# On the Cayley semigroup of a finite aperiodic semigroup

Avi Mintz\*

October 30, 2018

#### Abstract

Let S be a finite semigroup. In this paper we introduce the functions  $\varphi_s : S^* \to S^*$ , first defined by Rhodes, given by  $\varphi_s([a_1, a_2, \ldots, a_n]) = [sa_1, sa_1a_2, \ldots, sa_1a_2 \cdots a_n]$ . We show that if S is a finite aperiodic semigroup, then the semigroup generated by the functions  $\{\varphi_s\}_{s\in S}$  is finite and aperiodic.

## 1 Introduction

Let S be a finite semigroup. Rhodes considered in 1965 [1] a function defined on the free monoid  $S^*$ . He called this the machine of the semigroup. Formally, to each element s of the semigroup, he assigned a function  $\varphi_s : S^* \to S^*$ , defined by  $\varphi_s([a_1, a_2, \ldots, a_n]) =$  $[sa_1, sa_1a_2, \ldots, sa_1a_2 \cdots a_n]$ . Essentially, the  $\varphi_s$  arise from considering the Cayley graph to be a sequential machine and assigning a function to each state  $s \in S$  considered as a start state. We call the semigroup generated by all such functions the Cayley semigroup of S, and denote it by Cayley(S).

Rhodes showed that if S is finite, then S is aperiodic, that is, has no non-trivial subgroups, if and only if for every  $s \in S$ , there exists an  $n \in \mathbb{N}$  such that  $\varphi_s^n = \varphi_s^{n+1}$ . This construction played a key role in the original Krohn-Rhodes Decomposition Theorem.

Grigorchuk and others have intensively studied semigroups and groups generated by finite automata and these have many important properties. Let  $\mathbb{Z}_2$  denote the cyclic group of order 2, and denote its elements by  $\{1, x\}$ . The above gives two functions  $\varphi_1$  and  $\varphi_x$  which are both invertible as functions  $\mathbb{Z}_2^* \to \mathbb{Z}_2^*$ . A natural question is to describe the group generated by them.

In [3] and [4] this group was proved to be  $\mathbb{Z}_2 wr\mathbb{Z}$ , also known as the lamplighter group. Later on this result was generalized by Silva

<sup>\*</sup>This research was done as part of the requirement for a PhD in Bar Ilan University and was done under supervision of Stuart Margolis

and Steinberg to all abelian group in [6] with some results on nonabelian groups. Recently, Grigorchuk and Zuk, used these techniques to calculate the spectrum of the lamplighter group [4].

In this paper we study the Cayley semigroups of other finite semigroups. The first result is that if the semigroup S divides the semigroup T, then Cayley(S) divides Cayley(T). This motivates us to work with semigroups that are not divisible by groups, i.e. aperiodic semigroups. The main result, generalizing Rhodes [1] is that if S is a finite aperiodic semigroup then Cayley(S) is a finite and aperiodic semigroup.

## 2 Preliminaries

Let S be a semigroup. If S is not a monoid, we denote by  $S^1$  the monoid  $S \cup \{1\}$  with the obvious multiplication making 1 the identity element. If S happens to be a monoid already,  $S^1$  will equal S. In a similar way we can add a zero to a semigroup S, if it doesn't have one. This semigroup is denoted by  $S^0$ . For a set X we write  $X^*$  for the directed tree of all strings over X, and  $\epsilon$  for the empty word. For all  $s \in S$  define  $\varphi_s : (S^1)^* \to S^*$  by  $\varphi_s([a_1, a_2, \ldots, a_n]) = [sa_1, sa_1a_2, \ldots, sa_1a_2 \cdots a_n]$ , and  $\varphi_s(\epsilon) = \epsilon$ . We note that unless S is a group, these functions are not invertible. We consider the semigroup generated by  $\{\varphi_s\}_{s \in S}$ , and denote it by Cayley(S). We will use  $\varphi_s, \varphi_t$  to denote generators of Cayley(S).

## 2.1 Semigroup Actions

A semigroup S acts on the left of a set Y if there is a correspondence  $S \times Y \to Y$   $(s, y) \mapsto sy$  that satisfies (st)y = s(ty).

A special case of this is when Y has the structure of a rooted tree. In our case we mean that every  $y \in Y$  has a depth, denoted by |y| and every two elements  $y_1, y_2 \in Y$  have a least upper bound (lub) denoted by  $y_1 \vee y_2$ , which is the longest common path on the geodesics from the root to  $y_1$  and  $y_2$ .

We assume the reader is familiar with these notions, but mention that in the case of strings  $X^*$  over an alphabet X there is a natural structure of a tree.

For example |abbab| = 5 and  $abbaab \lor abbb = abb$ .

For two strings  $w_1, w_2$ , we call  $w_1$  a prefix of  $w_2$  if for some  $w_3$  we have  $w_1w_3 = w_2$ . Thus  $u \lor v$  is the longest common prefix of u and v.

**Definition 1.** Let  $f : X^* \to X^*$ . We say that f is a tree endomorphism if for every  $w_1, w_2 \in W^*$  we have

- 1.  $|w_1| = |f(w_1)|,$
- 2.  $f(w_1 \lor w_2)$  is a prefix of  $f(w_1) \lor f(w_2)$ .

### 2.2 Mealy Automata

We recall that a Mealy automata is a 5-tuple  $\langle A, Q, i, \delta, \lambda \rangle$ , with A, Q finite sets,  $i \in Q, \delta : Q \times A \to Q$  and  $\lambda : Q \times A \to A$ . A Mealy

automata has a representation as a labeled directed graph. The vertices of the graph are the elements of Q, and for every q in Q and a in A there is an edge from q to  $\delta(q, a)$  labeled with  $a/\lambda(q, a)$ . For every word  $w \in A^*$ , we have a walk on the graph, by starting at the vertex i and each time we see a letter a of w we walk from the state q to the state  $\delta(q, a)$ . Since this is a labeled graph, we can read the labels as we read the word  $w = [a_1, a_2, \ldots, a_n]$  and obtain the output word  $f_i(w) = [\lambda(i, a_1), \lambda(\delta(i, a_1), a_2), \ldots, \lambda(\delta(\cdots (\delta(i, a_1), \cdots, )a_{n-1}), a_n)]$ . Thus a Mealy automata defines a function  $f_i : A^* \to A^*$ .

We can also ignore the state i, and thus the Mealy automaton defines a collection of functions  $A^* \to A^*$ , each one determined by its initial state i.

Let S be a semigroup. The (right) Cayley graph of S is the graph described by a set of vertices  $S^1$ , and for every  $s_1, s_2$  in S there is an edge from  $s_1$  to  $s_1s_2$ .

We can consider the Cayley graph of a finite semigroup as a Mealy automaton by labeling the edge from  $s_1$  to  $s_1s_2$  with  $s_2/s_1s_2$ . Using the formalities of Mealy automata this becomes  $Q = S, A = S^1$  and  $\delta(q, a) = \lambda(q, a) = qa$ .

## 2.3 Examples

Let's consider the five semigroups of order 2, and their Cayley automata.

1.  $S_1 = \langle a, b | a^2 = ab = a, b^2 = ba = b \rangle$ , the left zero semigroup of order 2.

a,b,1/a b a b a,b,1/b

 $\varphi_a([x_1, x_2, \dots, x_n]) = [ax_1, ax_1x_2, \dots, ax_1x_2 \cdots x_n] = [a, a, \dots, a].$ We get  $Cayley(S_1) \cong S_1.$ 

2.  $S_2 = \langle a, b | a^2 = ba = a, b^2 = ab = b \rangle$ , the right zero semigroup of order 2.

$$a^{a,1/a} \bigcap_{a} \underbrace{\underbrace{b/b}_{a/a}}_{a/a} \underbrace{b}^{b,1/b} b^{b,1/b}$$

 $\varphi_a([x_1, x_2, \dots, x_n]) = [ax_1, ax_1x_2, \dots, ax_1x_2 \cdots x_n]$ . If we write this as  $\varphi_a([x_1, x_2, \dots, x_n]) = [y_1, y_2, \dots, y_n]$ , then we have  $y_i = x_j$  where j is the largest number less than i such that  $x_j \neq 1$ . If no such j exists, then  $y_i = a$  (this a comes from  $\varphi_a$ ).

We verify that  $\varphi_x \varphi_y = \varphi_y$  for  $x, y \in \{a, b\}$  so that  $Cayley(S_2) \cong S_2$ .

3.  $S_3 = (\{0, 1\}, \cdot)$ , the 2-element semilattice.

$$0,1/0$$
  $0 - 1^{1/1}$ 

 $S_3$  is a monoid so we don't need to add a 1 to the graph.

 $\varphi_1([x_1, x_2, \dots, x_n]) = [1x_1, 1x_1x_2, \dots, 1x_1x_2 \cdots x_n]$  $\varphi_0([x_1, x_2, \dots, x_n]) = [0, 0, 0, 0, 0]$ 

It is clear that  $\varphi_0$  inputs a string of length n and outputs a string of 0's of length n.

Let k be the smallest such that  $x_k = 0$ . Then  $\varphi_1([x_1, x_2, \dots, x_n]) = [1, 1, \dots, 1, 0, 0, \dots, 0]$  where the first 0 is at the k place. We get  $Cayley(S_3) \cong S_3$ .

4.  $S_4 = \langle x | x^2 = 0 \rangle$ , the 2 element nil semigroup.

 $\begin{array}{c}
\overset{0,x,1/0}{\underbrace{\bigcirc}} & \overbrace{x}^{1/x} \\
\varphi_x([x_1, x_2, \dots, x_n]) = [xx_1, xx_1x_2, \dots, xx_1x_2 \cdots x_n] = [0, 0, \dots, 0] \\
\varphi_x([1]) = [x] \\
\varphi_0([x_1, x_2, \dots, x_n]) = [0, 0, \dots, 0] \\
\text{We get } Cayley(S_4) \cong S_4.
\end{array}$ 

5.  $S_5 = \mathbb{Z}_2 = \langle x | x^2 = 1 \rangle$ , the cyclic group of order 2.

$$\int_{0}^{1/0} \left( \int_{1/0}^{1/1} \int_{1}^{0/2} \right)^{1/2}$$

It is proved in [6] that  $Cayley(S) \cong \{a, b\}^+$ , the free semigroup on two letters. In this case,  $\varphi_x$  and  $\varphi_1$  are invertible and the group generated by  $\{\varphi_x, \varphi_1\}$  is isomorphic to the lamplighter group  $\mathbb{Z}_2 wr\mathbb{Z}$ .

Another interesting example is the following. Let S be any monoid and 1 the identity element. In general,  $\varphi_1([a_1, a_2, \ldots, a_n]) = [a_1, a_1 a_2, \ldots, a_1 a_2 \cdots a_n] \neq [a_1, a_2, \ldots, a_n]$ , so the identity element of a semigroup is not the identity element of Cayley(S). Actually, except for trivial cases, Cayley(S) does not contain an identity element.

#### 2.4 Finite Semigroups

We assume standard terminology, facts and notation of finite semigroup theory and refer the reader to [1] and [2] for more details.

Let A and B denote finite sets. Let G be a finite group. Let  $C : B \times A \to G \cup \{0\}$ . We usually think of C as a  $B \times A$  matrix. Furthermore, assume C has the property that for every  $a \in A$   $(b \in B)$  there is a  $b \in B$   $(a \in A)$  such that  $C(b, a) \neq 0$ . A semigroup can be constructed, as follows, from A, B, G, C, denoted by  $\mathcal{M}^0(A, B, G; C)$  and called a Rees matrix semigroup.

