the line at infinity. This combined to the Hodge decomposition

$$
H_{D R}^{1}(\Gamma)=H^{0}\left(\Gamma, \Omega^{1}\right) \oplus H^{0}\left(\Gamma, \bar{\Omega}^{1}\right)
$$

and the obvious equalities

$$
\begin{gathered}
\operatorname{dim} H^{0}\left(\Gamma, \Omega^{1}\left(\infty_{1}+\infty_{2}+\ldots \infty_{n+1}\right)\right)=\operatorname{dim} H^{0}\left(\Gamma, \Omega^{1}\right)+n \\
\operatorname{dim} H_{D R}^{1}\left(f^{-1}(t)\right)=\operatorname{dim} H_{D R}^{1}(\Gamma)+n
\end{gathered}
$$

implies

$$
H_{D R}^{1}\left(f^{-1}(t)\right)=\operatorname{Span}\left\{\omega_{i}^{\prime}:|i|=i_{1}+i_{2} \leq n-1\right\} \oplus \operatorname{Span}\left\{\overline{\omega_{i}^{\prime}}:|i|=i_{1}+i_{2}<n-1\right\} .
$$

Let, for a fixed regular value $t, \delta \subset f^{-1}(t)$ be a closed loop representing a non-zero homology class in $H_{0}\left(f^{-1}(t), \mathbb{Z}\right)$. If $\int_{\delta} \omega_{i}^{\prime}=0, \forall i,|i|=i_{1}+i_{2} \leq n-1$, then $\int_{\delta} \overline{\omega_{i}^{\prime}}=$ $0, \forall i,|i|=i_{1}+i_{2}<n-1$ and hence the homology class of $\delta$ is zero. Proposition 2 is proved.

Let, more generally, $\delta(t) \subset f^{-1}(t)$ be a continuous family of closed loops representing a not zero element in gr $^{k} F_{t}, k \geq 1$. Let $V_{n}$ be the vector space of all pairs $(f, \omega)$, where $f$ is a bi-variate polynomial of degree at most $n+1$ and $\omega$ is a one-form of degree at most $n$.

Theorem 6. There is a dense open subset of $V_{n}$ with the following property: for every pair $(f, \omega)$ of this open subset and for every integer $k \geq 1$ there exists a continuous family of closed loops $\delta(t) \subset f^{-1}(t)$ representing a non-zero homology class in $\mathrm{gr}^{k} F_{t}$, such that the corresponding Poincaré-Pontryagin function $M_{k}(t)$ is not identically zero.

The following example shows that the result of the above theorem can not be improved.
Example 3. Let $f$ be a polynomial of degree $n+1$, with $n^{2}$ distinct critical values, where $n \geq 2$ (such polynomials form a Zarisky open set in the space of degree $n+1$ polynomials). The generic leaf $\{f=t\} \subset \mathbb{C}^{2}$ is a compact Riemann surface with $n+1$ removed points. Let $\alpha_{1}(t), \alpha_{2}(t) \subset\{f=t\}$ be two continuous families of loops which make one turn about two distinct removed points on $\{f=t\}$, and put $X=\left\{\alpha_{1}, \alpha_{2}\right\}$. The element

$$
\left(\left(\left(\alpha_{1}, \alpha_{2}\right), \alpha_{1}\right),\left(\alpha_{1}, \alpha_{2}\right)\right)
$$

is a basic commutator of degree 5 [22, p.23], and hence represents a non-zero equivalence class in $L_{X}^{5}=F_{5} / F_{6}$. Define the continuous family of loops

$$
\gamma(t)=\left(\left(\left(\alpha_{1}(t), \alpha_{2}(t)\right), \alpha_{1}(t)\right),\left(\alpha_{1}(t), \alpha_{2}(t)\right)\right) .
$$

We claim that for every polynomial one-form of degree at most $n$, the Poincaré-Pontrygin function $M_{5}$ associated to the deformed foliation (21) and to the family of loops $\gamma(t)$ is identically zero. Indeed, according to (23), the function $M_{5}$ is a polynomial in $\int_{\alpha_{i}(t)} \omega^{(k)}$, $i=1,2, k=0,1, \ldots, 4$. However, for $k \geq 2$ the one-form $\omega^{(k)}$ has no residues. Therefore (23) takes the form

$$
M_{k}(t)=\int_{\gamma(t)} \omega \omega^{\prime} \omega^{\prime} \omega^{\prime} \omega^{\prime}
$$

