

# Parallel Approximation, and Integer Programming Reformulation

Gábor Pataki and Mustafa Tural \*

Technical Report 2007-07

Department of Statistics and Operations Research, UNC Chapel Hill

## Abstract

We show that in a knapsack feasibility problem an integral vector  $p$ , which is short, and near parallel to the constraint vector gives a branching direction with small integer width.

We use this result to analyze two computationally efficient reformulation techniques on low density knapsack problems. Both reformulations have a constraint matrix with columns reduced in the sense of Lenstra, Lenstra, and Lovász. We prove an upper bound on the integer width along the last variable, which becomes 1, when the density is sufficiently small.

In the proof we extract from the transformation matrices a vector which is near parallel to the constraint vector  $a$ . The near parallel vector is a good branching direction in the original knapsack problem, and this transfers to the last variable in the reformulations.

## 1 Introduction and notation

### Geometry of Numbers and Integer Programming [22]

Starting with the work of H. W. Lenstra [18], algorithms based on the geometry of numbers have been an essential part of the Integer Programming landscape. Typically, these algorithms reduce an IP feasibility problem to a provably small number of smaller dimensional ones, and have strong theoretical properties. For instance, the algorithms of [18, 12, 19] have polynomial running time in fixed dimension; the algorithm of [7] has linear running time in dimension two. One essential tool in creating the subproblems is a “thin” branching direction, i.e. a  $c$  integral (row-)vector with the difference between the maximum and the minimum of  $cx$  over the underlying polyhedron being provably small. Basis reduction in lattices – in the Lenstra, Lenstra, Lovász (LLL) [17], or Korkine and Zolotarev (KZ) [13, 12] sense – is usually a key ingredient in the search for a thin direction. For implementations, and computational results, we refer to [4, 10, 21].

A simple, and experimentally very successful technique for integer programming based on LLL-reduction was proposed by Aardal, Hurkens and A. K. Lenstra in [2] for equality constrained IP problems; see also [1]. Consider the problem

$$\begin{aligned} Ax &= b \\ 0 &\leq x \leq v \\ x &\in \mathbb{Z}^n, \end{aligned} \tag{IP-EQ}$$

where  $A$  is an integral matrix with  $m$  independent rows, and let

$$\mathbb{N}(A) = \{x \in \mathbb{Z}^n \mid Ax = 0\}. \tag{1.1}$$

The full-dimensional reformulation proposed in [2] is

$$\begin{aligned} -x_b &\leq V\lambda \leq v - x_b \\ \lambda &\in \mathbb{Z}^{n-m}. \end{aligned} \tag{IP-EQ-N}$$

Here  $V$  and  $x_b$  satisfy

$$\{V\lambda \mid \lambda \in \mathbb{Z}^{n-m}\} = \mathbb{N}(A), \quad x_b \in \mathbb{Z}^n, \quad Ax_b = b,$$

the columns of  $V$  are reduced in the LLL-sense, and  $x_b$  is also short. For several classes of hard equality constrained integer programming problems – e.g. [5] – the reformulation turned out to be much easier to solve by commercial solvers than the original problem.

In [14] an experimentally just as effective reformulation method was introduced, which leaves the number of the variables the same, and is applicable to inequality or equality constrained problems as well. It replaces

$$\begin{aligned} Ax &\leq b \\ x &\in \mathbb{Z}^n \end{aligned} \tag{IP}$$

with

$$\begin{aligned} (AU)y &\leq b \\ y &\in \mathbb{Z}^n, \end{aligned} \tag{IP-R}$$

where  $U$  is a unimodular matrix that makes the columns of  $AU$  reduced in the LLL-, or KZ-sense. It applies the same way, even if some of the inequalities in the IP feasibility problem are actually equalities. Also, if the constraints are of the form  $b' \leq Ax \leq b$  in (IP), the reformulation is just  $b' \leq (AU)y \leq b$ , so we do not bring the system into a standard form. In [14] the authors also introduced a simplified method to compute a reformulation which is essentially equivalent to (IP-EQ-N).

We call (IP-R) the *rangespace reformulation* of (IP); and (IP-EQ-N) the *nullspace reformulation* of (IP-EQ).

These reformulation methods are very easy to describe (as opposed to say H. W. Lenstra's method), but seem difficult to analyze. The only analyses are for knapsack problems, with the weight vector having a given "decomposable" structure, i.e.

$$a = \lambda p + r \tag{1.2}$$

with  $p, r$ , and  $\lambda$  integral, and  $\lambda$  large with respect to  $\|p\|$ , and  $\|r\|$ , see [3, 14].

The results in these papers are a first step towards a general analysis. However, besides assuming the decomposable structure a priori, they only prove an upper bound on the width in the reformulations along the last variable.

The goal of this paper is to prove such width results on the knapsack feasibility problem

$$\begin{aligned} \beta_1 &\leq ax \leq \beta_2 \\ 0 &\leq x \leq v \\ x &\in \mathbb{Z}^n, \end{aligned} \tag{KP}$$

where  $a$  is a positive, integral row vector,  $\beta_1$ , and  $\beta_2$  are integers without assuming any structure on  $a$ . We will assume that  $a$  has low density. The density of a set of weights  $a = (a_1, \dots, a_n)$  is

$$d(a) = \frac{n}{\log_2 \|a\|_\infty}. \tag{1.3}$$

Subset sum problems (when  $\beta_1 = \beta_2 = \beta$ , and  $v$  is the vector of all ones) with the weight vector having low density have been extensively studied. The seminal paper of Lagarias and Odlyzko [16] proves that the solution of all but at most a fraction of  $1/2^n$  subset sum problems, which have a

solution, and have density less than  $c/n$  can be found in polynomial time, where  $c \approx 4.8$ . Clearly  $d(a) < c/n$  is equivalent to  $2^{n^2/c} < \|a\|_\infty$ .

