# Quantum hypothesis testing and sufficient subalgebras 

Anna Jenčová*<br>Mathematical Institute, Slovak Academy of Sciences<br>Štefánikova 49, 81473 Bratislava, Slovakia

#### Abstract

We introduce a new notion of a sufficient subalgebra for quantum states: a subalgebra is 2 - sufficient for a pair of states $\left\{\rho_{0}, \rho_{1}\right\}$ if it contains all Bayes optimal tests of $\rho_{0}$ against $\rho_{1}$. In classical statistics, this corresponds to the usual definition of sufficiency. We show this correspondence in the quantum setting for some special cases. Furthermore, we show that sufficiency is equivalent to 2 - sufficiency, if the latter is required for $\left\{\rho_{0}^{\otimes n}, \rho_{1}^{\otimes n}\right\}$, for all $n$.

MSC: 46L53, 81R15, 62B05.
Key words: quantum hypothesis testing, sufficient subalgebras, 2sufficiency, quantum Chernoff bound

## 1 Introduction

In order to motivate our results, let us consider the following problem of classical statistics. Suppose that $P_{0}$ and $P_{1}$ are two probability distributions and the task is to discriminate between them by an $n$-dimensional observation vector $X$. The problem is, if there is a function (statistic) $T: X \rightarrow Y$, such that the vector $Y=T(X)$ (usually of lower dimension) contains all information needed for the discrimination.

[^0]In the setting of hypothesis testing, the null hypothesis $H_{0}=P_{0}$ is tested against the alternative $H_{1}=P_{1}$. In the most general formulation, a test is a measurable function $\varphi: X \rightarrow[0,1]$, which can be interpreted as the probability of rejecting the hypothesis if $x \in X$ occurs. There are two kinds of errors appearing in hypothesis testing: it may happen that $H_{0}$ is rejected, although it is true (error of the first kind), or that it is not rejected when $H_{1}$ is true (error of the second kind). For a given test $\varphi$, the error probabilities are

$$
\begin{aligned}
& \alpha(\varphi)=\int \varphi(x) P_{0}(d x) \quad \text { first kind } \\
& \beta(\varphi)=\int(1-\varphi(x)) P_{1}(d x) \quad \text { second kind }
\end{aligned}
$$

The two kinds of errors are in some sense complementary and it is usually not possible to minimize both error probabilities simultaneously. In the Bayesian approach, we choose a prior probability distribution $\{\lambda, 1-\lambda\}$, $\lambda \in[0,1]$ on the two hypotheses and then minimize the average (Bayes) error probability

$$
\int \varphi(x) \lambda P_{0}(d x)+\int(1-\varphi(x))(1-\lambda) P_{1}(d x)=\lambda \alpha(\varphi)+(1-\lambda) \beta(\varphi) .
$$

Suppose now that $T$ is a sufficient statistic for $\left\{P_{0}, P_{1}\right\}$. Roughly speaking, this means that there exists a common version of the conditional expectation $\left.E[\cdot \mid T]=E_{P_{0}} \cdot \cdot \mid T\right], P_{0^{-}}$a.s. and $E[\cdot \mid T]=E_{P_{1}}[\cdot \mid T], P_{1^{-}}$a.s. If $\varphi$ is any test, then $E[\varphi \mid T]$ is another test having the same error probabilities. It follows that we can always have an optimal test that is a function of $T$, so that only values of $T(X)$ are needed for optimal discrimination between $P_{0}$ and $P_{1}$.

The following theorem states that this can happen if and only if $T$ is sufficient, so that the above property characterizes sufficient statistics. The theorem was proved by Pfanzagl, see also [16].

Theorem 1 [15] Let $T: X \rightarrow Y$ be a statistic. The following are equivalent.

1. For any $\lambda \in(0,1)$ and any test $\varphi: X \rightarrow[0,1]$, there exists a test $\psi: Y \rightarrow[0,1]$, such that

$$
\lambda \alpha(\psi \circ T)+(1-\lambda) \beta(\psi \circ T) \leq \lambda \alpha(\varphi)+(1-\lambda) \beta(\varphi)
$$

2. $T$ is a sufficient statistic for $\left\{P_{0}, P_{1}\right\}$.

The problem of hypothesis testing can be considered also in the quantum setting. Here we deal with a pair of density operators $\rho_{0}, \rho_{1} \in B(\mathcal{H})$, where $\mathcal{H}$ is a finite dimensional Hilbert space and all tests are given by operators $0 \leq M \leq 1, M \in B(\mathcal{H})$. The problem of finding the optimal tests (the quantum Neyman-Pearson tests) and average error probabilities was solved by Helstrom and Holevo [6, 8].

Here a question arises, if it is possible to discriminate the states optimally by measuring on a given subsystem. Then we can gain some information only on the restricted densities, which, in general, can be distinguished with less precision.

Let $M_{0} \subseteq B(\mathcal{H})$ be the subalgebra describing the subsystem we have access to. The average error probabilities for tests in $M_{0}$ are usually higher than the optimal ones. We will consider the situation that this does not happen and $M_{0}$ contains some optimal tests for all prior probabilities. In agreement with classical terminology (see [16]), such a subalgebra will be called sufficient with respect to testing problems, or 2-sufficient, for $\left\{\rho_{0}, \rho_{1}\right\}$.

The quantum counterpart of sufficiency was introduced and studied by Petz, see Chap. 9. in [13, in a more general context. According to this definition, the subalgebra $M_{0}$ is sufficient for $\left\{\rho_{0}, \rho_{1}\right\}$, if there exists a completely positive, trace preserving map $M_{0} \rightarrow B(\mathcal{H})$, that maps both restricted densities to the original ones. Then the restriction to $M_{0}$ preserves all information needed for discrimination between the states and it is quite easy to see that a sufficient subalgebra must be 2 -sufficient.

