A high order purely frequency-based harmonic balance formulation for continuation of periodic solutions

Bruno Cochelin^a Christophe Vergez^{a,*}

 $a_{\text{Laboratoire}}$ de Mécanique et d'Acoustique (LMA-CNRS). 31 Chemin Joseph Aiguier, 13402 Marseille Cedex 20, France

Abstract

Combinig the harmonic balance method (HBM) and a continuation method is a well-known technique to follow the periodic solutions of dynamical systems when a control parameter is varied. However, since deriving the algebraic system containing the Fourier coefficients can be a highly cumbersome procedure, the classical HBM is often limited to polynomial (quadratic and cubic) nonlinearities and/or a few harmonics. Several variations on the classical HBM, such as the incremental HBM or the alternating frequen
y/time domain HBM, have been presented in the literature to overcome this shortcoming. Here, we present an alternative approach that can be applied to a very large class of dynamical systems (autonomous or forced) with smooth equations. The main idea is to systematically recast the dynamical system in quadrati polynomial form before applying the HBM. On
e the equations have been rendered quadrati
, it be
omes obvious to derive the algebrai system and solve it by the soalled ANM ontinuation te
hnique. Several lassi
al examples are presented to illustrate the use of this numeri
al approa
h.

Key words: harmonic balance, frequency domain, asymptotic numerical method, ontinuation, bifur
ation, periodi solutions

1 Introdu
tion

In the field of engineering, especially when dealing with nonlinear vibrations. it is often required to ompute the periodi solutions of a system of nonlinear differential equations $([1,2])$ $([1,2])$ $([1,2])$. In the following, we focus on numerical methods to find periodic solutions. They are usually subdivided into two main groups : those relying on the time-domain formulation and those relying on the frequency-domain formulation. The first group consists of methods where a time integration algorithm, whi
h is generally limited to a single period, is used to transform the original differential system into a system of algebraic equations, whi
h are then solved by ontinuation. With these methods, the

nrs-mrs.fr (Christophe Vergez).

unknowns in the algebraic system are the values of the original unknown variables at grid points along the periodic orbit. The classical shooting technique $([3,4])$ $([3,4])$ $([3,4])$ and the orthogonal collocation methods used in AUTO $([5,7])$ $([5,7])$ $([5,7])$ belong to this group. The second group corresponds to the so-called harmonic balan
e method where the unknown variables are de
omposed into trun
ated Fourier series. In this case, the unknowns in the final algebraic system, which is obtained by balancing the harmonics featuring in the differential equations, are simply the Fourier coefficients of the original unknowns. Methods of both kinds are widely used in many applications and research is still required to improve them. In practical terms, the choice between the time-domain or the frequency-domain approach depends mainly on whether the periodic solution an be de
omposed with a few Fourier omponents. The method hosen to deal with a given problem an therefore depend on the operating point.

In this paper, we focus on the harmonic balance method (HBM) and some of its variations, which are briefly recalled here. Although the name "harmonic balance" seems to have first appeared in 1936 ($[8]$), this method has been widely used only since the sixties, and especially for electrical and mechanical engineering purposes. Forced vibrations were first studied ([9]), and self-sustained oscillations a decade later ([10]). The study by Nakhla & Vlach $(|11|)$ is often said to be a milestone in the modern formulation of HBM. The classical HBM is simple in its principle, but it can be cumbersome or even impracticable, as stated by Peng et al. (12) when the system contains complex nonlinearities and when a large number of harmoni
s is required, ie, more than 5 or 10. The first problem which arises is how to derive the algebraic system for the Fourier coefficients and the second problem is how to solve this strongly nonlinear system efficiently. To overcome these shortcomings, many variations on the basi HBM have been proposed in the literature. Here, we will simply give an overall pi
ture of in
remental harmoni balan
e (IHB) and alternating frequen
y/time domain harmoni balan
e (AFT) method. With the IHB method $([13])$, the incremental-iterative method used for the continuation is closely combined with the harmonic principle, so as to be able to apply the HB prin
iple to the in
remental linear problem instead of the nonlinear original system. Nonlinearity of all kinds can be treated using this technique $[14,15]$ $[14,15]$. In the AFT variant, the harmonic balance of the Fourier coefficients is not explicitly performed. At each increment (or iteration) in the continuation proedure, the unknowns are transferred to the time domain (using the inverse Fast Fourier Transform,whi
h is denoted IFFT below), so as be able to use the original system of equations. The nonlinear responses are then transferred ba
k to the frequen
y domain using the Fast Fourier Transform, (denoted FFT below). The use of $FFT/IFFT$ procedures seems to have started in [16]. This te
hnique has been used, for instan
e, to analyse nonlinear vibrations in mechanical systems with contact and dry friction [17]. Since the pioneering work on IHB and AFT, many variations have been proposed to extend the applications, as well as to decrease the computational cost (see [18] or [19] for

some re
ent examples).

An alternative strategy is proposed here for applying the classical HBM with a large number of harmonics, without avoiding explicit balancing. The idea is to apply a transformation to the original system of differential equations before applying the HBM. The aim of this pro
edure is to transform the nonlinearities present in the original system into purely polynomial quadrati terms. The lassi
al HBM pro
edure an then be easily applied. This transformation might seem to be a limitation of the method, sin
e not every system an be re
ast in polynomial quadrati form. However, it will be shown in this paper that a very large lass of systems with smooth equations an indeed be re
ast in quadrati form by making a few algebrai manipulations and a a few additions of equations and auxiliary variables. The idea of using a quadrati formulation to simplify the (Fourier) series expansion was inspired by another numeri
al method, the soalled Asymptoti Numeri
al Method (ANM) $(21,22)$ which was presented for the first time in 1990 (20) . ANM is a continuation technique (23) involving high order powers series expansion of the bran
hes of solutions. For reasons that will be given later on, this ANM continuation is the ideal means of solving the algebraic system resulting from the HB method proposed here.

The paper is organised as follows: details of the transformation into a polynomial quadrati form, the appli
ation of the HBM method and the prin
iple of ontinuation are given in se
tion 2 in the ases of autonomous systems. Three simple examples are given as an illustration. Se
tion 3 is devoted to periodi cally forced systems, and two further examples are presented. Section 4 gives the results of all the examples and ends with some on
luding omments and perspe
tives.

