Abstract. We write out the explicit form of the metric for a linearized gravitational wave in the transverse-traceless gauge for any multipole, thus generalizing the well-known quadrupole solution of Teukolsky. The solution is derived using the generalized Regge-Wheeler-Zerilli formalism developed by Sarbach and Tiglio.

1. Introduction

In the linearized approximation to general relativity, one assumes that the spacetime metric $g_{\alpha\beta}$ can be regarded as a small perturbation of the flat-space (Minkowski) metric $\eta_{\alpha\beta}$,

$$g_{\alpha\beta} = \eta_{\alpha\beta} + \delta g_{\alpha\beta},$$

where $|\delta g_{\alpha\beta}| \ll 1$. Solutions to the linearized Einstein equations have been known since the early days of general relativity. One usually works in the harmonic (or Lorentz, or de Donder) gauge, in which the perturbation satisfies

$$\nabla^\beta \delta g_{\alpha\beta} - \frac{1}{2} \nabla_\alpha \delta g = 0. \quad (1)$$

Here ∇ is the flat-space metric connection, $\delta g \equiv \delta g^\beta{}_\beta$, and indices are raised and lowered with η . Harmonic gauge does not fix the coordinates completely; one can impose four additional conditions. A popular choice is transverse-traceless (TT) gauge,

$$\delta g_{0\alpha} = 0, \quad (2)$$

$$\delta g = 0, \quad (3)$$

where 0 denotes the time component. (Only four of these equations are independent of the harmonic gauge condition (1).) Conversely, if one only imposes (2) as a gauge condition then the components $R_{0\alpha} = 0$ of the vacuum Einstein equations imply that the second time derivative of (3) and the first time derivative of (1) also hold.

A common way to represent the solutions is as expansions in tensor spherical harmonics, which are eigenfunctions of the (tensor) Laplace operator on the sphere (see [1] for a review article and [2] for an alternative approach). Teukolsky [3] wrote out the quadrupole ($\ell = 2$) solution, giving all the functions in explicit form. This is

particularly helpful for numerical relativists who need expressions that can readily be coded. Teukolsky's has become one of the most widely used solutions, both for code testing purposes and for the construction of vacuum initial data using the conformal method (the two earliest references being [4, 5]). As far as I know, such an explicit form of the solution has not appeared in the literature for $\ell > 2$. Having such a solution at hand will be useful in order to model higher-multipole gravitational waves. For instance, it can be used as a testbed for improved absorbing boundary conditions [6]. Being able to evolve the higher multipoles correctly is important, e.g. the contribution of octupole ($\ell = 3$) radiation is found to be substantial in non-equal-mass binary black hole mergers [7, 8].

In section 2, we present the general solution of the linearized vacuum Einstein equations in TT gauge. The radial functions are written out explicitly. The angular functions are given in terms of spin-weighted spherical harmonics or alternatively in terms of derivatives of the standard spherical harmonics. The number of independent angular functions needed is reduced considerably as compared with [3]. Explicit expressions in terms of elementary functions are listed for $\ell = 2, 3, 4$ in Appendix A. In section 3, we describe how the solution was derived using the improved gauge-invariant Regge-Wheeler-Zerilli [9, 10] formalism developed by Sarbach and Tiglio [11], which proves to be a powerful method for generating solutions of the linearized Einstein equations.

2. The solution for arbitrary $\ell \geq 2$

There are two independent polarization states, or equivalently even- and odd-parity waves. The even-parity metric is

$$g = -dt^2 + (1 + A\hat{Y})dr^2 + 2B\hat{Y}_\theta r dr d\theta + 2B\hat{Y}_\phi r \sin\theta dr d\phi \\ + (1 - \frac{1}{2}A\hat{Y} + C\hat{Y}_{\theta\theta})r^2 d\theta^2 + 2C\hat{Y}_{\theta\phi}r^2 \sin\theta d\theta d\phi \\ + (1 - \frac{1}{2}A\hat{Y} - C\hat{Y}_{\theta\theta})r^2 \sin^2\theta d\phi^2. \quad (4)$$