The conditions for sufficiency seem to be quite restrictive (see for example the factorization conditions in [9]) and might be too strong, if only hypothesis testing is considered. It is therefore natural to ask if there is a quantum version of Theorem 1, that is, if every 2 -sufficient subalgebra must be sufficient.

In this paper, we give a partial answer to this question. We show that 2 -sufficiency and sufficiency are equivalent under each of the following conditions: 1) the subalgebra $M_{0}$ is invariant under the modular group of one of the states, 2) $M_{0}$ is commutative, 3) $\rho_{0}$ and $\rho_{1}$ commute. Moreover, we show that if the 2 -sufficiency condition is strengthened to hold for $n$ independent copies of the densities for all $n$, then the two notions become equivalent.

The organization of the paper is as follows. In Section 2, some basic notions are introduced and several characterizations of a sufficient subalgebra are given. A new characterization, based on a version of the Radon-Nikodym derivative, is found, this will be needed for the main results. Section 3 gives the quantum Neyman-Pearson lemma and quantum Chernoff bound. Section 4 contains the main results: a convenient necessary condition for 2 -sufficiency is found and it is shown that it implies sufficiency in the three above described
cases. Finally, the quantum Chernoff bound is utilized to treat the case when 2-sufficiency holds for $n$ independent copies of the states, for all $n$.

## 2 Some basic definitions and facts

### 2.1 Generalized conditional expectation

Let $\mathcal{H}$ be a finite dimensional Hilbert space and let $\rho$ be an invertible density matrix. Let $M_{0} \subseteq B(\mathcal{H})$ be a subalgebra and let $E: B(\mathcal{H}) \rightarrow M_{0}$ be the trace preserving conditional expectation. Then $E(\rho)$ is the restricted density of the state $\rho$.

As we have seen, the classical sufficient statistic is defined by certain property of the conditional expectations. It is well known that in the quantum case, a state preserving conditional expectation does not always exist. Therefore we need the generalized conditional expectation, defined by Accardi and Cecchini [1]. In our setting, it can be given as follows.

Let us introduce the inner product $\langle X, Y\rangle_{\rho}=\operatorname{Tr} X^{*} \rho^{1 / 2} Y \rho^{1 / 2}$ in $B(\mathcal{H})$. Then the generalized conditional expectation $E_{\rho}$ is a map $B(\mathcal{H}) \rightarrow M_{0}$, defined by

$$
\left\langle X_{0}, Y\right\rangle_{\rho}=\left\langle X_{0}, E_{\rho}(Y)\right\rangle_{E(\rho)}, \quad X_{0} \in M_{0}, Y \in B(\mathcal{H})
$$

It is easy to see that we have

$$
\begin{equation*}
E_{\rho}(X)=E(\rho)^{-1 / 2} E\left(\rho^{1 / 2} X \rho^{1 / 2}\right) E(\rho)^{-1 / 2} \tag{1}
\end{equation*}
$$

It is known that $E_{\rho}$ is completely positive and unital and that it is a conditional expectation if and only if $\rho^{i t} M_{0} \rho^{-i t} \subseteq M_{0}$, for all $t \in \mathbb{R}$. It is also easy to see that $E_{\rho}$ preserves the state $\rho$, that is, $E_{\rho}^{*} \circ E(\rho)=\rho$.

Next we introduce two subalgebras, related to $E_{\rho}$. Let $F_{\rho}$ be the set of fixed points of $E_{\rho}$ and let $N_{\rho} \subseteq B(\mathcal{H})$ be the multiplicative domain of $E_{\rho}$,

$$
N_{\rho}=\left\{X \in B(\mathcal{H}), E_{\rho}\left(X^{*} X\right)=E_{\rho}(X)^{*} E_{\rho}(X), E_{\rho}\left(X X^{*}\right)=E_{\rho}(X) E_{\rho}(X)^{*}\right\}
$$

Then both $F_{\rho}$ and $N_{\rho}$ are subalgebras in $B(\mathcal{H})$. It is clear that $F_{\rho} \subseteq M_{0} \cap N_{\rho}$, moreover, $X \in F_{\rho}$ if and only if $\rho^{i t} X \rho^{-i t} \in M_{0}$ for all $t \in \mathbb{R}$. As for $N_{\rho}$, we have the following result.

Lemma $1 N_{\rho}=\rho^{1 / 2} M_{0} \rho^{-1 / 2} \cap \rho^{-1 / 2} M_{0} \rho^{1 / 2}$
Proof. It is clear from (1) that $X \in N_{\rho}$ if and only if

$$
\begin{aligned}
& E\left(\rho^{1 / 2} X^{*} X \rho^{1 / 2}\right)=E\left(\rho^{1 / 2} X^{*} \rho^{1 / 2}\right) E(\rho)^{-1} E\left(\rho^{1 / 2} X \rho^{1 / 2}\right) \\
& E\left(\rho^{1 / 2} X X^{*} \rho^{1 / 2}\right)=E\left(\rho^{1 / 2} X \rho^{1 / 2}\right) E(\rho)^{-1} E\left(\rho^{1 / 2} X^{*} \rho^{1 / 2}\right)
\end{aligned}
$$

Let $A=X \rho^{1 / 2}, B=\rho^{1 / 2}$. Similarly as in [11], we put $M=A-B \Lambda$, with $\Lambda=E(\rho)^{-1} E\left(\rho^{1 / 2} X \rho^{1 / 2}\right)$. Then from $E\left(M^{*} M\right) \geq 0$, we obtain

$$
E\left(A^{*} A\right) \geq E\left(A^{*} B\right) E(\rho)^{-1} E\left(B^{*} A\right)
$$

with equality if and only if $M=0$, this implies

$$
\rho^{-1 / 2} X \rho^{1 / 2}=E(\rho)^{-1} E\left(\rho^{1 / 2} X \rho^{1 / 2}\right) \in M_{0}
$$

Conversely, let $X_{0}=\rho^{-1 / 2} X \rho^{1 / 2} \in M_{0}$, then $E\left(\rho^{1 / 2} X \rho^{1 / 2}\right)=E(\rho) X_{0}$, this implies that $M=0$.