2 Presentation of the method for obtaining periodic solutions of autonomous systems

Let us consider an autonomous system of differential equations

$$
\dot{Y} = f(Y, \lambda) \tag{1}
$$

where Y is a vector of unknowns, f a smooth nonlinear vector valued function and λ a real parameter. The dot stands for the derivative with respect to time t. We assume that this system has branches of periodic solutions when λ varies. and we want to find and follow them by applying the harmonic balance method and a ontinuation pro
edure (path following te
hnique). The important ase of a for
ed (non-autonomous) system will be dealt with separately in se
tion [3.](#page-12-0)

2.1 The harmonic balance principle

As recalled in the Introduction, the HBM consists basically in decomposing $Y(t)$ into a truncated Fourier series :

$$
Y(t) = Y_0 + \sum_{k=1}^{H} Y_{c,k} \cos(k\omega t) + \sum_{k=1}^{H} Y_{s,k} \sin(k\omega t)
$$
 (2)

This ansatz is put into Eq. [\(1\)](#page-2-0) and $f(Y,\lambda)$ is expanded into Fourier series. By balancing the first $2H + 1$ harmonic terms, one obtains an algebraic system with $2H+1$ vector equations for the $2H+1$ vector unknowns Y_i , the unknown pulsation ω , and the parameter λ . Adding a phase condition ([3]) yields a system with N equations and $N+1$ variables. The branches of solutions of this algebraic system are then followed using a continuation technique. This procedure provides only approximate periodic solutions, since in the expansion of Eq. (1) , all the harmonic terms greater than H remain unbalanced. However, if the number of harmonics H is large enough, accurate solutions an be obtained.

The most crucial point is the expansion of the vector $f(Y, \lambda)$ into Fourier series. This can be quite a straighforward procedure if $f(Y, \lambda)$ is a polynomial of degree two or three, and if the number of harmonics H is sufficiently small. In this case, the expansion can be carried out by hand. But in the most general situation, where $f(Y, \lambda)$ shows nonlinearities of any kinds, this computation can be very cumbersome, even with the help of a symbolic software program. The only alternative is then to use numeri
al pro
edures to estimate the Fourier series of $f(Y, \lambda)$, by performing iterative FFT/IFFT steps, for example. This drawba
k was the starting-point in the developpment of many variants of the HBM as mentioned in the Introduction.

2.2 A key point: the quadratic recast

The main aim of this paper is to present a simple but powerful pro
edure that over
omes the drawba
k mentioned above. The idea is to re
ast the original system [\(1\)](#page-2-0) into a new system where the nonlinearities are at most quadratic polynomials . The appli
ation of the harmoni balan
e method subsequently becomes quite straighforward. This new quadratic system, which will be written as follows

$$
m(\dot{Z}) = c + l(Z) + q(Z, Z)
$$
\n(3)

can contain both differential and algebraic equations. N_e is taken to denote the number of equations. The unknown vector Z (size N_e) contains the original omponents of the ve
tor Y and some new variables whi
h are added to get the quadratic form. The right hand side of Eq. (3) is written as follows: c is a constant vector with respect to the unknown $Z, l(.)$ is a linear vector valued operator with respect to the vector entry, and $q(.,.)$ is a quadratic vector valued operator, which is linear with respect to both entries. At this stage, the three vectors c, $l(.)$ and $q(.)$. may depend on the real parameter λ . However, it is preferable for the quadratic operator $q(.,.)$ not to depend on λ , which may require introducting a new variable in Z (see example 1 below). on the left hand side, $m(.)$ is a linear vector valued operator with respect to the vector entry. The algebraic equations correspond to zero values of $m(.)$.

Since the nonlinearities are quadratic, the HBM can obviously be easily and systematically applied on Eq. [\(3\)](#page-3-0), even with a large number of harmonics. The question is now: an any system be easily put into the form of Eq. [\(3\)](#page-3-0) ? As we will see, the answer is yes, for a very large class of nonlinear systems.

The idea of recasting a nonlinear system into a new one with a quadratic polynomial nonlinearity is frequently used when considering the so-called ANM ontinuation method, whi
h onsists in omputing power series expansion of solution branches, see $([21, 22, 23, 24])$ $([21, 22, 23, 24])$ $([21, 22, 23, 24])$ $([21, 22, 23, 24])$ $([21, 22, 23, 24])$ $([21, 22, 23, 24])$ $([21, 22, 23, 24])$ for the basic algorithms and $([25, 26, 27])$ $([25, 26, 27])$ $([25, 26, 27])$ $([25, 26, 27])$ $([25, 26, 27])$ for some applications in mechanics. The quadratic recast gives a very simple and systemati algebra for the series determination, even with high orders of truncature. Similar benefits are obtained with the Fourier series expansions.

It is now worth illustrating this main idea by giving some elementary examples where the recast from Eq. (1) to Eq. (3) will be performed explicitely. We will deal first with the classical Van der Pol oscillator, the Rössler system and a model for clarinet-like musical instruments. Other examples, with nonlinearities of others kinds su
h as rational fra
tion, will be given later on.

Example 1: The Van der Pol oscillator. We take the following second order autonomous system, known as the Van der Pol os
illator, where the parameter λ governs the amplitude of the nonlinear damping term.

$$
\ddot{u} - \lambda (1 - u^2) \dot{u} + u = 0 \tag{4}
$$

This equation can be classically recast into first order system (as Eq. (1)) by introducing the velocity $v(t) = \dot{u}(t)$ as a new unknown. We obtain

$$
\dot{u} = v
$$

\n
$$
\dot{v} = \lambda (1 - u^2) v - u
$$
\n(5)

If we now introduce the auxiliary variables $w(t) = 1 - u^2(t)$ and $r(t) =$ $v(t)w(t)$, the system can be written in the form of Eq. [\(3\)](#page-3-0) with $Z = [u, v, w, r]^t$. The various terms are arranged below so that it will be lear to the readers how the different functions m, c, l and q are formed.

$$
\dot{u} = 0 + v
$$
\n
$$
\dot{v} = 0 -u + \lambda r
$$
\n
$$
0 = 1 -w -u^2
$$
\n
$$
\underbrace{0}_{m(\dot{z})} = \underbrace{0}_{c} \underbrace{+r}{u(z,\lambda)} \underbrace{-vw}_{q(z,z)}
$$
\n
$$
(6)
$$

We finally obtain two first order differential equations and two algebraic equations with quadratic polynomial nonlinearities. Only the operator l depends here on λ .