Let  $\mathcal{M}^0(A, B, G; C) = (A \times G \times B) \cup \{0\}$  as sets. 0 is a zero element. It remains to describe the product of elements in  $A \times G \times B$ .

 $(a_1, g_1, b_1) \cdot (a_2, g_2, b_2) = (a_1, g_1C(b_1, a_2)g_2, b_2)$  if  $C(b_1, a_2) \neq 0$  and  $(a_1, g_1, b_1) \cdot (a_2, g_2, b_2) = 0$  otherwise.

We state without proof the following theorem.

**Theorem 2** (Rees-Sushkevitch). A finite semigroup S is 0-simple if and only if it is isomorphic to a Rees matrix semigroup.

#### Corollary 3.

- 1. A simple aperiodic semigroup is of the form  $A \times B$ , with multiplication  $(a_1, b_1) \cdot (a_2, b_2) = (a_1, b_2)$ , and in particular, is an idempotent semigroup.
- 2. A 0-simple aperiodic semigroup is of the form  $(A \times B) \cup \{0\}$ , with multiplication defined by  $(a_1, b_1) \cdot (a_2, b_2) = (a_1, b_2)C(b_1, a_2)$ , where C is a  $B \times A$  matrix over  $\{0, 1\}$ .
- 3. A non regular  $\mathcal{J}$  class of a finite aperiodic semigroup is of the form  $A \times B$  with null multiplication.

#### Proof.

- 1. If S is a simple aperiodic semigroup, then  $S^0$  is a 0-simple semigroup, and thus  $S^0$  is isomorphic to  $M = \mathcal{M}^0(A, B, G; C)$ . Since M has a subgroup isomorphic to G (this can be shown by choosing a, b such that  $C(b, a) \neq 0$  and considering  $\{(a, g, b)\}_{g \in G}$ ), and M is aperiodic, we see that  $G = \{1\}$ . Since S is a subsemigroup of  $S^0$ , the matrix C does not contain any zeros.
- 2. The proof of the second point is similar.
- 3. This follows from the basic theorems and definitions of the Schützenberger group. See [2].

Another important corollary is the following.

**Corollary 4.** In a 0-simple semigroup,  $s_1s_2 \cdots s_n = 0$  if and only if  $s_is_{i+1} = 0$  for some  $1 \le i \le n-1$ .

We would like to extend the last two corollaries to a semigroup acting on a 0-minimal ideal.

**Lemma 5.** Let S be an aperiodic semigroup, and  $I \cong A \times B \cup \{0\}$  a 0-minimal regular ideal. Let  $s \in S$  and  $(a, b) \in I \setminus \{0\}$ .

- 1. s(a,b) = 0 if and only if s(a,b') = 0 for every (a,b') in the  $\mathcal{R}$  class of (a,b).
- 2. If  $s(a,b) \neq 0$  then s(a,b) = (a',b) for some  $a' \in A$  which depends only on a and s.

We will write this a' as sa.

*Proof.* Both statements are a result of the fact that the  $\mathcal{R}$  relation is a left congruence  $(a\mathcal{R}b \text{ implies } xa\mathcal{R}xb)$ . For the second point, choose an  $a_b \in A$  such that  $C(b, a_b) = 1$  and apply the associative law to  $s(a, b)(a_b, b)$ .

**Notation 6.** This justifies an extended notation for the structure matrix of *I*.  $C: S \times A \rightarrow \{0, 1\}$ . C(s, a) = 0 if s(a, b) = 0 and C(s, a) = 1 if  $s(a, b) \in A \times B$ .

**Notation 7.** Furthermore this shows that *S* has a left action on the set  $A \cup \{0\}$ , where *sa* is the *a'* in the formula s(a, b) = (a', b). We have shown that this does not depend on choice of *b*.

With every  $\mathcal{J}$  class of a semigroup S we can associate a 0-simple or null semigroup, which we will now define.

### 2.5 Trace of a $\mathcal{J}$ class

Let S be a semigroup, and J a  $\mathcal{J}$  class of S. Let  $\theta$  be an element disjoint from S and consider the following multiplication on J. If  $j_1 \cdot j_2$  isn't in J we write their product as  $\theta$ . The set  $J \cup \{\theta\}$  with  $\theta$  as a zero element is a semigroup called the trace of J, and denoted by  $J^{tr}$ . It is known (and easy to show) that  $J^{tr} \prec S$ . Another possible construction of  $J^{tr}$ is by defining T to be the ideal  $S^1 J S^1 \setminus J$  and then  $J^{tr} \cong S^1 J S^1 / T$ .

## 2.6 Semidirect product of semigroups

Let S and T be finite semigroups. Suppose that T acts on S on the left. That is, for every  $s \in S$  and  $t \in T$  there is an element of S denoted by  ${}^{t}s$  such that  ${}^{t_1}({}^{t_2}s) = {}^{t_1t_2}s$  and  ${}^{t}(s_1s_2) = {}^{t}s_1^{t}s_2$ . In this case we can define the (left) semidirect product of S and T whose underlying set is  $S \times T$  with multiplication given by  $(s_1, t_1)(s_2, t_2) = (s_1^{t_1}s_2, t_1t_2)$ . This semigroup is denoted by  $S \rtimes T$ . There is also the dual notion of a right semidirect product.

## **3** Fractalness Property of Cayley(S)

### 3.1 The Pascal Array

In [1] Rhodes introduced the notion of a Pascal array. This gives some intuition to the action of Cayley(S). This construction motivates many of the following proofs.

Let  $s_1, s_2, \ldots, s_n \in S$  and  $a_1, a_2, \ldots, a_k \in S^1$ . We describe the  $(n+1) \times (k+1)$  table  $(t_{ij})$ .  $t_{00}$  is left empty,  $t_{0i} = a_i$  and  $t_{j0} = s_j$ . The table is completed by the formula  $t_{mn} = t_{m(n-1)} \cdot t_{(m-1)n}$ .

	$a_1 = t_{01}$	$a_2 = t_{02}$	$a_3 = t_{03}$	• • •
$s_1 = t_{10}$	$s_1 a_1 = t_{11}$	$s_1 a_1 a_2 = t_{12}$	$s_1 a_1 a_2 a_3 = t_{13}$	• • •
$s_2 = t_{20}$	$s_2 s_1 a_1 = t_{21}$	$s_2 s_1 a_1 s_1 a_1 a_2 = t_{22}$	$s_2 s_1 a_1 s_1 a_1 a_2 s_1 a_1 a_2 a_3 = t_{23}$	• • •
$s_3 = t_{30}$	$s_3 s_2 s_1 a_1 = t_{31}$	$t_{31}t_{22} = t_{32}$	$t_{32}t_{23} = t_{33}$	• • •

The table describes the action of the function  $\varphi_{s_n} \cdots \varphi_{s_3} \varphi_{s_2} \varphi_{s_1}$  on the word  $[a_1, a_2, \ldots, a_k]$ . The bottom row (excluding the first column) is the output.

#### 3.2 Fractalness

Let  $f = \varphi_{s_n} \dots \varphi_{s_2} \varphi_{s_1} \in Cayley(S)$  and let  $v \in (S^1)^*$ . Since Cayley(S) is a semigroup of tree endomorphisms, the function  $g : (S^1)^* \to S^*$  defined by  $f(vw) = f(v) \circ g(w) \forall w \in (S^1)^*$  is well-defined. We denote this function g by  $f_v$ .

The following theorem will show that  $f_v$  is in Cayley(S) whenever  $f \in Cayley(S)$  and  $v \in (S^1)^*$ . Let  $p: S^* \setminus \{\epsilon\} \to S$  be the function defined by  $p([v_1, v_2, \ldots, v_n]) = v_n$ . Observe that for every  $f \in Cayley(S)$  and every  $w \in (S^1)^*$  we have  $pf(w) \in S$  (and not<sup>1</sup> in  $S^*$ ). This shows that writing  $\varphi_{pf(w)}$  is meaningful.

**Theorem 8.** Let  $f \in Cayley(S)$ . Let  $v \in (S^1)^*$ , and let  $f_v : (S^1)^* \to S^*$  be defined by  $f(vw) = f(v) \circ f_v(w)$ . If we write f as  $f = \varphi_{s_n} \dots \varphi_{s_2} \varphi_{s_1}$  then  $f_v = \varphi_{(p\varphi_{s_n} \dots \varphi_{s_1}(v))} \dots \varphi_{(p\varphi_{s_2}\varphi_{s_1}(v))} \varphi_{(p\varphi_{s_1}(v))}$ . We also have  $f_{\epsilon} = f$ . Thus if  $f \in Cayley(S)$ , so is  $f_v$  for all  $v \in (S^1)^*$ .

*Proof.* This can be seen by observing the Pascal array. When we apply  $\varphi_{s_n} \cdots \varphi_{s_1}$  to vw, we can look at the column of the last letter of v. The elements there are acting on w, describing the action of  $f_v$  on w. For a full proof we induct on n. If n = 1 then let  $w = [w_1, w_2, \ldots, w_k]$  and  $v = [v_1, v_2, \ldots, v_l]$  and write  $\bar{v} = v_1 v_2 \ldots v_l$ . Notice that  $p\varphi_s(v) = s\bar{v}$  for every s. We need to show that  $\varphi_s(vw) = \varphi_s(v) \circ \varphi_{p(\varphi_s(v))}(w)$ .

Calculating gives us

$$\begin{aligned} \varphi_s(vw) &= \varphi_s([v_1, v_2, \dots, v_{l-1}, v_l, w_1, \dots, w_k]) \\ &= [sv_1, sv_1v_2, \dots, sv_1v_2v_{l-1}, s\bar{v}, s\bar{v}w_1, \dots, s\bar{v}w_1 \cdots w_k] \\ &= [sv_1, sv_1v_2, \dots, sv_1v_2v_{l-1}, s\bar{v}] \circ [s\bar{v}w_1, \dots, s\bar{v}w_1 \cdots w_k] \\ &= \varphi_s(v) \circ \varphi_{s\bar{v}}(w) \\ &= \varphi_s(v) \circ \varphi_{p(\varphi_s(v))}(w) \end{aligned}$$

Let's assume this is correct for n - 1. Let v and w be as before. Using the induction assumption (at the first = sign) and the n = 1 case (at the second), we get:

$$\begin{split} \varphi_{s_n}\varphi_{s_{n-1}}\dots\varphi_{s_1}(vw) &= \\ \varphi_{s_n}(\varphi_{s_{n-1}}\dots\varphi_{s_1}(v)\circ\varphi_{(p\varphi_{s_{n-1}}\cdots\varphi_{s_1}(v))}\cdots\varphi_{(p\varphi_{s_2}\varphi_{s_1}(v))}\varphi_{(p\varphi_{s_1}(v))}(w)) &= \\ \varphi_{s_n}(\varphi_{s_{n-1}}\dots\varphi_{s_1}(v))\circ\varphi_{(p\varphi_{s_n}(\varphi_{s_{n-1}}\cdots\varphi_{s_1}(v)))}\dots\varphi_{(p\varphi_{s_2}\varphi_{s_1}(v))}\varphi_{(p\varphi_{s_1}(v))}(w)) &= \\ \varphi_{s_n}\varphi_{s_{n-1}}\dots\varphi_{s_1}(v)\circ(\varphi_{(p\varphi_{s_n}\cdots\varphi_{s_1}(v))}\dots\varphi_{(p\varphi_{s_2}\varphi_{s_1}(v))}\varphi_{(p\varphi_{s_1}(v))})(w) \end{split}$$