and hence

$$
\begin{aligned}
M_{5}(t)= & \int_{\left(\left(\alpha_{1}(t), \alpha_{2}(t)\right), \alpha_{1}(t)\right)} \omega \omega^{\prime} \omega^{\prime} \int_{\left(\alpha_{1}(t), \alpha_{2}(t)\right)} \omega^{\prime} \omega^{\prime} \\
& -\int_{\left(\alpha_{1}(t), \alpha_{2}(t)\right)} \omega \omega^{\prime} \int_{\left(\left(\alpha_{1}(t), \alpha_{2}(t)\right), \alpha_{1}(t)\right)} \omega^{\prime} \omega^{\prime} \omega^{\prime} \\
\equiv & 0 .
\end{aligned}
$$

Proof of Theorem [6. Let $f^{0}$ be a degree $n+1$ polynomial, non-degenerate at infinity, and $\omega^{0}$ a degree $n$ one-form. Denote by $\delta(t) \subset\left\{f^{0}=t\right\}$ a continuous family of closed loops representing a not zero element in $\operatorname{gr}^{k} F_{t}, k \geq 1$. The function $M_{k}(t)$, associated to the pair $(f, \omega) \in V_{n}$ and the family of loops $\delta(t) \subset f^{-1}(t)$ is well defined, at least for $(f, \omega)$ sufficiently close to $\left(f^{0}, \omega^{0}\right)$. Therefore the condition that $M_{k}(t)$ is identically zero defines a closed subset of $V_{n}$ (possibly equal to $V_{n}$ ). It remains to show that there exists a point $\left(f^{0}, \omega^{0}\right) \in V_{n}$ at which the corresponding function $M_{k}(t)$ is not identically zero. Let $f^{0}$ be a homogeneous, degree $n+1$ polynomial, which is non-degenerate at infinity. We shall show that there exists a one-form $\omega$ of degree at most $n$, and a continuous family of closed loops representing a not zero element in $\mathrm{gr}^{k} F_{t}$, such that the associated function $M_{k}(t)$ is not identically zero.

The proof is an application of the $\pi_{1}$ de Rham theorem formulated in 43 Let $X$ be the set of $n^{2}$ co-homology classes defined by the one-forms $\omega_{i}$ in $H_{D R}^{1}\left(f^{-1}(t)\right)$, see (18) . By making use of the Picard-Fuchs system satisfied by $\omega_{i}$ we can represent the Poincaré-Pontryagin function $M_{k}(t)$, (23), in the form

$$
\begin{equation*}
M_{k}(t)=\int_{\delta(t)} P_{k}(\omega), \tag{25}
\end{equation*}
$$

where $P_{k}(\omega) \in \operatorname{Ass}_{X}^{k}$ is a suitable degree $k$ non-commutative polynomial. If the function $M_{k}(t)$ were identically zero for all family of cycles $\delta(t)$, then the polynomial $P_{k}(\omega)$ would belong, for every regular value $t$, to the space $S_{X}^{k}$ generated by shuffle products. Let $V$ be the vector space generated by $\omega_{i}$ 's. It is easy to check that the set $\left\{\omega \in V \mid P_{k}(\omega) \in S_{X}^{k}\right\}$ is algebraic. We are going to prove that it is not the whole $V$.

Taking into consideration the non-degeneracy of $f$ at infinity, we deduce that the Picard-Fuchs system associated to $\omega_{i}$ is diagonal

$$
t \omega_{i}^{\prime}=w_{i} \omega_{i}, \text { where } w_{i}=\operatorname{weight}\left(\omega_{i}\right):=\frac{|i|+2}{n+1} .
$$

This allows to deduce an explicit formula for $P_{k}(\omega)$. Let, for instance, $\omega=\alpha_{1} \omega_{1}+\alpha_{2} \omega_{2}$, where $\operatorname{weight}\left(\omega_{i}\right)=w_{i}$. One easily proves by induction that

$$
\begin{equation*}
P_{k}(\omega)=\frac{1}{t^{k-1}} \sum_{i=0}^{k} \alpha_{1}^{i} \alpha_{2}^{k-i} \sum c_{i_{1} i_{2} \ldots i_{k}} \omega_{i_{1}} \omega_{i_{2}} \ldots \omega_{i_{k}} \tag{26}
\end{equation*}
$$

where

$$
c_{i_{1} i_{2} \ldots i_{k}}=w_{i_{k}}\left(w_{i_{k}}+w_{i_{k-1}}-1\right) \ldots\left(w_{i_{k}}+w_{i_{k-1}}+\cdots+w_{i_{2}}-k+2\right)
$$

and in the second sum of (26), the index $i_{1} i_{2} \ldots i_{k}$ runs through all the shuffles of

$$
\underbrace{(1 \ldots 1)}_{i \text { times }} \text { and } \underbrace{(2 \ldots 2)}_{k-i \text { times }} .
$$