Example 2: The Rössler system. We take the following first order autonomous system of three equations known as the Rössler system.

$$
\begin{aligned}\n\dot{x} &= -y - z \\
\dot{y} &= x + ay \\
\dot{z} &= b + z(x - \lambda)\n\end{aligned} \tag{7}
$$

where x, y, z are functions of time and a, b, c are float parameters. This system an be written in the form of Eq. [\(3\)](#page-3-0) without any auxiliary variables (i.e. $Z = [x, y, z]^t$):

$$
\begin{array}{rcl}\n\dot{x} & = & 0 & -y - z \\
\dot{y} & = & 0 & +x + ay \\
\dot{z} & = & \underbrace{b} & -\lambda z & +zx \\
\frac{m(z)}{z} & = & \underbrace{1(z,\lambda)} & \underbrace{+zx} & \\
\end{array} \tag{8}
$$

Here again, only the operator l depends on λ . This example will be used here to show that the approach presented in this paper can be used to find period-doubling and bifur
ations with period 4.

Example 3: A model for clarinet-like musical instruments. In the case of small amplitude oscillations, a simple model for reed instruments (clarinet,

saxophone, etc) can be written using a modal formulation (see $[28]$):

$$
\ddot{x} + q_r \omega_r \dot{x} + \omega_r^2 x = \omega_r^2 p
$$
\n
$$
\ddot{p}_n + 2\alpha_n c \dot{p}_n + \omega_n^2 p_n = \frac{2c}{l} \dot{u} \qquad \forall n \in [1 \dots N]
$$
\n
$$
u = \zeta (1 - \lambda + x) \sqrt{\lambda - p}
$$
\n
$$
p = \sum_{n=1}^N p_n
$$
\n(9)

where the unknowns x, $p_{n=1..N}$, p, u are functions of time and $q_r, \omega_r, \alpha_n, \omega_n, c$, l, ζ are given parameters describing either the physics or the player's action. N is the number of acoustic modes. λ stands here for the blowing pressure.

It is worth noting that even if this system contains a square root, it can be recast in the form of Eq. [\(3\)](#page-3-0): if we introduce the auxiliary variables $y = \dot{x}, z_n =$ p_n and $v = \sqrt{\lambda - p}$, system [\(9\)](#page-6-0) can be rewritten, with $Z = [x, y, p_1, \dots, p_N, z_1 \dots z_N, u, v]^t$ as follows:

$$
\dot{x} = 0 \qquad +y
$$
\n
$$
\dot{y} = 0 \qquad +\omega_r^2 p - q_r \omega_r y - \omega_r^2 x
$$
\n
$$
\dot{p}_n = 0 \qquad +z_n \qquad \forall n \in [1...N]
$$
\n
$$
\dot{z}_n - \frac{2c}{l} \dot{u} = 0 \qquad -2\alpha_n c z_n - \omega_n^2 p_n \qquad \forall n \in [1...N] \quad (10)
$$
\n
$$
0 = 0 \qquad -u + \zeta(1 - \lambda)v \qquad +\zeta xv
$$
\n
$$
0 = 0 \qquad -p + p_1 + \dots + p_N
$$
\n
$$
\underbrace{0}_{m(\dot{Z})} = \underbrace{\lambda}_{c(\lambda)} \underbrace{-p}_{l(Z,\lambda)} \underbrace{-v^2}_{q(Z,\dot{Z})}
$$

Here, the linear term l, but also the constant term c, are functions of λ .

2.3 The harmonic balance method applied to a quadratic system

In this section, the harmonic balance method is applied to the system [\(3\)](#page-3-0). The unknown (column) vector Z is decomposed into Fourier series with H harmoni
s:

$$
Z(t) = Z_0 + \sum_{k=1}^{H} Z_{c,k} \cos(k\omega t) + \sum_{k=1}^{H} Z_{s,k} \sin(k\omega t)
$$
 (11)

The omponents of the Fourier series are olle
ted into a large (
olumn) ve
tor U, with size $(2H + 1) \times N_e$, where N_e is the number of equations in [\(3\)](#page-3-0).

$$
U = [Z_0^t, Z_{c,1}^t, Z_{s,1}^t, Z_{c,2}^t, Z_{s,2}^t, \dots, Z_{c,H}^t, Z_{s,H}^t]^t
$$
\n(12)

By introducing the expansion (11) into the set of Eqs. (3) , collecting the terms of the same harmoni index, and negle
ting the higher order harmoni
s, one obtains a large system of $(2H+1) \times N_e$ equations for the unknown vector U,

$$
\omega M(U) = C + L(U) + Q(U, U) \tag{13}
$$

The new operators $M(.)$, C, $L(.)$, and $Q(.)$ that apply to U depend only on the operators $m(.)$, c, $l(.)$ and $q(.,.)$ of Eq. [\(3\)](#page-3-0) and on the number of harmonics H. The explicit formulas have been given in annex 1 for a sake of brevity. It should be noted that these expressions for $M(.)$, $L(.)$ and $Q(.,.)$ are the same in all the examples presented. The change from one particular system to another only involves the operators $m(.)$, $l(.)$ and $q(.,.)$.

The final system [\(13\)](#page-7-0) contains $(2H+1) \times N_e$ equations for the $(2H+1) \times N_e$ unknowns U plus the angular frequency ω and the continuation parameter λ . Sin
e the original system is autonomous, a phase ondition has to be added to Eq. (13) to define a unique orbit. Indeed, the time t does not appear in Eq. [\(3\)](#page-3-0) and if $U(t)$ is a solution of Eq. [\(13\)](#page-7-0) then $U(t + \tau)$ is also a solution, for any τ . We refer here to textbooks dealing with periodic solution continuation $(3,7,4)$ $(3,7,4)$ $(3,7,4)$ for the choice of the phase condition.

2.4 The continuation procedure

2.4.1 Framework

As the result of the harmoni balan
e operation, we now have to solve an algebrai system

$$
\mathbf{R}(\mathbf{U}) = 0\tag{14}
$$

with $\mathbf{R} \in \mathbb{R}^N$ and $\mathbf{U} = [U^t, \lambda, \omega]^t \in \mathbb{R}^{N+1}$ $(N = (2H + 1) \times N_e + 1)$. Any numerical continuation method $([29,30,3])$ $([29,30,3])$ $([29,30,3])$ and any suitable software (see $([31]$) for an overview) an be used for this purpose. However, in this paper we will use the so-called Asymptotic-Numerical-Method (ANM), on which the idea of the quadratic recasting was based. It is worth noting that the final system [\(13\)](#page-7-0) is already quadratic with respect to U and ω , and that the application of the ANM is therefore quite straighforward.