## 4 Preliminary Results

#### 4.1 Cayley as a Functor

**Lemma 9.** 1. If T is a quotient semigroup of S then Cayley(T) is a quotient of Cayley(S).

<sup>&</sup>lt;sup>1</sup>We do not identify strings of length 1 over S with S

#### 2. If T is a subsemigroup of S then $Cayley(T) \prec Cayley(S)$ .

- $\begin{array}{ll} \textit{Proof.} & 1. \ \text{Let} \ F: S \to T \ \text{be a surjective morphism. We extend} \ F \ \text{to} \\ F: S^1 \to T^1 \ \text{and verify that this is a semigroup morphism. Write} \\ \bar{s} \ \text{for} \ F(s). \ \text{Suppose we have in} \ Cayley(S) \ \text{the following equation} \\ \varphi_s([a_1,a_2,\ldots,a_n]) = [sa_1,sa_1a_2,\ldots,sa_1a_2\cdots a_n]. \ \text{Then, applying} \ t \to \bar{t} \ \text{gives us} \ \varphi_{\overline{s}}([\overline{a_1},\overline{a_2},\ldots,\overline{a_n}]) = [\overline{sa_1},\overline{sa_1a_2},\ldots,\overline{sa_1a_2}\cdots a_n] \\ \text{This shows that the mapping} \ s \mapsto \bar{s} \ \text{can be extended to} \ \varphi_s \mapsto \varphi_{\overline{s}}. \\ \text{We now extend this mapping to} \ Cayley(S) \to Cayley(T). \ \text{It} \\ \text{remains to show that this is well defined, i.e. if} \ \varphi_{s_n}\cdots\varphi_{s_2}\varphi_{s_1} = \\ \varphi_{r_m}\cdots\varphi_{r_2}\varphi_{r_1} \ \text{in} \ Cayley(S) \ \text{then} \ \varphi_{\overline{s_n}}\cdots\varphi_{\overline{s_2}}\varphi_{\overline{s_1}} = \varphi_{\overline{r_m}}\cdots\varphi_{\overline{r_2}}\varphi_{\overline{r_1}} \\ \text{in} \ Cayley(T). \ \text{This follows from the previous calculation} \end{array}$ 
  - 2. Denote by C the subsemigroup of Cayley(S) generated by  $\{\varphi_t | t \in T\}$ . An element of C acts on the tree  $(S^1)^*$ .

Assume first that  $T = T^1$ . In this case  $(T^1)^*$  is a subtree of  $(S^1)^*$ and is therefore invariant under the action of C, the map sending an element of C to its restriction on  $(T^1)^*$  is an onto morphism  $C \to Cayley(T)$ .

We now consider the case  $T \neq T^1$  and write  $1_{T^1}$  for the identity of  $T^1$ . We can identify  $1_{T^1}$  with  $1_{S^1}$ , and think of  $T^1$  as a subsemigroup of  $S^1$ , so again  $(T^1)^*$  is a subtree of  $(S^1)^*$ , so Cayley(T) is a quotient of C.

The above proof actually shows that Cayley is a functor, i.e. if  $\psi : S \to T$  is a semigroup morphism, then  $\psi$  induces a  $Cayley(\psi) : Cayley(S) \to Cayley(T)$ .

**Corollary 10.** Let S and T be semigroups. If  $S \prec T$  then  $Cayley(S) \prec Cayley(T)$ .

**Remark 11.** Notice that if S contains a zero element 0, then  $\varphi_0$  is the zero element of Cayley(S).

**Remark 12.** If  $s \neq t$  then  $\varphi_s \neq \varphi_t$ .

*Proof.* This is immediate by considering the action of both elements on the word [1].

### 4.2 Idempotent Semigroups

Every  $f \in Cayley(S)$  is a tree endomorphism, and therefore f is determined by its action on each node of the tree  $(S^1)^*$  (where the action is some function  $S^1 \to S$ ). By the portrait of f we mean the tree  $(S^1)^*$ , and for every node, a function  $S^1 \to S$ . We mention an obvious but important fact, that two elements of Cayley(S) are equal if and only if the are decorated with the same portrait. See [3] for more on this notation, and examples of how useful this is for proofs.

Notation 13. Denote by  $l_s$  the function  $l_s: S^1 \to S$  given by  $l_s(t) = st$ .

Every element of Cayley(S) is determined by its action on the top level of the tree and by its restrictions to the subtrees. Thus, every  $f \in Cayley(S)$  can be represented by a pair  $((f_{[s]})_{s\in S}, l_s)$ , where we recall the definition of  $f_{[s]}$  as given in the fractalness section, and the fact that  $f_{[s]} \in Cayley(S)$ . If  $f \in Cayley(S)$  is associated with the pair  $((f_{[s]})_{s\in S}, l_s)$ , then  $f([a_1, a_2, \ldots, a_n]) = [l_s(a_1)] \circ f_{[sa_1]}([a_2, \ldots, a_n])$ . It is easy to see that for generators,  $\varphi_s \mapsto ((\varphi_{sx})_{x\in S}, l_s)$ , and that  $(\varphi_t \varphi_s) \mapsto ((\varphi_{tsx} \varphi_{sx})_{x\in S}, l_{ts})$ .

We can then extend this to any product of generators,  $\varphi_{s_n} \dots \varphi_{s_2} \varphi_{s_1} \mapsto ((\varphi_{s_n \dots s_2 s_1 x} \dots \varphi_{s_2 s_1 x} \varphi_{s_1 x})_{x \in S}, l_{s_n \dots s_2 s_1}).$ 

**Lemma 14.** Let S be an idempotent semigroup, Then  $Cayley(S) \cong S$ .

*Proof.* Let  $s, t \in S$ . Consider the word  $w = [a_1, a_2, \ldots, a_n]$ . We will show that  $\varphi_t \varphi_s(w) = \varphi_{ts}(w)$ . Let  $b_i = a_1 a_2 \cdots a_i$ , and observe that since S is an idempotent semigroup we have  $sb_ib_j = sb_j$  when  $i \leq j$  for every  $s \in S$ . We now calculate  $\varphi_t \varphi_s(w) = \varphi_t([sa_1, sa_1a_2, \ldots, sa_1a_2 \cdots a_n]) = \varphi_t([sb_1, sb_2, \ldots, sb_n]) = [tsb_1, tsb_1b_2, \ldots, tsb_1b_2 \cdots b_n] = [tsb_1, tsb_2, \ldots, tsb_n] = \varphi_{ts}([a_1, a_2, \ldots, a_n]) = \varphi_{ts}(w).$ 

Since the action of the generators is faithful by Remark 12, the mapping  $s \mapsto \varphi_s$  is 1-1 and unto Cayley(S). This completes the proof.

**Corollary 15.** Let S be a finite simple aperiodic semigroup. Then  $Cayley(S) \cong S$ .

*Proof.* As seen before, a simple aperiodic semigroup is of the form  $A \times B$ , with A a left zero semigroup, and B a right zero semigroup. (i.e.  $(a_1, b_1)(a_2, b_2) = (a_1, b_2)$ ), and in particular is an idempotent semigroup. By the above it immediately follows that  $Cayley(S) \cong S$ .

### 4.3 Nilpotent Semigroups

We recall here the definition of a nilpotent semigroup. We say that a semigroup with zero is nilpotent of index n if for every  $m \ge n$  we have  $s_m \cdots s_2 s_1 = 0$  for every  $s_m, \ldots, s_2, s_1 \in S$ , and n is the smallest with this property. The following observation shows that a finitely generated nilpotent semigroup is finite. If S is such a semigroup, Xa generating set and n the nilpotency index, then  $|S| \le \frac{|X|^n - 1}{|X| - 1} + 1$ (unless |X| = 1 in which case the semigroup has n elements).

Here we will see another example where S is similar to Cayley(S).

**Lemma 16.** If S is a finite nilpotent semigroup of index n then Cayley(S) is nilpotent with nilpotency index at most n.

*Proof.* We use the wreath product notation. Let S be a nilpotent semigroup of index n. Let  $\prod_{i=1}^{n} \varphi_{s_i} = ((\prod_{i=1}^{n} \varphi_{b_i})_{x \in S}, l_0)$  be a product of n generators, for some  $b_i$  who depend on x. Since every  $b_i$  is a product of at least one element of S, the portrait is decorated by an  $l_0$  in each node.

Since S is finite, Cayley(S) is a finitely generated nilpotent semigroup, and therefore is finite

Recall that a monogenic semigroup is a semigroup which is generated by one element.

**Corollary 17.** If S is a monogenic aperiodic semigroup, then Cayley(S) is nilpotent.

A monogenic finite aperiodic semigroup is of the form  $\{x, x^2, \ldots, x^n\}$  satisfying the relation  $x^n = x^{n+1}$  for some  $n \in \mathbb{N}$ . Obviously, a monogenic semigroup is commutative.

In general (i.e. |S| not too small) if S is monogenic, then Cayley(S) is not monogenic and not even commutative. For example let  $S = \langle x | x^5 = x^6 \rangle$ . In Cayley(S) we have the following computation.  $\varphi_x \varphi_{x^2}([1,1]) = \varphi_x([x^2, x^2]) = [x^3, x^5]$  and  $\varphi_{x^2} \varphi_x([1,1]) = \varphi_{x^2}([x,x]) = [x^3, x^4]$ .

### 4.4 Basic Structure

We end this section with some structure facts about Cayley(S). Recall that the definition of a monoid acting on a set does not require the identity of the monoid to have a trivial action.

**Theorem 18.** Let S be an aperiodic monoid, and 1 the identity of S. The following are equivalent.

- 1. Cayley(S) is a monoid, and the identity of Cayley(S) acts trivially on S<sup>\*</sup>.
- 2.  $\varphi_1$  has a trivial action on  $S^*$ .
- 3.  $S = \{1\}.$

*Proof.* (3) implies (2) implies (1) is obvious. Assume that Cayley(S) has an identity which acts trivially on  $S^*$ . Let  $f = \varphi_{s_n} \cdots \varphi_{s_2} \varphi_{s_1}$  be the identity. We have  $[1] = f([1]) = [s_n \cdots s_2 s_1]$ . This shows that  $s_i \mathcal{J}1$ , and in a finite aperiodic semigroup, this implies  $s_i = 1$ . We now have  $f = \varphi_1^n$ . Consider the word [x, 1].  $[x, 1] = \varphi_1^n([x, 1]) = [x, x^n]$ . Therefore,  $x^n = 1$ , and by aperiodicity x = 1. This shows that  $S = \{1\}$ .

**Theorem 19.** Let S be an aperiodic monoid, and 1 the identity of S. The following are equivalent.

- 1.  $\varphi_1$  is an idempotent.
- 2.  $\varphi_1$  is regular.
- 3. S is an idempotent monoid.

*Proof.* We saw that if S is idempotent, then  $S \cong Cayley(S)$ . This shows that (3) implies (1) and (1) implies (2). Now suppose  $\varphi_1$  is regular. For some  $f \in Cayley(S)$ ,  $\varphi_1 f \varphi_1 = \varphi_1$ . Considering the word [1], we have  $\varphi_1 f \varphi_1([1]) = \varphi_1([1]) = [1]$ . If we write  $f = \varphi_{s_n} \cdots \varphi_{s_2} \varphi_{s_1}$ , then  $\varphi_1 f \varphi_1([1]) = [s_n \cdots s_2 s_1]$ , thus  $s_n \cdots s_2 s_1 = 1$ . In an aperiodic

semigroup, this implies  $s_n = \cdots = s_2 = s_1 = 1$ , and so  $f = \varphi_1^n$  for some *n*. This gives us  $\varphi_1 = \varphi_1^{n+2}$ . Applying both functions on [x, 1]gives  $[x, x] = [x, x^{n+2}]$ . This gives  $x = x^{n+2}$  and by aperiodicity,  $x = x^2$  for every  $x \in S$ .