Let

$$G_n(M) = \{a \in \mathbb{Z}^n \mid a_i \in \{1, \dots, M\}\}. \quad (1.4)$$

Furst and Kannan in [9] showed that for some  $c > 0$  constant, if  $M \geq 2^{cn \log n}$ , then for almost all  $a \in G_n(M)$  and all  $\beta$  the problem (KP) has a polynomial size proof of feasibility or infeasibility. Their second result shows that for some  $d > 0$  constant, if  $M \geq 2^{dn^2}$ , then for almost all  $a \in G_n(M)$  and all  $\beta$  the problem (KP) can be *solved* in polynomial time. Their proof works by constructing a candidate solution to (KP), and showing that for almost all  $a \in G_n(M)$ , if there is a feasible solution, then it is unique, and the candidate solution must be it.

If we assume the availability of a *lattice oracle*, which finds the shortest vector in a lattice, then the result of [16] can be strengthened to only requiring the density to be less than 0.6463. The current best result on finding the solution of almost all (solvable) subset sum problems using a lattice oracle is by Coster et al [6]: they require only  $d(a) < 0.9408$ .

The rangespace reformulation of (KP) is

$$\begin{aligned} \beta_1 &\leq aUy \leq \beta_2 \\ 0 &\leq Uy \leq v \\ y &\in \mathbb{Z}^n, \end{aligned} \quad (\text{KP-R})$$

where  $U$  is a unimodular matrix that makes the columns of  $\begin{pmatrix} a \\ I \end{pmatrix} U$  reduced in the LLL-sense (we do not analyze it with KZ-reduction). The nullspace reformulation is

$$\begin{aligned} -x_\beta &\leq V\lambda \leq v - x_\beta \\ \lambda &\in \mathbb{Z}^{n-m}, \end{aligned} \quad (\text{KP-N})$$

where  $x_\beta \in \mathbb{Z}^n$ ,  $ax_\beta = \beta$ ,  $\{V\lambda \mid \lambda \in \mathbb{Z}^{n-m}\} = \mathbb{N}(a)$ , and the columns of  $V$  are reduced in the LLL-sense.

We will assume  $\|a\| \geq 2^{(n/2+1)n}$ , which is satisfied, when  $d(a) < 2/(n+2)$ . We will not assume any a priori structure on  $a$ . In fact, a key point will be that a decomposable structure is automatically “discovered” by the reformulations. Precisely, we will prove that in both reformulations a decomposition  $a = \lambda p + r$  can be found from the transformation matrices, now with only  $p$  integral, and that branching on the last variable in the reformulations will be equivalent to branching on  $px$  in the original problem.

There are crucial differences between the results that *assume* a decomposable structure, and the results of this paper. For instance, in [14] one needs to assume

$$\lambda \geq 2^{(n-1)/2} \|p\| (\|r\| + 1)^2, \quad (1.5)$$

$$\lambda \geq 2^{(n-1)/2} \|p\|^2 \|r\|^2, \quad (1.6)$$

for the analysis of the rangespace- and nullspace reformulations, respectively. A decomposition with any of these properties is unlikely to exist no matter how large  $\|a\|$  is, so we cannot plug the decomposition result of this paper into the argument used in [14]. We will prove a weaker lower bound on  $\lambda$ , and an upper bound on  $\|r\|/\lambda$  in Theorems 3, and 4, and we will use these bounds in Theorem 5 quite differently from how it is done in [14].

**Notation** Vectors are column vectors, unless said otherwise. The  $i$ th unit row-vector is  $e_i$ . In general, when writing  $p_1, p_2$ , etc, we refer to vectors in a family of vectors. When  $p_i$  refers to the  $i$ th component of vector  $p$ , we will say this explicitly. For a rational vector  $b$  we denote by  $\text{round}(b)$  the vector obtained by rounding the components of  $b$ .

We will assume  $0 \leq \beta_1 \leq \beta_2 \leq av$ , and that the gcd of the components of  $a$  is 1.

For a polyhedron  $Q$ , and an integral row-vector  $c$ , the width, and the integer width of  $Q$  along  $c$  are

$$\begin{aligned} \text{width}(c, Q) &= \max \{ cx \mid x \in Q \} - \min \{ cx \mid x \in Q \}, \text{ and} \\ \text{iwidth}(c, Q) &= \lceil \max \{ cx \mid x \in Q \} \rceil - \lfloor \min \{ cx \mid x \in Q \} \rfloor + 1. \end{aligned}$$

The integer width is the number of nodes generated by branch-and-bound when branching on the hyperplane  $cx$ ; in particular,  $\text{iwidth}(e_i, Q)$  is the number of nodes generated when branching on  $x_i$ . If the integer width along any integral vector is zero, then  $Q$  has no integral points. Given an integer program labeled by (P), and  $c$  an integral vector, we also write  $\text{width}(c, (P))$ , and  $\text{iwidth}(c, (P))$  for the width, and the integer width of the LP-relaxation of (P) along  $c$ , respectively.

A lattice in  $\mathbb{R}^n$  is a set of the form

$$L = \mathbb{L}(B) = \{ Bx \mid x \in \mathbb{Z}^n \}, \quad (1.7)$$

where  $B$  is a real matrix with  $n$  independent columns, called a *basis* of  $L$ . A square, integral matrix  $U$  is *unimodular* if  $\det U = \pm 1$ . It is well known that if  $B_1$  and  $B_2$  are bases of the same lattice, then  $B_2 = B_1 U$  for some unimodular  $U$ . The determinant of  $L$  is

$$\det L = (\det B^T B)^{1/2}, \quad (1.8)$$

where  $B$  is a basis of  $L$ ; it is easy to see that  $\det L$  is well-defined.