Here the functions A, B and C depend on t and r only; they are defined below in (8). The functions $\hat{Y}, \hat{Y}_\theta, \hat{Y}_\phi, \hat{Y}_{\theta\theta}$ and $\hat{Y}_{\theta\phi}$ depend on θ and ϕ only; they are defined below in (10) or equivalently (11). The odd-parity metric is

$$g = -dt^2 + dr^2 + 2K\hat{S}_\theta r dr d\theta + 2K\hat{S}_\phi r \sin\theta dr d\phi + (1 + L\hat{S}_{\theta\theta})r^2 d\theta^2 \\ + 2L\hat{S}_{\theta\phi}r^2 \sin\theta d\theta d\phi + (1 - L\hat{S}_{\theta\theta})r^2 \sin^2\theta d\phi^2. \quad (5)$$

Again the functions K and L depend on r and t only and are defined in (9). The functions $\hat{S}_\theta, \hat{S}_\phi, \hat{S}_{\theta\theta}$ and $\hat{S}_{\theta\phi}$ are directly related to the even-parity angular functions via (12). Note that when written in this form, the perturbation is manifestly traceless, and we have reduced the number of independent angular functions to five as opposed to (seemingly) twelve in [3].

The solutions are specified in terms of mode functions $F(x)$ for even parity and $G(x)$ for odd parity that can be chosen arbitrarily. We set $F^{(k)}(x) \equiv d^k/dx^k F(x)$ and similarly for G . Outgoing (ingoing) solutions are obtained by taking the argument of the functions $F^{(k)}$ and $G^{(k)}$ to be $r - t$ ($r + t$). (By using $r - t$ instead of $t - r$ as in [3] we achieve the same form of the radial functions (8) and (9) for both directions of propagation.) We define the coefficients c_j , $0 \leq j \leq \ell$, recursively by

$$c_\ell = 1, \quad c_{j-1} = -\frac{j(2\ell - j + 1)}{2(\ell - j + 1)}c_j \text{ for } j = \ell, \ell - 1, \dots, 1, \quad (6)$$

Explicit solution of the linearized Einstein equations in TT gauge for all multipoles 3

or equivalently,

$$c_j = \frac{(-2)^{j-\ell}(2\ell-j)!}{(\ell-j)!j!}. \quad (7)$$

The radial functions appearing in the even-parity metric (4) are now given by

$$\begin{aligned} A &= \sum_{j=0}^{\ell} c_j r^{j-\ell-3} [-8(\ell-j)r^2 F^{(j+2)} + 4(3j^2 - j\ell^2 - 7j\ell + j + \ell^3 + 3\ell^2 - 2\ell)r F^{(j+1)} \\ &\quad + (2j^2 - 4j\ell + \ell^2 - \ell)(2j - \ell^2 - 3\ell - 2)F^{(j)}], \\ B &= \sum_{j=0}^{\ell} c_j r^{j-\ell-3} [4(\ell-j)r^2 F^{(j+2)} - (6j^2 - 12j\ell - 2j + 5\ell^2 + \ell - 2)r F^{(j+1)} \\ &\quad - (2j^2 - 4j\ell + \ell^2 - \ell)(j - \ell - 2)F^{(j)}], \end{aligned} \quad (8)$$

$$C = \sum_{j=0}^{\ell} c_j r^{j-\ell-3} [-2r^2 F^{(j+2)} - 2(2j - 2\ell + 1)r F^{(j+1)} - (2j^2 - 4j\ell + \ell^2 - \ell)F^{(j)}],$$

and those in the odd-parity metric (5) are

$$\begin{aligned} K &= \sum_{j=0}^{\ell} c_j r^{j-\ell-2} [2(j-\ell)r G^{(j+1)} + (j-\ell+1)(j-\ell-2)G^{(j)}], \\ L &= \sum_{j=0}^{\ell} c_j r^{j-\ell-2} [2r G^{(j+1)} + 2(j-\ell+1)G^{(j)}]. \end{aligned} \quad (9)$$

For a multipole ℓ we need the derivatives of the mode functions up to order $\ell + 2$ for even parity and up to order $\ell + 1$ for odd parity.

