# The parabolic Sturmian-function basis representation of the six-dimensional Coulomb Green's function 

S. A. Zaytsev*<br>Pacific National University, Khabarovsk, 680035, Russia

#### Abstract

The square integrable basis set representation of the resolvent of the asymptotic three-body Coulomb wave operator in parabolic coordinates is obtained. The resulting six-dimensional Green's function matrix is expressed as a convolution integral over separation constants.

## I. INTRODUCTION

It is well known that the Schrödinger equation for a three-body Coulomb system is asymptotically separable in terms of parabolic coordinates [1]

$$
\begin{equation*}
\xi_{j}=r_{l s}+\hat{\mathbf{k}}_{l s} \cdot \mathbf{r}_{l s}, \quad \eta_{j}=r_{l s}-\hat{\mathbf{k}}_{l s} \cdot \mathbf{r}_{l s} \tag{1}
\end{equation*}
$$

where $\mathbf{r}_{l s}$ and $\mathbf{k}_{l s}$ are the relative coordinate and momentum vectors between the particles $l$ and $s$. Here $j, l, s$ is a cyclic permutation of $1,2,3$. The long-ranged six-dimensional operator, which provides a three-body continuum wave function, 3C-function [2, 3], that satisfies exact asymptotic boundary conditions for Coulomb systems in the region where the distances between the particles are large, reads as the sum of two-dimensional operators [1]:

$$
\begin{equation*}
\sum_{j=1}^{3} \frac{1}{\mu_{l s}\left(\xi_{j}+\eta_{j}\right)}\left[\hat{h}_{\xi_{j}}+\hat{h}_{\eta_{j}}+2 k_{l s} t_{l s}\right] \tag{2}
\end{equation*}
$$

where $t_{l s}=\frac{Z_{l} Z_{s} \mu_{l s}}{k_{l s}}, \mu_{l s}=\frac{m_{l} m_{s}}{m_{l}+m_{s}}$. Here the one-dimensional operators $\hat{h}_{\xi_{j}}$ and $\hat{h}_{\eta_{j}}$ are defined by

$$
\begin{align*}
& \hat{h}_{\xi_{j}}=-2\left(\frac{\partial}{\partial \xi_{j}} \xi_{j} \frac{\partial}{\partial \xi_{j}}+i k_{l s} \xi_{j} \frac{\partial}{\partial \xi_{j}}\right) \\
& \hat{h}_{\eta_{j}}=-2\left(\frac{\partial}{\partial \eta_{j}} \eta_{j} \frac{\partial}{\partial \eta_{j}}-i k_{l s} \eta_{j} \frac{\partial}{\partial \eta_{j}}\right) . \tag{3}
\end{align*}
$$

In the previous paper [4] we introduce the six-dimensional operator $\mathfrak{h}$ which is obtained by multiplying (21) on the left by $\prod_{j=1}^{3} \mu_{l s}\left(\xi_{j}+\eta_{j}\right)$ :

$$
\begin{equation*}
\hat{\mathfrak{h}}=\mu_{13}\left(\xi_{2}+\eta_{2}\right) \mu_{12}\left(\xi_{3}+\eta_{3}\right) \hat{\mathfrak{h}}_{1}+\mu_{23}\left(\xi_{1}+\eta_{1}\right) \mu_{12}\left(\xi_{3}+\eta_{3}\right) \hat{\mathfrak{h}}_{2}+\mu_{23}\left(\xi_{1}+\eta_{1}\right) \mu_{13}\left(\xi_{2}+\eta_{2}\right) \hat{\mathfrak{h}}_{3}, \tag{4}
\end{equation*}
$$

where

$$
\begin{equation*}
\hat{\mathfrak{h}}_{j}=\hat{h}_{\xi_{j}}+\hat{h}_{\eta_{j}}+2 k_{l s} t_{l s} . \tag{5}
\end{equation*}
$$

The resolvent of the operator (4) can be used in the corresponding Lippmann-Schwinger equation for the three-body Coulomb wave function.

It has been suggested [4] to treat the operator (4) within the context of $L^{2}$ parabolic Sturmian basis set [5]

$$
\begin{gather*}
|\mathcal{N}\rangle=\prod_{j=1}^{3} \phi_{n_{j} m_{j}}\left(\xi_{j}, \eta_{j}\right),  \tag{6}\\
\phi_{n_{j} m_{j}}\left(\xi_{j}, \eta_{j}\right)=\psi_{n_{j}}\left(\xi_{j}\right) \psi_{m_{j}}\left(\eta_{j}\right),  \tag{7}\\
\psi_{n}(x)=\sqrt{2 b} e^{-b x} L_{n}(2 b x), \tag{8}
\end{gather*}
$$

where $b$ is the scaling parameter. In particular, a matrix representation $\mathbf{G}_{j}$ of the resolvent for the two-dimensional operator

$$
\begin{equation*}
\hat{\mathfrak{h}}_{j}+\mu_{l s} C_{j}\left(\xi_{j}+\eta_{j}\right) \tag{9}
\end{equation*}
$$

has been obtained which is formally the matrix inverse to the infinite matrix $\left[\mathbf{h}_{j}+\mu_{l s} C_{j} \mathbf{Q}_{j}\right]$ of the operator (9)):

$$
\begin{equation*}
\left[\mathbf{h}_{j}+\mu_{l s} C_{j} \mathbf{Q}_{j}\right] \mathbf{G}_{j}\left(t_{l s} ; \mu_{l s} C_{j}\right)=\mathbf{I}_{j} \tag{10}
\end{equation*}
$$

Here

$$
\begin{equation*}
\mathbf{h}_{j}=\mathbf{h}_{\xi_{j}} \otimes \mathbf{I}_{\eta_{j}}+\mathbf{I}_{\xi_{j}} \otimes \mathbf{h}_{\eta_{j}}+2 k_{l s} t_{l s} \mathbf{I}_{j} \tag{11}
\end{equation*}
$$

is the matrix of the operator $\hat{\mathfrak{h}}_{j}$ (5) in the basis (7), $\mathbf{I}_{\xi_{j}}, \mathbf{I}_{\eta_{j}}$ and $\mathbf{I}_{j}=\mathbf{I}_{\xi_{j}} \otimes \mathbf{I}_{\eta_{j}}$ are the unit matrices. $\mathbf{Q}_{j}=\mathbf{Q}_{\xi_{j}} \otimes \mathbf{I}_{\eta_{j}}+\mathbf{I}_{\xi_{j}} \otimes \mathbf{Q}_{\eta_{j}}$, where $\mathbf{Q}_{\xi_{j}}$ and $\mathbf{Q}_{\eta_{j}}$ are the matrices of $\xi_{j}$ and $\eta_{j}$ in basis (8), respectively.