In the continuation procedure, a pseudo-arc length parametrization will be used in order to be able to pass the limit points with respect to λ . The parameter λ will therefore now become an unknown, like U and ω . It is now mandatory to specify how the operators m, c, l and q in Eq. [\(3\)](#page-3-0) depend on λ . In the three examples presented here, we have organised the terms of equations so that the parmeter λ only appears in the operators c and l. In addition, we have managed to make this dependence linear. Once again, this formulation is not limited to the three example presented here, but it an be obtained for a very large lass of dynami
al systems provided suitable additional variables are introduced. We recall that the parameter λ should not appear in the operator q , for which the HBM algebra is the more complex. For example, if there is a term λu^2 in Eq. [\(3\)](#page-3-0), it should be rewritten as λv with the auxiliary variable $v = u^2$, and put into l instead of q.

In what follows, it is therefore assumed that c and l can be written:

$$
c = c_0 + \lambda c_1
$$

$$
l(.) = l_0(.) + \lambda l_1(.)
$$
 (15)

where c_0 , c_1 , l_0 and l_1 are independent of λ . Under this assumption, the operators C and L simply become

$$
C = C_0 + \lambda C_1
$$

$$
L(.) = L_0(.) + \lambda L_1(.)
$$
 (16)

Note that the expression for C_0 , C_1 and L_0 , L_1 in terms of c_0 , c_1 and l_0 , l_1 are exactely the same as those given in annexe 1 for C and L in terms of c and l . The final algebraic system [\(14\)](#page-7-1) becomes

$$
\mathbf{R}(\mathbf{U}) = \mathbf{L}0 + \mathbf{L}(\mathbf{U}) + \mathbf{Q}(\mathbf{U}, \mathbf{U}) \tag{17}
$$

with $\mathbf{U} = [U^t, \lambda, \omega]^t$ and

$$
\begin{aligned}\n\mathbf{L}(U) &= C_0 \\
\mathbf{L}(U) &= L_0(U) + \lambda C_1 \\
\mathbf{Q}(U, U) &= Q(U, U) + \lambda L_1(U) - \omega M(U)\n\end{aligned} \tag{18}
$$

In Eq. (17) , L0 is a constant vector, L(.) is a linear vector valued operator and $\mathbf{Q}(\ldots)$ is a bilinear vector valued operator. We will now briefly review the ANM continuation technique for solving quadratic system $Eq(17)$ $Eq(17)$.

One of the main particularities of the ANM is that it gives access to branches of solution in the form of power series. Assuming that we know a regular solution point U_0 , the branch of solution passing through this point is computed in the form of a power series expansion (truncated at order n) of the pseudoarclength path parameter $a = (\mathbf{U} - \mathbf{U}_0)^t \mathbf{U}_1$, where \mathbf{U}_1 is the tangent vector at \mathbf{U}_0 :

$$
U(a) = U_0 + aU_1 + a^2U_2 + a^3U_3 + \dots + a^nU_n.
$$
 (19)

The series [\(19\)](#page-9-0) is replaced in Eq. [\(17\)](#page-8-0) and each power of a is equated to zero, giving a series of linear systems :

- order $0: L0 + L(U_0) + Q(U_0, U_0) = 0$, which is obvious since U_0 is a solution of Eq. [\(17\)](#page-8-0).
- order $1: L(U_1) + Q(U_0, U_1) + Q(U_1, U_0) = 0$, which can also be written $\mathbf{J}_{\mathbf{U}_0}\mathbf{U}_1 = 0$ where $\mathbf{J}_{\mathbf{U}_0} \in \mathbb{R}^{N \times N+1}$ is the jacobian matrix of **R** evaluated at \mathbf{U}_0 .
- order $\mathbf{2} \leq \mathbf{p} \leq \mathbf{n}$: $\mathbf{J}_{\mathbf{U}_0}\mathbf{U}_p + \Sigma_{i=1}^{p-1}\mathbf{Q}(\mathbf{U}_i, \mathbf{U}_{p-i}) = 0$

The original nonlinear problem has therefore been reduced to a series of n linear systems of N_e equations. However, at each order, the linear systems are under-dimensioned since they have N_e+1 unknowns. The additional equations required are obtained by inserting Eq. (19) into the definition of the path parameter a given above. This gives:

• order
$$
1: U_1^tU_1 = 1
$$

 $\bullet\ \mathbf{order}\ \mathbf{2}\leq \mathbf{p}\leq \mathbf{n} \mathbf{:}\ \mathbf{U}_1^t\mathbf{U}_p=0$

2.4.3 Comments:

- The original nonlinear system of N_e equations has been transformed into n linear systems of N_e equations, which have to be solved successively (as in classical perturbation methods), i.e., U_p is deduced from terms occuring at lower orders.
- The range of utility of a truncated power series is generally limited because the series have a finite radius of convergence. Once each U_p $(p \in [1...N])$ has been found, the range of utility of the series expansion [\(19\)](#page-9-0) is defined by the value a_{max} such that

$$
\forall a \in [0 \ a_{max}], ||\mathbf{R}(\mathbf{U}(a))|| \le \epsilon_r \tag{20}
$$

where ϵ_r is a user-defined tolerance parameter (see ([\[24](#page-24-11),32]) for details of

the a_{max} calculation). Note that the range of utility a_{max} is generally approximately equal to the radius of convergence of the series $([33])$.

- The series expansion and the associated range of utility a_{max} only define one part of the bran
h of solutions, whi
h is alled a se
tion. To determine the entire bran
h, it is ne
essary to restart the whole series al
ulation from successively updated starting points U_0 . The simplest way of performing this updating is to take the end point of a previously omputed se
tion as the starting point for the next section. This is the principle of continuation with the ANM. Finally, the entire branch is given as a succession of different bran
h se
tions, where the length of ea
h se
tion is automati
ally given by its range of utility a_{max} .
- The ANM continuation approach has the following advantages:
	- the solution branch is known analytically, section by section.
	- · sin
	e all the linear systems to be solved have the same Ja
	obian matrix, the omputational ost of the series [\(19\)](#page-9-0) is low.
	- · sin
	e the size of the se
	tion is given by the onvergen
	e properties of the current step, ie, by the values of a_{max} , the ANM continuation algorithm does not require any special step-length control strategies.
	- · the ANM ontinuation algorithm is highly robust, even when the bran
	h ontains sharp turns. Bran
	h swit
	hing an therefore be easily performed, using small pertubations in the system.