**Lemma 20.**  $Cayley(S \times T)$  is a subsemigroup of  $Cayley(S) \times Cayley(T)$ .

Proof.  $\Phi : Cayley(S \times T) \to Cayley(S) \times Cayley(T)$  defined by  $\Phi : \prod_{i=1}^{n} \varphi_{(s_i,t_i)} \mapsto (\prod_{i=1}^{n} \varphi_{s_i}, \prod_{i=1}^{n} \varphi_{t_i})$  maps  $Cayley(S \times T)$  onto the subsemigroup of  $Cayley(S) \times Cayley(T)$  of pairs of functions which can be written as elements of the same length. To see that this is well defined let  $f \in Cayley(S \times T)$  map the string w to w' = f(w), where  $w, w' \in ((S \times T)^1)^*$ . If we denote by  $w_S$  the string obtained from w by replacing every pair  $(s_i, t_i)$  with  $s_i$ , then we can see that  $\Phi(f)$  maps  $w_S$ to  $w'_S$ , regardless of the presentation of f as a product of generators. The same argument works for T.

To see that this is a morphism, let  $f = \prod_{i=1}^{n} \varphi_{(s_i,t_i)}$ , and  $g = \prod_{i=1}^{m} \varphi_{(s'_i,t'_i)}$ . We have  $\Phi(f) = (\prod_{i=1}^{n} \varphi_{s_i}, \prod_{i=1}^{n} \varphi_{t_i})$ , and  $\Phi(g) = (\prod_{i=1}^{m} \varphi_{s'_i}, \prod_{i=1}^{m} \varphi_{t'_i})$ . Thus

$$\begin{split} \Phi(f)\Phi(g) &= \\ (\Pi_{i=1}^n \varphi_{s_i}, \Pi_{i=1}^n \varphi_{t_i})(\Pi_{i=1}^m \varphi_{s'_i}, \Pi_{i=1}^m \varphi_{t'_i}) &= \\ (\Pi_{i=1}^n \varphi_{s_i} \Pi_{i=1}^m \varphi_{s'_i}, \Pi_{i=1}^n \varphi_{t_i} \Pi_{i=1}^m \varphi_{t'_i}) &= \\ \Phi(fg). \end{split}$$

## 5 The Action on Minimal Ideals

We assume henceforth that all semigroups have an identity and a zero. We do not lose any generality for the main results since  $Cayley(S) \prec Cayley(S^1)$  and  $Cayley(S) \prec Cayley(S^0)$ .

Let S be a finite aperiodic semigroup, and I a 0-minimal ideal. We will show that the restriction of Cayley(S) to I is finite and aperiodic.

**Notation 21.** Cayley(S, I) will denote the restriction of Cayley(S) to  $I^*$ , i.e. Cayley(S, I) is the semigroup of functions  $I^* \to I^*$ , generated by the functions  $\{\varphi_s\}_{s \in S}$ .

More generally, Cayley(S, T) will denote the restriction of Cayley(S) to the tree  $T^*$  for some ideal T of S.

### 5.1 The Rhodes Expansion

Let S be a finite semigroup. The right Rhodes expansion  $\hat{S}$  was introduced by Rhodes in 1969 [5].

Consider the set M(S) of all strings in  $S^*$  of the form  $[s_1, s_1s_2, s_1s_2s_3, \ldots, s_1s_2\cdots s_n]$ . Define a multiplication on M(S) by

$$[s_1, \ldots, s_1 s_2 \cdots s_n][t_1, \ldots, t_1 t_2 \cdots t_m] = [s_1, \ldots, s_1 s_2 \cdots s_n, s_1 \cdots s_n t_1, \ldots, s_1 \cdots s_n t_1 \cdots t_m]$$

Consider the case where  $s_1 \cdots s_{i-1} s_i \mathcal{R} s_1 \cdots s_{i-1}$ . Equivalently, for some  $x \in S$ ,  $s_1 \cdots s_{i-1} s_i x = s_1 \cdots s_{i-1}$ . A one step reduction replaces  $w = [s_1, \ldots, s_1 \cdots s_{i-1}, s_1 \cdots s_{i-1} s_i, \ldots, s_1 \cdots s_n]$  with

 $w' = [s_1, \ldots, s_1 \cdots s_{i-2}, s_1 \cdots s_{i-1} s_i, \ldots, s_1 \cdots s_n]$ . If no such *i* exists, w is called reduced. It is easy to see that every element w of M(S) has a unique reduced form red(w) obtained from w by applying finitely many one step reductions.

**Definition 22.** The right Rhodes expansion of a finite semigroup S is the collection of reduced words in M(S) with multiplication  $w \cdot w' = red(ww')$ . We denote it by  $\widehat{S}^R$ .

The Rhodes expansion is closely related to the following construction.

### 5.2 The Memory Semigroup of S

Let S be a finite semigroup. Define a multiplication on the set  $S \times P(S)$  by

$$(s,\alpha) \cdot (t,\beta) = (st,\alpha t \cup \{t\} \cup \beta)$$

where, if  $\alpha \in P(S)$  and  $t \in S$ , then  $\alpha t = \{xt | x \in \alpha\}$ . We will first verify that this multiplication is associative.

 $[(s,\alpha)(t,\beta)](x,\gamma) = (st,\alpha t \cup \{t\} \cup \beta)(x,\gamma) = (stx,\alpha tx \cup \{tx\} \cup \beta x \cup \{x\} \cup \gamma)$  $(s,\alpha)[(t,\beta)(x,\gamma)] = (s,\alpha)(tx,\beta x \cup \{x\} \cup \gamma) = (stx,\alpha tx \cup \{tx\} \cup \beta x \cup \{x\} \cup \gamma).$ 

**Definition 23.** We call the above the (right) memory semigroup of S, and denote it by mem(S).

Note that  $f : mem(S) \to S, f(s, \alpha) = s$  is a surjective morphism. Thus  $S \prec mem(S)$ .

The finiteness of mem(S) is trivial. Furthermore, we observe the following.

**Lemma 24.** Let S be a finite semigroup. Then mem(S) is aperiodic if and only S is.

Proof. A simple induction shows that  $(s, \alpha)^n = (s^n, \alpha \cup \alpha \{s, s^2, \dots, s^{n-1}\} \cup \{s, s^2, \dots, s^{n-1}\})$ . Thus if  $s^n = s^{n+1}$  for every s in S then  $(s, \alpha)^{n+1} = (s, \alpha)^{n+2}$  for every  $(s, \alpha)$  in mem(S). The converse follows since  $S \prec mem(S)$ .

We now proceed with the action of Cayley(S) on  $I^*$ .

### 5.3 Some Lemmas

**Lemma 25.** Let S be an aperiodic semigroup. Let  $I \cong (A \times B) \cup \{0\}$  be a 0-minimal ideal,  $f \in Cayley(S, I)$ , and  $w \in I^* \setminus \{\epsilon\}$ .

1. f(w) is of the form  $[(a, b_1), (a, b_2), \dots, (a, b_k), 0, \dots, 0]$ , with  $a \in A, b_i \in B$  and  $k \ge 0$ .

- 2. The first k elements of w are  $[(a_1, b_1), (a_2, b_2), \dots, (a_k, b_k)]$ , for some  $a_i \in A$ .
- 3. Assume k > 0. If we write  $f = \varphi_{s_n} \cdots \varphi_{s_2} \varphi_{s_1}$  then a is given by  $s_n \cdots s_2 s_1(a_1, b_1) = (a, b_1)$ , that is,  $s_n \cdots s_2 s_1 a_1 = a$ , assuming f(w) is not a string of zeros.
- **Proof.** 1. It is enough to show this for the case when f is a generator of Cayley(S, I). It is also clear that once we have a 0 in f(w) all elements beyond it will be 0. Let  $w = [(a_1, b_1), (a_2.b_2), \ldots, (a_k, b_k)]$ , and  $\varphi_s$  a generator.
  - $\varphi_s(w) = [s(a_1, b_1), s(a_1, b_1)(a_2, b_2), \dots, s(a_1, b_1) \cdots (a_k, b_k)] = [s(a_1, b_1), s(a_1, b_2), \dots, s(a_1, b_k)]$
  - 2. We cannot have a 0 in the first k entries of w because then we would also have a 0 in the first k entries of f(w). We see that applying  $\varphi_s$  to w doesn't change  $b_i$  for  $i \leq k$ .
  - 3. The last statement is immediate.

The following lemma will be needed to cover the last cases for the main theorem of this section.

**Lemma 26.** Let  $\varphi_s \in Cayley(S, I)$  be a generator and  $w = [\dots, (a_i, b_i), (a_{i+1}, b_{i+1}), \dots] \in I^*$ . Furthermore assume that the first i - 1 entries of w are  $\neq 0$ .

- 1. Assume  $\varphi_s(w)$  is non zero in the *i* position. Then  $\varphi_s(w)$  has a zero in the *i* + 1 position if and only  $C(b_i, a_{i+1}) = 0$  where *C* is the structure matrix of  $I \setminus \{0\}$ .
- 2. Let  $f = \varphi_{s_n} \cdots \varphi_{s_2} \varphi_{s_1}$  and let  $w = [(a, b), \ldots]$ . Then  $f(w) = [0, 0, \ldots, 0]$  if and only if  $s_n \cdots s_2 s_1(a, b) = 0$ .

*Proof.* A direct calculation can verify both facts. We notice that for the second statement there are two possibilities for f when  $s_n \cdots s_2 s_1(a, b) = 0$ . Either  $s_n \cdots s_2 s_1 = 0$  in which case f is the zero function. If not,  $(s_n \cdots s_2 s_1)(a, b) = 0$  in which case f is not the zero function, but f acts as the zero function on any string of the form  $[(a, b'), \ldots]$  for any  $b' \in B$ .

#### **Proposition 27.** Let S, I be as before. Then $Cayley(S, I) \prec mem(S)$ .

The proof is motivated by the following idea: Let  $v \in I^*$ , and let  $f = \varphi_{s_n} \cdots \varphi_{s_1} \in Cayley(S, I)$ . The output f(v), is of the form  $[(a, b_1), (a, b_2), \ldots, (a, b_k), 0, 0, \ldots, 0]$ . Applying f doesn't change the  $b_i$ 's of v. The action of f on v is determined by the following two questions: 1. what is a? 2. what is k? (i.e. from what point does f(v) consist of zeros?).

If  $v = [(a_1, b_1), \ldots]$  then we answer the first question by  $(a, b_1) = s_n \cdots s_2 s_1(a_1, b_1)$ , i.e. the first question is answered by the first component of an element of mem(S).

For the second we will observe that the appearance of a 0 will depend on the set-component of mem(S). Each time we apply a  $\varphi_{s_i}$  to v we get a string of the form  $[s_i \cdots s_2 s_1(a_1, b_1), \ldots]$ , so the set-component determines the set of a's we will see along the way. Part 2 of Lemma 26 tells us that if  $v' = \varphi_{s_i} \cdots \varphi_{s_1}(v) = [(a, b_1), \ldots]$ , then a 0 will be created in v' when we find a  $b_i$  such that  $C(b_i, a) = 0$ .