In the previous paper [4] it has been suggested that the matrices $\mathbf{G}_{j}$ of the twodimensional Green's functions be used to construct the matrix $\underline{\mathfrak{G}}$ which is inverse to the operator (4) matrix

$$
\begin{equation*}
\underline{\mathfrak{h}}=\mu_{13} \mu_{12} \mathbf{h}_{1} \otimes \mathbf{Q}_{2} \otimes \mathbf{Q}_{3}+\mu_{23} \mu_{12} \mathbf{Q}_{1} \otimes \mathbf{h}_{2} \otimes \mathbf{Q}_{3}+\mu_{23} \mu_{13} \mathbf{Q}_{1} \otimes \mathbf{Q}_{2} \otimes \mathbf{h}_{3} \tag{12}
\end{equation*}
$$

Namely, we proposed to express the six-dimensional Green's function matrix $\underline{\mathfrak{G}}$ as the convolution integral

$$
\begin{equation*}
\underline{\mathfrak{G}}=\aleph \iint d C_{1} d C_{2} \mathbf{G}_{1}\left(t_{23} ; \mu_{23} C_{1}\right) \otimes \mathbf{G}_{2}\left(t_{13} ; \mu_{13} C_{2}\right) \otimes \mathbf{G}_{3}\left(t_{12} ;-\mu_{12}\left(C_{1}+C_{2}\right)\right) \tag{13}
\end{equation*}
$$

where $\aleph$ is a normalizing factor. Thus, our problem is now to determine the pathes of integration over the separation constants $C_{1}$ and $C_{2}$ in (13) and to find the corresponding normalizing factor $\aleph$ such that the condition

$$
\begin{equation*}
\underline{\mathfrak{h} G}=\mathbf{I}_{1} \otimes \mathbf{I}_{2} \otimes \mathbf{I}_{3} \tag{14}
\end{equation*}
$$

holds. For this purpose consider the product $\underline{\mathfrak{h}} \underline{\mathfrak{G}}$. From the relation (10) we obtain

$$
\begin{gather*}
\underline{\mathfrak{h}} \underline{\mathfrak{G}}=\aleph\left\{\iint d C_{1} d C_{2}\left[\mathbf{I}_{1}-\mu_{23} C_{1} \mathbf{Q}_{1} \mathbf{G}_{1}\left(t_{23} ; \mu_{23} C_{1}\right)\right] \otimes \mu_{13} \mathbf{Q}_{2} \mathbf{G}_{2}\left(t_{13} ; \mu_{13} C_{2}\right)\right. \\
\otimes \mu_{12} \mathbf{Q}_{3} \mathbf{G}_{3}\left(t_{12} ;-\mu_{12}\left(C_{1}+C_{2}\right)\right) \\
\iint d C_{1} d C_{2} \mu_{23} \mathbf{Q}_{1} \mathbf{G}_{1}\left(t_{23} ; \mu_{23} C_{1}\right) \otimes\left[\mathbf{I}_{2}-\mu_{13} C_{2} \mathbf{Q}_{2} \mathbf{G}_{2}\left(t_{13} ; \mu_{13} C_{2}\right)\right] \\
\otimes \mu_{12} \mathbf{Q}_{3} \mathbf{G}_{3}\left(t_{12} ;-\mu_{12}\left(C_{1}+C_{2}\right)\right)  \tag{15}\\
\iint d C_{1} d C_{2} \mu_{23} \mathbf{Q}_{1} \mathbf{G}_{1}\left(t_{23} ; \mu_{23} C_{1}\right) \otimes \mu_{13} \mathbf{Q}_{2} \mathbf{G}_{2}\left(t_{13} ; \mu_{13} C_{2}\right) \\
\left.\otimes\left[\mathbf{I}_{3}+\mu_{12}\left(C_{1}+C_{2}\right) \mathbf{Q}_{3} \mathbf{G}_{3}\left(t_{12} ;-\mu_{12}\left(C_{1}+C_{2}\right)\right)\right]\right\}
\end{gather*}
$$

and hence

$$
\begin{align*}
& \underline{\mathfrak{h}} \underline{\mathfrak{G}}=\aleph\left\{\int \int d C _ { 1 } d C _ { 2 } \left[\mathbf{I}_{1} \otimes \mu_{13} \mathbf{Q}_{2} \mathbf{G}_{2}\left(t_{13} ; \mu_{13} C_{2}\right) \otimes \mu_{12} \mathbf{Q}_{3} \mathbf{G}_{3}\left(t_{12} ;-\mu_{12}\left(C_{1}+C_{2}\right)\right)\right.\right. \\
&\left.+\mu_{23} \mathbf{Q}_{1} \mathbf{G}_{1}\left(t_{23} ; \mu_{23} C_{1}\right) \otimes \mathbf{I}_{2} \otimes \mu_{12} \mathbf{Q}_{3} \mathbf{G}_{3}\left(t_{12} ;-\mu_{12}\left(C_{1}+C_{2}\right)\right)\right]  \tag{16}\\
&\left.+\left[\mu_{23} \mathbf{Q}_{1} \int d C_{1} \mathbf{G}_{1}\left(t_{23} ; \mu_{23} C_{1}\right)\right] \otimes\left[\mu_{13} \mathbf{Q}_{2} \int d C_{2} \mathbf{G}_{2}\left(t_{13} ; \mu_{13} C_{2}\right)\right] \otimes \mathbf{I}_{3}\right\} .
\end{align*}
$$

As a first step towards our goal we consider the integrals

$$
\begin{equation*}
\int d C_{j} \mathbf{G}_{j}\left(t_{l s} ; \mu_{l s} C_{j}\right) \tag{17}
\end{equation*}
$$

inside the figure brackets on the right-hand side of (16).
In Sec. II completeness of the eigenfunctions of the two-dimensional operator (9) is considered. In particular, an integral representation of the matrix $\mathbf{A}$ which is inverse to the infinite matrix $\mathbf{Q}$ of the operator $(\xi+\eta)$ in the basis (7) is obtained. In Sec. III it is demonstrated that the integral (17) taken along an appropriate contour is proportional to the matrix A obtained in the previous section. Finally, Sec. IV presents a convolution integral representation of the six-dimensional Coulomb Green' function matrix.

## II. COMPLETENESS RELATIONS

## A. The continuous spectrum

Of particular interest are the regular solutions

$$
\begin{equation*}
f(\gamma, \tau, \xi, \eta)=u(\gamma, \tau, \xi) v(\gamma, \tau, \eta) \tag{18}
\end{equation*}
$$

of the system

$$
\begin{gather*}
{\left[\hat{h}_{\xi}+2 k t+\mu C \xi\right] u(\gamma, \tau, \xi)=0}  \tag{19}\\
{\left[\hat{h}_{\eta}+2 k\left(t_{0}-t\right)+\mu C \eta\right] v(\gamma, \tau, \xi)=0} \tag{20}
\end{gather*}
$$