2.5 Implementation in the MANLAB software program

2.5.1 A brief presentation of MANLAB

MANLAB is an intera
tive software program for the ontinuation and bifur cation analysis of algebraic systems, based on ANM continuation. The latest version is programmed in Matlab using an objet-oriented approach $(|34|)$. MANLAB has a Graphi
al User Interfa
e (GUI) with buttons, on-line inputs and graphical windows for generating, displaying and analysing the bifurcation diagram and the solution of the system. To enter the system of equations, the user has to provide three ve
tor valued Matlab fun
tions orresponding to the constant, linear and quadratic operators L_0 , L and Q . As an example, take the biochemical reaction system used by Doedel et Al in $([5])$

$$
r_1(u_1, u_2, \lambda) = 2u_1 - u_2 + 100 \frac{u_1}{1 + u_1 + u_1^2} - \lambda = 0
$$

\n
$$
r_2(u_1, u_2, \lambda) = 2u_2 - u_1 + 100 \frac{u_2}{1 + u_2 + u_2^2} - (\lambda + \mu) = 0.
$$
\n(21)

Introducing the following additional variables $v_1 = u_1 + u_1^2$, $v_2 = u_2 + u_2^2$, $v_3 =$ 1 $\frac{1}{1+v_1}$ and $v_4 = \frac{1}{1+v_1}$ $_{1+v_2}$, and system can be rewritten with quadratic polynomial nonlinearities as follows,

$$
0 + 2u_1 - u_2 - \lambda + 100u_1v_3 = 0
$$

\n
$$
-\mu + 2u_2 - u_1 - \lambda + 100u_2v_4 = 0
$$

\n
$$
0 + v_1 - u_1 - u_1^2 = 0
$$

\n
$$
0 + v_2 - u_2 - u_2^2 = 0
$$

\n
$$
-1 + v_3 + v_1v_3 = 0
$$

\n
$$
-\frac{1}{L_0} + \frac{v_4}{L(U)} + \frac{v_2v_4}{Q(U,U)} = 0
$$
\n(22)

The first two equations correspond directly to Eq (21) (21) . The last four define the auxilliary variables v_1, v_2, v_3, v_4 . The constant, linear and quadratic terms in each equation have been split to define the three operators L_0 , L and Q . In the MANLAB software program, the unknowns are collected in a single vector $\mathbf{U} = [u_1, u_2, v_1, v_2, v_3, v_4, \lambda],$ and the three operators are given by the following vector valued functions ($\mu = 0.05$ in the case of this example):

2.5.2 Implementation of the periodic solution continuation in MANLAB

To compute the branches of periodic solutions, the system has to be first recasted in the form of Eq. (3) with account of the additional decomposition [\(15\)](#page-8-1). This is probably the most unusual and difficult task for a new user. Subsequently, it is only ne
essary to provide the MANLAB software program with the operator $m(.)$, c_0 , c_1 , $l(.)$ $l_1(.)$ and $q(.,.)$. The functions **L**0, **L** and Q, whi
h are the a
tual input for MANLAB, have been programmed on
e for all, using the expression in Eq. [\(18\)](#page-8-2) and the formulas given in annex 1. The examples presented in this paper are available online $([6])$.

3 The ase of a periodi
ally for
ed system

We now focus on periodically forced (non-autonomous) systems:

$$
\dot{Y} = f(t, Y, \lambda) \tag{23}
$$

where f is periodic in t, with the period T (forcing period). We look for periodic solutions (responses) with a period pT or $\frac{T}{p}$, where p is an integer. A classical strategy onsists in transforming Eq. [\(23\)](#page-12-1) into an augmented autonomous system $([3])$, by adding an oscillator with the desired forcing period in the system of equations, for instance $([7])$.

In what follows, a dire
t approa
h will be used. It onsists in expanding the forcing term into harmonics, and taking them into account in the balance of individual harmoni
s. This apprao
h is illustrated below with two further examples.

Example 4: Forced Duffing oscillator.

The normalized forced Duffing oscillator is the non-autonomous equation:

$$
\ddot{u} + 2\mu \dot{u} + u + u^3 = f \cos(\lambda t) \tag{24}
$$

We take the damping coefficient μ and the force amplitude f constant, and use the forcing angular frequency as the varying parameter λ . By using $v(t) = \dot{u}(t)$ and $w(t) = u^2(t)$, this equation can be recast as follows

$$
\dot{u} = v
$$
\n
$$
\dot{v} = f \cos(\lambda t) -2\mu v - u - uw
$$
\n
$$
\underbrace{0}_{m(\dot{Z})} = \underbrace{0}_{c(t,\lambda)} \underbrace{w}_{l(Z)} \underbrace{-uu}_{q(Z,Z)} \underbrace{-uu}_{q(Z,Z)}
$$
\n(25)

where $Z = [u, v, w]^t$, and the forcing term is deliberately put into c. The forcing frequency is now related to the response frequency by putting $\lambda = \omega$ or possibly, $\lambda = p\omega$ (p is an integer). The term $c(t)$ is then expanded into harmonics with respect to ω .

This results in slight hanges in the pro
edure:

• because of the synchronization of the response and the forcing, the phase condition has to be removed. Note that the parameter λ is no longer an unknown, since it was chosen as a multiple of ω . In comparison with the case of an autonomous system, both the number of equations and the number of unknowns have de
reased by one.

• in the final system [\(17\)](#page-8-0)[\(18\)](#page-8-2), the operators C_1 and L_1 disappear and the forcing amplitude f has to be accounted for in L_0

Lastly, we take the Raylegh-Plesset equation, whi
h is used to model the large amplitude vibrations of a gas bubble in a fluid. The forcing is handled slightly differently and this example also shows how to cope with a power of -3 .

Example 5: The forced Rayleigh-Plesset equation ([35]).

Let R be the radius of the vibrating bubble, and R_0 the radius at rest. The equation of motion of the bubble is

$$
R\ddot{R} + \frac{3}{2}\dot{R}^{2} = A\{(\frac{R_{0}}{R})^{3} - 1\} + B\cos(\lambda t)
$$
\n(26)

where A and B are fixed. We introduce the normalized radius $u = \frac{R}{R_c}$ R_0 and the (normalized) velocity $v = \frac{\dot{R}}{R}$ $\frac{R}{R_0}$. Dividing Eq [\(26\)](#page-13-0) by R_0^2 and defining $a = \frac{A}{R_0^2}$, $b = \frac{B}{R_0^2}$, we get the first order system

$$
\dot{u} = v
$$

\n
$$
u\dot{v} = a(u^{-3} - 1) - \frac{3}{2}v^2 + b\cos(\lambda t)
$$
\n(27)

We now introduce the following auxiliary variables $x = \frac{1}{u}$ $\frac{1}{u}$, $y = x^2$, and $z = v^2$, and arrive at

$$
\dot{u} = v
$$

\n
$$
\dot{v} = a(y^2 - x) - \frac{3}{2}xz + bx \cos(\lambda t)
$$
\n(28)

After undergoing this transformation, the system is quadratic but the forcing term has now been multiplied by the unknown function x , and it is no longer a onstant term with respe
t to the unknown. We introdu
e another auxilliary variable $r(t) = \cos(\lambda t)$, and replace the term $bx \cos(\lambda t)$ by bxr . Finally, we obtain the following system, where the first two equations stand for Eq (28)

and the last four define the auxilliary variables.