Note that the first sum in (26) is with respect to all partitions $i+(k-i)$ of $k$. This fact reflects a further decomposition of $S_{X}^{k}$ and $L_{X}^{k}$ in direct orthogonal sums corresponding to partitions of $k$. The polynomial $P_{k}(\omega)$ belongs to $S_{X}^{k}$ if and only if it is orthogonal to $L_{X}^{k}$ (Theorem (2). It suffices to show that the coefficient of at least one monomial $\alpha_{1}^{i} \alpha_{2}^{k-i}$
in (26) is not orthogonal to $L_{X}^{k}$. Take for instance the partition $k=1+(k-1)$. The coefficient of $\alpha_{1} \alpha_{2}^{k-1}$ takes the form

$$
\begin{aligned}
P_{k}^{1}\left(\omega_{1}, \omega_{2}\right)= & \omega_{1} \omega_{2}^{k-1} w_{2}\left(2 w_{2}-1\right) \ldots\left((k-1) w_{2}-k+2\right) \\
+ & \omega_{2} \omega_{1} \omega_{2}^{k-2} w_{2}\left(2 w_{2}-1\right) \ldots\left((k-2) w_{2}-k+3\right)\left((k-2) w_{2}+w_{1}-k+2\right) \\
& \vdots \\
+ & \omega_{2}^{k-1} \omega_{1} w_{1}\left(w_{1}+w_{2}-1\right) \ldots\left((k-2) w_{2}+w_{1}-k+2\right) .
\end{aligned}
$$

The subspace of $L_{X}^{k}$ corresponding to the partition $k=1+(k-1)$ is one-dimensional and generated by the Lie polynomial

$$
L_{k}^{1}\left(\omega_{1}, \omega_{2}\right)=\left[\left[\ldots\left[\left[\omega_{1}, \omega_{2}\right], \omega_{2}\right], \ldots, \omega_{2}\right], \omega_{2}\right] .
$$

Consider the scalar product

$$
\begin{equation*}
C_{k}\left(w_{1}, w_{2}\right)=\left\langle P_{k}^{1}\left(\omega_{1}, \omega_{2}\right), L_{k}^{1}\left(\omega_{1}, \omega_{2}\right)\right\rangle . \tag{27}
\end{equation*}
$$

The identities

$$
\begin{aligned}
\left\langle L_{k}^{1}, \omega_{i_{1}} \omega_{i_{2}} \ldots \omega_{i_{k}}\right\rangle= & \left\langle\left[L_{k-1}^{1}, \omega_{2}\right], \omega_{i_{1}} \omega_{i_{2}} \ldots \omega_{i_{k}}\right\rangle \\
= & \left\langle L_{k-1}^{1}, \omega_{i_{1}} \omega_{i_{2}} \ldots \omega_{i_{k-1}}\right\rangle\left\langle\omega_{2}, \omega_{i_{k}}\right\rangle \\
& -\left\langle\omega_{2}, \omega_{i_{1}}\right\rangle\left\langle L_{k-1}^{1}, \omega_{i_{2}} \omega_{i_{3}} \ldots \omega_{i_{k}}\right\rangle
\end{aligned}
$$

applied to the scalar product $C_{k}$ lead to the following recursive formula

$$
C_{k}\left(w_{1}, w_{2}\right)=\left(w_{2}-w_{1}\right) C_{k-1}\left(w_{1}+w_{2}-1, w_{2}\right), k \geq 3, \quad C_{2}\left(w_{1}, w_{2}\right)=w_{2}-w_{1}
$$

and hence

$$
C_{k}\left(w_{1}, w_{2}\right)=\left(w_{2}-w_{1}\right) \Pi_{i=1}^{k-2}\left(i-w_{1}-(i-1) w_{2}\right) .
$$

Recall now that $w_{i}:=\frac{|i|+2}{n+1}$, where $|i|+2 \leq n-1$. If we choose $w_{1} \neq w_{2}$ and $w_{1}<1$ then the scalar product $C_{k}\left(w_{1}, w_{2}\right)$ is not zero. The Theorem is proved.