The angular functions in (4) are most easily written in terms of spin-weighted harmonics [12] ${}_s Y_{\ell m}(\theta, \phi)$. These can be obtained recursively from the standard spherical harmonics $Y_{\ell m}$ by

$$\begin{aligned} {}_0 Y_{\ell m} &= Y_{\ell m}, \\ {}_{s+1} Y_{\ell m} &= [(\ell-s)(\ell+s+1)]^{-1/2} \bar{\partial}_s Y_{\ell m}, \\ {}_{s-1} Y_{\ell m} &= -[(\ell+s)(\ell-s+1)]^{-1/2} \bar{\partial}_s Y_{\ell m}, \end{aligned}$$

where the operators $\bar{\partial}$ and $\bar{\partial}_s$ are defined by

$$\begin{aligned} \bar{\partial}_s Y_{\ell m} &\equiv (-\partial_\theta - i \csc \theta \partial_\phi + s \cot \theta) {}_s Y_{\ell m}, \\ \bar{\partial}_s Y_{\ell m} &\equiv (-\partial_\theta + i \csc \theta \partial_\phi - s \cot \theta) {}_s Y_{\ell m}. \end{aligned}$$

For simplicity we omit the indices ℓ and m . We have

$$\begin{aligned} \hat{Y} &= {}_0 Y, \\ \hat{Y}_\theta &= -\frac{1}{2} \sqrt{\ell(\ell+1)} ({}_1 Y - {}_{-1} Y), \\ \hat{Y}_\phi &= \frac{i}{2} \sqrt{\ell(\ell+1)} ({}_1 Y + {}_{-1} Y), \\ \hat{Y}_{\theta\theta} &= \frac{1}{4} \sqrt{(\ell-1)\ell(\ell+1)(\ell+2)} ({}_2 Y + {}_{-2} Y), \\ \hat{Y}_{\theta\phi} &= -\frac{i}{4} \sqrt{(\ell-1)\ell(\ell+1)(\ell+2)} ({}_2 Y - {}_{-2} Y). \end{aligned} \quad (10)$$

If preferred the following expressions in terms of the standard spherical harmonics and their partial derivatives may be used,

$$\begin{aligned}
 \hat{Y} &= Y, \\
 \hat{Y}_\theta &= Y_{,\theta}, \\
 \hat{Y}_\phi &= \csc \theta Y_{,\phi}, \\
 \hat{Y}_{\theta\theta} &= Y_{,\theta\theta} + \frac{1}{2}\ell(\ell+1)Y, \\
 \hat{Y}_{\theta\phi} &= \csc \theta(Y_{,\theta\phi} - \cot \theta Y_{,\phi}).
 \end{aligned} \tag{11}$$

The odd-parity angular functions in (5) are related to the even-parity ones by

$$\hat{S}_\theta = -\hat{Y}_\phi, \quad \hat{S}_\phi = \hat{Y}_\theta, \quad \hat{S}_{\theta\theta} = -\hat{Y}_{\theta\phi}, \quad \hat{S}_{\theta\phi} = \hat{Y}_{\theta\theta}. \tag{12}$$

For each ℓ there are $2\ell+1$ independent real solutions. These are obtained by replacing $Y_{\ell m}$ with $\text{Re } Y_{\ell m}$ if $m \geq 0$ and with $\text{Im } Y_{\ell|m|}$ if $m < 0$. The mode functions F and G must then be taken to be real.

3. Derivation of the solution

We have derived the solution using the generalized Regge-Wheeler-Zerilli [9, 10] formalism of Sarbach and Tiglio [11]. In this formalism, the background spacetime is assumed to be a direct product $\tilde{M} \otimes S^2$ of a Lorentzian 2-manifold \tilde{M} and the 2-sphere. The metric on \tilde{M} is denoted by \tilde{g} , its volume element by $\tilde{\epsilon}$ and its associated covariant derivative by $\tilde{\nabla}$. In our case \tilde{g} is flat,

$$\tilde{g} = -dt^2 + dr^2,$$

and $\tilde{\nabla}$ reduces to the partial derivative. The standard metric on S^2 is denoted by \hat{g} , its volume element by $\hat{\epsilon}$ and its associated covariant derivative by $\hat{\nabla}$. We have

$$\hat{g} = d\theta^2 + \sin^2 \theta d\phi^2.$$

The metric perturbation (in an arbitrary gauge for the time being) is decomposed as

$$\begin{aligned}
 \delta g_{ab} &= H_{ab}Y, \\
 \delta g_{Ab} &= Q_b Y_A + g_b S_A, \\
 \delta g_{AB} &= r^2(K\hat{g}_{AB}Y + GY_{AB}) + 2kS_{AB}.
 \end{aligned} \tag{13}$$