Here the unknown vector is $Z = [u, v, x, y, z, r]^t$, and the forcing term is clearly present in the operator c.

4 Numeri
al results on sele
ted examples

In the following selected examples, the numerical results obtained using the approa
h presented in this paper are either ompared with time-domain simulations to show the validity of our approach, or used to illustrate particular features: the influence of the number of harmonics in the case of the Van der Pol oscillator, the ability to follow period-doubling bifurcations in that of the Rössler system, the ability to follow a direct or inverse Hopf bifurcation in that of the larinet model, and to illustrate a for
ed system, in that of the Duffing oscillator.

Figure 1. The Van der Pol oscillator $(Eq. (4))$ $(Eq. (4))$ $(Eq. (4))$: Comparison between the harmonic balance results and those obtained with a time domain simulation. Influence of the number of harmonics H taken into account ((a) $H=10$, (b) $H=50$).

Example 1: The Van der Pol oscillator. Numerical results obtained on the Van der Pol os
illator (Eq. [\(4\)](#page-4-0)) are presented in Fig. [1.](#page-14-0) Good agreement was obtained with the results of a time domain simulation, performed using Matlab ODE solvers. As expected, the number of harmonics H in the solution sought by the harmoni balan
e method had to be adapted to span the bandwith of the solution obtained by direct integration. In the case of Fig. [1,](#page-14-0) $\lambda = 3$, which requires having a relatively high H to match the reference solution.

Example 2: The Rössler system. The ability to follow period-doubling bi-furcations is illustrated in Fig. [2.](#page-16-0) Following these bifurcations is more difficult in the ase of autonomous systems than in for
ed systems, sin
e the period of os
illation is also unknown. Moreover, sin
e a T -periodi solution is also a 2T-periodic solution, one cannot expect the value of the period obtained by the harmoni balan
e pro
ess to be doubled when rossing a period-doubling bifur
ation. The strategy used here therefore onsists in introdu
ing omplex subharmonic amplitudes as additional unknowns. To detect K period-doubling bifur
ations, the solution is then sought as:

$$
Z(t) = Z_0 + \sum_{k=1}^{H} Z_{c,k} \cos(\frac{k}{2^K} \omega t) + \sum_{k=1}^{H} Z_{s,k} \sin(\frac{k}{2^K} \omega t)
$$
(30)

When the solution belongs to the T-periodic solution branch, $Z_{c,k}|_{k=1..K-1} = 0$ and $Z_{s,k}|_{k=1,K-1} = 0$. When the solution belongs to the 2T-periodic solution branch, $Z_{c,k}|_{k=1..K-1,k\neq 2^{K-1}} = 0$ and $Z_{s,k}|_{k=1..K-1,k\neq 2^{K-1}} = 0$. One practical consequence in terms of the computational cost is that in order to span the same bandwidth, the number of harmonics has be mulitplied by 2^K . This case is illustrated in Fig. [2](#page-16-0) where $H = 10$ from the T-periodic solution to $H = 2^2 \times 10 = 40$ after two period-doubling bifurcations.

Example 3: The clarinet model.

Two typi
al examples of the bifur
ation diagrams obtained with the larinet model are shown in Fig. [3.](#page-17-0) These pictures focus on the oscillation threshold in order to show the robustness of the method, even at singular points. As an be seen from both pi
tures, the radius of onvergen
e of the power series expansion decreases when approaching a bifurcation point (and hence the length of each section of a branch lying between two consecutive points in Fig. [3](#page-17-0) decreases). This behaviour is typical of ANM ([33]).

Example 4: The forced Duffing oscillator

Figure 4 shows the frequen
y-amplitude diagram of the response obtained with the method presented here. A lassi
al bent resonan
e urve an be observed,

Figure 2. The Rössler system (Eq. [\(7\)](#page-5-0) with $a = b = 0.2$): Comparison between the results obtained using the harmoni balan
e method and a time domain simulation. These three figures show the ability of the method to follow the sub-harmonic cascade from (a) $\lambda = 2.5$ (perdiod T), to (b) $\lambda = 3.5$ (period 2T after a first period-doubling bifurcation) and (c) $\lambda = 4$ (period 4T after a second period-doubling bifurcation)

Figure 3. The clarinet model (Eq. [\(9\)](#page-6-0) with $q_r = 0.01$, $\omega_r = 6597$, $H = 3$, $N = 5$ $c = 340, \zeta = 0.2, l_t = 5.6e - 08, l_v = 4e - 08, C_{pv} = 1.4, r = 0.007, w_1 = 2426.5,$ $w_2 = 7279.5, w_3 = 12132.5, w_4 = 16985.4, w_5 = 21838.4, \alpha_1 = 0.11, \alpha_2 = 0.19,$ $\alpha_3 = 0.25, \alpha_4 = 0.3, \alpha_5 = 0.34$: depending on the length of the resonator, the bifurcation will be either a direct Hopf bifurcation (left picture, $L = 0.22$) or an inverse Hopf bifurcation (right picture, $L = 0.2$).

Figure 4. Duffing oscillator, Eq. [\(24\)](#page-12-2) with $\mu = 0.1$ and $f = 1.25$ as in ([19]). The figure shows the amplitude of the harmonics $1, 3$ and 5 versus the frequency forcing ω . Solid line : results when 5 harmonics are included (H=5 in Eq. [\(11\)](#page-6-1)). Dash line : results when 9 harmoni
s are in
luded. The gure on the right is a zoom of the region $\omega < 0.6$.

as well as some additional peaks corresponding to superharmonic resonances. Note that only the individual amplitude $A_i = \sqrt{(u_{c\,i}^2 + u_{s\,i}^2)}$ of the odd harmonics have been plotted, since the even harmonics (A_0, A_2, A_4, \ldots) are zero. The computation of this branch of periodic orbits required 25 steps of MANontinuation when 5 harmoni
s were in
luded, and 35 steps when 9 harmoni
s were in
luded. The urves obtained for harmoni
s 1 and 3 were slightly hanged when shifting from $H = 5$ to $H = 9$ harmonics in Eq. [\(11\)](#page-6-1). The curve obtained for A_5 is more affected, which confirms the logical result that more than 5 harmonics have to be used to obtain an accurate result with harmonic 5. We also checked that the curve obtained for A_5 was only very slightly modified when shifting from $H = 9$ to $H = 11$ harmonics in Eq. [\(11\)](#page-6-1).