Similarly, we get that $\rho^{-1 / 2} X^{*} \rho^{1 / 2} \in M_{0}$ is equivalent with the second equality.

It is also known that $E_{\rho}(X Y)=E_{\rho}(X) E_{\rho}(Y), E_{\rho}(Y X)=E_{\rho}(Y) E_{\rho}(X)$ for all $X \in N_{\rho}, Y \in B(\mathcal{H})$, this can be also shown from the above Lemma. Note that in the case that $E_{\rho}$ is a conditional expectation, $F_{\rho}=N_{\rho}=M_{0}$.

### 2.2 A Radon-Nikodym derivative and relative entropies

Let $\rho_{0}, \rho_{1}$ be invertible density matrices in $B(\mathcal{H})$. We will use the quantum version of the Radon-Nikodym derivative introduced in [5]. In our setting, the derivative $d_{\rho_{0}, \rho_{1}}$ of $\rho_{1}$ with respect to $\rho_{0}$ is defined as the unique element in $B(\mathcal{H})$, such that $\operatorname{Tr} \rho_{1} X=\left\langle X^{*}, d_{\rho_{0}, \rho_{1}}\right\rangle_{\rho_{0}}$. Then clearly

$$
d_{\rho_{0}, \rho_{1}}=\rho_{0}^{-1 / 2} \rho_{1} \rho_{0}^{-1 / 2}
$$

so that $d_{\rho_{0}, \rho_{1}}$ is positive, and $\left\|d_{\rho_{0}, \rho_{1}}\right\| \leq \lambda$ for any $\lambda>0$, such that $\rho_{1} \leq \lambda \rho_{0}$. It is also easy to see that

$$
E_{\rho_{0}}\left(d_{\rho_{0}, \rho_{1}}\right)=d_{E\left(\rho_{0}\right), E\left(\rho_{1}\right)}
$$

Let us recall that the Belavkin - Staszewski relative entropy is defined as [5]

$$
S_{B S}\left(\rho_{1}, \rho_{0}\right)=-\operatorname{Tr} \rho_{0} \eta\left(\rho_{0}^{-1 / 2} \rho_{1} \rho_{0}^{-1 / 2}\right)=-\operatorname{Tr} \rho_{0} \eta\left(d_{\rho_{0}, \rho_{1}}\right)
$$

where $\eta(x)=-x \log (x)$. Let $S$ be the Umegaki relative entropy

$$
S\left(\rho_{1}, \rho_{0}\right)=\operatorname{Tr} \rho_{1}\left(\log \rho_{1}-\log \rho_{0}\right)
$$

then $S\left(\rho_{1}, \rho_{0}\right) \leq S_{B S}\left(\rho_{1}, \rho_{0}\right)$, 7] and $S\left(\rho_{1}, \rho_{0}\right)=S_{B S}\left(\rho_{1}, \rho_{0}\right)$ if $\rho_{0}$ and $\rho_{1}$ commute. Both relative entropies are monotone in the sense that

$$
S\left(\rho_{1}, \rho_{0}\right) \geq S\left(E\left(\rho_{1}\right), E\left(\rho_{0}\right)\right), \quad S_{B S}\left(\rho_{1}, \rho_{0}\right) \geq S_{B S}\left(E\left(\rho_{1}\right), E\left(\rho_{0}\right)\right)
$$

holds for any subalgebra $M_{0}$. As we will see in the next section, equality in the monotonicity for $S$ is equivalent with sufficiency of the subalgebra $M_{0}$ with respect to $\left\{\rho_{0}, \rho_{1}\right\}$. For $S_{S B}$, we have the following result.

Lemma 2 The following are equivalent.
(i) $S_{B S}\left(\rho_{1}, \rho_{0}\right)=S_{B S}\left(E\left(\rho_{1}\right), E\left(\rho_{0}\right)\right)$
(ii) $d_{\rho_{0}, \rho_{1}} \in N_{\rho_{0}}$
(iii) $\rho_{1} \rho_{0}^{-1} \in M_{0}$
(iv) $\rho_{1} \rho_{0}^{-1}=E\left(\rho_{1}\right) E\left(\rho_{0}\right)^{-1}$

Proof. Since the function $-\eta(x)=x \log (x)$ is operator convex,

$$
\begin{equation*}
\eta\left(d_{E\left(\rho_{0}\right), E\left(\rho_{1}\right)}\right)=\eta\left(E_{\rho_{0}}\left(d_{\rho_{0}, \rho_{1}}\right)\right) \leq E_{\rho_{0}}\left(\eta\left(d_{\rho_{0}, \rho_{1}}\right)\right) \tag{2}
\end{equation*}
$$

by Jensen's inequality. We have

$$
\operatorname{Tr} \rho_{0}\left(E_{\rho_{0}}\left(\eta\left(d_{\rho_{0}, \rho_{1}}\right)\right)-\eta\left(E_{\rho_{0}}\left(d_{\rho_{0}, \rho_{1}}\right)\right)\right)=S_{B S}\left(\rho_{1}, \rho_{0}\right)-S_{B S}\left(E\left(\rho_{1}\right), E\left(\rho_{0}\right)\right)
$$

and since $\rho_{0}$ is invertible, equality in the monotonicity of $S_{B S}$ is equivalent with equality in (2). As it was proved in [14], this happens if and only if $d_{\rho_{0}, \rho_{1}} \in N_{\rho_{0}}$. This shows the equivalence (i) $\leftrightarrow$ (ii). The equivalence of (ii) and (iii) follows by Lemma (iii) $\Longleftrightarrow$ (iv) is rather obvious.