Here lower-case Latin indices a, b, \dots range over t and r and upper-case Latin indices A, B, \dots range over θ and ϕ . The even-parity basis tensor spherical harmonics are derived from the standard scalar spherical harmonics Y according to

$$\begin{aligned}
 Y_A &\equiv \hat{\nabla}_A Y, \\
 Y_{AB} &\equiv [\hat{\nabla}_A \hat{\nabla}_B Y]^{\text{tf}} = \hat{\nabla}_A \hat{\nabla}_B Y + \frac{1}{2}\ell(\ell+1)\hat{g}_{AB}Y,
 \end{aligned}$$

where tf denotes the tracefree part. The odd-parity basis harmonics are

$$\begin{aligned}
 S_A &\equiv \epsilon^B{}_A Y_B, \\
 S_{AB} &\equiv \nabla_{(A} S_{B)} = [S_{AB}]^{\text{tf}}.
 \end{aligned}$$

Indices ℓ and m have been omitted and a sum over these in (13) is implied.

3.1. Master equation

Solutions of the linearized Einstein equations can be described in terms of two gauge invariant scalars $\Phi^{(\pm)}$, the (generalized) Regge-Wheeler-Zerilli (RWZ) scalars. Here + refers to even and - to odd parity. They obey the master equations

$$[-\tilde{\nabla}^a \tilde{\nabla}_a + V_{\pm}(r)]\Phi^{(\pm)}.$$

For a flat-space background, $V_{\pm}(r) = \ell(\ell + 1)/r^2$ and hence

$$\left[\partial_t^2 - \partial_r^2 + \frac{\ell(\ell + 1)}{r^2} \right] \Phi^{(\pm)} = 0, \quad (14)$$

an example of the Euler-Poisson-Darboux equation [13]. This equation is easily solved by making the ansatz

$$\Phi^{(\pm)}(t, r) = \sum_{j=0}^{\ell} c_j r^{j-\ell} F_{\pm}^{(j)}(x) \quad (15)$$

where $F_{\pm}^{(j)}(x) \equiv d^j/dx^j F_{\pm}(x)$ and the argument is taken to be $x = r - t$ for an outgoing solution and $x = r + t$ for an ingoing solution. The F_{\pm} are precisely the mode functions appearing in the final solution (section 2), with $F \equiv F_+$ and $G \equiv F_-$. For both directions of propagation (14) implies

$$j(2\ell - j + 1)c_j + 2(\ell - j + 1)c_{j-1} = 0,$$

and hence together with the convention $c_{\ell} = 1$ we obtain (6) and (7).

We need to reconstruct the metric perturbation from the RWZ scalars and impose the TT gauge. The two parities are treated separately. Throughout we use the notation $\dot{} \equiv \partial/\partial t$ and $\prime \equiv \partial/\partial r$. The reader is referred to [11] for further explanation of the formalism underlying the following calculation.

3.2. Odd parity

From the Regge-Wheeler scalar $\Phi^{(-)}$, we first compute the gauge-invariant potential

$$h_b^{(\text{inv})} = \tilde{\epsilon}_{ab} \tilde{\nabla}^a (r\Phi^{(-)}) = \left[-(r\Phi^{(-)})', -r\dot{\Phi}^{(-)} \right].$$

The bracket denotes the components $[h_t^{(\text{inv})}, h_r^{(\text{inv})}]$ of the one-form $h_b^{(\text{inv})}$. The gauge-invariant potential is related to the amplitudes of the perturbation via

$$h_b^{(\text{inv})} = h_b - r^2 \tilde{\nabla}_b \left(\frac{k}{r^2} \right) = \left[h_t - \dot{k}, h_r - r^2 \left(\frac{k}{r^2} \right)' \right].$$

The gauge condition (2) implies $h_t = 0$ and so we obtain first

$$k = - \int h_t^{(\text{inv})} dt$$

and finally

$$h_r = h_r^{(\text{inv})} + r^2 \left(\frac{k}{r^2} \right)'.$$

We define the integral to simply lower the index of the $F_{\pm}^{(j)}$ by one, and in the case of the outgoing solution multiply the result by -1 . No integration constant is being added.

