

Photoemission kinks and phonons in cuprates.

D. Reznikⁱ, G. Sangiovanniⁱⁱ, O. Gunnarssonⁱⁱ, and T. P. Devereauxⁱⁱⁱ

One of the possible mechanisms of high T_c superconductivity is Cooper pairing with the help of bosons, which change the slope of the electronic dispersion as observed by photoemission. Giustino et al.¹ calculated that in the high temperature superconductor $\text{La}_{1.85}\text{Sr}_{0.15}\text{CuO}_4$ crystal lattice vibrations (phonons) should have a negligible effect on photoemission spectra and concluded that phonons do not play an important role. We show that the calculations employed by Giustino et al. fail to reproduce huge influence of electron-phonon coupling on important phonons observed in experiments. Thus one would expect these calculations to similarly fail in explaining the role of electron-phonon coupling for the electronic dispersion.

Density functional theory (DFT) calculations used in Ref. 1 treat electrons and phonons as independent entities, which scatter each other. Because of this scattering the electronic states acquire finite lifetimes and abrupt changes in dispersions (kinks) at the phonon energies. In addition, the phonons soften and broaden in energy. These effects are calculated from first principles without adjustable parameters. Thus if DFT is appropriate for the high T_c cuprates, it ought to accurately reproduce the electronic contribution to phonon softening and broadening deduced from neutron or x-ray scattering experiments.

DFT predicts that the phonon branch in large part responsible for the calculated electronic dispersion kink is the optical bond-stretching branch involving the bond-stretching motion of CuO_2 plane oxygen against copper.¹ Several experimental papers

highlighted large anomalous renormalization of these phonons²⁻⁶. They have huge low temperature dispersion dips and/or linewidth maxima around half-way ($h=0.3$) to the zone boundary in the superconductors $\text{La}_{1.85}\text{Sr}_{0.15}\text{CuO}_4$ ² and $\text{YBa}_2\text{Cu}_3\text{O}_7$ ⁵ (Fig. 1). However, DFT predicts a smooth dispersion without any pronounced features in neither the dispersion nor linewidth around $h=0.3$ (Fig. 1). Furthermore, the very small calculated linewidths in Fig. 1b illustrate that the calculated electron-phonon coupling is very weak in absolute terms.

Substantial evidence points to electronic origin of the phonon effect. First, the phonon anomaly weakens at elevated temperatures,^{2,3} whereas alternatives such as phonon-phonon scattering and structural inhomogeneity should either show the opposite trend or have no temperature dependence. Second, the phonon effect appears at specific wavevectors and is phenomenologically similar to anomalies observed in conventional systems with strong electron-phonon coupling. Third, both phonon renormalization² and the photoemission kink⁸ become bigger when hole concentration decreases from high doping where superconductivity is suppressed towards so-called “optimal” doping with the maximum superconducting T_c . This simultaneous enhancement of the two features may result from an increase of electron-phonon coupling due to enhanced electronic correlations or reduced screening not included in DFT. Reference 1 cannot rule out such scenarios. The same holds for $\text{YBa}_2\text{Cu}_3\text{O}_7$ where there is a similar disagreement between the experiment and DFT results for both the phonon dispersions and the photoemission kink⁹.

It is interesting that many-body calculations predict a substantial enhancement of the coupling to bond-stretching phonons compared to DFT and describe anomalous doping

dependence of the zone boundary phonons^{10,11}, suggesting that strong correlation effects might be relevant. Recent high resolution photoemission measurements have found an oxygen isotope effect in the dispersion kink at the half-breathing phonon energy, hinting at an important role of oxygen phonons.¹² We conclude that more work is necessary to establish phonon contribution to the photoemission kink.