### 2.3 Sufficient subalgebras

We say that the subalgebra $M_{0} \subseteq B(\mathcal{H})$ is sufficient for $\left\{\rho_{0}, \rho_{1}\right\}$ if there is a completely positive trace preserving map $T: M_{0} \rightarrow B(\mathcal{H})$, such that $T \circ E\left(\rho_{0}\right)=\rho_{0}$ and $T \circ E\left(\rho_{1}\right)=\rho_{1}$. The following characterizations of sufficiency were obtained by Petz.

Theorem 2 [10, 13] The following are equivalent.
(i) $M_{0} \subseteq B(\mathcal{H})$ is sufficient for $\left\{\rho_{0}, \rho_{1}\right\}$
(ii) $S\left(\rho_{1}, \rho_{0}\right)=S\left(E\left(\rho_{1}\right), E\left(\rho_{0}\right)\right)$
(iii) $\operatorname{Tr} \rho_{0}^{s} \rho_{1}^{1-s}=\operatorname{Tr} E\left(\rho_{0}\right)^{s} E\left(\rho_{1}\right)^{1-s}$ for some $s \in(0,1)$
(iv) $\operatorname{Tr} E_{\rho_{0}}(X) \rho_{1}=\operatorname{Tr} X \rho_{1}$ for all $X \in B(\mathcal{H})$
(v) $E_{\rho_{0}}=E_{\rho_{1}}$.

The next characterization is based on the Radon-Nikodym derivative.

Theorem 3 The subalgebra $M_{0} \subseteq B(\mathcal{H})$ is sufficient for $\left\{\rho_{0}, \rho_{1}\right\}$ if and only if $d_{\rho_{0}, \rho_{1}} \in F_{\rho_{0}}$.

Proof. Let us denote $d=d_{\rho_{0}, \rho_{1}}$ and $d_{0}=d_{E\left(\rho_{0}\right), E\left(\rho_{1}\right)}$. Since $d_{0} \in M_{0}$, we have by definition that

$$
\operatorname{Tr} \rho_{1} E_{\rho_{0}}(X)=\left\langle d_{0}, E_{\rho_{0}}(X)\right\rangle_{E\left(\rho_{0}\right)}=\left\langle d_{0}, X\right\rangle_{\rho_{0}}
$$

so that $\operatorname{Tr} \rho_{1} E_{\rho_{0}}(X)=\operatorname{Tr} \rho_{1} X$ if and only if $\left\langle d_{0}, X\right\rangle_{\rho_{0}}=\langle d, X\rangle_{\rho_{0}}$. It follows that $d=d_{0}$ is equivalent with sufficiency of $M_{0}$, by Theorem 2 (iv). Since $E_{\rho_{0}}(d)=d_{0}$, this is equivalent with $d_{\rho_{0}, \rho_{1}} \in F_{\rho_{0}}$.

## 3 Quantum hypothesis testing

Let us now turn to the problem of hypothesis testing. Any test of the hypothesis $H_{0}=\rho_{0}$ against the alternative $H_{1}=\rho_{1}$ is represented by an operator $0 \leq M \leq 1$, which corresponds to rejecting the hypothesis. Then we have the error probabilities

$$
\begin{array}{cl}
\alpha(M)=\operatorname{Tr} \rho_{0} M & \text { first kind } \\
\beta(M)=\operatorname{Tr} \rho_{1}(1-M) & \text { second kind }
\end{array}
$$

For $\lambda \in(0,1)$, we define the Bayes optimal test to be a minimizer of the expression

$$
\begin{equation*}
\lambda \alpha(M)+(1-\lambda) \beta(M) \tag{3}
\end{equation*}
$$

It is clear that minimizing (3) is the same as maximizing

$$
\operatorname{Tr}\left(\rho_{1}-t \rho_{0}\right) M, \quad t=\frac{\lambda}{1-\lambda}
$$

### 3.1 The quantum Neyman-Pearson lemma

The following is the quantum version of the Neyman-Pearson lemma. The obtained optimal tests are called the (quantum) Neyman-Pearson tests. We give a simple proof for completeness.

Lemma 3 Let $t \geq 0$ and let us denote $P_{t,+}:=\operatorname{supp}\left(\rho_{1}-t \rho_{0}\right)_{+}, P_{t,-}:=$ $\operatorname{supp}\left(\rho_{1}-t \rho_{0}\right)_{-}$and $P_{t, 0}:=1-P_{t,+}-P_{t,-}$. Then the operator $0 \leq M_{t} \leq 1$ is a Bayes optimal test of $\rho_{0}$ against $\rho_{1}$ if and only if

$$
M_{t}=P_{t,+}+X_{t}
$$

where $0 \leq X_{t} \leq P_{t, 0}$.

Proof. Let $0 \leq M \leq 1$, then

$$
\begin{align*}
\operatorname{Tr}\left(\rho_{1}-t \rho_{0}\right) M & =\operatorname{Tr}\left(\rho_{1}-t \rho_{0}\right)_{+} M-\operatorname{Tr}\left(\rho_{1}-t \rho_{0}\right)_{-} M \leq \operatorname{Tr}\left(\rho_{1}-t \rho_{0}\right)_{+} M \\
& \leq \operatorname{Tr}\left(\rho_{1}-t \rho_{0}\right)_{+}=\operatorname{Tr}\left(\rho_{1}-t \rho_{0}\right) P_{t,+} \tag{4}
\end{align*}
$$