3.3. Even parity

From the Zerilli scalar $\Phi^{(+)}$ we obtain the Zerilli one-form

$$Z_a = \lambda \tilde{\nabla}_a \Phi^{(+)} = \left[\lambda \dot{\Phi}^{(+)}, \lambda \Phi^{(+)\prime} \right],$$

where $\lambda \equiv (\ell - 1)(\ell + 2)$. Next we form the gauge-invariant potential

$$K^{(\text{inv})} = -\frac{\ell(\ell + 1)}{r} \Phi^{(+)} - \frac{2}{\lambda} Z_a \tilde{\nabla}^a r = -\frac{\ell(\ell + 1)}{r} \Phi^{(+)} - \frac{2}{\lambda} Z_r.$$

From this the one-form C is defined by

$$C_a = Z_a + r \tilde{\nabla}_a K^{(\text{inv})} = \left[Z_t + r \dot{K}^{(\text{inv})}, Z_r + r K^{(\text{inv})\prime} \right].$$

The gauge-invariant potential $H_{ab}^{(\text{inv})}$ can be deduced using

$$C_b = H_{ab}^{(\text{inv})} \tilde{\nabla}^a r$$

and the fact that $H_{ab}^{(\text{inv})}$ is tracefree. We find

$$H_{tt}^{(\text{inv})} = H_{rr}^{(\text{inv})} = C_r, \quad H_{rt}^{(\text{inv})} = C_t.$$

The metric amplitude H_{ab} is related to this via

$$H_{ab} = H_{ab}^{(\text{inv})} + 2\tilde{\nabla}_{(a} p_{b)},$$

where p_b are gauge parameters that we compute first. The gauge condition (2) implies $H_{tt} = H_{tr} = 0$ and hence subsequently

$$\begin{aligned} p_t &= -\frac{1}{2} \int H_{tt}^{(\text{inv})} dt, \\ p_r &= -\int (H_{tr}^{(\text{inv})} + p_t') dt, \\ H_{rr} &= H_{rr}^{(\text{inv})} + 2p_r'. \end{aligned}$$

The gauge parameters p_a can also be expressed in terms of the amplitudes of the perturbation as

$$p_a = Q_a - \frac{1}{2} r^2 \tilde{\nabla}_a G = \left[Q_t - \frac{1}{2} r^2 \dot{G}, Q_r - \frac{1}{2} r^2 G' \right].$$

The gauge condition (2) implies $Q_t = 0$ and hence subsequently

$$\begin{aligned} G &= -\frac{2}{r^2} \int p_r dt, \\ Q_r &= p_r + \frac{1}{2} r^2 G'. \end{aligned}$$

Finally

$$K = K^{(\text{inv})} + \frac{2}{r} p_a \tilde{\nabla}^a r - \frac{1}{2} \ell(\ell + 1) G = K^{(\text{inv})} + \frac{2}{r} p_r - \frac{1}{2} \ell(\ell + 1) G.$$

3.4. Final form of the solution

Starting from the solution (15) of the master equation and going through the calculation described above, we arrive at the radial functions (9) and (8), where we identify

$$A = H_{rr}, \quad B = \frac{Q_r}{r}, \quad C = G, \quad K = \frac{h_r}{r}, \quad L = \frac{2k}{r^2}.$$

Because of the integrations involved we have raised the derivative index of the $F^{(j)}$ by 2 and of the $G^{(j)}$ by 1 so that no negative derivative indices appear in the final form of the solution. The modified angular functions are defined by

$$\hat{Y}_\phi = \csc \theta Y_\phi, \quad \hat{S}_\phi = \csc \theta S_\phi, \quad \hat{Y}_{\theta\phi} = \csc \theta Y_{\theta\phi}, \quad \hat{S}_{\theta\phi} = \csc \theta S_{\theta\phi}$$

and the remaining ones are equal to their unhatted counterparts.

In our derivation of the solution, we have only imposed the gauge condition (2). It can be checked directly that the remaining conditions (1) and (3) are also satisfied. This also follows more generally from the argument given below equation (3) in the introduction, noting that our definition of the time integral merely lowers the derivative index of the $F^{(j)}$ while leaving the expressions formally unchanged.

I thank Luisa Buchman, Mark Scheel and Harald Pfeiffer for collaboration on [6], which motivated this work, and John Stewart for helpful discussions. Financial support through a Research Fellowship at King's College Cambridge is gratefully acknowledged.