Theorem 7. Let $f$ be a degree three polynomial, whose degree three homogeneous part is non-degenerate (has an isolated critical point). Let $\delta(t) \subset\{f=t\}$ be a continuous family of loops representing a non-zero element in $F_{X}^{2} / F_{X}^{3}$, where $X$ is a basis of the first homology group $H_{1}(\{f=t\}, \mathbb{Z})$. Then there exists a one-form $\omega$ of degree at most two, such that

$$
M_{2}(t)=\int_{\delta(t)} \omega \omega^{\prime} \not \equiv 0
$$

For a generic $f$ and a particular class of cycles $\delta(t)$ one can say that $M_{2}=0$ if and only if $\omega$ is exact. For more details on this see [16. Before proving the above theorem we need some preparation. For a generic $t$ the affine algebraic curve $\{f=t\}$ is a topological torus with three removed points, and $f$ has four critical points. Let $h_{i} \in \operatorname{Aut}\left(H_{1}\left(\left\{f=t_{0}\right\}, \mathbb{Z}\right)\right), \quad i=1,2,3,4$ be the associated monodromy operators $\left(t_{0}\right.$ is a fixed regular value). Let $\delta_{i}(t), \alpha_{i}(t), i=1,2$, be continuous family of cycles in $H_{1}(\{f=t\}, \mathbb{Z})$ which form a basis. We suppose moreover that $\delta_{1}(t), \delta_{2}(t)$ are vanishing cycles, while $\alpha_{1}(t), \alpha_{2}(t)$ are homologous to zero on the compactified curve $\{f=t\}$. Without loss of generality we have $h_{i}\left(\alpha_{j}\right)=\alpha_{j}, h_{i}\left(\delta_{i}\right)=\delta_{i}$, and

$$
h_{1}\left(\delta_{2}\right)=\delta_{2}+\delta_{1}, h_{2}\left(\delta_{1}\right)=\delta_{1}-\delta_{2} .
$$

Identifying $F_{X}^{2} / F_{X}^{3}$ to $L_{X}^{2}$, where

$$
X=\left\{\delta_{1}, \delta_{2}, \alpha_{1}, \alpha_{2}\right\}
$$

we represent an element $\delta \in F_{X}^{2} / F_{X}^{3}$ as a linear combination of commutators

$$
\left[\delta_{1}, \delta_{2}\right],\left[\delta_{i}, \alpha_{j}\right],\left[\alpha_{1}, \alpha_{2}\right], \quad i, j=1,2
$$

The monodromy operators $h_{i}$ induce automorphisms of $F_{X}^{2} / F_{X}^{3}$ denoted by the same letter.
Proposition 3. Let $\delta(t)$ be a continuous family of loops representing a non-zero equivalence class in $F_{X}^{2} / F_{X}^{3}$. There exists a polynomial $P$ in $h_{i}$ and with integer coefficients, such that

$$
P\left(h_{1}, h_{2}, h_{3}, h_{4}\right)(\delta)=k\left[\alpha_{1}, \alpha_{2}\right],
$$

where $k$ is a non-zero integer.
Proof. The proof is straightforward. Let $\delta_{i}, i=1,2,3,4$ be vanishing cycles associated to the critical values of $f$. The Dynkin diagram of $f$ is of type $D_{4}$ and we may suppose that the intersection matrix is

$$
\left(\delta_{i} \cdot \delta_{j}\right)=\left(\begin{array}{cccc}
0 & 1 & 0 & 0 \\
-1 & 0 & 1 & 1 \\
0 & -1 & 0 & 0 \\
0 & -1 & 0 & 0
\end{array}\right)
$$

$\alpha_{1}=\delta_{1}-\delta_{3}$ and $\alpha_{2}=\delta_{1}-\delta_{4}$ and

$$
h_{i}(\delta)=\delta-\left(\delta \cdot \delta_{i}\right) \delta_{i}
$$

(the Picard-Lefschetz formula). Every $\delta \in F_{X}^{2} / F_{X}^{3}$ is of the form

$$
\begin{equation*}
\delta=\left[\delta_{1}, a\right]+\left[\delta_{2}, b\right]+m\left[\delta_{1}, \delta_{2}\right]+n\left[\alpha_{1}, \alpha_{2}\right] \tag{28}
\end{equation*}
$$

where $m, n \in \mathbb{Z}$ and $a, b$ are integer linear combinations in $\alpha_{1}, \alpha_{2}$. We have

$$
\begin{align*}
\left(h_{1}-i d\right)(\delta) & =\left[\delta_{1}, b\right]  \tag{29}\\
\left(h_{2}-i d\right)(\delta) & =-\left[\delta_{2}, a\right] \tag{30}
\end{align*}
$$

which shows that it is enough to prove the Proposition for $\delta$ as in (28) with $m=n=0$ (provided that either $a$ or $b$ is non-zero). In the case $m=0$ we have

$$
\begin{align*}
\left(h_{3}-i d\right)(\delta) & =-\left[\delta_{3}, b\right]  \tag{31}\\
\left(h_{4}-i d\right)(\delta) & =-\left[\delta_{4}, b\right] \tag{32}
\end{align*}
$$