It follows that $M_{t}=P_{t,+}+X_{t}, X_{t} \leq P_{t, 0}$ is a Bayes optimal test. Conversely, let $M_{t}$ be some Bayes optimal test, then we must have

$$
\operatorname{Tr}\left(\rho_{1}-t \rho_{0}\right) M_{t}=\operatorname{Tr}\left(\rho_{1}-t \rho_{0}\right)_{+} M_{t}=\operatorname{Tr}\left(\rho_{1}-t \rho_{0}\right) P_{t,+}
$$

so that $\operatorname{Tr}\left(\rho_{1}-t \rho_{0}\right)_{-} M_{t}=0$. By positivity, this implies that $P_{t,-} M_{t}=$ $M_{t} P_{t,-}=0$, so that

$$
M_{t}\left(P_{t,+}+P_{t, 0}\right)=\left(P_{t,+}+P_{t, 0}\right) M_{t}=M_{t}
$$

which is equivalent with $M_{t} \leq P_{t,+}+P_{t, 0}$. Furthermore, from

$$
\operatorname{Tr}\left(\rho_{1}-t \rho_{0}\right)_{+}\left(P_{t,+}+P_{t, 0}-M_{t}\right)=0
$$

we obtain $P_{t,+}-P_{t,+} M_{t} P_{t,+}=P_{t,+}\left(1-M_{t}\right) P_{t,+}=0$, hence $\left(1-M_{t}\right) P_{t,+}=0$. We obtain $P_{t,+} \leq M_{t}$ and by putting $X_{t}:=M_{t}-P_{t,+}$, we get the result.

Let us denote by $\Pi_{e, \lambda}$ the minimum Bayes error probability. Then

$$
\begin{align*}
\Pi_{e, \lambda} & =\lambda \alpha\left(M_{\lambda /(1-\lambda)}\right)+(1-\lambda) \beta\left(M_{\lambda /(1-\lambda)}\right)= \\
& =\frac{1}{2}\left(1-\left\|(1-\lambda) \rho_{1}-\lambda \rho_{0}\right\|_{1}\right) \tag{5}
\end{align*}
$$

where the last equality follows from

$$
1-t=\operatorname{Tr}\left(\rho_{1}-t \rho_{0}\right)=\operatorname{Tr}\left(\rho_{1}-t \rho_{0}\right)_{+}-\operatorname{Tr}\left(\rho_{2}-t \rho_{0}\right)_{-}
$$

and

$$
\left\|\rho_{1}-t \rho_{0}\right\|_{1}=\operatorname{Tr}\left|\rho_{1}-t \rho_{0}\right|=\operatorname{Tr}\left(\rho_{1}-t \rho_{0}\right)_{+}+\operatorname{Tr}\left(\rho_{2}-t \rho_{0}\right)_{-}
$$

### 3.2 The quantum Chernoff bound

Suppose now that we have $n$ copies of the states $\rho_{0}$ and $\rho_{1}$, so that we test the hypothesis $\rho_{0}^{\otimes n}$ against $\rho_{1}^{\otimes n}$ by means of an operator $0 \leq M_{n} \leq 1$, $M_{n} \in \mathcal{B}\left(\mathcal{H}^{\otimes n}\right)$. Again, we may use the Neyman-Pearson lemma to find the minimum Bayes error probability

$$
\Pi_{e, \lambda, n}=\frac{1}{2}\left(1-\left\|(1-\lambda) \rho_{1}^{\otimes n}-\lambda \rho_{0}^{\otimes n}\right\|_{1}\right)
$$

The following important result, obtained in [3] and [12] (see also [4), is the quantum version of the classical Chernoff bound:

$$
\begin{equation*}
\lim _{n}\left(-\frac{1}{n} \log \Pi_{e, \lambda, n}\right)=-\log \left(\inf _{0 \leq s \leq 1} \operatorname{Tr} \rho_{0}^{1-s} \rho_{1}^{s}\right)=: \xi_{Q C B}\left(\rho_{0}, \rho_{1}\right) \tag{6}
\end{equation*}
$$

The expression $\xi_{Q C B}$ has a number of interesting properties. For example, it was proved that it is always nonnegative and equal to 0 if and only if $\rho_{0}=\rho_{1}$, moreover, it is monotone in the sense that

$$
\xi_{Q C B}\left(\rho_{0}, \rho_{1}\right) \geq \xi_{Q C B}\left(E\left(\rho_{0}\right), E\left(\rho_{1}\right)\right)
$$

Therefore, although it is not symmetric, $\xi_{Q C B}$ provides a reasonable distance measure on density matrices, called the quantum Chernoff distance. Note also that in the case that the matrices are invertible, the infimum is always attained in some $s^{*} \in[0,1]$.

## 4 2-sufficiency

We say that $M_{0}$ is sufficient with respect to testing problems, or 2-sufficient, for $\left\{\rho_{0}, \rho_{1}\right\}$ if for any test $M$ and any $\lambda \in(0,1)$, there is some test $N_{\lambda} \in M_{0}$, such that

$$
\lambda \alpha\left(N_{\lambda}\right)+(1-\lambda) \beta\left(N_{\lambda}\right) \leq \lambda \alpha(M)+(1-\lambda) \beta(M)
$$

It is quite clear that $M_{0}$ is 2 -sufficient if and only if for all $t \geq 0$, we can find a Neyman-Pearson test $M_{t} \in M_{0}$. Moreover, suppose that $M_{0}$ is a sufficient subalgebra for $\left\{\rho_{0}, \rho_{1}\right\}$ and let $T=E_{\rho_{0}}=E_{\rho_{1}}$. Then, if $M_{t}$ is a Neyman-Pearson test, then $T\left(M_{t}\right) \in M_{0}$ is a Neyman-Pearson test as well. Hence, a sufficient subalgebra is always 2-sufficient. In this section, we find the opposite implication in some special cases.

Lemma $4 P_{t, 0} \neq 0$ if and only if $t$ is an eigenvalue of $d:=d_{\rho_{0}, \rho_{1}}$. Moreover, the rank of $P_{t, 0}$ is equal to multiplicity of $t$.