The LLL basis reduction algorithm [17] computes a reduced basis of a lattice in which the columns are “short” and “nearly” orthogonal. It runs in polynomial time for rational lattices. For simplicity, we use Schrijver’s definition from [23]. Suppose that  $B$  has  $n$  independent columns, i.e.

$$B = [b_1, \dots, b_n], \quad (1.9)$$

and  $b_1^*, \dots, b_n^*$  form the Gram-Schmidt orthogonalization of  $b_1, \dots, b_n$ , that is  $b_1 = b_1^*$ , and

$$b_i = b_i^* + \sum_{j=1}^{i-1} \mu_{ij} b_j^* \text{ with } \mu_{ij} = b_i^T b_j^* / \|b_j^*\|^2 \quad (i = 2, \dots, n; j \leq i - 1). \quad (1.10)$$

We call  $b_1, \dots, b_n$  an *LLL-reduced basis* of  $\mathbb{L}(B)$ , if

$$|\mu_{ij}| \leq 1/2 \quad (i = 2, \dots, n; j = 1, \dots, i-1), \text{ and} \quad (1.11)$$

$$\|b_i^*\|^2 \leq 2 \|b_{i+1}^*\|^2 \quad (i = 1, \dots, n-1). \quad (1.12)$$

For an integral lattice  $L$ , its *orthogonal lattice* is defined as

$$L^\perp = \{y \in \mathbb{Z}^n \mid y^T x = 0 \forall x \in L\},$$

and it holds that (see e.g. [20])

$$\det L^\perp \leq \det L. \quad (1.13)$$

Suppose  $A$  is an integral matrix with independent rows. Then recalling (1.1),  $\mathbb{N}(A)$  is the same as  $\mathbb{L}(A^T)^\perp$ . A lattice  $L \subseteq \mathbb{Z}^n$  is called *complete*, if

$$L = \text{lin } L \cap \mathbb{Z}^n.$$

The following lemma summarizes some basic results in lattice theory that we will use later on; for a proof, see for instance [20].

**Lemma 1.** *Let  $V$  be an integral matrix with  $n$  rows, and  $k$  independent columns, and  $L = \mathbb{L}(V)$ . Then (1) through (3) below are equivalent.*

- (1)  $L$  is complete;
- (2)  $\det L^\perp = \det L$ ;
- (3) There is a unimodular matrix  $Z$  s.t.

$$ZV = \begin{pmatrix} I_k \\ 0_{(n-k) \times k} \end{pmatrix}.$$

Furthermore, if  $Z$  is as in part (3), then the last  $n - k$  rows of  $Z$  are a basis of  $L^\perp$ .

□

For an  $n$ -vector  $a$ , we will write

$$\begin{aligned} f(a) &= 2^{n/4} / \|a\|^{1/n} \\ g(a) &= 2^{(n-2)/4} / \|a\|^{1/(n-1)}. \end{aligned} \quad (1.14)$$

## 2 Main results

In this section we will review the main results of the paper, give some examples, explanations, and some proofs that show their connection. The bulk of the work is the proof of Theorems 3, 4, and 5, which is done in Section 3.

The main purpose of this paper is an analysis of the reformulation methods. This is done in Theorem 1, which proves an upper bound on the number of branch-and-bound nodes, when branching on the last variable in the reformulations. However, some of the intermediate results may be of interest on their own right.

We will rely on Theorem 2, proven in the companion paper [22], which gives a bound on the determinant of a sublattice in an LLL-reduced basis, thus generalizing the well-known result from [17] showing that the first vector in such a basis is short.

Theorems 3 and 4 show that an integral vector  $p$ , which is “near parallel” to  $a$  can be extracted from the transformation matrices of the reformulations. The notion of near parallelness that we use is stronger than just requiring  $|\sin(a, p)|$  to be small, and the relationship of the two parallelness concepts is clarified in Proposition 1. A method to find a near parallel vector using simultaneous diophantine approximation was described by Frank and Tardos in [8]. Their goal was quite different from ours, and a near parallel vector derived via diophantine approximation is not suitable for the analysis of the reformulation methods. For completeness, we will give an overview of their method in subsection 4.1.

Theorem 5 proves an upper bound on  $\text{iwidth}(p, (\text{KP}))$ , where  $p$  is an integral vector. A novelty of the bound is that it does not depend on  $\beta_1$ , and  $\beta_2$ , only on their difference. We show through examples that this bound is quite useful when  $p$  is a near parallel vector found according to Theorems 3 and 4.

In the end, a transference result between branching directions in the original, and reformulated problems completes the proof of Theorem 1.

**Theorem 1.** *Suppose  $\|a\| \geq 2^{(n/2+1)n}$ . Then*

$$(1) \text{ iwidth}(e_n, (\text{KP-R})) \leq \lfloor f(a)(2\|v\| + (\beta_2 - \beta_1)) \rfloor + 1.$$

$$(2) \text{ iwidth}(e_{n-1}, (\text{KP-N})) \leq \lfloor 2g(a)\|v\| \rfloor + 1.$$

□

The integer width, and the width differ by at most one, and are frequently used interchangeably in integer programming algorithms. For instance, the algorithms of [18, 19] find a branching direction in which the width is bounded by an exponential function of the dimension. The goal is proving polynomial running time in fixed dimension, and this would still be achieved if the width were larger by a constant.

In contrast, when  $\|a\|$  is sufficiently large, Theorem 1 implies that the integer width is at most *one* in both reformulations.

The following was proven in [22]:

**Theorem 2.** *Suppose that  $b_1, \dots, b_n$  form an LLL-reduced basis of the lattice  $L$ , and denote by  $L_\ell$  the lattice generated by  $b_1, \dots, b_\ell$ . Then*

$$\det L_\ell \leq 2^{\ell(n-\ell)/4} (\det L)^{\ell/n}. \quad (2.15)$$

Theorem 2 is a natural generalization of  $\|b_1\| \leq 2^{(n-1)/4} (\det L)^{1/n}$  (see [17]).