*Proof.* Denote by  $S^+$  the free semigroup over S, with S considered as a set. Denote by  $\Gamma: S^+ \to Cayley(S, I)$  the canonical morphism.

$$\Gamma: ([s_n, \ldots, s_2, s_1]) \mapsto \varphi_{s_n} \cdots \varphi_{s_2} \varphi_{s_1}$$

Let  $\Phi: S^+ \to mem(S)$  be defined by

$$\Phi:([s_1])\mapsto(s_1,\emptyset)$$

By induction on n it is easy to see that

$$\Phi: ([s_n, \cdots, s_2, s_1]) \mapsto (s_n \cdots s_2 s_1, \{s_{n-1} \cdots s_2 s_1, \dots, s_2 s_1, s_1\})$$

We will denote by  $\sim_{\Gamma}$  and  $\sim_{\Phi}$  the congruences on  $S^+$  corresponding to  $\Gamma$  and  $\Phi$ .

We show that  $v_1 \sim_{\Phi} v_2$  implies  $v_1 \sim_{\Gamma} v_2$ . Let  $v_1, v_2 \in S^+$  and let  $f = \Gamma(v_1), g = \Gamma(v_2)$ . Let  $v_1 = [s_n, \ldots, s_2, s_1]$ , and  $v_2 = [t_m, \ldots, t_2, t_1]$ . We want to show that  $\Phi(v_1) = \Phi(v_2)$  implies  $\Gamma(v_1) = \Gamma(v_2)$ . This is equivalent to f = g in Cayley(S, I) if  $(s_n \cdots s_1, \{s_{n-1} \cdots s_1, \ldots, s_1\}) = (t_m \cdots t_1, \{t_{m-1} \cdots t_1, \ldots, t_1\})$ . If f is the zero function then  $s_n \cdots s_1(a, b) = 0$  for every  $(a, b) \in A \times B$ . Thus,  $\Phi(v_1) = (s_n \cdots s_1, \alpha)$  for some  $\alpha \in P(S)$ , and since  $\Phi(v_1) = \Phi(v_2), \Phi(v_2) = (s_n \cdots s_1, \alpha)$ . In other words,  $s_n \cdots s_2 s_1 = t_m \cdots t_2 t_1$  and we see that g is also the zero function on  $I^*$ .

Throughout the rest of this proof, we will assume  $f \neq \varphi_0 \neq g$ . Write  $\Phi(v_1) = \Phi(v_2) = (\sigma, \alpha), \sigma \in S, \alpha \in P(S)$ , with  $\sigma(a, b) \neq 0$  for some (a, b). Finally, let  $w \in I^*$ .

Let  $k_1$  denote the position of the last nonzero entry in f(w) (and  $k_1 = 0$  if f(w) = [0, 0, ..., 0]) and  $k_2$  the position of the last nonzero entry in g(w). By Lemma 25, and since  $\Phi(v_1) = \Phi(v_2)$  (in particular  $s_n \cdots s_2 s_1 = t_m \cdots t_2 t_1$ ) it follows that f(w) equals g(w) in the first  $\min(k_1, k_2)$  entries.

It remains to show that  $k_1 = k_2$ .

First, assume  $k_1 = 0$ . Let  $w = [(a_1, b_1), \ldots]$ . This means that  $f(w) = [0, 0, \ldots, 0]$ . Since  $f \neq \varphi_0$  this means that  $C(s_n \cdots s_2 s_1, a_1) = 0$  i.e.  $C(\sigma, a_1) = 0$  and so  $g(w) = [0, 0, \ldots, 0]$  and  $k_2 = 0$ , so  $k_1 = k_2$ .

We may assume now that  $k_1, k_2 > 0$ . Without loss of generality  $k_1 \leq k_2$ .

If  $k_1 = |w|$ , then all entries of f(w) are nonzero and since  $k_1 \le k_2$ we are done in this case. So we may assume that  $k_1 < |w|$ .

If w has a zero in the  $k_1 + 1$  place then it is immediate that g(w) has a zero in the  $k_1 + 1$  place, so in this case  $k_2 \leq k_1$ . We may therefore assume that the first  $k_1 + 1$  entries in w are not zero, and  $w = [(a_1, b_1), (a_2, b_2), \dots, (a_{k_1}, b_{k_1}), (a_{k_1+1}, b_{k_1+1}), \dots].$ 

We know that f(w) has a zero in the  $k_1+1$  place, and  $f = \varphi_{s_n} \cdots \varphi_{s_2} \varphi_{s_1}$ . Let r be such that  $\varphi_{s_r} \cdots \varphi_{s_2} \varphi_{s_1}(w)$  has a zero in the  $k_1 + 1$  place but  $\varphi_{s_{r-1}} \cdots \varphi_{s_2} \varphi_{s_1}(w)$  does not.

If r = 1 (i.e. if  $\varphi_{s_1}(w)$  has a zero in the  $k_1 + 1$  position) then part 1 of Lemma 26 shows that  $\varphi_{t_1}(w)$  has a zero in the  $k_1 + 1$  position, and so g(w) has a zero in the  $k_1 + 1$  position. Thus  $k_2 \leq k_1$  and the claim is proved.

Assume r > 1. Let  $w' = \varphi_{s_{r-1}} \cdots \varphi_{s_1}(w) = [(c, b_1), \ldots, (c, b_{k_1}), (c, b_{k_{1+1}}), \ldots]$ , where c is determined by  $s_{r-1} \cdots s_2 s_1(a_1, b_1) = (s_{r-1} \cdots s_2 s_1 a_1, b_1) = (c, b_1)$ . Applying  $\varphi_{s_r}$  to w' creates a zero in the  $k_1 + 1$  place and leaves the  $k_1$  place nonzero. We calculate  $\varphi_{s_r}(w') = [(s_r, c, b_1), \ldots, (s_r, c, b_{k_1}), (c, b_{k_1+1}), \ldots]$ . Since  $(s_r, b_{k_1}) \neq 0$  and  $(s_r, b_{k_1})(c, b_{k_1+1}) = 0$  we see that the structure matrix of I has  $C(b_{k_1}, c) = 0$ . Thus,  $C(b_{k_1}, s_{r-1} \cdots s_2 s_1) = 0$ .

We observe that for  $\Phi(v_2) = (\sigma, \alpha)$ ,  $\alpha$  describes the set of elements of S that w is multiplied by, as we apply  $\varphi_{s_i}, 1 \leq i \leq n$ . Since  $\Phi(v_1) = \Phi(v_2)$ , and since  $s_{r-1} \cdots s_2 s_1 \in \alpha$ , we see that  $s_{r-1} \cdots s_1$  belongs to the set-component of  $\Phi(v_2)$ . This implies that g can also be decomposed as  $g = g_2 \varphi_t g_1$  for some  $t \in S$  with  $g_1 \in Cayley(S, I), g_2 \in Cayley(S, I) \cup$  $\{id\}$ , and  $g_1([(a_1, b_1)]) = [s_{r-1} \cdots s_2 s_1(a_1, b_1)].$ 

We write  $g_1(w) = [(d, b_1), \dots, (d, b_{k_1}), (d, b_{k_1+1}), \dots]$  (We assume that the  $k_1$  and  $k_1 + 1$  places are not zero or else we will have  $k_2 \le k_1$  and the proof is over). Since  $[(d, b_1)] = g_1[(a_1, b_1)] = [(s_{r-1} \cdots s_2 s_1 a_1, b_1)] = f_r[(a_1, b_1)] = [(c, b_1)]$  we see that c = d. We rewrite,  $g_1(w) = [(c, b_1), \dots, (c, b_{k_1}), (c, b_{k_1+1}), \dots]$ .

Calculating  $\varphi_t g_1(w) = [t(c, b_1), \ldots, t(c, b_1) \cdots (c, b_{k_1})(c, b_{k_1+1})]$ , we see that the  $k_1 + 1$  position has a right factor  $(c, b_{k_1}) \cdot (c, b_{k_1+1})$ . We noticed before that the structure matrix has  $C(b_{k_1}, c) = 0$ , so  $\varphi_t g_1(w)$  has a zero in the  $k_1 + 1$  position, and so does g(w). We have showed that  $k_2 \leq k_1$ .

We now have  $k_1 = k_2$ . Thus we have showed that f(w) = g(w) and thus f = g. Thus,  $\Phi(v_1) = \Phi(v_2)$  implies  $\Gamma(v_1) = f = g = \Gamma(v_2)$ .

Since we have proved that  $\sim_{\Phi} \subset \sim_{\Gamma}$ , there is an induced surjective morphism from  $S^+/\sim_{\Phi}$  onto  $Cayley(S,I)\S^+/\sim_{\Gamma}$ . Therefore, Cayley(S,I) divides  $S^+/\sim \Phi$  which is a subsemigroup of mem(S).

**Theorem 28.** Let S be a finite aperiodic semigroup, and I a 0-minimal ideal. Then Cayley(S, I) is finite and aperiodic.

This was proved for the regular case. For a nonregular 0-minimal ideal, the theorem is trivial. This is because such a  $\mathcal{J}$  class is null, so for any  $\varphi_s \in Cayley(S, I)$  and  $w = [w_1, w_2, \ldots] \in I^*$  we have  $\varphi_s(w) = [sw_1, sw_1w_2 = 0, 0, \ldots, 0]$ , so the action of  $\varphi_{s_n} \cdots \varphi_{s_1}$  on w is determined by  $s_n \cdots s_1$ , with  $\varphi_{s_n} \cdots \varphi_{s_1}(w) = [s_n \cdots s_2 s_1 w_1, 0, \ldots, 0]$  and Cayley(S, I) is the quotient of S obtained by identifying two elements if they act the same on the left of I.

For future purposes we extend the previous result.

**Definition 29.** Let S be a finite aperiodic semigroup, and let I be a 0-minimal ideal of S. Let  $f \in Cayley(S, I)$ , and  $w = [v_1, \ldots, v_l] \in I^*$ . We say that a zero is created in the ith position of w by f, if there exists a decomposition of f,  $f = \varphi_{s_n} \cdots \varphi_{s_2} \varphi_{s_1}$  such that

- 1.  $\varphi_{s_{k-1}} \cdots \varphi_{s_2} \varphi_{s_1}(w)$  does not have a zero in the *i* position.
- 2.  $\varphi_{s_k} \cdots \varphi_{s_2} \varphi_{s_1}(w)$  has a zero in the *i* position but is nonzero in the *i* 1 position.

If we need to be more specific we will say that the zero is created by the kth generator of the above decomposition of f.

**Definition 30.** Let S be a finite aperiodic semigroup, and I a 0minimal ideal of S, such that  $I \cong (A \times B) \cup \{0\}$ . Let  $f = \varphi_{s_n} \cdots \varphi_{s_2} \varphi_{s_1} \in Cayley(S, I)$  and  $a \in A$ , such that  $s_n \cdots s_2 s_1(a, b) \neq 0$  for any (and therefore all)  $b \in B$ .

- 1. For  $1 \le i \le n+1$  let  $\pi_a(i) = s_{i-1} \cdots s_2 s_1 a$  (and  $\pi_a(1) = a$ ). We recall the notation sa from Notation 7.
- 2.  $new_a(s_n, \cdots, s_1) = \{1 \le i \le n | \pi_a(i) \ne \pi_a(j) \forall j < i\}.$

Notice that  $|new_a(s_n, \ldots, s_1)| \leq |A|$ , for any  $s_n, \ldots, s_1 \in S$ .

**Lemma 31.** Let  $f = \varphi_{s_n} \cdots \varphi_{s_2} \varphi_{s_1}$ . Let  $w \in Cayley(S)(I^*)$  (i.e. w is the output of Cayley(S, I) acting on some string in  $I^*$ ) such that w is not a string of 0s. Let  $w = [(a_1, b_1), \ldots]$  and let  $a = a_1$ . If the kth generator of f creates a new zero, then  $k \in new_a(s_n, \ldots, s_2, s_1)$ .