Obviously, the regular solutions $u$ and $v$ are proportional to confluent hypergeometric functions [6]:

$$
\begin{equation*}
u(\gamma, \tau, \xi)=e^{\frac{i}{2}(\gamma-k) \xi}{ }_{1} F_{1}\left(\frac{1}{2}+i \tau, 1,-i \gamma \xi\right) \tag{21}
\end{equation*}
$$

and

$$
\begin{align*}
v(\gamma, \tau, \eta) & =e^{-\frac{i}{2}(\gamma-k) \eta}{ }_{1} F_{1}\left(\frac{1}{2}+i\left(\tau-\tau_{0}\right), 1, i \gamma \eta\right)  \tag{22}\\
& =e^{\frac{i}{2}(\gamma+k) \eta}{ }_{1} F_{1}\left(\frac{1}{2}+i\left(\tau_{0}-\tau\right), 1,-i \gamma \eta\right),
\end{align*}
$$

where

$$
\begin{equation*}
\mu C=\frac{k^{2}}{2}-\frac{\gamma^{2}}{2}, \quad \tau=\frac{k}{\gamma}\left(t+\frac{i}{2}\right), \quad \tau_{0}=\frac{k}{\gamma} t_{0} \tag{23}
\end{equation*}
$$

It should be noted that since the representation of the two- and six-dimensional Coulomb Green's functions matrix elements involves an integration over $\tau$ from $-\infty$ to $\infty$, in the subsequent discussion we assume that $\tau$ is real. With this assumption it is readily seen that the solutions (21) and (22) coincide, except for normalization and the phase factors $e^{-\frac{i}{2} k \xi}$ and $e^{\frac{i}{2} k \eta}$, with parabolic Coulomb Sturmians treated in Ref. [7]. In this case $\gamma$ plays the role of the momentum and $\mathcal{E}=\frac{\gamma^{2}}{2}$ is the energy. From this we conclude that for $\gamma>0$ the solutions (21) and (22) correspond to the continuous spectrum of $\mathcal{E}$.

It is readily verified that the solutions $u(\gamma, \tau, \xi)$ and $v(\gamma, \tau, \eta)$ are expressed by basis set (8) expansions

$$
\begin{gather*}
u(\gamma, \tau, \xi)=\frac{2 \sqrt{2 b}}{2 b-i(\gamma-k)}\left(\frac{2 b-i(\gamma-k)}{2 b+i(\gamma+k)}\right)^{i \tau+\frac{1}{2}} \sum_{n=0}^{\infty} \theta^{n} p_{n}(\tau ; \zeta) \psi_{n}(\xi),  \tag{24}\\
v(\gamma, \tau, \eta)=\frac{2 \sqrt{2 b}}{2 b-i(\gamma+k)}\left(\frac{2 b-i(\gamma+k)}{2 b+i(\gamma-k)}\right)^{i\left(\tau_{0}-\tau\right)+\frac{1}{2}} \sum_{n=0}^{\infty} \lambda^{-n} p_{n}\left(\tau_{0}-\tau ; \zeta\right) \psi_{n}(\eta), \tag{25}
\end{gather*}
$$

where

$$
\begin{equation*}
\theta=\frac{2 b+i(\gamma-k)}{2 b-i(\gamma-k)}, \quad \lambda=\frac{2 b-i(\gamma+k)}{2 b+i(\gamma+k)}, \quad \zeta=\frac{\lambda}{\theta} . \tag{26}
\end{equation*}
$$

The expansion (24) and (25) coefficients contain the polynomials [4]

$$
\begin{equation*}
p_{n}(\tau ; \zeta)=\frac{(-1)^{n}}{n!} \frac{\Gamma\left(n+\frac{1}{2}-i \tau\right)}{\Gamma\left(\frac{1}{2}-i \tau\right)}{ }_{2} F_{1}\left(-n, \frac{1}{2}+i \tau ;-n+\frac{1}{2}+i \tau ; \zeta\right) \tag{27}
\end{equation*}
$$

The basis set (8) representation of the equation (19) is the three-term recursion relation (4]

$$
\begin{equation*}
a_{n} y_{n-1}+b_{n} y_{n}+d_{n+1} y_{n+1}=0, \quad n \geq 1 \tag{28}
\end{equation*}
$$

where

$$
\begin{gather*}
b_{n}=\left(b+\frac{\mu C}{2 b}+i k\right)+2\left(b+\frac{\mu C}{2 b}\right) n+2 k t,  \tag{29}\\
a_{n}=\left(b-\frac{\mu C}{2 b}-i k\right) n, \quad d_{n}=\left(b-\frac{\mu C}{2 b}+i k\right) n .
\end{gather*}
$$

The functions

$$
\begin{equation*}
s_{n}(t ; \mu C)=\theta^{n} p_{n}(\tau ; \zeta) \tag{30}
\end{equation*}
$$

are the "regular" solutions of (28) with the initial conditions: $s_{0} \equiv 1, s_{-1} \equiv 0$. The polynomials $p_{n}$ (27) of degree $n$ in $\tau$ are orthogonal with respect to the weight function [4]

$$
\begin{equation*}
\rho(\tau ; \zeta)=\frac{\Gamma\left(\frac{1}{2}-i \tau\right) \Gamma\left(\frac{1}{2}+i \tau\right)}{2 \pi i}(-\zeta)^{i \tau+\frac{1}{2}}, \tag{31}
\end{equation*}
$$

where it is considered that $|\arg (-\zeta)|<\pi$. The corresponding orthogonality relation reads

$$
\begin{equation*}
\frac{i}{\zeta^{m}}\left(\frac{\zeta-1}{\zeta}\right) \int_{-\infty}^{\infty} d \tau \rho(\tau ; \zeta) p_{n}(\tau ; \zeta) p_{m}(\tau ; \zeta)=\delta_{n m} \tag{32}
\end{equation*}
$$

## B. The discrete spectrum

For $t_{0}<0$ the eigenfunctions of (19) corresponding to the discrete spectrum: $\mathcal{E}^{(\ell)}=\frac{\gamma_{\ell}^{2}}{2}$, $\gamma_{\ell}=i \kappa_{\ell}, \kappa_{\ell}=-\frac{k t_{0}}{\ell}, \ell=1,2, \ldots, \infty$, are [8]

$$
\begin{equation*}
f_{\ell, m}(\xi, \eta)=u_{\ell, m}(\xi) v_{\ell, \ell-m-1}(\eta), \quad m=0,1, \ldots, \ell-1 \tag{33}
\end{equation*}
$$

where

$$
\begin{equation*}
u_{\ell, m}(\xi)=e^{-\frac{i}{2} k \xi} e^{-\frac{\kappa_{\ell} \xi}{2}}{ }_{1} F_{1}\left(-m, 1 ; \kappa_{\ell} \xi\right)=e^{-\frac{i}{2} k \xi} e^{-\frac{\kappa_{\ell} \xi}{2}} L_{m}\left(\kappa_{\ell} \xi\right) \tag{34}
\end{equation*}
$$

and

$$
\begin{equation*}
v_{\ell, m}(\eta)=e^{\frac{i}{2} k \eta} e^{-\frac{\kappa_{\ell} \eta}{2}}{ }_{1} F_{1}\left(-m, 1 ; \kappa_{\ell} \eta\right)=e^{\frac{i}{2} k \eta} e^{-\frac{\kappa_{\ell} \eta}{2}} L_{m}\left(\kappa_{\ell} \eta\right) . \tag{35}
\end{equation*}
$$