Given  $a$  and  $p$  integral vectors, we will need the notion of their near parallelness. The obvious thing would be to require that  $|\sin(a, p)|$  is small. Instead, we will write a decomposition

$$a = \lambda p + r, \text{ with } \lambda \in \mathbb{Q}, r \in \mathbb{Q}^n, r \perp p, \quad (\text{DECOMP})$$

and ask for  $\|r\|/\lambda$  to be small. The following proposition clarifies the connection of the two near parallelness concepts, and shows two useful consequences of the latter one.

**Proposition 1.** *Suppose that  $a, p \in \mathbb{Z}^n$ , and  $r$  and  $\lambda$  are defined to satisfy (3.27). Assume w.l.o.g.  $\lambda > 0$ . Then*

- (1)  $\sin(a, p) \leq \|r\|/\lambda$ .
- (2) For any  $M$  there is  $a, p$  with  $\|a\| \geq M$  such that the inequality in (1) is strict.
- (3) Denote by  $p_i$  and  $a_i$  the  $i$ th component of  $p$ , and  $a$ . If  $\|r\|/\lambda < 1$ , and  $p_i \neq 0$ , then the signs of  $p_i$  and  $a_i$  agree. Also, if  $\|r\|/\lambda < 1/2$ , then  $\lfloor a_i/\lambda \rfloor = p_i$ .

**Proof** Statement (1) follows from

$$\sin(a, p) = \|r\|/\|a\| \leq \|r\|/\|\lambda p\| \leq \|r\|/\lambda, \quad (2.16)$$

where in the last inequality we used the integrality of  $p$ .

To see (2), one can choose  $a$  and  $p$  to be near orthogonal, to make  $\|r\|/\lambda$  arbitrarily large, while  $\sin(a, p)$  will always be bounded by 1. A more interesting example is from considering the family of  $a$ , and  $p$  vectors

$$\begin{aligned} a &= \begin{pmatrix} m^2 + 1, & m^2 \end{pmatrix}, \\ p &= \begin{pmatrix} m + 1, & m \end{pmatrix} \end{aligned} \quad (2.17)$$

with  $m$  an integer. Letting  $\lambda$  and  $r$  be defined as in the statement of the proposition, a straightforward computation (or experimentation) shows that as  $m \rightarrow \infty$

$$\begin{aligned} \sin(a, p) &\rightarrow 0, \\ \|r\|/\lambda &\rightarrow 1/\sqrt{2}. \end{aligned}$$

Statement (3) is straightforward from

$$a_i/\lambda = p_i + r_i/\lambda. \quad (2.18)$$

□

The next two theorems show how the near parallel vectors can be found from the transformation matrices of the reformulations.

**Theorem 3.** *Suppose  $\|a\| \geq 2^{(n/2+1)n}$ . Let  $U$  be a unimodular matrix such that the columns of*

$$\begin{pmatrix} a \\ I \end{pmatrix} U$$

*are LLL-reduced, and  $p$  the last row of  $U^{-1}$ . Define  $r$  and  $\lambda$  to satisfy (3.27), and assume w.l.o.g.  $\lambda > 0$ .*

*Then*

- (1)  $\|p\| (1 + \|r\|^2)^{1/2} \leq \|a\| f(a)$ ;
- (2)  $\lambda \geq 1/f(a)$ ;
- (3)  $\|r\| / \lambda \leq 2f(a)$ .

□

**Theorem 4.** *Suppose  $\|a\| \geq 2^{(n/2+1)n}$ . Let  $V$  be a matrix whose columns are an LLL-reduced basis of  $\mathbb{N}(a)$ ,  $b$  an integral column vector with  $ab = 1$ , and  $p$  the  $(n - 1)$ st row of  $(V, b)^{-1}$ . Define  $r$  and  $\lambda$  to satisfy (3.27), and assume w.l.o.g.  $\lambda > 0$ .*

*Then  $r \neq 0$ , and*

- (1)  $\|p\| \|r\| \leq \|a\| g(a)$ ;
- (2)  $\|r\| / \lambda \leq 2g(a)$ .

□

It is important to note that  $p$  is integral, but  $\lambda$  and  $r$  may not be. Also, the measure of parallelness to  $a$ , i.e. the upper bound on  $\|r\| / \lambda$  is quite similar for the  $p$  vectors found in Theorems 3 and 4, but their length can be quite different. When  $\|a\|$  is large, the  $p$  vector in Theorem 3 is guaranteed to be much shorter than  $a$  by  $\lambda \geq 1/f(a)$ . On the other hand, the  $p$  vector from Theorem 4 may be much *longer* than  $a$ : the upper bound on  $\|p\| \|r\|$  does not guarantee any bound on  $\|p\|$ , since  $r$  can be fractional.

The following example illustrates this:

**Example 1.** Consider the vector

$$a = (3488, 451, 1231, 6415, 2191). \quad (2.19)$$

We computed  $p_1, r_1, \lambda_1$  according to Theorem 3:

$$\begin{aligned} p_1 &= (62, 8, 22, 114, 39), \\ r_1 &= (0.2582, 0.9688, -6.5858, 2.0554, -2.9021), \\ \lambda_1 &= 56.2539, \\ \|r_1\|/\lambda_1 &= 0.1342. \end{aligned} \quad (2.20)$$

We also computed  $p_2, r_2, \lambda_2$  according to Theorem 4; note  $\|p_2\| > \|a\|$ :

$$\begin{aligned} p_2 &= (12204, 1578, 4307, 22445, 7666) \\ r_2 &= (-0.0165, -0.0071, 0.0194, 0.0105, -0.0140) \\ \lambda_2 &= 0.2858 \\ \|r_2\|/\lambda_2 &= 0.1110. \end{aligned} \quad (2.21)$$

□

Theorem 5 below gives an upper bound on the number of branch-and-bound nodes when branching on a hyperplane in (KP).