*Proof.* Suppose the kth generator creates a zero in the *i*th entry. Without loss of generality  $f = \varphi_{s_k} \cdots \varphi_{s_2} \varphi_{s_1}$ . Let  $f' = \varphi_{s_{k-1}} \cdots \varphi_{s_2} \varphi_{s_1}$ . We then have  $f'(w) = [(a', b_1), \ldots, (a', b_{i-1}), (a', b_i), \ldots]$ , where  $a' = s_{k-1} \cdots s_2 s_1 a = \pi_a(k)$ . This is true even if k = 1 and f' is the identity function, since we assume  $w \in Cayley(S)(I^*)$ . Since the zero is created in the *i*th entry we have

 $f(w) = \varphi_{s_k}(f'(w)) = [(s_ka', b_1), \dots, (s_ka', b_{i-1}), (s_ka', b_{i-1})(a', b_i) = 0, \dots].$  This shows that  $C(b_{i-1}, a') = 0$ . If k = 1 then it is immediate that  $k \in new_a(s_n, \dots, s_1)$ . Suppose that  $1 < k \notin new_a(s_n, \dots, s_1)$ . Then for some l < k we have  $s_{l-1} \cdots s_2 s_1 a = a'$  and by a similar calculation the zero will be created by the *l*th generator and not the *k*th generator.

**Corollary 32.** Let S be an aperiodic semigroup, and let I be a 0minimal ideal of S. There exists an  $N \leq |A|^2 + 1 \in \mathbb{N}$  such that every  $f = \varphi_{s_n} \cdots \varphi_{s_2} \varphi_{s_1} \in Cayley(S, I)$  can be written as  $f = g_{k+1} \varphi_{s_{i_k}} g_k \cdots g_2 \varphi_{s_{i_1}} g_1$ for some  $k \leq N$ , with  $g_l \in Cayley(S, I) \cup \{id\}$  and such that all zeros are created by the  $\varphi_{s_{i_k}}$ ,  $1 \leq j \leq k$  for every  $w \in I^*$ ,

*Proof.* In order to use the previous lemma w needs to be in  $Cayley(S)(I^*)$ . Instead of  $f = \varphi_{s_n} \cdots \varphi_{s_2} \varphi_{s_1}$  acting on w we may consider  $f = \varphi_{s_n} \cdots \varphi_{s_2}$  acting on  $\varphi_{s_1}(w)$ .

For every  $a \in A$  consider the set  $new_a(s_n, \ldots, s_1)$ , and let  $X = \bigcup_{a \in A} new_a(s_n, \ldots, s_1)$ . By the previous lemma, all the zeros must be created by the *r*th generator for some  $r \in X$ . In fact, every  $a \in A$  contributes at most |A| elements to X. Thus, for any word w, the zeroes will be created by an *r*th generator for some  $r \in X$ . Thus, in the product  $f = \varphi_{s_n} \cdots \varphi_{s_2} \varphi_{s_1}$  we can single out |X| generators which are the only ones that can create a zero. We also have  $|X| \leq |A|^2 + 1$ . The +1 in this formula comes from the beginning of the proof.

## 6 Finiteness

Before the next lemma, recall the definition of  $p: S^+ \to S$  given by  $p([a_1, a_2, \ldots, a_l]) = a_l$  and in particular, p([a]) = a.

**Lemma 33.** Let S be a finite aperiodic semigroup, and  $A \times B$  a regular  $\mathcal{J}$  class of S. Let  $[v_1, v_2, \ldots, v_k] = v \in (A \times B)^+$ . Let  $f \in Cayley(S)$ . Write  $f = \varphi_{s_n} \cdots \varphi_{s_1}$  and  $v_i = (a_i, b_i)$ . Furthermore assume that  $f(v) \in (A \times B)^+$ . Then

$$f_v = \varphi_{(s_n \cdots s_2 s_1 a_1, b_k)} \cdots \varphi_{(s_2 s_1 a_1, b_k)} \varphi_{(s_1 a_1, b_k)}$$

*Proof.* Since  $f(v) \in (A \times B)^*$  we have  $v_1 v_2 \cdots v_k \in A \times B$ , so  $v_1 v_2 \cdots v_i = (a_1, b_i)$  for  $1 \le i \le k$ .  $\varphi_{s_1}(v) = [s_1 v_1, s_1 v_1 v_2, \dots, s_1 v_1 \cdots v_k] = [(s_1 a_1, b_1), \dots, (s_1 a_1, b_k)]$ . Proceeding from here (by inducting on i) we have

$$\varphi_{s_i} \cdots \varphi_{s_1}(v) = [(s_i \cdots s_2 s_1 a_1, b_1), \dots, (s_i \cdots s_2 s_1 a_1, b_k)]$$

We now recall the formula for  $f_v$  from Theorem 8. We have  $f_v = \varphi_{(p\varphi_{s_1}\cdots\varphi_{s_1}(v))}\cdots \varphi_{(p\varphi_{s_2}\varphi_{s_1}(v))}\varphi_{(p\varphi_{s_1}(v))}$ . Since  $p\varphi_{s_i}\cdots\varphi_{s_1}(v) = (s_i\cdots s_2s_1a_1, b_k)$ , we have our result.

**Remark 34.** With the previous definitions, assume that  $f(v) \in (A \times B)^+$ . Then  $\varphi_1(v) \in (A \times B)^+$ .

*Proof.* We write  $f = \varphi_{s_n} \cdots \varphi_{s_2} \varphi_{s_1}$ . We observe that every entry in the word  $\varphi_1([v_1, v_2, \ldots, v_k]) = [v_1, v_1 v_2, \ldots, v_1 v_2 \cdots v_k]$ , is  $\mathcal{L}$  above the corresponding entry of f(v). This follows from the fact that f(v) can be obtained from  $\varphi_1(v)$  by multiplying each element on the left by  $s_1$ , and then by applying  $\varphi_{s_n} \cdots \varphi_{s_2}$  to the resulting word, which again is just left multiplication. Since  $v \in (A \times B)^+$  and  $f(v) \in (A \times B)^+$  we have that  $\varphi_1(v) \in (A \times B)^+$ .

**Corollary 35.** Let S be a finite aperiodic semigroup,  $A \times B$  a  $\mathcal{J}$  class of S. Let  $[v_1, v_2, \ldots, v_k] = v \in (A \times B)^+$  and let  $f \in Cayley(S)$ . Write  $f = \varphi_{s_n} \cdots \varphi_{s_1}$  and  $v_i = (a_i, b_i)$ . Assume that  $f(v) \in (A \times B)^+$ . Furthermore, let  $j = p\varphi_1(v) = (a_1, b_k)$ . Then  $f_v = f_{[j]}$ .

*Proof.* We first show that  $f([j]) \in (A \times B)^+$ . We calculate  $f([j]) = [s_n \cdots s_2 s_1(a_1, b_k)]$ . Since  $f(v) \in (A \times B)^+$ , and since the first letter of f(v) is  $s_n \cdots s_2 s_1(a_1, b_1)$  it follows that  $s_n \cdots s_2 s_1(a_1, b_k) \in A \times B$ , so  $f([j]) \in (A \times B)^+$ .

Now,  $f_v = \varphi_{(s_n \cdots s_2 s_1(a_1, b_k))} \cdots \varphi_{(s_2 s_1(a_1, b_k))} \varphi_{(s_1(a_1, b_k))}$ . We also have  $f_{[j]} = \varphi_{(s_n \cdots s_2 s_1(a_1, b_k))} \cdots \varphi_{(s_2 s_1(a_1, b_k))} \varphi_{(s_1(a_1, b_k))}$ .

**Definition 36.** Let S be a finite semigroup. Let T be an ideal of S and J a  $\mathcal{J}$  class of S not in T. We say that J is directly above T if  $J \cup T$  is an ideal of S. Equivalently, J is a 0-minimal  $\mathcal{J}$  class of S/T.

Let S be a semigroup with an ideal T and a  $\mathcal{J}$  class J directly above T. Let  $w \in (T \cup J)^*$ . Since every letter in w is in J or in T, w can be uniquely decomposed as  $w = w_J$  or  $w = w_J w'_T w'$  such that  $w_J \in J^*, w'_T \in T$  and  $w' \in (J \cup T)^*$ . In the case that w is of the form  $w = f(w_0)$  for some  $f \in Cayley(S, T \cup J)$  and  $w_0 \in (T \cup J)^*$  we can decompose  $w = w_J w_T$  with  $w_J \in J^*$  and  $w_T \in T^*$ . In both cases, we call  $w_J$  the prefix of w in J.

**Definition 37.** Let S be a finite aperiodic semigroup. Let T be an ideal of S, and let J be a  $\mathcal{J}$  class directly above T. For an  $f \in Cayley(S, T \cup J)$ , the set of f-J-stable words is the set of words  $st(f, J) \subset (T \cup J)^*$  such that the prefix of w in J has the same length as the prefix of f(w) in J.

We observe that in general, the length of the prefix of w in J is larger or equal to the length of the prefix of f(w) in J.

Consider the following relation on  $Cayley(S, T \cup J)$ . We write  $f \sim g$  if and only if st(f, J) = st(g, J) and the restrictions of f and g to this set is equal.

**Lemma 38.** Let  $S, T, J, \sim$  be as before.  $\sim$  is a congruence on  $Cayley(S, T \cup J)$ .

*Proof.* It is clear that ~ is an equivalence relation. Suppose that  $f \sim f'$  and  $g \sim g'$ . Let  $w \in st(fg, J)$ . In particular this means that  $w \in st(g, J)$  and that  $g(w) \in st(f, J)$ . This implies g(w) = g'(w) and that f(g(w)) = f'(g(w)) = f'(g'(w)). Thus  $w \in st(f'g', J)$  and fg(w) = f'(g(w)) = f'(g'(w)). The dual argument completes the proof.

**Notation 39.** We write  $Cayley_{st-J}(S, T \cup J)$  for the quotient of  $Cayley(S, T \cup J)$  by ~.

We point out, that for  $[f]_{\sim} \in Cayley_{st-J}(S, T \cup J)$  and  $w \in st(f, J)$ ,  $[f]_{\sim}(w)$  is always well defined, i.e. every  $g \sim f$  can act on w and all these g's give the same g(w). We will refer to  $[f]_{\sim}(w)$  as  $\tilde{f}(w)$ , whenever  $[f]_{\sim}(w)$  is defined. In general we will write  $\tilde{f}$  for  $[f]_{\sim}$ .

Until now, the notation Cayley(S,T) was used when T was an ideal of S. It can actually be used where T is any semigroup which S acts on from the left, by defining  $\varphi_s([t_1, t_2, \ldots, t_k]) = [st_1, st_1t_2, \ldots, st_1t_2 \cdots t_k]$ . However, in general, Cayley(S,T) is no longer a divisor of Cayley(S).

Let S be an aperiodic semigroup, T an ideal of S and J a  $\mathcal{J}$  class directly above T. Let  $\alpha : (T \cup J) \to J^{tr} \cong (T \cup J)/T$  be the ideal quotient.  $\varphi_s$  can act on strings in  $J^{tr}$  in the following way: Let  $w = [j_1, \ldots, j_n] \in (J^{tr})^*$ . We have  $\varphi_s([j_1, j_2, \ldots, j_n]) = [\overline{sj_1}, \overline{sj_1j_2}, \ldots, \overline{sj_1j_2}, \ldots, \overline{sj_n}]$ , with  $\overline{s} = \alpha(s)$ , i.e.  $\overline{s} = s$  if  $s \in J$  and  $\overline{s} = 0$  otherwise.