5 Dis
ussion and Con
lusion

The key idea in this study is the quadratic recast. It is worth pointing out that the present method contains two quadratic recasts. The first one, which occurs in the time domain, transforms the original system (1) into (3) , and is presented in section [2.2.](#page-3-1) The second one transforms the algebraic system (13) obtained with the HBM, into the final system (17) which is solved by the ANM. The operators in [\(13\)](#page-7-0) and [\(17\)](#page-8-0) are linked by [\(16\)](#page-8-3) and [\(18\)](#page-8-2). This point accounts for many of the characteristics of the method presented here:

- The whole procedure takes place in the frequency domain using an analytical expression for the system to be solved (as with the classical harmonic balan
e) and allows to use an arbitrarily high number of harmoni
s (as with the AFT pro
edures).
- In the ANM continuation, no iterative process are used to solve the algebraic system, and hence no problems of convergence arise. The computational cost is almost predi
tible and fairly rather low. On the ontrary, onvergen
e of the iterative process can be difficult with AFT procedures $(39, \text{ sect. } 4.6,$ $p117$.
- There is no need for FFT/IFFT procedures, which increases the computational load in the ase of AFT approa
hes.
- No temporal discretization has to be performed (since the whole procedure is in the frequency domain), and there is therefore no need to cope with aliasing.
- There is no need to use numerical schemes to compute derivatives. Since the problem is a quadrati one , the Ja
obian is al
ulated analyti
ally and this an be done very easily. This is a onsiderable advantage of the approa
h presented here. Indeed, as stated by $[39, p17]$ $[39, p17]$, usually "analytical calculation of the Ja
obian involves onsiderable al
ulation and transformation" but on the other hand, when considering numerical calculation of the Jacobian, "for very nonlinear circuits, the error introduced in the Jacobian estimation results in inaccurate updates of the unknowns and a large number of iterations and possibly no convergence".

As stated in [12], to apply HB, "it is always necessary to write specific computation programs for different nonlinear models". Here, on the contrary, the pro
edure is simple and rather general be
ause of the natural splitting between the automated part, whi
h is independent of the problem (i.e. the transformation from operators c, l, q to operators L_0, L, Q and the ensuing solving using the ANM), and the part which depends on the particular problem to be solved (the writing of operators c, l, q) which is let to the users. From the point of view of the users, this means that the work required is relatively easy and the software is simple to use. In addition, very few parameters have to be defined by the users: the number of harmonics in the solution and parameter ϵ_r in Eq.

[\(20\)](#page-9-1), which controls the accury of the ANM computation.

In this paper, we have presented only small-sized systems for the sake of simpli
ity. The method an be obviously extended in prin
iple to large systems of equations although this may require some additional technical work, and introduce limitations due to the lack of computer ressources. In [36], the method has been applied to compute the forced responses of geometrically nonlinear elastic structures discretized using the finite element method. It is well known that with problems of this kind, the equations of motion are se
ond order differential equations in terms of the displacement nodal variables u , and that they show a polynomial cubic nonlinarity. Choosing the nodal velocity v and the second Piola-Kirchhoff S (at the Gauss point) as auxiliary variables, the system of equations can easily be written in the form of a first order system with quadrati polynomial non linearities.When a osine for
ing term is applied, they read (in the dis
rete form)

$$
\dot{u} = v
$$

\n
$$
\mathbf{M}\dot{v} = -\int_{V} (B_L + B_{NL}(u))^t S dv + \mathbf{F} \cos(\lambda t)
$$

\n
$$
S = D(B_L + \frac{1}{2} B_{NL}(u))u
$$
\n(31)

where **M** is the mass matrix, D is the Hooke operator and B_L and B_{NL} are the linear and nonlinear strain-displacement operators $[37]$. In this form, the governing equations consist in a group of first order differential equations (velocity definition, equation of motion) and a group of algebraic equations (constitutive law at the Gauss point of the finite elements). Both groups are quadratic in u and S . The algebra given in annex 1 has been directely introduced into a home-made FEM ode, at the element level.

To on
lude, it is proposed to dis
uss the limitations of this method and suggest some possible lines of future resear
h. First of all, it is worth noting that when the original system is not directly in the same quadratic form as Eq. [\(3\)](#page-3-0), introdu
ting auxiliary variables, as done in this paper, examples may lead to additional (possibly non-physi
al) solutions. For example, in the ase of the clarinet model (example 3), a variable $v = \sqrt{\gamma - p}$ is introduced, and then further defined by the quadratic equation $v^2 = \gamma - p$. This definition corresponds to $v = \pm \sqrt{\gamma - p}$. In practical terms, this means that the user has to check that the branch of solution computed corresponds to a positive v .

The main limitation of the method presented is that the original systems annot all be put into the quadrati form Eq. [\(3\)](#page-3-0). For this reason, problems where one or several relations are given in the frequency domain (typically, when some variables are linked through an impedance) cannot be treated. Similar difficulties arise when the original system contains functions (trigonometric functions, exponential functions, non-integer powers function, etc) that are applied to the unknowns. The classical pendulum model $\hat{\theta} + \sin(\theta) = 0$ is a good example of systems of this kind. In these cases, we can generally introduce new variables and new differential equations, so that the functions are generated by the system itself. In the case of pendulum model, $v = \theta$ and the two new variables $s(t) = \sin(\theta(t))$ and $c(t) = \cos(\theta(t))$ are introduced. Taking the derivative with respe
t to time for the last two equations, we obtain

$$
\dot{\theta} = v
$$

\n
$$
\dot{v} = -s
$$

\n
$$
\dot{s} = cv
$$

\n
$$
\dot{c} = -sv
$$
\n(32)

This quadratic system corresponds to the pendulum model, provided the following two initial onditions are added

$$
s(0) = \sin(\theta(0))
$$

$$
c(0) = \cos(\theta(0))
$$
 (33)

The application of the HBM to Eq. [\(32\)](#page-20-0) will now be quite straighforward. but, because of Eq. [\(33\)](#page-20-1), the final algebraic system will not be quadratic. In these ases, the appli
ation of the ANM ontinuation is still feasible but this requires more elaborate algebra for omputating the power series, as explained in $([38,32])$ $([38,32])$ $([38,32])$. The efficiency of the present method on the pendulum model will be tested in a near future. Another interesting idea would be to test whether this method can be used to solve regularized non-smooth dynamic problems, and for instance, the case of vibrating systems with contact conditions and friction laws.