Proof. By definition,

$$
\left(\rho_{1}-t \rho_{0}\right) P_{t, 0}=\rho_{0}^{1 / 2}(d-t) \rho_{0}^{1 / 2} P_{t, 0}=0
$$

so that $(d-t) \rho_{0}^{1 / 2} P_{t, 0} \rho_{0}^{1 / 2}=0$. Suppose $P_{t, 0} \neq 0$, then $t$ is an eigenvalue of $d$ and any vector in the range of $\rho_{0}^{1 / 2} P_{t, 0} \rho_{0}^{1 / 2}$ is an eigenvector. This implies that $r\left(P_{t, 0}\right)=r\left(\rho^{1 / 2} P_{t, 0} \rho^{1 / 2}\right) \leq r(F)$, where $F$ is the eigenprojection of $t$.

Conversely, let $t$ be an eigenvalue of $d$ with the eigenprojection $F$, then

$$
\left(\rho_{1}-t \rho_{0}\right) \rho_{0}^{-1 / 2} F \rho_{0}^{-1 / 2}=\rho_{0}^{1 / 2}(d-t) F \rho_{0}^{-1 / 2}=0
$$

so that the range of $\rho^{-1 / 2} F \rho^{-1 / 2}$ is in the kernel of $\rho_{1}-t \rho_{0}$, this implies $r(F) \leq r\left(P_{t, 0}\right)$.

Let us denote $Q_{t,+}=\operatorname{supp}\left(E\left(\rho_{1}\right)-t E\left(\rho_{0}\right)\right)_{+}, Q_{t, 0}=\operatorname{ker}\left(E\left(\rho_{1}\right)-t E\left(\rho_{0}\right)\right)$ and let $\Pi_{e, \lambda}^{0}$ be the minimal Bayes error probability for the restricted densities

$$
\Pi_{e, \lambda}^{0}:=\inf _{M \in M_{0}} \lambda \alpha(M)+(1-\lambda) \beta(M)=\frac{1}{2}\left(1-\left\|(1-\lambda) E\left(\rho_{1}\right)-\lambda E\left(\rho_{0}\right)\right\|_{1}\right)
$$

Lemma 5 The following are equivalent.
(i) The subalgebra $M_{0}$ is 2 -sufficient for $\left\{\rho_{0}, \rho_{1}\right\}$.
(ii) $\Pi_{e, \lambda}^{0}=\Pi_{e, \lambda}$ for all $\lambda \in(0,1)$.
(iii) $Q_{t, 0}=P_{t, 0}$ and $Q_{t,+}=P_{t,+}$ for all $t \geq 0$.

Proof. It is obvious that (i) implies (ii). Suppose (ii) and let us denote $f(t):=\max _{0 \leq M \leq 1} \operatorname{Tr}\left(\rho_{1}-t \rho_{0}\right) M$. If $N_{t}$ is any Neyman-Pearson test for $\left\{E\left(\rho_{0}\right), E\left(\rho_{1}\right)\right\}$, then

$$
\operatorname{Tr}\left(\rho_{1}-t \rho_{0}\right) N_{t}=\operatorname{Tr}\left(E\left(\rho_{1}\right)-t E\left(\rho_{0}\right)\right) N_{t}=f(t),
$$

so that $N_{t}$ is a Neyman-Pearson test for $\left\{\rho_{0}, \rho_{1}\right\}$ as well. Putting $N_{t}=Q_{t,+}$ and $N_{t}=Q_{t,+}+Q_{t, 0}$, we get by Lemma 3 that

$$
Q_{t,+}=P_{t,+}+X_{t}, \quad Q_{t,+}+Q_{t, 0}=P_{t,+}+Y_{t}
$$

with $X_{t}, Y_{t} \leq P_{t, 0}$. This implies that $Q_{t, 0} \leq P_{t, 0}$ and $Q_{t,+}=P_{t,+}$ if $P_{t, 0}=0$.
Let $t$ be an eigenvalue of $d_{0}$, then $P_{t, 0} \geq Q_{t, 0} \neq 0$, hence $t$ is also an eigenvalue of $d$, and its multiplicity in $d_{0}$ is not greater that its multiplicity in $d$. Since the sum of multiplicities must equal to $m=\operatorname{dim}(\mathcal{H})$, we must have $r\left(Q_{t, 0}\right)=r\left(P_{t, 0}\right)$, so that $Q_{t, 0}=P_{t, 0}$. This implies that $X_{t} \leq Q_{t, 0}$, hence $X_{t}=0$ and $P_{t,+}=Q_{t,+}$ for all $t$.

The implication (iii) $\rightarrow$ (i) is again obvious.
Note that the condition (ii) is equivalent with

$$
\left\|E\left(\rho_{1}\right)-t E\left(\rho_{0}\right)\right\|_{1} \geq\left\|\rho_{1}-t \rho_{0}\right\|_{1}, \quad \text { for all } t \geq 0
$$

This condition, with $E\left(\rho_{0}\right)$ and $E\left(\rho_{1}\right)$ replaced by arbitrary densities $\sigma_{0}$ and $\sigma_{1}$ was studied in [2]. It was shown that for $2 \times 2$ matrices, this is equivalent with the existence of a completely positive trace preserving map $T$, such that $T\left(\rho_{0}\right)=\sigma_{0}$ and $T\left(\rho_{1}\right)=\sigma_{1}$. In our case, this means that 2-sufficiency implies sufficiency for $2 \times 2$ matrices. Since any nontrivial subalgebra in $\mathcal{M}\left(\mathbb{C}^{2}\right)$ is commutative, this agrees with our results below.

The above Lemma gives characterizations of 2-sufficiency, but the conditions are not easy to check. The next Theorem gives a simple necessary condition.