The solutions $f_{\ell, m}$ meet the orthogonality relation

$$
\begin{equation*}
\frac{\kappa_{\ell}^{3}}{2 \ell} \int_{0}^{\infty} \int_{0}^{\infty}(\xi+\eta) d \xi d \eta f_{\ell, m}(\xi, \eta)\left[f_{\ell^{\prime}, m^{\prime}}(\xi, \eta)\right]^{*}=\delta_{\ell, \ell^{\prime}} \delta_{m, m^{\prime}} \tag{36}
\end{equation*}
$$

It is readily verified that the expansions of $u_{\ell, m}(\xi)$ and $v_{\ell, m}(\eta)$ in a basis function (8) series are

$$
\begin{equation*}
u_{\ell, m}(\xi)=\sum_{n=0}^{\infty} \mathcal{S}_{n}^{(\ell, m)} \psi_{n}(\xi) \tag{37}
\end{equation*}
$$

and

$$
\begin{equation*}
v_{\ell, m}(\eta)=\sum_{n=0}^{\infty}\left[\mathcal{S}_{n}^{(\ell, m)}\right]^{*} \psi_{n}(\eta), \tag{38}
\end{equation*}
$$

where the coefficients are given by

$$
\begin{align*}
\mathcal{S}_{n}^{(\ell, m)}= & 2 \sqrt{2 b}(-)^{n} \frac{(m+1)_{n}}{n!} \frac{\left(2 b-\kappa_{\ell}-i k\right)^{n}\left(2 b-\kappa_{\ell}+i k\right)^{m}}{\left(2 b+\kappa_{\ell}+i k\right)^{n+m+1}}  \tag{39}\\
& \times{ }_{2} F_{1}\left(-n,-m,-n-m ; \frac{\left(2 b+\kappa_{\ell}\right)^{2}+k^{2}}{\left(2 b-\kappa_{\ell}\right)^{2}+k^{2}}\right) .
\end{align*}
$$

## One-dimensional completeness relations

The eigensolution $u(\gamma, \tau, \xi)$ of (19) corresponding to the continuous spectrum $(\gamma>0)$ for large $\xi$ behaves as

$$
\begin{equation*}
u(\gamma, \tau, \xi) \underset{\xi \rightarrow \infty}{\sim} \frac{e^{-\frac{i}{2} k \xi} e^{\frac{\pi \tau}{2}}}{\left|\Gamma\left(\frac{1}{2}+i \tau\right)\right|} \frac{2 i}{\sqrt{\gamma \xi}} \sin \left(\frac{\gamma \xi}{2}-\tau \ln (\gamma \xi)+\frac{\pi}{4}+\sigma\right) \tag{40}
\end{equation*}
$$

where $\sigma=\arg \Gamma\left(\frac{1}{2}+i \tau\right)$. Therefore (see e. g. [9]),

$$
\begin{equation*}
\frac{\gamma}{4}\left|\Gamma\left(\frac{1}{2}+i \tau\right)\right|^{2} e^{-\pi \tau} \int_{0}^{\infty} \xi d \xi u(\gamma, \tau, \xi)\left[u\left(\gamma^{\prime}, \tau, \xi\right)\right]^{*}=\pi \delta\left(\gamma-\gamma^{\prime}\right) \tag{41}
\end{equation*}
$$

and for $\tau>0$

$$
\begin{equation*}
\xi \int_{0}^{\infty} \gamma d \gamma \frac{\left|\Gamma\left(\frac{1}{2}+i \tau\right)\right|^{2}}{4 \pi} e^{-\pi \tau} u(\gamma, \tau, \xi)\left[u\left(\gamma, \tau, \xi^{\prime}\right)\right]^{*}=\delta\left(\xi-\xi^{\prime}\right) \tag{42}
\end{equation*}
$$

On the other hand, if the functions $u(\gamma, \tau, \xi)$ are regarded as charge Sturmians [7], i. e. the parameter $\tau$ is considered as eigenvalue of the problem, whereas the momentum $\gamma$ remains constant, the corresponding orthogonality and completeness relations are given by [7]

$$
\begin{equation*}
\gamma\left|\Gamma\left(\frac{1}{2}+i \tau\right)\right|^{2} e^{-\pi \tau} \int_{0}^{\infty} d \xi u(\gamma, \tau, \xi)\left[u\left(\gamma, \tau^{\prime}, \xi\right)\right]^{*}=2 \pi \delta\left(\tau-\tau^{\prime}\right) \tag{43}
\end{equation*}
$$

and

$$
\begin{equation*}
\gamma \int_{-\infty}^{\infty} d \tau \frac{\left|\Gamma\left(\frac{1}{2}+i \tau\right)\right|^{2}}{2 \pi} e^{-\pi \tau} u(\gamma, \tau, \xi)\left[u\left(\gamma, \tau, \xi^{\prime}\right)\right]^{*}=\delta\left(\xi-\xi^{\prime}\right) \tag{44}
\end{equation*}
$$

Taking matrix elements of the completeness relation (44) we find

$$
\begin{equation*}
\frac{8 b \gamma \theta^{n-m}}{\sqrt{\left[4 b^{2}+(\gamma+k)^{2}\right]\left[4 b^{2}+(\gamma-k)^{2}\right]}} \int_{-\infty}^{\infty} d \tau \frac{\left|\Gamma\left(\frac{1}{2}+i \tau\right)\right|^{2}}{2 \pi}(-\zeta)^{i \tau} p_{n}(\tau ; \zeta)\left[p_{n}(\tau ; \zeta)\right]^{*}=\delta_{n, m} . \tag{45}
\end{equation*}
$$

It may be noted that (45) is closely related to (32). To see this, let $\gamma>0$. Then, it follows from the definitions (26) that

$$
\begin{equation*}
\frac{(\zeta-1)}{\zeta}(-\zeta)^{\frac{1}{2}}=\frac{8 b \gamma}{\sqrt{\left[4 b^{2}+(\gamma+k)^{2}\right]\left[4 b^{2}+(\gamma-k)^{2}\right]}} \tag{46}
\end{equation*}
$$

Further, the regular solution $\theta^{n} p_{n}(\tau ; \zeta)$ of the three-term recursion relation (28) is an even function of $\gamma$, since the coefficients $a_{n}, b_{n}$ and $d_{n}$ depend on $\gamma$ only through $\mu C=\frac{1}{2}\left(k^{2}-\gamma^{2}\right)$. Thus, replacing $\gamma$ by $-\gamma$, and hence $\tau$ by $-\tau(\theta \rightarrow \lambda$ and $\lambda \rightarrow \theta)$ and $\zeta$ by $\zeta^{-1}$ in Eq. (27) gives

$$
\begin{equation*}
\theta^{n} p_{n}(\tau ; \zeta)=\lambda^{n} \frac{(-1)^{n}}{n!} \frac{\Gamma\left(n+\frac{1}{2}+i \tau\right)}{\Gamma\left(\frac{1}{2}+i \tau\right)}{ }_{2} F_{1}\left(-n, \frac{1}{2}-i \tau ;-n+\frac{1}{2}-i \tau ; \zeta^{-1}\right) \tag{47}
\end{equation*}
$$

Comparing Eqs. (27) and (47) then yields the relation

$$
\begin{equation*}
\theta^{n} p_{n}(\tau ; \zeta)=\lambda^{n}\left[p_{n}(\tau ; \zeta)\right]^{*}, \tag{48}
\end{equation*}
$$

and hence

$$
\begin{equation*}
\left[p_{n}(\tau ; \zeta)\right]^{*}=\zeta^{-n} p_{n}(\tau ; \zeta) \tag{49}
\end{equation*}
$$

From the argument above, we conclude that for $\gamma>0$ the orthogonality relation (32) reduces to (45).

