In a study of interacting Bose particles the effective interaction, g , which contains pairwise interaction between atoms is an essential factor. In 3D it depends on the scattering length only such as $g(3) = 4\pi\hbar^2 a/m$, where m is the atomic mass and a is the s-wave scattering length. However, in general, it depends on momentum, too. In $D < 4$ dimensional case, the form of the D-dimensional effective interaction $g(D)$ has been suggested by Nogueira and Kleinert in 2006.¹ The final form is shown at the Eq. (8) of the paper as

$$g(D) = \frac{4\pi^{D/2}\hbar^2 a^{D-2}}{m} \frac{1}{2^{2-D}\Gamma(1 - \frac{D}{2})\gamma^{D-2} + \Gamma(\frac{D}{2} - 1)}, \quad (1)$$

where Γ is the Gamma function and γ is the dimensionless gas parameter in D-dimension given by $\gamma = na^D \ll 1$, where n is the D-dimensional gas density.

However, actually, the above form of $g(D)$ is not correct. The correct form is slightly different from Eq. (1)

in the exponent of the γ . It is

$$g(D) = \frac{4\pi^{D/2}\hbar^2 a^{D-2}}{m} \frac{1}{2^{2-D}\Gamma(1 - \frac{D}{2})\gamma^{D/2-1} + \Gamma(\frac{D}{2} - 1)}. \quad (2)$$

The mistake of the Eq. (1) came from the error that in the final step of the derivation of the paper they chose $pa \rightarrow na^D = \gamma$ instead of $pa \rightarrow \sqrt{na^D} = \sqrt{\gamma}$, where p is the momentum.

The mistake is trivial but a direct substitution of the formula in Eq. (1) into any D-dimensional problem leads a wrong result. For example, the Eq. (1) cannot reproduce the well-known 2D results of Bosons by M. Schick.² Only the formula in Eq. (2) in a D-dimensional Boson research produces correct ones.³ Average theoretical physicist who uses the formula $g(D)$ would not make the mistake, but we feel to comment for that because its role of $g(D)$ is critical in D-dimensional researches.