Appendix A. Explicit expressions for $\ell = 2, 3, 4$

The (real) angular functions are listed below in the order $m = \ell, \ell - 1, \dots, 1, 0$. We use the shorthand

$$R_m \equiv \begin{bmatrix} \cos m\phi \\ \sin m\phi \end{bmatrix}, \quad I_m \equiv \begin{bmatrix} -\sin m\phi \\ \cos m\phi \end{bmatrix},$$

where the two elements of each of these correspond to the two independent real solutions for each $m > 0$ (the real and imaginary parts of the spherical harmonics). The odd-parity angular functions are immediately obtained from the even-parity ones using (12). For simplicity we leave out the normalization factors of the spherical harmonics.

For $\ell = 2$ we have

$$\begin{aligned} A &= 24 \left[-\frac{F^{(2)}}{r^3} + \frac{3F^{(1)}}{r^4} - \frac{3F}{r^5} \right], \\ B &= 4 \left[-\frac{F^{(3)}}{r^2} + \frac{3F^{(2)}}{r^3} - \frac{6F^{(1)}}{r^4} + \frac{6F}{r^5} \right], \\ C &= 2 \left[-\frac{F^{(4)}}{r} + \frac{2F^{(3)}}{r^2} - \frac{3F^{(2)}}{r^3} + \frac{3F^{(1)}}{r^4} - \frac{3F}{r^5} \right], \\ K &= 4 \left[\frac{G^{(2)}}{r^2} - \frac{3G^{(1)}}{r^3} + \frac{3G}{r^4} \right], \\ L &= 2 \left[\frac{G^{(3)}}{r} - \frac{2G^{(2)}}{r^2} + \frac{3G^{(1)}}{r^3} - \frac{3G}{r^4} \right], \end{aligned}$$

Explicit solution of the linearized Einstein equations in TT gauge for all multipoles 8

$$\begin{aligned}
\hat{Y} &= \sin^2 \theta R_2, \cos \theta \sin \theta R_1, 2 - 3 \sin^2 \theta, \\
\hat{Y}_\theta &= 2 \cos \theta \sin \theta R_2, (1 - 2 \sin^2 \theta) R_1, -6 \cos \theta \sin \theta, \\
\hat{Y}_\phi &= 2 \sin \theta I_2, \cos \theta I_1, 0, \\
\hat{Y}_{\theta\theta} &= (2 - \sin^2 \theta) R_2, -\cos \theta \sin \theta R_1, 3 \sin^2 \theta, \\
\hat{Y}_{\theta\phi} &= 2 \cos \theta I_2, -\sin \theta I_1, 0.
\end{aligned}$$

This solution agrees with that of Teukolsky [3] up to an overall constant factor (depending on m and the parity).

For $\ell = 3$ we have

$$\begin{aligned}
A &= 120 \left[-\frac{F^{(3)}}{r^3} + \frac{6F^{(2)}}{r^4} - \frac{15F^{(1)}}{r^5} + \frac{15F}{r^6} \right], \\
B &= 10 \left[-\frac{F^{(4)}}{r^2} + \frac{6F^{(3)}}{r^3} - \frac{21F^{(2)}}{r^4} + \frac{45F^{(1)}}{r^5} - \frac{45F}{r^6} \right], \\
C &= 2 \left[-\frac{F^{(5)}}{r} + \frac{5F^{(4)}}{r^2} - \frac{15F^{(3)}}{r^3} + \frac{30F^{(2)}}{r^4} - \frac{45F^{(1)}}{r^5} + \frac{45F}{r^6} \right], \\
K &= 10 \left[\frac{G^{(3)}}{r^2} - \frac{6G^{(2)}}{r^3} + \frac{15G^{(1)}}{r^4} - \frac{15G}{r^5} \right], \\
L &= 2 \left[\frac{G^{(4)}}{r} - \frac{5G^{(3)}}{r^2} + \frac{15G^{(2)}}{r^3} - \frac{30G^{(1)}}{r^4} + \frac{30G}{r^5} \right],
\end{aligned}$$