## The two-dimensional completeness relation

It follows from the relations (41) and (43) and analogous relations for $v(\gamma, \tau, \xi)$ that the two-dimensional orthogonality relation for $\gamma>0$ is given by

$$
\begin{array}{r}
e^{-\pi \tau_{0}} \frac{\gamma^{2}}{4} \frac{\left|\Gamma\left(\frac{1}{2}+i \tau\right)\right|^{2}}{2 \pi} \frac{\left|\Gamma\left(\frac{1}{2}+i\left(\tau_{0}-\tau\right)\right)\right|^{2}}{2 \pi} \int_{0}^{\infty} \int_{0}^{\infty}(\xi+\eta) d \xi d \eta\{f(\gamma, \tau, \xi, \eta)  \tag{50}\\
\left.\times\left[f\left(\gamma^{\prime}, \tau^{\prime}, \xi, \eta\right)\right]^{*}\right\}=\delta\left(\gamma-\gamma^{\prime}\right) \delta\left(\tau-\tau^{\prime}\right)
\end{array}
$$

In turn, in the case $t_{0}>0$ (where there are no bound states) it would appear reasonable that the two-dimensional completeness relation would be given by

$$
\begin{align*}
& (\xi+\eta)\left\{\alpha \int_{0}^{\infty} d \gamma \gamma^{2} e^{-\pi \tau_{0}} \int_{-\infty}^{\infty} d \tau \frac{\left|\Gamma\left(\frac{1}{2}+i \tau\right)\right|^{2}}{2 \pi} \frac{\left|\Gamma\left(\frac{1}{2}+i\left(\tau_{0}-\tau\right)\right)\right|^{2}}{2 \pi}\right.  \tag{51}\\
& \left.\times f(\gamma, \tau, \xi, \eta)\left[f\left(\gamma, \tau, \xi^{\prime}, \eta^{\prime}\right)\right]^{*}\right\}=\delta\left(\xi-\xi^{\prime}\right) \delta\left(\eta-\eta^{\prime}\right)
\end{align*}
$$

The integration over $\tau$ in (51) is performed on the assumption that $\tau$ is independent of $\gamma$. To test this hypothesis and determine the normalizing factor $\alpha$, we carried out the following numerical experiments. First with some parameters $t_{0}>0, k>0$ and $b$ we calculate the matrix elements $A_{n_{1}, n_{2} ; m_{1}, m_{2}}$ for the expression in the figure braces on the right-hand side of (51) in the basis (7):

$$
\begin{align*}
& A_{n_{1}, n_{2} ; m_{1}, m_{2}}=\alpha \int_{0}^{\infty} d \gamma \frac{64 b^{2} \gamma^{2}\left(-\zeta \zeta^{i \tau_{0}}\right.}{\left[4 b^{2}+(\gamma+k)^{2}\right]\left[4 b^{2}+(\gamma-k)^{2}\right]} \theta^{n_{1}-m_{1}} \lambda^{m_{2}-n_{2}} \\
& \times \int_{-\infty}^{\infty} d \tau \frac{\left|\Gamma\left(\frac{1}{2}+i \tau\right)\right|^{2}}{2 \pi} \frac{\left|\Gamma\left(\frac{1}{2}+i\left(\tau_{0}-\tau\right)\right)\right|^{2}}{2 \pi} p_{n_{1}}(\tau ; \zeta) p_{n_{2}}\left(\tau_{0}-\tau ; \zeta\right)\left[p_{m_{1}}(\tau ; \zeta) p_{m_{2}}\left(\tau_{0}-\tau ; \zeta\right)\right]^{*} . \tag{52}
\end{align*}
$$

It should be noted that the value of $(-\zeta)^{i \tau_{0}}$ in this formula is determined by the condition $|\arg (-\zeta)|<\pi$. Then the resulting matrix $\mathbf{A}$ is multiplied by the matrix

$$
\begin{equation*}
\mathbf{Q}=\mathbf{Q}_{\xi} \otimes \mathbf{I}_{\eta}+\mathbf{I}_{\xi} \otimes \mathbf{Q}_{\eta} \tag{53}
\end{equation*}
$$

of the operator $(\xi+\eta)$. Finally, using the condition

$$
\begin{equation*}
\mathbf{Q} \mathbf{A}=\mathbf{I}_{\xi} \otimes \mathbf{I}_{\eta} \tag{54}
\end{equation*}
$$

we have obtained that $\alpha=\frac{1}{2}$. Notice that the infinite symmetric matrices $\mathbf{Q}_{\xi}$ and $\mathbf{Q}_{\eta}$ are tridiagonal [4], therefore the equations on the left hand-side of the linear system (54) each contain no more than six terms.

For for $t_{0}<0$ the completeness relation (51) transforms into

$$
\begin{gather*}
(\xi+\eta)\left\{\frac{1}{2} \int_{0}^{\infty} d \gamma \gamma^{2} e^{-\pi \tau_{0}} \int_{-\infty}^{\infty} d \tau \frac{\left|\Gamma\left(\frac{1}{2}+i \tau\right)\right|^{2}}{2 \pi} \frac{\left|\Gamma\left(\frac{1}{2}+i\left(\tau_{0}-\tau\right)\right)\right|^{2}}{2 \pi} f(\gamma, \tau, \xi, \eta)\left[f\left(\gamma, \tau, \xi^{\prime}, \eta^{\prime}\right)\right]^{*}\right.  \tag{55}\\
\left.+\sum_{\ell=1}^{\infty} \frac{\kappa_{\ell}^{3}}{\ell \ell} \sum_{m=0}^{\ell-1} f_{\ell, m, \ell-m-1}(\xi, \eta)\left[f_{\ell, m, \ell-m-1}\left(\xi^{\prime}, \eta^{\prime}\right)\right]^{*}\right\}=\delta\left(\xi-\xi^{\prime}\right) \delta\left(\eta-\eta^{\prime}\right) .
\end{gather*}
$$