Theorem 4 Let $M_{0}$ be 2-sufficient for $\left\{\rho_{1}, \rho_{0}\right\}$. Then $d_{\rho_{1}, \rho_{0}} \in N_{\rho_{0}}$.
Proof. By the previous Lemma, we have $P_{t, 0}=Q_{t, 0} \in M_{0}$ for all $t$. Let $t_{1}, \ldots, t_{k}$ be the eigenvalues of $d$ and denote $P_{i}=P_{t_{i}, 0}$. Then from $\left(d-t_{i}\right) \rho_{0}^{1 / 2} P_{i}=0$ we get

$$
d \rho_{0}^{1 / 2} \sum_{i} P_{i}=\rho_{0}^{1 / 2} \sum_{i} t_{i} P_{i}
$$

By Lemma 4 and its proof, $\operatorname{supp}\left(\rho_{0}^{1 / 2} P_{i} \rho_{0}^{1 / 2}\right) \leq F_{i}$ and $r\left(P_{i}\right)=r\left(F_{i}\right)$, with $F_{i}$ the eigenprojection of $t_{i}$. It follows that $\sum_{i} \rho_{0}^{1 / 2} P_{i} \rho_{0}^{1 / 2}$, and hence also $\sum_{i} P_{i}$, is invertible. Therefore,

$$
d \rho_{0}^{1 / 2}=\rho_{0}^{1 / 2} c, \quad c:=\sum_{i} t_{i} P_{i}\left(\sum_{j} P_{j}\right)^{-1}
$$

that is, $d=\rho_{0}^{1 / 2} c \rho_{0}^{-1 / 2}$, with $c \in M_{0}$. Moreover, $d=d^{*}=\rho_{0}^{-1 / 2} c^{*} \rho_{0}^{1 / 2}$, so that $d \in \rho_{0}^{1 / 2} M_{0} \rho_{0}^{-1 / 2} \cap \rho_{0}^{-1 / 2} M_{0} \rho_{0}^{1 / 2}$. By Lemma 回, this entails that $d \in N_{\rho_{0}}$.

Theorem 5 Let the subalgebra $M_{0}$ be 2-sufficient for $\left\{\rho_{0}, \rho_{1}\right\}$. Then $M_{0}$ is sufficient for $\left\{\rho_{0}, \rho_{1}\right\}$ in each of the following cases.
(1) $\rho_{0}^{i t} M_{0} \rho_{0}^{-i t} \subseteq M_{0}$ for all $t \in \mathbb{R}$
(2) $M_{0}$ is commutative
(3) $\rho_{0}$ and $\rho_{1}$ commute

Proof. (1) By Theorem 4, we have $d \in N_{\rho_{0}}$. Since $\rho_{0}^{i t} M_{0} \rho_{0}^{-i t} \subseteq M_{0}$, we have $d \in N_{\rho_{0}}=F_{\rho_{0}}$. By Theorem 3, this implies that $M_{0}$ is sufficient.
(2) Since $d \in N_{\rho_{0}}$, we have $S_{B S}\left(\rho_{1}, \rho_{0}\right)=S_{B S}\left(E\left(\rho_{1}\right), E\left(\rho_{0}\right)\right)$, by Lemma 2. Since $M_{0}$ is commutative,

$$
S\left(E\left(\rho_{1}\right), E\left(\rho_{0}\right)\right)=S_{B S}\left(E\left(\rho_{1}\right), E\left(\rho_{0}\right)\right)=S_{B S}\left(\rho_{1}, \rho_{0}\right) \geq S\left(\rho_{1}, \rho_{0}\right)
$$

By monotonicity of the relative entropy, this implies $S\left(\rho_{1}, \rho_{0}\right)=S\left(E\left(\rho_{1}\right), E\left(\rho_{0}\right)\right)$, so that $M_{0}$ is sufficient for $\left\{\rho_{0}, \rho_{1}\right\}$, by Theorem 2 (ii).
(3) Let $M_{1}$ be the subalgebra generated by all $P_{t,+}, t \in \mathbb{R}$. Then $M_{1}$ is commutative and 2 -sufficient for $\left\{\rho_{0}, \rho_{1}\right\}$, hence sufficient by (2). If $M_{0}$ is 2 -sufficient, we must have $M_{1} \subseteq M_{0}$ by Lemma [5, so that $M_{0}$ must be sufficient for $\left\{\rho_{0}, \rho_{1}\right\}$ as well.

It is clear from the proof of (1) that 2-sufficiency implies sufficiency whenever $N_{\rho_{0}}=F_{\rho_{0}}$ (or, equivalently, $N_{\rho_{1}}=F_{\rho_{1}}$ ). In fact, it can be shown that $N_{\rho_{0}}=F_{\rho_{0}}$ whenever $M_{0}$ is commutative, which gives an alternative proof of (2). Next we give a further example of this situation.

Example 1 Let $\mathcal{H}=\mathbb{C}^{4}$ and let $M_{0}=\mathcal{M}\left(\mathbb{C}^{2}\right) \otimes I \subset B(\mathcal{H})$. Let $\rho$ be a block-diagonal density matrix $\rho=\left(\begin{array}{cc}\rho_{1} & 0 \\ 0 & \rho_{2}\end{array}\right)$, where $\rho_{1}, \rho_{2}$ are positive invertible matrices in $\mathcal{M}\left(\mathbb{C}^{2}\right)$, and let $\sigma$ be any density matrix. Suppose that $M_{0}$ is 2-sufficient for $\{\rho, \sigma\}$.

By Theorem 4, $d_{\sigma, \rho} \in N_{\rho}$, which by Lemma 2 is equivalent with $\sigma \rho^{-1} \in$ $M_{0}$. This implies that $\sigma$ must be block-diagonal as well, $\sigma=\left(\begin{array}{cc}\sigma_{1} & 0 \\ 0 & \sigma_{2}\end{array}\right)$.