$$\begin{aligned}
\hat{Y} &= \sin^3 \theta R_3, \cos \theta \sin^2 \theta R_2, \sin \theta (4 - 5 \sin^2 \theta) R_1, \cos \theta (2 - 5 \sin^2 \theta), \\
\hat{Y}_\theta &= 3 \cos \theta \sin^2 \theta R_3, \sin \theta (2 - 3 \sin^2 \theta) R_2, \cos \theta (4 - 15 \sin^2 \theta) R_1, \\
&\quad 3 \sin \theta (5 \sin^2 \theta - 4), \\
\hat{Y}_\phi &= 3 \sin^2 \theta I_3, 2 \cos \theta \sin \theta I_2, (4 - 5 \sin^2 \theta) I_1, 0, \\
\hat{Y}_{\theta\theta} &= 3 \sin \theta (2 - \sin^2 \theta) R_3, \cos \theta (2 - 3 \sin^2 \theta) R_2, 5 \sin \theta (3 \sin^2 \theta - 2) R_1, \\
&\quad 15 \cos \theta \sin \theta, \\
\hat{Y}_{\theta\phi} &= 6 \cos \theta \sin \theta I_3, 2(1 - 2 \sin^2 \theta) I_2, -10 \cos \theta \sin \theta I_1, 0.
\end{aligned}$$

Finally, for $\ell = 4$ we have

$$\begin{aligned}
A &= 360 \left[-\frac{F^{(4)}}{r^3} + \frac{10F^{(3)}}{r^4} - \frac{45F^{(2)}}{r^5} + \frac{105F^{(1)}}{r^6} - \frac{105F}{r^7} \right], \\
B &= 18 \left[-\frac{F^{(5)}}{r^2} + \frac{10F^{(4)}}{r^3} - \frac{55F^{(3)}}{r^4} + \frac{195F^{(2)}}{r^5} - \frac{420F^{(1)}}{r^6} + \frac{420F}{r^7} \right], \\
C &= 2 \left[-\frac{F^{(6)}}{r} + \frac{9F^{(5)}}{r^2} - \frac{45F^{(4)}}{r^3} + \frac{150F^{(3)}}{r^4} - \frac{360F^{(2)}}{r^5} + \frac{630F^{(1)}}{r^6} - \frac{630F}{r^7} \right], \\
K &= 18 \left[\frac{G^{(4)}}{r^2} - \frac{10G^{(3)}}{r^3} + \frac{45G^{(2)}}{r^4} - \frac{105G^{(1)}}{r^5} + \frac{105G}{r^6} \right], \\
L &= 2 \left[\frac{G^{(5)}}{r} - \frac{9G^{(4)}}{r^2} + \frac{45G^{(3)}}{r^3} - \frac{150G^{(2)}}{r^4} + \frac{315G^{(1)}}{r^5} - \frac{315G}{r^6} \right],
\end{aligned}$$

$$\begin{aligned}
 \hat{Y} &= \sin^4 \theta R_4, \cos \theta \sin^3 \theta R_3, \sin^2 \theta (6 - 7 \sin^2 \theta) R_2, \cos \theta \sin \theta (4 - 7 \sin^2 \theta) R_1, \\
 &\quad 35 \sin^4 \theta - 40 \sin^2 \theta + 8, \\
 \hat{Y}_\theta &= 4 \cos \theta \sin^3 \theta R_4, \sin^2 \theta (3 - 4 \sin^2 \theta) R_3, 4 \cos \theta \sin \theta (3 - 7 \sin^2 \theta) R_2, \\
 &\quad (28 \sin^4 \theta - 29 \sin^2 \theta + 4) R_1, 20 \cos \theta \sin \theta (7 \sin^2 \theta - 4), \\
 \hat{Y}_\phi &= 4 \sin^3 \theta I_4, 3 \cos \theta \sin^2 \theta I_3, 2 \sin \theta (6 - 7 \sin^2 \theta) I_2, \cos \theta (4 - 7 \sin^2 \theta) I_1, 0, \\
 \hat{Y}_{\theta\theta} &= 6 \sin^2 \theta (2 - \sin^2 \theta) R_4, 6 \cos^3 \theta \sin \theta R_3, 6(7 \sin^4 \theta - 8 \sin^2 \theta + 2) R_2, \\
 &\quad 6 \cos \theta \sin \theta (7 \sin^2 \theta - 3) R_1, 30 \sin^2 \theta (6 - 7 \sin^2 \theta), \\
 \hat{Y}_{\theta\phi} &= 12 \cos \theta \sin^2 \theta I_4, 3 \sin \theta (2 - 3 \sin^2 \theta) I_3, 6 \cos \theta (2 - 7 \sin^2 \theta) I_2, \\
 &\quad 3 \sin \theta (7 \sin^2 \theta - 6) I_1, 0.
 \end{aligned}$$