In this case the matrix $\mathbf{A}$ with elements

$$
\begin{align*}
& A_{n_{1}, n_{2} ; m_{1}, m_{2}}=\int_{0}^{\infty} d \gamma \frac{32 b^{2} \gamma^{2}(-\zeta)^{i \tau_{0}}}{\left[4 b^{2}+(\gamma+k)^{2}\right]\left[4 b^{2}+(\gamma-k)^{2}\right]} \theta^{n_{1}-m_{1}} \lambda^{m_{2}-n_{2}} \\
& \times \int_{-\infty}^{\infty} d \tau \frac{\left|\Gamma\left(\frac{1}{2}+i \tau\right)\right|^{2}}{2 \pi} \frac{\left|\Gamma\left(\frac{1}{2}+i\left(\tau_{0}-\tau\right)\right)\right|^{2}}{2 \pi} p_{n_{1}}(\tau ; \zeta) p_{n_{2}}\left(\tau_{0}-\tau ; \zeta\right)\left[p_{m_{1}}(\tau ; \zeta) p_{m_{2}}\left(\tau_{0}-\tau ; \zeta\right)\right]^{*}  \tag{56}\\
& \quad+\sum_{\ell=1}^{\infty} \frac{\kappa_{\ell}^{3}}{2 \ell} \sum_{m=0}^{\ell-1} \mathcal{S}_{n_{1}}^{(\ell, m)} \mathcal{S}_{m_{2}}^{(\ell, \ell-m-1)}\left[\mathcal{S}_{n_{2}}^{(\ell, \ell-m-1)} \mathcal{S}_{m_{1}}^{(\ell, m)}\right]^{*},
\end{align*}
$$

is also inverse to the matrix $\mathbf{Q}$ (53). The expression (56) can be rewritten, in view of (46) and (49), as

$$
\begin{align*}
A_{n_{1}, n_{2} ; m_{1}, m_{2}}= & -\frac{1}{2} \int_{0}^{\infty} d \gamma\left\{\left(\frac{\zeta-1}{\zeta}\right)^{2} \frac{\frac{\theta}{}_{n_{1}+m_{2}}^{\lambda^{n_{2}+m_{1}}} \int_{-\infty}^{\infty} d \tau \rho(\tau ; \zeta) \rho\left(\tau_{0}-\tau ; \zeta\right)}{} \times p_{n_{1}}(\tau ; \zeta) p_{n_{2}}\left(\tau_{0}-\tau ; \zeta\right) p_{m_{1}}(\tau ; \zeta) p_{m_{2}}\left(\tau_{0}-\tau ; \zeta\right)\right\} \\
& +\sum_{\ell=1}^{\infty} \frac{\kappa_{\ell}^{3}}{2 \ell} \sum_{m=0}^{\ell-1} \mathcal{S}_{n_{1}}^{(\ell, m)} \mathcal{S}_{m_{2}}^{(\ell, \ell-m-1)}\left[\mathcal{S}_{n 2}^{(\ell, \ell-m-1)} \mathcal{S}_{m_{1}}^{(\ell, m)}\right]^{*} \tag{57}
\end{align*}
$$

## III. CONTOUR INTEGRALS

Notice that expressing the resolvent of the one-dimensional operator $\left[\hat{h}_{\xi}+2 k t+\mu C \xi\right]$ requires two linearly independent solutions of (19). Irregular solutions of (19) are expressed in terms the confluent hypergeometric function [6]

$$
\begin{equation*}
w^{( \pm)}(\gamma, \tau, \xi)=e^{\frac{i}{2}( \pm \gamma-k) \xi} U\left(\frac{1}{2} \pm i \tau, 1 ; \mp \gamma \xi\right) \tag{58}
\end{equation*}
$$

The corresponding solutions of the three-term recursion relation (28) are

$$
\begin{align*}
& c_{n}^{(+)}(t ; \mu C)=\theta^{n+1} q_{n}^{(+)}(\tau ; \zeta), \\
& c_{n}^{(-)}(t ; \mu C)=\lambda^{n+1} q_{n}^{(-)}(\tau ; \zeta), \tag{59}
\end{align*}
$$

where

$$
\begin{align*}
q_{n}^{(+)}(\tau ; \zeta) & =(-)^{n} \frac{n!\Gamma\left(\frac{1}{2}+i \tau\right)}{\Gamma\left(n+\frac{3}{2}+i \tau\right)}{ }_{2} F_{1}\left(\frac{1}{2}+i \tau, n+1 ; n+\frac{3}{2}+i \tau ; \zeta^{-1}\right), \\
q_{n}^{(-)}(\tau ; \zeta) & =(-)^{n} \frac{n!\Gamma\left(\frac{1}{2}-i \tau\right)}{\Gamma\left(n+\frac{3}{2}-i \tau\right)}{ }_{2} F_{1}\left(\frac{1}{2}-i \tau, n+1 ; n+\frac{3}{2}-i \tau ; \zeta\right) . \tag{60}
\end{align*}
$$

In particular, the functions

$$
\begin{array}{r}
\widetilde{w}^{( \pm)}(\gamma, \tau, \xi)=\frac{2 i \sqrt{2 b}}{2 b-i(\gamma-k)}\left(-\frac{2 b+i(\gamma-k)}{2 b-i(\gamma+k)}\right)^{i \tau+\frac{1}{2}}  \tag{61}\\
\times \frac{e^{-\pi \tau}}{\theta \Gamma\left(\frac{1}{2} \pm i \tau\right)} \sum_{n=0}^{\infty} c_{n}^{( \pm)}(t ; \mu C) \psi_{n}(\xi)
\end{array}
$$

tend to $w^{( \pm)}(\gamma, \tau, \xi)$ as $\xi \rightarrow \infty$.
The matrix elements of the resolvent of $\left[\hat{h}_{\xi}+2 k t+\mu C \xi\right]$ can be written in the form [4]

$$
\begin{equation*}
g_{n, m}^{(+)}(t ; \mu C)=\frac{i}{2 \gamma}\left(\frac{\zeta-1}{\zeta}\right) \frac{\theta^{n-m}}{\zeta^{m}} p_{n<}(\tau ; \zeta) q_{n>}^{(+)}(\tau ; \zeta) \tag{62}
\end{equation*}
$$

and

$$
\begin{equation*}
g_{n, m}^{(-)}(t ; \mu C)=\frac{i}{2 \gamma}\left(\frac{\zeta-1}{\zeta}\right) \frac{\theta^{n-m}}{\zeta^{m}} p_{n_{<}}(\tau ; \zeta) \zeta^{n>+1} q_{n>}^{(-)}(\tau ; \zeta) \tag{63}
\end{equation*}
$$

where $n_{>}$and $n_{<}$are the greater and lesser of $n$ and $m$. Notice that $c_{n}^{(+)}\left(c_{n}^{(-)}\right)$are defined in the upper (lower) half of the complex $\gamma$-plane where $|\zeta| \geq 1(|\zeta| \leq 1)$. To analytically continue $c_{n}^{(+)}$onto the lower half of the $\gamma$-plane the relation [4]

$$
\begin{equation*}
c_{n}^{(+)}(t ; \mu C)=c_{n}^{(-)}(t ; \mu C)+2 \pi i \rho(\tau ; \zeta) \theta^{n+1} p_{n}(\tau ; \zeta) \tag{64}
\end{equation*}
$$