Notation 40. We write  $Cayley(S, J^{tr})$  for the semigroup of transformations  $(J^{tr})^* \to (J^{tr})^*$  generated by  $\{\varphi_s\}_{s \in S}$ .

We define a morphism  $Cayley(S, T \cup J) \rightarrow Cayley(S, J^{tr})$ . Write  $f^{tr}$  for the image of f.  $f^{tr}$ 's action on  $w \in (J^{tr})^*$  can be described as follows. We first replace any 0 in w with any element of T. Next,

apply f to this new word. Finally, replace all elements of T with 0 (the zero of  $J^{tr}$ ).

Let  $f \in Cayley(S, J \cup T)$  and  $w \in (J \cup T)^*$ . Let  $f^{tr}$  be as defined above and let  $w^{tr}$  denote the word obtained from w be replacing elements of T with 0. We easily see that  $w \in st(f, J)$  if and only if  $w^{tr} \in st(f^{tr}, J)$  (J is a  $\mathcal{J}$  class of  $J^{tr}$ , so  $st(f^{tr}, J)$  makes sense).

We will use the above notations throughout the next proofs. We summarize.

**Definition 41.** Let S be an aperiodic finite semigroup. Let T be an ideal and let J be a  $\mathcal{J}$  class directly above T. We have defined:

- 1. For  $w \in (T \cup J)^*$ , the word  $w^{tr} \in (J^{tr})^*$  is obtained from w by replacing elements of T with 0.
- 2. Let  $f \in Cayley(S, T \cup J)$ . The function  $f^{tr} \in Cayley(S, J^{tr})$  is given by  $f^{tr}(w) = (f(w'))^{tr}$ , where w' is any word in  $(J \cup T)^*$  satisfying  $(w')^{tr} = w$ . It is obvious that this is well defined.
- 3. Let  $f \in Cayley(S, T \cup J)$ . We define  $st(f^{tr}, J)$  to be the set of  $f^{tr}$ -J-stable words in  $(J^{tr})^*$ . For  $w \in (J \cup T)^*$ , we have  $w \in st(f, J)$ if and only if  $w^{tr} \in st(f^{tr}, J)$ .

We see that the mapping  $f \mapsto f^{tr}$  is a morphism  $Cayley(S, T \cup J) \to Cayley(S, J^{tr})$ , i.e.  $f^{tr}g^{tr} = (fg)^{tr}$ . We will now show that it induces a morphism  $Cayley_{st-J}(S, T \cup J) \to Cayley_{st-J}(S, J^{tr})$ .

**Definition 42.** Let  $\tilde{f} \in Cayley_{st-J}(S, T \cup J)$  and let  $w \in (J^{tr})^*$ . Write  $f^{tr}(w)$  for the word  $(f(w))^{tr}$  where f is an element of  $Cayley(S, T \cup J)$  such that f maps to  $\tilde{f}$ , and the action of f on  $J^{tr}$  is understood as in Notation 40. It is clear that this is well defined. Thus we have defined a mapping  $Cayley_{st-J}(S, T \cup J) \rightarrow Cayley_{st-J}(S, J^{tr})$ .

**Lemma 43.** Let S be an aperiodic semigroup, T an ideal of S and J a  $\mathcal{J}$  class directly above T. Let  $\tilde{f}, \tilde{g} \in Cayley_{st-J}(S, T \cup J)$ , and let  $f, g \in Cayley(S, T \cup J)$  be preimages of  $\tilde{f}, \tilde{g}$ . Then  $(fg)^{tr} = f^{tr}g^{tr}$ .

*Proof.* This follows from the fact that the mapping  $f \mapsto f^{tr}$  is a morphism, and that  $\tilde{f} \mapsto f^{tr}$  is well defined. Furthermore, we see that this does not depend on the choice of f and g.

We wish to extend all result we had previously obtained for Cayley(S, I)where I was a 0-minimal ideal of S. When we consider  $Cayley(S, J^{tr})$ ,  $J^{tr}$  is a 0-simple semigroup, however it's not an ideal of S.

**Theorem 44.** Let S be an aperiodic semigroup, let J be a  $\mathcal{J}$  class of S, and let  $T = S^1 J S^1 \setminus J$ . Denote by  $\sim_T$  the ideal congruence associated with T. Then  $(J \cup T) / \sim_T$  is a 0-minimal ideal of  $S / \sim_T$ and  $Cayley(S, J^{tr}) \cong Cayley(S / \sim_T, (J \cup T) / \sim_T)$ . Furthermore, since  $\sim_T$  is 1 - 1 on J we have  $J / \sim_T = J$ .

*Proof.* It is obvious that  $(J \cup T) / \sim_T$  is a 0-minimal ideal of  $S / \sim_T$ . To show the isomorphism, consider  $\varphi_s \in Cayley(S, J^{tr})$ . If  $s \in T$ , then the action of  $\varphi_s$  on  $(J^{tr})^*$  is seen as sending any string to a string of

zeros, so in this case  $\varphi_s$  corresponds to  $\varphi_0$  where 0 is the 0 element of  $S/\sim_T$  and it sends any string in  $((J \cup T)/\sim_T)^*$  to a string of zeros.

If  $s \notin T$  then the action of  $\varphi_s$  on  $(J^{tr})^*$  is the same as in  $Cayley(S/\sim_T, (J \cup T)/\sim_T)$ .

We can extend this from  $\{\varphi_s\}$ , the generators of  $Cayley(S, J^{tr})$  to the whole semigroup, and obtain an isomorphism  $Cayley(S, J^{tr}) \cong Cayley(S/\sim_T, (J \cup T)/\sim_T)$ .

Let  $Cayley(S,T)^{J^{tr}}$  denote the semigroup of all functions  $J^{tr} \to Cayley(S,T)$  with pointwise multiplication. We now define a right action of  $Cayley_{st-J}(S,J^{tr})$  on  $Cayley(S,T)^{J^{tr}}$ . Let  $\tilde{f} \in Cayley_{st-J}(S,J^{tr})$  and let  $H: J^{tr} \to Cayley(S,T)$ . Let  $j \in J$ . If  $[j] \in st(\tilde{f},J)$  then we let  $H^{\tilde{f}}(j) = H(\tilde{f}(j))$ . Otherwise we let  $H^{\tilde{f}}(j) = \varphi_0$  (Recall that  $\varphi_0$ , the function sending any string to a string of zeros is the zero element of Cayley(S,T)).

Notice the slight abuse of notation for f(j) where we identify elements of the semigroup S with strings of length 1. Formally, instead of  $\tilde{f}(j)$  we should have written  $p(\tilde{f}([j]))$ , where p is the projection  $p([v_1]) = v_1$ .

To show that this is indeed an action, let  $\tilde{f}, \tilde{g} \in Cayley_{st-J}(S, J^{tr})$ . We first need to show that  $H^{\tilde{f}\tilde{g}}(j) = (H^{\tilde{f}})^{\tilde{g}}(j)$  for every  $j \in J$ . Consider the following cases:

- 1. If j = 0 then both sides are H(0). [0] is a *J*-stable word for every function in  $Cayley_{st-J}(S, T \cup J)$ .
- 2. If  $j \in J$  and  $[j] \in st(\tilde{f}\tilde{g}, J)$  then we also have  $[j] \in st(\tilde{g}, J)$ ,  $j' = \tilde{g}(j)$  and  $[\tilde{f}(j')] \in st(\tilde{g}, J)$ . Now both sides of the equation equal  $H(\tilde{f}(j'))$ .
- 3. If  $j \in J$  and  $[j] \notin st(\tilde{f}\tilde{g}, J)$ . This implies that either  $[j] \notin st(\tilde{g}, J)$  or  $[\tilde{g}(j)] \notin st(\tilde{f}, J)$ . In both cases this gives  $\varphi_0$  on both sides of the equation.

It is clear that  $(FG)^{\tilde{h}} = F^{\tilde{h}}G^{\tilde{h}}$  for  $F, G: J^{tr} \to Cayley(S, T)$ , and  $\tilde{h} \in Cayley_{st-J}(S, J^{tr})$ .

We may now define the semidirect product  $Cayley_{st-J}(S, J^{tr}) \rtimes Cayley(S, T)^{J^{tr}}$ .

Now for the main theorem of this section.

**Theorem 45.** Let S be a finite semigroup. Let T be an ideal of S, and let J be a  $\mathcal{J}$  class of S directly above T. Cayley<sub>st-J</sub>(S,  $T \cup J$ ) is isomorphic to a subsemigroup of Cayley<sub>st-J</sub>(S,  $J^{tr}$ )  $\rtimes$  (Cayley(S,T))<sup>J<sup>tr</sup></sup>.

Before proceeding with the proof we would like to show the reasoning behind this theorem. The action of  $\tilde{f}$  on a stable word w can be thought of as two actions. The first is modifying the prefix of w in Jto some other prefix in J. This can be thought of as  $\tilde{f} \mapsto f^{tr}$ . The second part is the action of  $\tilde{f}$  is on the remainder, the part in  $T^*$ . In general this action depends on the prefix of w in J. However, Corollary 35 says that this action only depends on an element in J. *Proof.* Let  $f \in Cayley_{st-J}(S, T \cup J)$  and let f be any element in  $Cayley(S, J \cup T)$  that maps onto  $\tilde{f}$ . Denote by  $\hat{f}$  the function  $\hat{f} : J^{tr} \to Cayley(S, T)$  defined by

$$(\hat{f}(j))(w) = \begin{cases} f(w) & j = 0\\ f_{[j]}(w) & [j] \in st(f, J), j \in J\\ \varphi_0(w) & [j] \notin st(f, j), j \in J \end{cases}$$

restricted to  $T^*$  (i.e.  $w \in T^*$ ). This is well defined. The first case because every word in  $T^*$  is J-stable. The second case, since if  $f(j) \in J$ , then for every  $w = [t_1, \ldots, t_k] \in T^*$  we can express  $f_{[j]}(w)$  as the klength suffix of  $f([j, t_1, t_2, \ldots, t_k])$ . Furthermore this does not depend on the choice of f.

Let  $\Pi : Cayley_{st-J}(S, T \cup J) \to Cayley_{st-J}(S, J^{tr}) \rtimes Cayley(S, T)^{J^{tr}}$ be given by  $\Pi(\tilde{f}) \mapsto (f^{tr}, \hat{f})$ ,  $\Pi$  is obviously well-defined. To show that it is a semigroup morphism, consider  $\tilde{f}, \tilde{g} \in Cayley_{st-J}(S, T \cup J)$ . We have  $\Pi(\tilde{f})\Pi(\tilde{g}) = (f^{tr}, \hat{f})(g^{tr}, \hat{g})$ . We have seen that  $(fg)^{tr} = f^{tr}g^{tr}$ . In order to show that  $\Pi$  is a morphism, it remains to show that for every  $j \in J^{tr}$  the equation  $(\widehat{fg}(j))(w) = (\widehat{f}^{(g^{tr})}(j)\widehat{g}(j))(w)$  holds for every  $w \in T^*$ .