A
knowledgements

The authors want to warmly thank Marie-Christine Pauzin and Olivier Thomas for their suggestions and for testing the programs avaible at http://manlab.lma.

t.

A Appendix

Here, we give the expression for the operators M, C, L and Q in Eq. [\(13\)](#page-7-0) in terms of m, c, l, q and H. We recall that Eq. (13) is obtained by substituting Eq. (11) into Eq. (3) and by collecting the terms with the same harmonic index (cosines and sines). The inputs of M , L and Q are the vector U , which contains the Fourier coefficients of $Z(t)$

$$
U = [Z_0^t, Z_{c,1}^t, Z_{s,1}^t, Z_{c,2}^t, Z_{s,2}^t, \dots, Z_{c,H}^t, Z_{s,H}^t]^t
$$
\n(A.1)

A.1 Constant term

The constant vector c is associated with the harmonic zero. The operator C is simply

$$
C = [c^t, 0^t, 0^t, \dots]^t
$$
\n(A.2)

A.2 Linear term

For the linear operator l , we have

$$
l(Z(t)) = l(Z_0 + \sum_{k=1}^{H} Z_{c,k} \cos(k\omega t) + Z_{s,k} \sin(k\omega t))
$$

= $l(Z_0) + l(Z_{c,1}) \cos(\omega t) + l(Z_{s,1}) \sin(\omega t) + l(Z_{c,2}) \cos(2\omega t) + ...$ (A.3)

The operator L is

$$
L(U) = [l(Z_0)^t, l(Z_{c,1})^t, l(Z_{s,1})^t, l(Z_{c,2})^t, l(Z_{s,2})^t, \dots, l(Z_{c,H})^t, l(Z_{s,H})^t]^t \tag{A.4}
$$

For the linear operator m , we have

$$
m(\dot{Z}(t)) = m(\sum_{k=1}^{H} Z_{s,k}k\omega \cos(k\omega t) - Z_{c,k}k\omega \sin(k\omega t))
$$

= 0 + m(Z_{s,1})\omega \cos(\omega t) - m(Z_{c,1})\omega \sin(\omega t)
+2m(Z_{s,2})\omega \cos(2\omega t) + ... (A.5)

The operator M is

$$
M(U) = [0t, m(Zs,1)t, -m(Zc,1)t, 2m(Zs,2)t, -2m(Zc,2)t,, Hm(Zs,H)t, -Hm(Zc,H)t]t
$$
\n(A.6)

A.3 Quadrati term

With the notation $Z^{(0)} = Z_0$ and $Z^{(i)} = Z_{c,i} \cos(\omega t) + Z_{s,i} \sin(\omega t)$, the decomposition of $Z(t)$ is conveniently rewritten as

$$
Z(t) = \sum_{i=0}^{H} Z^{(i)} \tag{A.7}
$$

For the operator q , we have

$$
q(X(t), Y(t)) = \sum_{i=0}^{H} \sum_{j=0}^{H} q(X^{(i)}, Y^{(j)})
$$

= $q(X^{(0)}, Y^{(0)}) + \sum_{i=1}^{H} q(X^{(i)}, Y^{(0)})$
+ $\sum_{j=1}^{H} q(X^{(0)}, Y^{(j)}) + \sum_{i=1}^{H} \sum_{j=1}^{H} q(X^{(i)}, Y^{(j)})$ (A.8)

When $i \geq 1$ and $j \geq 1$, $q(X^{(i)}, Y^{(j)})$ give harmonics $i + j$ and $i - j$ as follows:

$$
q(X^{(i)}, Y^{(j)}) = \frac{1}{2} \{ q(X_{c,i}, Y_{c,j}) - q(X_{s,i}, Y_{s,j}) \} \cos((i+j)\omega t) + \frac{1}{2} \{ q(X_{c,i}, Y_{s,j}) + q(X_{s,i}, Y_{c,j}) \} \sin((i+j)\omega t) + \frac{1}{2} \{ q(X_{c,i}, Y_{c,j}) + q(X_{s,i}, Y_{s,j}) \} \cos((i-j)\omega t) + \frac{1}{2} \{ q(X_{s,i}, Y_{c,j}) - q(X_{c,i}, Y_{s,j}) \} \sin((i-j)\omega t)
$$
\n(A.9)

By grouping the terms with the same harmonics index, and canceling any harmonics higher than index H , we have

$$
q(X(t), Y(t)) = q_0 + \sum_{k=1}^{H} q_{c,k} \cos(k\omega t) + q_{s,k} \sin(k\omega t)
$$
 (A.10)

with

$$
q_0 = q(X_0, Y_0) + \sum_{j=1}^{H} \frac{1}{2} \{ q(X_{c,j}, Y_{c,j}) + q(X_{s,j}, Y_{s,j}) \}
$$
\n(A.11)

and when $i\geq 1$

$$
q_{c,i} = \{q(X_{c,i}, Y_0) + q(X_0, Y_{c,i})\} + \sum_{j=1}^{i-1} \frac{1}{2} \{q(X_{c,j}, Y_{c,i-j}) - q(X_{s,j}, Y_{s,i-j})\}
$$

+
$$
\sum_{j=i+1}^{H} \frac{1}{2} \{q(X_{c,j}, Y_{c,j-i}) + q(X_{s,j}, Y_{s,j-i})\} + \frac{1}{2} \{q(X_{c,j-i}, Y_{c,j}) + q(X_{s,j-i}, Y_{s,j})\}
$$
(A.12)

$$
q_{s,i} = \{q(X_{s,i}, Y_0) + q(X_0, Y_{s,i})\} + \sum_{j=1}^{i-1} \frac{1}{2} \{q(X_{c,j}, Y_{s,i-j}) + q(X_{s,j}, Y_{c,i-j})\}
$$

+
$$
\sum_{j=i+1}^{H} \frac{1}{2} \{-q(X_{c,j}, Y_{s,j-i}) + q(X_{s,j}, Y_{c,j-i})\} + \frac{1}{2} \{q(X_{c,j-i}, Y_{s,j}) - q(X_{s,j-i}, Y_{c,j})\}
$$