**Theorem 5.** Suppose that  $a = \lambda p + r$ , with  $p \geq 0$ . Then

$$\text{width}(p, (KP)) \leq \left\lfloor \frac{\|r\| \|v\|}{\lambda} + \frac{\beta_2 - \beta_1}{\lambda} \right\rfloor + 1. \quad (2.22)$$

This bound is quite strong for near parallel vectors computed from Theorems 3 and 4. For instance, let  $a, p_1, r_1, \lambda_1$  be as in Example 1. If  $\beta_1 = \beta_2$  in a knapsack problem with weight vector  $a$ , and each  $x_i$  is bounded between 0 and 11, then Theorem 5 implies that the integer width is at most one. At the other extreme, it also implies that the integer width is at most one, if each  $x_i$  is bounded between 0 and 1, and  $\beta_2 - \beta_1 \leq 39$ . However, this bound does not seem as useful, when  $p$  is a “simple” vector, say a unit vector.

We now complete the proof of Theorem 1, based on a simple transference result between branching directions, taken from [14].

### Proof of Theorem 1

Let us denote by  $Q, \tilde{Q}$ , and  $\hat{Q}$  the feasible sets of the LP-relaxations of (KP), of (KP-R), and of (KP-N), respectively.

First, let  $U$ , and  $p$  be the transformation matrix, and the near parallel vector from Theorem 3. It was shown in [14] that  $\text{iwidth}(p, Q) = \text{iwidth}(pU, \tilde{Q})$ . But  $pU = \pm e_n$ , so

$$\text{iwidth}(p, Q) = \text{iwidth}(e_n, \tilde{Q}). \quad (2.23)$$

On the other hand,

$$\begin{aligned} \text{iwidth}(p, Q) &\leq \left\lfloor \frac{\|r\| \|v\|}{\lambda} + \frac{\beta_2 - \beta_1}{\lambda} \right\rfloor + 1 \\ &\leq \lfloor f(a)(2 \|v\| + (\beta_2 - \beta_1)) \rfloor + 1 \end{aligned} \quad (2.24)$$

with the first inequality coming from Theorem 5, and the second from using the bounds on  $1/\lambda$  and  $\|r\|/\lambda$  from Theorem 3. Combining (2.23) and (2.24) yields (1) in Theorem 1.

Now let  $V$ , and  $p$  be the transformation matrix, and the near parallel vector from Theorem 4. It was shown in [14] that  $\text{iwidth}(p, Q) = \text{iwidth}(pV, \hat{Q})$ . But  $pV = \pm e_{n-1}$ , so

$$\text{iwidth}(e_{n-1}, \hat{Q}) = \text{iwidth}(p, Q). \quad (2.25)$$

On the other hand,

$$\begin{aligned} \text{iwidth}(p, Q) &\leq \left\lfloor \frac{\|r\| \|v\|}{\lambda} \right\rfloor + 1 \\ &\leq \lfloor g(a)(2 \|v\|) \rfloor + 1. \end{aligned} \quad (2.26)$$

with the first inequality coming from Theorem 5, and the second from using the bound on  $\|r\|/\lambda$  in Theorem 4. Combining (2.25) and (2.26) yields (2) in Theorem 1.

### 3 Proofs

#### 3.1 Near parallel vectors: intuition, and proofs for Theorems 3 and 4

**Intuition for Theorem 3** We review a proof from [14], which applies when we know *a priori* the existence of a decomposition

$$a = p\lambda + r, \quad (3.27)$$

with  $\lambda$  large with respect to  $\|p\|$ , and  $\|r\|$ . The reason that the columns of

$$\begin{pmatrix} a \\ I \end{pmatrix} = \begin{pmatrix} \lambda p + r \\ I \end{pmatrix}$$

are *not* short and orthogonal is the presence of the  $\lambda_i p_i$  components in the first row. So if postmultiplying by a unimodular  $U$  results in reducedness, it is natural to expect that many components of  $pU$  will be zero; indeed it follows from the properties of LLL-reduction, that the first  $n-1$  components *will* be zero. Since  $U$  has full rank, the  $n$ th component of  $pU$  must be nonzero. So  $p$  will be the a multiple of the last row of  $U^{-1}$ , in other words, the last row of  $U^{-1}$  will be near

parallel to  $a$ . (In [14] it was assumed that  $p$ ,  $r$ , and  $\lambda$  are integral, but the proof would work even if  $\lambda$  and  $r$  were rational. )

It is then natural to expect that the last row of  $U^{-1}$  will give a near parallel vector to  $a$ , even if a decomposition like (3.27) is not known in advance. This is indeed what we show in Theorem 3, when  $\|a\|$  is sufficiently large.

**Proof of Theorem 3** First note that the lower bound on  $\|a\|$  implies

$$f(a) \leq \sqrt{3}/2. \quad (3.28)$$

Let  $L_\ell$  be the lattice generated by the first  $\ell$  columns of  $\begin{pmatrix} a \\ I \end{pmatrix} U$ , and

$$Z = \begin{pmatrix} 0 & U^{-1} \\ 1 & -a \end{pmatrix}.$$

Clearly,  $Z$  is unimodular, and

$$Z \begin{pmatrix} aU \\ U \end{pmatrix} = \begin{pmatrix} I_n \\ 0_{1 \times n} \end{pmatrix}. \quad (3.29)$$

So Lemma 1 implies that  $L_\ell$  is complete, and the last  $n+1-\ell$  rows of  $Z$  generate  $L_\ell^\perp$ . The last row of  $Z$  is  $(1, -a)$ , and the next-to-last is  $(0, p)$ , so we get

$$\begin{aligned} \det L_n &= \det L_n^\perp = (\|a\|^2 + 1)^{1/2}, \\ \det L_{n-1} &= \det L_{n-1}^\perp = \|p\| (1 + \|r\|^2)^{1/2}. \end{aligned} \quad (3.30)$$

Theorem 2 implies

$$\det L_{n-1} \leq 2^{(n-1)/4} (\det L_n)^{1-1/n}. \quad (3.31)$$

Substituting into (3.31) from (3.30) gives

$$\begin{aligned} \|p\| (1 + \|r\|^2)^{1/2} &\leq 2^{(n-1)/4} (\sqrt{\|a\|^2 + 1})^{1-1/n} \\ &\leq 2^{n/4} \|a\|^{1-1/n} \\ &= \|a\| f(a), \end{aligned} \quad (3.32)$$

with the second inequality coming from the lower bound on  $\|a\|$ . This shows (1).