If we choose j as the zero element of  $J^{tr}$  the equation is immediate. Choose a  $j \in J$ . If  $[j] \notin st(g^{tr}, J)$  then we also have  $[j] \notin st((fg)^{tr}, J)$ , so  $\widehat{fg}(j) = \varphi_0 = \widehat{f}^{(g^{tr})}(j)\varphi_0 = \widehat{f}^{(g^{tr})}(j)\widehat{g}(j)$ . If  $[j] \in st(g^{tr}, J), g^{tr}([j]) = [j']$  and  $[j'] \notin st(f^{tr}, J)$ , then as before, we have  $[j] \notin st((fg)^{tr}, J)$  so  $\widehat{fg}(j) = \varphi_0 = \varphi_0 \widehat{g}(j) = \widehat{f}^{(g^{tr})}(j)\widehat{g}(j)$ . Finally, we consider the case  $[j] \in st((fg)^{tr}, J)$ .

In this case  $\widehat{fg}(j) = (fg)_{[j]}$ ,  $\widehat{g}(j) = g_{[j]}$ , and  $(\widehat{f})^{(g^{tr})}(j) = f_{[g(j)]}$ , all restricted to  $T^*$ . Let  $\varphi_{s_n} \cdots \varphi_{s_1}$  be any representative of f, and  $\varphi_{t_m} \cdots \varphi_{t_1}$  a representative of g. Let  $\overline{t} = t_m \cdots t_1$ . By Lemma 33  $\widehat{fg}(j) = (fg)_{[j]} = (\varphi_{s_n} \cdots \varphi_{s_1} \varphi_{t_m} \cdots \varphi_{t_1})_{[j]} =$ 

 $\begin{array}{l} \varphi_{(s_n\cdots s_1t_m\cdots t_1j)}\cdots\varphi_{(s_1t_m\cdots t_1j)}\varphi_{(t_m\cdots t_1j)}\cdots\varphi_{(t_1j)}=f_{[\bar{t}j]}g_{[j]}=\hat{f}(\bar{t}j)\hat{g}(j).\\ \text{Since } [j]\in st(g^{tr},J), \text{ we have } g^{tr}(j)=t_m\cdots t_1j=\bar{t}j\in J. \text{ Furthermore, since } [j]\in st((fg)^{tr},J) \text{ we have } g^{tr}([j])\in st(f^{tr},J), \text{ i.e. } [\bar{t}j]\in st(f^{tr},J). \end{array}$ 

We now show that  $\Pi$  is 1-1. Let  $\hat{f}, \tilde{g} \in Cayley_{st-J}(S, T \cup J)$  and assume that  $\Pi(\tilde{f}) = \Pi(\tilde{g})$ . As before we will write  $\Pi(\tilde{f}) = (f^{tr}, \hat{f})$  and  $\Pi(\tilde{g}) = (g^{tr}, \hat{g})$ . Let  $w \in st(f, J)$ . We need to show that  $\tilde{f}(w) = \tilde{g}(w)$ (this will show that  $w \in st(g, J)$ ). Furthermore, since  $f(w) = \tilde{f}(w)$ this is the same as showing that f(w) = g(w). If  $w \in T^*$  then this is clear since  $f(w) = (\hat{f}(0))(w) = (\hat{g}(0))(w) = g(w)$ . If  $w \in J^*$ , then (recall that w is in st(f, J) so f(w) is in  $J^*$ )  $f(w) = f^{tr}(w) =$  $g^{tr}(w)$ . Since  $g^{tr}(w)$  has no zeros (because  $g^{tr}(w) = f^{tr}(w)$ ), we have that  $g^{tr}(w) = g(w)$ . We now assume that f(w) has a prefix in  $J^*$ and a suffix in  $T^*$ . Write this as  $f(w) = w' = w'_1 \circ w'_2$  and write a decomposition for w as  $w = w_1 \circ w_2$  such that  $|w_1| = |w'_1|$  and  $|w_2| = |w'_2|$ .  $w \in st(f, J)$  implies that  $w_1 \in J^*$  and  $w_2 \in T(T \cup J)^*$ (the first letter of  $w_2$  is in T). We need to show that g(w) = w'. By definition we have  $g(w) = g(w_1) \circ g_{w_1}(w_2)$ . Recall that  $f(w_1) \in J^*$ , which implies that  $f(w_1) = f^{tr}(w_1) = g^{tr}(w_1) = g(w_1)$ , It remains to show that  $g_{w_1}(w_2) = w'_2 = f_{w_1}(w_2)$ . Let  $w_1 = [(a_1, b_1), \cdots, (a_n, b_n)]$ , and let  $j = p\varphi_1(w_1) = (a_1, b_n)$ . Corollary 35 shows that  $f_{w_1} = f_{[j]}$ , and  $g_{w_1} = g_{[j]}$ . In particular the restriction of this equation to  $T^*$ remains valid. Summing up, we have  $f_{w_1}(w_2) = f_{[j]}(w_2) = \hat{f}(j)(w_2) =$  $\hat{g}(j)(w_2) = g_{[j]}(w_2) = g_{w_1}(w_2)$  which completes the proof.

**Corollary 46.** Let S be an aperiodic semigroup, T an ideal of S, and J a  $\mathcal{J}$  class directly above T. If Cayley(S,T) is finite then  $Cayley_{st-J}(S,T\cup J)$  is finite.

*Proof.* It is enough to show that  $Cayley_{st-J}(S, J^{tr})$  is finite. This follows from Theorem 28 and Theorem 44. When applying Theorem 44 we recall that the quotient of a finite aperiodic semigroup is also aperiodic.

**Theorem 47.** Let S be an aperiodic semigroup, T an ideal of S, and J a  $\mathcal{J}$  class directly above T. If Cayley(S,T) is finite then  $Cayley(S,T \cup J)$  is finite.

*Proof.* We will do this by showing that for some constant N, every  $f \in Cayley(S, T \cup J)$  can be written as a product of N or less generators.

Let  $f \in Cayley(S, T \cup J)$  be given, and let  $f = \varphi_{s_n} \cdots \varphi_{s_2} \varphi_{s_1}$ be a presentation of f. Since the mapping  $f \mapsto f^{tr}$  is a morphism  $Cayley(S, T \cup J) \to Cayley(S, J^{tr})$ , we have  $f^{tr} = \varphi_{s_n}^{tr} \cdots \varphi_{s_2}^{tr} \varphi_{s_1}^{tr}$ , an element in  $Cayley(S, J^{tr})$ .

We observe here that the elements  $\{\varphi_s^{tr}\}_{s\in S}$  are a generating set for  $Cayley(S, J^{tr})$ .

By Corollary 32 there is a constant N' (depending only on J) such that we can write  $f^{tr} = g_{k+1}^{tr} \varphi_{s_k}^{tr} g_k^{tr} \varphi_{s_{k-1}}^{tr} \cdots \varphi_{s_2}^{tr} g_2^{tr} \varphi_{s_1}^{tr} g_1^{tr}$  for some k < N', where the  $g_i^{tr}$ 's never create new zeros on any input.

It is obvious that for any word  $w \in (T \cup J)^*$ , w is  $g_i$ -J stable if and only if  $w^{tr}$  is  $g_i^{tr}$ -J stable. In other words, the  $g_i^{tr}$  never create new zeros if and only if the  $g_i$  never map a letter from J to a letter in T.

Since the  $g_i^{tr}$  never create zeros, we may say that the  $g_i^{tr}$  only act on  $g_i^{tr}$ -J stable words. This means that inside the above presentation of f, the  $g_i$  will only get to act on J- $g_i$  stable words, thus we can identify  $g_i$  with  $\tilde{g}_i$ , its image in  $Cayley_{st-J}(S, T \cup J)$ .

By Corollary 46  $Cayley_{st-J}(S, T \cup J)$  is finite, so we may assume there is another constant l such that every  $g_i$  can be written as (or replaced by) a product of l or less generators, without changing the value of f(w) for any word w.

This shows that there is a number N such that every  $f \in Cayley(S, T \cup J)$  can be written as a product of N or less generators.

Finally, we have the main theorem of this section.

**Proposition 48.** If S is an aperiodic semigroup, Cayley(S) is finite.

*Proof.* Choose an ordering of the  $\mathcal{J}$  classes of  $S \{J_i\}_{i=1}^n$ , such that for every  $1 \leq k \leq n$  we have  $\bigcup_{i=1}^k J_i$  is an ideal of S. It is obvious that such an ordering exists and that  $J_1 \cup J_2$  is a 0-minimal ideal. We have shown that  $Cayley(S, J_1 \cup J_2)$  is finite, and the last theorem shows that  $Cayley(S, \bigcup_{i=1}^k J_i)$  is finite for every k. This completes the proof.  $\Box$ 

## 7 Aperiodicity

**Lemma 49.** Let S be a finite semigroup. Let T be an ideal of S such that  $f^n = f^{n+1}$  for every  $f \in Cayley(S,T)$  for some  $n \in \mathbb{N}$ . Let J be a  $\mathcal{J}$  class of S directly above T, such that  $f^l = f^{l+1}$  for every  $f \in Cayley(S, J^{tr})$  for some  $l \in \mathbb{N}$ . Then  $f^{n+l} = f^{n+l+1}$  for all  $f \in Cayley(S, T \cup J)$ .

*Proof.* Let  $w \in (T \cup J)^*$ . Let  $f \in Cayley(S, T \cup J)$ . Consider  $w_0 = (f)^l(w)$ .  $w_0$  has a prefix  $w_J$  in  $J^*$  and a suffix  $w_T$  in  $T^*$ . This implies that  $(f^{tr})^l(w^{tr})$  has the same prefix  $w_J$  in  $J^*$  as  $f^l(w)$ , and a suffix of zeros. Furthermore, since  $(f^{tr})^l(w^{tr}) = (f^{tr})^{l+1}(w^{tr})$ , this gives  $f^{tr}(w_J) = w_J$ .

We now have

$$f^{n+l}(w) = f^{n}(w_{0}) = f^{n}(w_{J} \circ w_{T}) = f^{n-1}(f(w_{J}) \circ f_{w_{J}}(w_{T})) = f^{n-1}(w_{J} \circ f_{w_{J}}(w_{T})) = (w_{J} \circ f_{w_{J}}^{n}(w_{T})) = (w_{J} \circ f_{w_{J}}^{n+1}(w_{T})) = f^{n+1}(w_{J} \circ w_{T}) = f^{n+1}(w_{0}) = f^{n+l+1}(w).$$

**Corollary 50.** Let S be a finite aperiodic semigroup. Then  $\exists n \in \mathbb{N}$  such that  $f^n = f^{n+1}$  for all  $f \in Cayley(S)$ .

*Proof.* As before, let  $\{J_i\}_{i=1}^k$  be an enumeration of the  $\mathcal{J}$  classes of S, such that  $\bigcup_{i=1}^k J_i$  is an ideal of S for all  $1 \leq i \leq k$ . We saw earlier that for some  $N \in \mathbb{N}$ , we have  $f^N = f^{N+1}$  for every  $f \in Cayley(S, J_1)$ . Continuing by induction on the number of  $\mathcal{J}$  classes in S, and by applying the previous lemma, the result follows.

## 8 Summary

The results of this paper may be summed up as follows.

**Proposition 51.** Let S be a finite semigroup. The following are equivalent.

- 1. S is an aperiodic semigroup.
- 2. Cayley(S) is finite.
- 3. Cayley(S) is aperiodic.

*Proof.* That (1) implies (2) and (1) implies (3), are the main results of this paper. Suppose that (1) does not hold. Then S contains a non trivial group G. By results of Silva and Steinberg [6], Cayley(G) is a free semigroup on |G| generators. Since  $Cayley(G) \prec Cayley(S)$  we see that if (1) is not true, then (2) and (3) are not true.

## 9 Acknowledgments

The author would like to thank the anonymous referee for his careful reading and helpful comments, and the Bar-Ilan President's Fellowship for funding this research.