Therefore by (29), (301), (31) there is a polynomial $P$ (a linear combination in $h_{1}, h_{3}, h_{4}, i d$ ) such that $P(\delta)=\left[\alpha_{1}, b\right]$ or $P(\delta)=\left[\alpha_{2}, b\right]$. If $b \neq 0$ the Proposition is proved. If $b=0$ but $a \neq 0$ then using (30) we replace without loss of generality $\delta$ by $\left[\delta_{2}, a\right]$ and conclude as above. It remains the case $a=b=0$ but $m \neq 0$. We have

$$
\begin{align*}
\left(h_{3}-i d\right)(\delta) & =-\left[\delta_{1}, \delta_{3}\right]  \tag{33}\\
\left(h_{4}-i d\right)(\delta) & =-\left[\delta_{1}, \delta_{4}\right] \tag{34}
\end{align*}
$$

and hence $\left(h_{3}-h_{4}\right)(\delta)=\left[\delta_{1}, \delta_{4}-\delta_{3}\right]=\left[\delta_{1}, \alpha_{1}-\alpha_{2}\right]$. We may therefore replace $\delta$ by [ $\delta_{1}, \alpha_{1}-\alpha_{2}$ ] and conclude as above. Proposition 3 is proved.

Proof of Theorem 7. If $M_{2}(t)$ were identically zero then each analytic continuation of $M_{2}(t)$ would be zero too. By Proposition 3 we conclude that the function

$$
F_{\omega}(t)=\int_{\left[\alpha_{1}(t), \alpha_{2}(t)\right]} \omega \omega^{\prime}=\operatorname{det}\left(\begin{array}{ll}
\int_{\alpha_{1}(t)} \omega & \int_{\alpha_{2}(t)} \omega \\
\int_{\alpha_{1}(t)} \omega^{\prime} & \int_{\alpha_{2}(t)} \omega^{\prime}
\end{array}\right)
$$

is identically zero. We shall show that that there is a polynomial one-form $\omega$ of degree at most two, such that $F_{\omega}(t) \not \equiv 0$. Indeed, the affine curve $\{f=t\}$ is a topological torus with three removed points $\infty_{1}, \infty_{2}, \infty_{3}$ and the vector space $W$, (24), of meromorphic one-forms with at most simple poles at $\infty_{i}$ is three dimensional and generated by

$$
\omega_{00}^{\prime}=\frac{d x}{f_{y}}, \omega_{10}^{\prime}=2 \frac{x d x}{f_{y}}, \omega_{01}^{\prime}=2 \frac{y d x}{f_{y}}
$$

(see the proof of Proposition [2 and [2, Lemma 3]) where

$$
d \omega_{00}=d x \wedge d y, d \omega_{10}=x d x \wedge d y, d \omega_{01}=y d x \wedge d y
$$

and $\omega^{\prime}$ is the Gelfand-Leray residue of $d \omega$. Furthermore, the integrals $\int_{\alpha_{i}(t)} \omega$ are just the residues of $\omega$ at $\infty_{i}$. These residues are linear in $t$ when $\omega \in W$. The identity $F_{\omega}(t) \equiv 0$ (for every fixed $\omega \in W$ ) and the linearity of $\int_{\alpha_{i}(t)} \omega$ imply that the direction of the vector

$$
\left(\int_{\alpha_{1}(t)} \omega, \int_{\alpha_{2}(t)} \omega\right)
$$

does not depend on $\omega \in W$ neither on $t$ (when it is defined). This shows that a suitable linear combination of $\omega_{10}^{\prime}, \omega_{01}^{\prime}$ with constant coefficients has no residues and hence is a holomorphic one-form. Therefore the one-forms $\omega_{00}^{\prime}, \omega_{10}^{\prime}, \omega_{01}^{\prime}$ are linearly dependent, which is a contradiction. Theorem 7 is proved.