can be used.
In [4] we obtained the basis set (7) representation of the resolvent for the two-dimensional operator $\left[\hat{h}_{\xi}+2 k t+\mu C \xi\right]+\left[\hat{h}_{\eta}+2 k\left(t_{0}-t\right)+\mu C \eta\right]$. In particular, the matrix elements of the two-dimensional Green's function can be expressed as the convolution integral

$$
\begin{align*}
G_{n_{1}, n_{2} ; m_{1}, m_{2}}^{( \pm)}\left(t_{0} ; \mu C\right)=i\left(\frac{\zeta-1}{\zeta}\right) \frac{\lambda^{m_{2}-n_{2}}}{\zeta^{m_{2}}} \int_{-\infty}^{\infty} d \tau \rho\left(\tau_{0}-\tau ; \zeta\right)  \tag{65}\\
\times g_{n_{1}, m_{1}}^{( \pm)}(t ; \mu C) p_{n_{2}}\left(\tau_{0}-\tau ; \zeta\right) p_{m_{2}}\left(\tau_{0}-\tau ; \zeta\right) .
\end{align*}
$$

Notice that in this case only the regular solutions of (20) discrete analogues $\lambda^{-n} p_{n}\left(\tau_{0}-\tau ; \zeta\right)$ are used.

Let us consider the integral

$$
\begin{equation*}
\mathcal{I}_{1}=\frac{1}{2 \pi i} \int_{-\infty}^{\infty} \gamma d \gamma G_{n_{1}, n_{2} ; m_{1}, m_{2}}^{(+)}\left(t_{0} ; \mu C\right) \tag{66}
\end{equation*}
$$

Notice that by replacing $\gamma \rightarrow-\gamma$ (and hence $\theta \rightarrow \lambda, \lambda \rightarrow \theta, \zeta \rightarrow 1 / \zeta, \tau \rightarrow-\tau$ and $\left.\tau_{0} \rightarrow-\tau_{0}\right)$ in Eq. (65) $G_{n_{1}, n_{2} ; m_{1}, m_{2}}^{(+)}\left(t_{0} ; \mu C\right)$ is transformed to $G_{n_{1}, n_{2} ; m_{1}, m_{2}}^{(-)}\left(t_{0} ; \mu C\right)$. Thus, for the integral $\mathcal{I}_{1}$ we obtain

$$
\begin{equation*}
\mathcal{I}_{1}=\frac{1}{2 \pi i} \int_{0}^{\infty} \gamma d \gamma\left\{G_{n_{1}, n_{2} ; m_{1}, m_{2}}^{(+)}\left(t_{0} ; \mu C\right)-G_{n_{1}, n_{2} ; m_{1}, m_{2}}^{(-)}\left(t_{0} ; \mu C\right)\right\} \tag{67}
\end{equation*}
$$

Inserting Eqs. (65), (62) and (63) into Eq. (67), we find, in view of (64), that $\mathcal{I}_{1}$ coincides with the integral on the right hand-side of (57).

Now, we consider the integral

$$
\begin{equation*}
\frac{1}{2 \pi i} \int_{\mathcal{C}} d \mathcal{E} \mathbf{G}^{(+)}\left(t_{0} ; \frac{k^{2}}{2}-\mathcal{E}\right) \tag{68}
\end{equation*}
$$

taken along the contour in the complex $\mathcal{E}$-plane shown in Fig. 1. The contour $\mathcal{C}$ passes in a negative direction (clockwise) round all the points $\mathcal{E}^{(\ell)}=-\frac{\kappa_{\varepsilon}^{2}}{2}$ (filled circles in Fig. 1 which accumulate at the origin) and the cut along the right half of the real axis and is closed at
infinity (see e. g. [10]). The corresponding matrix element of the integral along the two sides of the cut is equal to $\mathcal{I}_{1}$ (66) (this is circumstantial evidence that the normalizing factor $\alpha$ in the completeness relation (51) is equal to $\frac{1}{2}$ ). On the other hand, the integration along a contour enclosing $\mathcal{E}^{(\ell)}$ reduces to $(-1)$ times the double sum of the residues of the integrand at the points $\tau^{(m)}=i\left(m+\frac{1}{2}\right), m=0,1, \ldots$ and $\mathcal{E}^{(\ell)}=-\frac{\left(k t_{0}\right)^{2}}{2 \ell^{2}}, \ell=1,2, \ldots$, which are the poles of the gamma functions $\Gamma\left(\frac{1}{2}+i \tau\right)$ and $\Gamma\left(\frac{1}{2}+i\left(\tau_{0}-\tau\right)\right)=\Gamma\left(m+1+\frac{k t_{0}}{\sqrt{-2 \mathcal{E}^{(\ell)}}}\right)$, respectively. It is readily shown that the matrix element of this part of the integral (68) coincides with the double sum in (57). Thus, the integral (68) is equal to the matrix $\mathbf{A}$. The contour $\mathcal{C}$ can be deformed, for instance, into a straight line parallel to the real axis. The resulting path $\mathcal{C}_{1}$ shown in Fig. 2 runs above the cut and the bound-state poles of $\mathbf{G}^{(+)}\left(t_{0} ; \frac{k^{2}}{2}-\mathcal{E}\right)$. Then, to make the integral amenable to numerical integration, rotate $\mathcal{C}_{1}$ about some point $\mathcal{E}_{0}$ on the right half of the real axis through a negative angle $\varphi$ [10]; see the contour $\mathcal{C}_{2}$ in Fig. 2. The part of $\mathcal{C}_{2}$ on the unphysical sheet is depicted by the dashed line. Thus, we obtain the following representation of the matrix $\mathbf{A}$ (which is inverse to the $\operatorname{matrix} \mathbf{Q}$ (531)):

$$
\begin{equation*}
\mathbf{A}=\frac{1}{2 \pi i} \int_{\mathcal{C}_{2}} d \mathcal{E} \mathbf{G}^{(+)}\left(t_{0} ; \frac{k^{2}}{2}-\mathcal{E}\right)=\mathbf{Q}^{-1} \tag{69}
\end{equation*}
$$