**Proof of (2)** From (1) we directly obtain

$$\begin{aligned} \frac{f(a)^2 \|a\|^2 - \|r\|^2}{\|p\|^2} &\geq \frac{f(a)^2 \|a\|^2 - \|p\|^2 \|r\|^2}{\|p\|^2} \\ &\geq 1 \\ &= \frac{f(a)^2 \|a\|^2}{f(a)^2 \|a\|^2}, \end{aligned} \quad (3.33)$$

where in the first inequality we used  $\|p\| \geq 1$ . Now note

$$\|p\|^2 \leq f(a)^2 \|a\|^2,$$

i.e. the denominator of the first expression in (3.33) is not larger than the denominator of the last expression. So if we replace  $f(a)^2$  by 1 in the *numerator* of both, the inequality will remain valid. The result is

$$\frac{\|a\|^2 - \|r\|^2}{\|p\|^2} \geq \frac{1}{f(a)^2}, \quad (3.34)$$

which is the square of the required inequality.

**Proof of (3)** We have

$$\begin{aligned} \frac{\|r\|^2}{\lambda^2} &\leq \frac{\|p\|^2 \|r\|^2}{\|\lambda p\|^2} \\ &\leq \frac{\|p\|^2 \|r\|^2}{\|a\|^2 - \|r\|^2} \\ &\leq \frac{f(a)^2 \|a\|^2}{\|a\|^2 - \|r\|^2} \\ &\leq \frac{f(a)^2 \|a\|^2}{\|a\|^2 - f(a)^2 \|a\|^2} \\ &= \frac{f(a)^2}{1 - f(a)^2} \\ &\leq 4f(a)^2, \end{aligned} \quad (3.35)$$

where the first inequality comes from Proposition 1, the last from (3.28), and the others are straightforward. □

**Intuition for Theorem 4** We recall a proof from [14], which applies when we know *a priori* the existence of a decomposition like in (3.27) with  $\lambda$  large with respect to  $\|p\|$ , and  $\|r\|$ , and  $p$  not a multiple of  $r$ . It is shown there that the first  $n - 2$  components of  $pV$  will be zero. Denote by  $L_\ell$  the lattice generated by the first  $\ell$  columns of  $V$ . So  $p$  is in  $L_{n-2}^\perp$ , and it is not a multiple of  $a$ , but it is near parallel to it.

So one can expect that an element of  $L_{n-2}^\perp$  which is distinct from  $a$  will be near parallel to  $a$ , even if a decomposition like (3.27) is not known in advance. The  $p$  described in Theorem 4 will be such a vector.

**Proof of Theorem 4** The lower bound on  $\|a\|$  implies

$$g(a) \leq \sqrt{3}/2. \quad (3.36)$$

As noted above, let  $L_\ell$  be the lattice generated by the first  $\ell$  columns of  $V$ . We have

$$(V, b)^{-1}V = \begin{pmatrix} I_{n-1} \\ 0 \end{pmatrix}. \quad (3.37)$$

So Lemma 1 implies that  $L_\ell$  is complete, and the last  $n - \ell$  rows of  $(V, b)^{-1}$  generate  $L_\ell^\perp$ . It is elementary to see that the last row of  $(V, b)^{-1}$  is  $a$ , and by definition the next-to-last row is  $p$ , and these rows are independent, so  $r \neq 0$ . Also,

$$\begin{aligned}\det L_{n-1} &= \det L_{n-1}^\perp = \|a\|, \\ \det L_{n-2} &= \det L_{n-2}^\perp = \|p\| \|r\|.\end{aligned}\tag{3.38}$$

Theorem 2 with  $n - 1$  in place of  $n$ , and  $n - 2$  in place of  $\ell$  implies

$$\det L_{n-2} \leq 2^{(n-2)/4} (\det L_{n-1})^{1-1/(n-1)}.\tag{3.39}$$

Substituting into (3.39) from (3.38) gives

$$\begin{aligned}\|p\| \|r\| &\leq 2^{(n-2)/4} \|a\|^{1-1/(n-1)} \\ &= \|a\| g(a),\end{aligned}\tag{3.40}$$

as required.

**Proof of (2)** It is enough to note that in proof of (3) in Theorem 3 we only used the inequality  $\|p\|^2 \|r\|^2 \leq f(a)^2 \|a\|^2$ . So the exact same argument works here as well with  $g(a)$  instead of  $f(a)$ , and invoking (3.36) as well.

□

### 3.2 Branching on a near parallel vector: proof of Theorem 5

This proof is somewhat technical, so we state, and prove some intermediate claims, to improve readability. Let us fix  $a$ ,  $p$ ,  $\beta_1$ ,  $\beta_2$ , and  $v$ . For a row-vector  $w$ , and an integer  $\ell$  we write

$$\begin{aligned}\max(w, \ell) &= \max \{ wx \mid px \leq \ell, 0 \leq x \leq v \} \\ \min(w, \ell) &= \min \{ wx \mid px \geq \ell, 0 \leq x \leq v \}.\end{aligned}\tag{3.41}$$

The dependence on  $p$ , on  $v$ , and on the sense of the constraint (i.e.  $\leq$ , or  $\geq$ ) is not shown by this notation; however, we always use  $px \leq \ell$  with “max”, and  $px \geq \ell$  with “min”, and  $p$  and  $v$  are fixed. Note that as  $a$  is a row-vector, and  $v$  a column-vector,  $av$  is their inner product, and the meaning of  $pv$  is similar.