## IV. SIX-DIMENSIONAL GREEN'S FUNCTION MATRIX

Using the relation (69) we can rewrite the expression (13) for the six-dimensional Coulomb Green' function matrix as the contour integral

$$
\begin{equation*}
\underline{\mathfrak{G}}=\frac{\aleph}{\mu_{23} \mu_{13}} \int_{\mathcal{C}_{2}} d \mathcal{E}_{1} \int_{\mathcal{C}_{2}} d \mathcal{E}_{2} \mathbf{G}_{1}\left(t_{23} ; \frac{k_{23}^{2}}{2}-\mathcal{E}_{1}\right) \otimes \mathbf{G}_{2}\left(t_{13} ; \frac{k_{13}^{2}}{2}-\mathcal{E}_{2}\right) \otimes \mathbf{G}_{3}\left(t_{12} ; \frac{k_{12}^{2}}{2}-\mathcal{E}_{3}\right) \tag{70}
\end{equation*}
$$

where $\mathcal{E}_{j}=\frac{k_{l s}^{2}}{2}-\mu_{l s} C_{j}$ and $C_{1}+C_{2}+C_{3}=0$. This also allows us to determine the normalizing factor $\aleph$. Indeed, it follows from (69) that the third term inside the figure brackets on the right-hand side of (16) is proportional to the unit matrix:

$$
\begin{gather*}
{\left[\mathbf{Q}_{1} \int_{\mathcal{C}_{2}} d \mathcal{E}_{1} \mathbf{G}_{1}\left(t_{23} ; \frac{k_{23}^{2}}{2}-\mathcal{E}_{1}\right)\right] \otimes\left[\mathbf{Q}_{2} \int_{\mathcal{C}_{2}} d \mathcal{E}_{2} \mathbf{G}_{2}\left(t_{13} ; \frac{k_{13}^{2}}{2}-\mathcal{E}_{2}\right)\right] \otimes \mathbf{I}_{3}}  \tag{71}\\
=(2 \pi i)^{2} \mathbf{I}_{1} \otimes \mathbf{I}_{2} \otimes \mathbf{I}_{3}
\end{gather*}
$$

Consider the first two terms in the figure braces in (16). For the energy $\mathcal{E}_{3}=\frac{k_{12}^{2}}{2}+\mu_{12}\left(C_{1}+C_{2}\right)$ we have

$$
\begin{equation*}
\mathcal{E}_{3}=\frac{k_{12}^{2}}{2}+\frac{\mu_{12}}{\mu_{23}}\left(\frac{k_{23}^{2}}{2}-\mathcal{E}_{1}\right)+\frac{\mu_{12}}{\mu_{13}}\left(\frac{k_{13}^{2}}{2}-\mathcal{E}_{2}\right) . \tag{72}
\end{equation*}
$$

On the other hand, on the contours $\mathcal{C}_{2}$ the energy variables $\mathcal{E}_{j}, j=1,2$ are given by

$$
\begin{equation*}
\mathcal{E}_{j}=\mathcal{E}_{0 j}+E_{j} e^{i \varphi}, \tag{73}
\end{equation*}
$$

where $\varphi<0, \mathcal{E}_{0 j}$ is an arbitrary positive parameter, $E_{j}$ is real and runs from $-\infty$ to $\infty$. Hence, for the energy $\mathcal{E}_{3}(172)$ we obtain

$$
\begin{equation*}
\mathcal{E}_{3}=\left[\frac{k_{12}^{2}}{2}+\frac{\mu_{12}}{\mu_{23}}\left(\frac{k_{23}^{2}}{2}-\mathcal{E}_{01}\right)+\frac{\mu_{12}}{\mu_{13}}\left(\frac{k_{13}^{2}}{2}-\mathcal{E}_{02}\right)\right]+\left(-\frac{\mu_{12}}{\mu_{23}} E_{1}-\frac{\mu_{12}}{\mu_{13}} E_{2}\right) e^{i \varphi} . \tag{74}
\end{equation*}
$$

Thus, $\mathcal{E}_{3}$ can be expressed in the form

$$
\begin{equation*}
\mathcal{E}_{3}=\mathcal{E}_{03}+E_{3} e^{i \varphi} \tag{75}
\end{equation*}
$$

where $\mathcal{E}_{03}$ and $E_{3}$ denote the term in the square braces and the real factor in front of the exponent in (174), respectively. Since $\mathcal{E}_{03}$ should be positive, the positive parameters $\mathcal{E}_{01}$ and $\mathcal{E}_{02}$ have to satisfy the constraint

$$
\begin{equation*}
\frac{\mu_{12}}{\mu_{23}} \mathcal{E}_{01}+\frac{\mu_{12}}{\mu_{13}} \mathcal{E}_{02}<\frac{k_{12}^{2}}{2}+\frac{\mu_{12}}{\mu_{23}} \frac{k_{23}^{2}}{2}+\frac{\mu_{12}}{\mu_{13}} \frac{k_{13}^{2}}{2} \tag{76}
\end{equation*}
$$

Now, we consider the integral

$$
\begin{equation*}
\mathcal{I}_{2}=\int_{\mathcal{C}_{2}} d \mathcal{E}_{1} \mathbf{G}_{3}\left(t_{12} ; \frac{k_{12}^{2}}{2}-\mathcal{E}_{3}\right) \tag{77}
\end{equation*}
$$

With fixed $\mathcal{E}_{2}$, in view (74), (75) and (69), we see that

$$
\begin{gather*}
\mathcal{I}_{2}=e^{i \varphi} \int_{-\infty}^{\infty} d E_{1} \mathbf{G}_{3}\left(t_{12} ; \frac{k_{12}^{2}}{2}-\mathcal{E}_{3}\right)=-\frac{\mu_{23}}{\mu_{12}} e^{i \varphi} \int_{-\infty}^{\infty} d E_{3} \mathbf{G}_{3}\left(t_{12} ; \frac{k_{12}^{2}}{2}-\mathcal{E}_{3}\right)  \tag{78}\\
=-\frac{\mu_{23}}{\mu_{12}} \int_{\mathcal{C}_{2}} d \mathcal{E}_{3} \mathbf{G}_{3}\left(t_{12} ; \frac{k_{12}^{2}}{2}-\mathcal{E}_{3}\right)=-2 \pi i \frac{\mu_{23}}{\mu_{12}} \mathbf{Q}_{3}^{-1} .
\end{gather*}
$$

Similarly, we obtain

$$
\begin{equation*}
\int_{\mathcal{C}_{2}} d \mathcal{E}_{2} \mathbf{G}_{3}\left(t_{12} ; \frac{k_{12}^{2}}{2}-\mathcal{E}_{3}\right)=-2 \pi i \frac{\mu_{13}}{\mu_{12}} \mathbf{Q}_{3}^{-1} \tag{79}
\end{equation*}
$$

Inserting (78), (79) and (71) into (16) then yields

$$
\begin{equation*}
\underline{\mathfrak{h}} \underline{\mathfrak{G}}=\aleph 4 \pi^{2} \mathbf{I}_{1} \otimes \mathbf{I}_{2} \otimes \mathbf{I}_{3} . \tag{80}
\end{equation*}
$$

Thus, from (80) we conclude that

$$
\begin{equation*}
\aleph=\frac{1}{4 \pi^{2}} \tag{81}
\end{equation*}
$$

## V. CONCLUSION

The Sturmian basis-set representation of the resolvent for the asymptotic three-body Coulomb wave operator is obtained, which can be used in the discrete analog of the Lippmann-Schwinger equation for the three-body continuum wave function. The sixdimensional Green's function matrix is expressed as a convolution integral over separation constants. The integrand of this contour integral involves Green's function matrices corresponding to the two-dimensional operators which are constituents of the full six-dimensional wave operator. The completeness relation of the eigenfunctions of these two-dimensional operators is used to define the appropriate pathes of integration of the convolution integral.