**Claim 1.** *Suppose that  $\ell_1$  and  $\ell_2$  are integers in  $\{0, \dots, pv\}$ . Then*

$$\min(a, \ell_2) - \max(a, \ell_1) \geq -\|r\| \|v\| + \lambda(\ell_2 - \ell_1).\tag{3.42}$$

**Proof** The decomposition of  $a$  shows

$$\begin{aligned}\max(a, \ell_1) &\leq \max(r, \ell_1) + \lambda \ell_1, \text{ and} \\ \min(a, \ell_2) &\geq \min(r, \ell_2) + \lambda \ell_2.\end{aligned}\tag{3.43}$$

So we get the following chain of inequalities, with ensuing explanation:

$$\begin{aligned}
\min(a, \ell_2) - \max(a, \ell_1) &\geq \min(r, \ell_2) - \max(r, \ell_1) + \lambda(\ell_2 - \ell_1) \\
&\geq rx_2 - rx_1 + \lambda(\ell_2 - \ell_1) \\
&= r(x_2 - x_1) + \lambda(\ell_2 - \ell_1) \\
&\geq -\|r\| \|v\| + \lambda(\ell_2 - \ell_1).
\end{aligned} \tag{3.44}$$

Here  $x_2$  and  $x_1$  are the solutions that attain the maximum, and the minimum in  $\min(r, \ell_2)$  and  $\max(r, \ell_1)$ , respectively. The last inequality follows from the fact that the  $i$ th component of  $x_2 - x_1$  is at most  $v_i$  in absolute value, and the Cauchy-Schwartz inequality.

### End of proof of Claim 1

Next, let us note

$$\min(a, k) \leq \max(a, k) \text{ for } k \in \{0, \dots, pv\}. \tag{3.45}$$

Indeed, (3.45) holds, since the feasible sets of the optimization problems defining  $\min(a, k)$ , and  $\max(a, k)$  contain  $\{x \mid px = k, 0 \leq x \leq v\}$ .

The nonnegativity of  $p$  and of  $a$  imply  $\min(a, 0) = 0$ , and  $\max(a, pe) = av$ . The proof of the following claim is trivial, hence omitted.

**Claim 2.** *Suppose that  $\ell_1$  and  $\ell_2$  are integers in  $\{0, \dots, pv\}$  with  $\ell_1 + 1 \leq \ell_2$ , and*

$$\max(a, \ell_1) < \beta_1 \leq \beta_2 < \min(a, \ell_2). \tag{3.46}$$

*Then for all  $x$  with  $\beta_1 \leq ax \leq \beta_2$ ,  $0 \leq x \leq v$*

$$\ell_1 < px < \ell_2 \tag{3.47}$$

*holds.*

We assume for simplicity

$$\max(a, 0) < \beta_1 \leq \beta_2 < \min(a, pe); \tag{3.48}$$

the cases when this fails to hold are easy to handle separately. Let  $\ell_1$  be the largest, and  $\ell_2$  the smallest integer such that

$$\max(a, \ell_1) < \beta_1 \leq \beta_2 < \min(a, \ell_2). \tag{3.49}$$

From (3.45)  $\ell_2 \geq \ell_1 + 1$  follows, and Claim 2 yields

$$\text{iwidth}(p, (\text{KP})) \leq \ell_2 - \ell_1 - 1. \tag{3.50}$$

By the choices of  $\ell_1$ , and  $\ell_2$  we have

$$\beta_1 \leq \max(a, \ell_1 + 1), \text{ and } \beta_2 \geq \min(a, \ell_2 - 1), \tag{3.51}$$

hence Claim 1 leads to

$$\begin{aligned}\beta_2 - \beta_1 &\geq \min(a, \ell_2 - 1) - \max(a, \ell_1 + 1) \\ &\geq -\|r\| \|v\| + \lambda(\ell_2 - \ell_1 - 2),\end{aligned}\tag{3.52}$$

that is

$$\ell_2 - \ell_1 - 2 \leq \frac{\beta_2 - \beta_1}{\lambda} + \frac{\|r\| \|v\|}{\lambda}.\tag{3.53}$$

Comparing (3.50) and (3.53) yields completes the proof.

□

## 4 Discussion

### 4.1 Connection with diophantine approximation, and other notions of near parallelness

Given a rational vector  $b$ , simultaneous diophantine approximation (see e.g. [17, 15]) computes an integral vector  $p$ , and an integer  $q$ , such that  $q$ , and  $\|b - (1/q)p\|$  are both small. Frank and Tardos in [8] has explored the following methodology to compute a vector  $p$  that is near parallel to an *integral* vector  $a$ . They apply diophantine approximation to  $(1/\|a\|_\infty)a$ , then set  $\lambda = \|a\|_\infty / q$ ,  $r = a - \lambda p$ . Then  $\|r\| / \lambda$  will be small, and if  $\|a\|$  is large, then  $\lambda$  will be large.<sup>1</sup>

The relevance of Theorems 3 and 4 is not just finding near parallel vectors: it is finding a near parallel  $p$ , which corresponds to a unit vector in the rangespace- and nullspace reformulations, thus leading to the analysis of Theorem 1.

Finding an integral vector, which is near parallel to an other integral or rational one has other applications as well. In [11] Huyer, and Neumaier studied several notions of near parallelness, presented numerical algorithms, and applications to verifying the feasibility of a linear system of inequalities.

### 4.2 Successive approximation

Theorems 3 and 4 approximate  $a$  by a single vector. It is natural to ask: if one row of  $U^{-1}$ , or of  $(V, b)^{-1}$  is a good approximation of  $a$ , can we construct a better approximation from 2, 3,  $\dots$ ,  $k$  rows?

The answer is yes, and we outline the corresponding results below, and their proofs, which are slight modifications of the proofs of Theorems 3 and 4. As of now, we don't know how to use the general results for a better analysis of the reformulations than what is already given in Theorem 1.

---

<sup>1</sup>Thanks are due to Laci Lovász and Fritz Eisenbrand for pointing out this connection

So we mainly state the successive approximation results for the interesting geometric intuition they give. Let us define

$$\begin{aligned} f(a, k) &= 2^{(k(n-k)+1)/4} / \|a\|^{k/n} \\ g(a, k) &= 2^{k(n-1-k)/4} / \|a\|^{(k-1)/n} . \end{aligned} \quad (4.54)$$

The successive version of Theorem 3 is given below:

**Theorem 6.** *Let  $a \in \mathbb{Z}^n$  be a row-vector, with  $\|a\| \geq 2^{(n/2+1)n}$ ,  $U$  a unimodular matrix such that the columns of*

$$\begin{pmatrix} a \\ I \end{pmatrix} U$$

*are LLL-reduced, and  $P_k$  the (integral) submatrix of  $U^{-1}$  consisting of the last  $k$  rows. Furthermore, let  $a(k)$  be the projection of  $a$  onto the subspace spanned by the rows of  $P_k$ ,  $r = a - a(k)$ , and*

$$\lambda_k := \|a(k)\| / \det(P_k P_k^T)^{1/2}.$$

*Then*

- (1)  $(\det(P_k P_k^T))^{1/2} (1 + \|r\|^2)^{1/2} \leq \|a\| f(a, k)$ ;
- (2)  $\lambda_k \geq 1/f(a, k)$ ;
- (3)  $|\sin(a, a(k))| \leq \|r\| / \lambda_k \leq 2f(a, k)$ .

**Proof sketch** We will use the notation of Theorem 3. In its proof we simply change (3.30) (we copy the first expression for  $\det L_n$  for easy reference) to

$$\begin{aligned} \det L_n &= \det L_n^\perp = (\|a\|^2 + 1)^{1/2}, \\ \det L_{n-k} &= \det L_{n-k}^\perp = (\det(P_k P_k^T))^{1/2} (1 + \|r\|^2)^{1/2}, \end{aligned} \quad (4.55)$$

and (3.31) to

$$\det L_{n-k} \leq 2^{k(n-k)/4} (\det L_n)^{1-k/n}. \quad (4.56)$$

Then substituting into (4.56) from (4.55) gives

$$\begin{aligned} (\det(P_k P_k^T))^{1/2} (1 + \|r\|^2)^{1/2} &\leq 2^{(k(n-k))/4} (\sqrt{\|a\|^2 + 1})^{1-k/n} \\ &\leq 2^{(k(n-k)+1)/4} / \|a\|^{k/n} \\ &= \|a\| f(a, k), \end{aligned} \quad (4.57)$$

with the second inequality coming the lower bound on  $\|a\|$ . This shows (1), and the rest of the proof follows verbatim the proof of Theorem 3.  $\square$

Theorem 4 also has a successive variant, which is

**Theorem 7.** Suppose  $\|a\| \geq 2^{(n/2+1)n}$ . Let  $V$  be a matrix whose columns are an LLL-reduced basis of  $\mathbb{N}(a)$ ,  $b$  an integral column vector with  $ab = 1$ ,  $k \leq n - 1$  an integer, and  $P_k$  the (integral) submatrix of  $(V, b)^{-1}$  consisting of the next-to-last  $k$  rows.

Furthermore, let  $a(k)$  be the projection of  $a$  onto the subspace spanned by the rows of  $P_k$ ,  $r = a - a(k)$ , and

$$\lambda_k := \|a(k)\| / \det(P_k P_k^T)^{1/2}.$$

Then  $r \neq 0$ , and

$$(1) \quad (\det(P_k P_k^T))^{1/2} \|r\| \leq \|a\| g(a, k);$$

$$(2) \quad |\sin(a, a(k))| \leq \|r\| / \lambda \leq 2g(a, k).$$

**Proof sketch** We will use the notation of Theorem 4. We need to replace (3.38) with

$$\begin{aligned} \det L_{n-1} &= \det L_{n-1}^\perp = \|a\|, \\ \det L_{n-1-k} &= \det L_{n-1-k}^\perp = (\det(P_k P_k^T))^{1/2} \|r\|. \end{aligned} \tag{4.58}$$

Theorem 2 with  $n - 1$  in place of  $n$ , and  $n - 1 - k$  in place of  $\ell$  implies

$$\det L_{n-1-k} \leq 2^{k(n-1-k)/4} (\det L_{n-1})^{1-k/(n-1)}. \tag{4.59}$$

Plugging the expressions for  $\det L_{n-1}$  and  $\det L_{n-1-k}$  from (4.58) into (4.59) gives

$$\begin{aligned} (\det(P_k P_k^T))^{1/2} \|r\| &\leq 2^{k(n-1-k)/4} \|a\|^{1-k/(n-1)} \\ &= g(a, k) \|a\|, \end{aligned} \tag{4.60}$$

proving (1). The rest of the proof is an almost verbatim copy of the corresponding proof in Theorem 4.  $\square$

**Acknowledgement** We thank Don Coppersmith for his generous, and kind help on the  $n = 2$  case. Thanks are due to Ravi Kannan for helpful discussions; to Laci Lovász and Fritz Eisenbrand for discussions on the connection with diophantine approximation; and to Jeff Lagarias and Andrew Odlyzko for pointing out reference [6].