By Lemma 5, $P_{t,+} \in M_{0}$ for all $t \geq 0$, so that $P_{t,+}=\left(\begin{array}{cc}p_{t} & 0 \\ 0 & p_{t}\end{array}\right)$, where $p_{t}=\operatorname{supp}\left(\sigma_{1}-t \rho_{1}\right)_{+}=\operatorname{supp}\left(\sigma_{2}-t \rho_{2}\right)_{+}$. Since $p_{t}$ is a projection in $\mathcal{M}\left(\mathbb{C}^{2}\right)$, we have he following two possibilities: either $p_{t}=I$ for $t<t_{0}$ and $p_{t}=0$ for $t \geq t_{0}$, or $p_{t}$ is one-dimensional for $t$ in some interval $\left(t_{0}, t_{1}\right)$. Since $\rho=\sigma$ in the first case, we may suppose that the latter is true, so that $p_{t}$ is a common eigenprojection of $\sigma_{1}-t \rho_{1}$ and $\sigma_{2}-t \rho_{2}$ for $t \in\left(t_{0}, t_{1}\right)$. It follows that $\sigma_{1}-t \rho_{1}$ commutes with $\sigma_{2}-t \rho_{2}$ for $t \in\left(t_{0}, t_{1}\right)$, which implies that $\rho_{1}$ commutes with $\rho_{2}$.

Let $X \in N_{\rho}$, then $X=\rho^{1 / 2} X_{0} \rho^{-1 / 2}$, where both $X_{0}, \rho X_{0} \rho^{-1} \in M_{0}$. Let $X_{0}=Y \otimes I \in M_{0}$, then $\rho X_{0} \rho^{-1} \in M_{0}$ if and only if $\rho_{1} Y \rho_{1}^{-1}=\rho_{2} Y \rho_{2}^{-1}$, that is, $Y$ commutes with $\rho_{2}^{-1} \rho_{1}$. If $\rho_{2}^{-1} \rho_{1}$ is a constant, then $\rho^{i t} M_{0} \rho^{-i t} \subseteq M_{0}$, so that $F_{\rho}=M_{0}=N_{\rho}$. Otherwise, $Y$ must commute with both $\rho_{1}$ and $\rho_{2}$ and in this case, $X=\rho^{1 / 2} X_{0} \rho^{-1 / 2}=X_{0} \in F_{\rho}$.

In conclusion, if $M_{0}$ is 2 -sufficient for $\{\rho, \sigma\}$, we must have $N_{\rho}=F_{\rho}$, so that $M_{0}$ must be a sufficient subalgebra.

Let us now suppose that we have $n$ independent copies of the states, $\rho_{0}^{\otimes n}$ and $\rho_{1}^{\otimes n}$. An optimal test for $H_{1}: \rho_{0}^{\otimes n}$ against $H_{1}: \rho_{1}^{\otimes n}$ usually cannot be obtained as the product of optimal tests, but we may ask if there is some
optimal test in $M_{0}^{\otimes n}$. If this is the case for all $\lambda$, we say that $M_{0}$ is $(2, n)$ sufficient for $\left\{\rho_{0}, \rho_{1}\right\}$.

Theorem 6 The following conditions are equivalent.
(i) $M_{0}$ is $(2, n)$-sufficient for $\left\{\rho_{0}, \rho_{1}\right\}$, for all $n$.
(ii) $M_{0}$ is a sufficient subalgebra for $\left\{\rho_{0}, \rho_{1}\right\}$.

Proof. Let us denote

$$
\Pi_{e, \lambda, n}^{0}:=\frac{1}{2}\left(1-\left\|(1-\lambda) E\left(\rho_{1}\right)^{\otimes n}-\lambda E\left(\rho_{0}\right)^{\otimes n}\right\|_{1}\right)
$$

By Lemma 5 (ii), the condition (i) implies that $\Pi_{e, \lambda, n}=\Pi_{e, \lambda, n}^{0}$ for all $n$, hence also

$$
\lim _{n}\left(-\frac{1}{n} \log \Pi_{e, \lambda, n}\right)=\lim _{n}\left(-\frac{1}{n} \log \Pi_{e, \lambda, n}^{0}\right)
$$

By (6), this entails that

$$
\inf _{0 \leq s \leq 1} \operatorname{Tr} \rho_{0}^{1-s} \rho_{1}^{s}=\inf _{0 \leq s \leq 1} \operatorname{Tr} E\left(\rho_{0}\right)^{1-s} E\left(\rho_{1}\right)^{s}
$$

By monotonicity, we have $\operatorname{Tr} \rho_{0}^{1-s} \rho_{1}^{s} \leq \operatorname{Tr} E\left(\rho_{0}\right)^{1-s} E\left(\rho_{1}\right)^{s}$ for all $s \in[0,1]$. Suppose that the infimum on the RHS is attained in some $s_{0} \in[0,1]$. Then

$$
\operatorname{Tr} E\left(\rho_{0}\right)^{1-s_{0}} E\left(\rho_{1}\right)^{s_{0}}=\inf _{0 \leq s \leq 1} \operatorname{Tr} \rho_{0}^{1-s} \rho_{1}^{s} \leq \operatorname{Tr} \rho_{0}^{1-s_{0}} \rho_{1}^{s_{0}} .
$$

If $s_{0}=0$ or 1 , then the quantum Chernoff distance is equal to 0 , so that $\rho_{0}=\rho_{1}$ and the subalgebra $M_{0}$ is trivially sufficient. Otherwise, we must have $\operatorname{Tr} E\left(\rho_{0}\right)^{1-s_{0}} E\left(\rho_{1}\right)^{s_{0}}=\operatorname{Tr} \rho_{0}^{1-s_{0}} \rho_{1}^{s_{0}}$ for $s_{0} \in(0,1)$, which implies that $M_{0}$ is sufficient for $\left\{\rho_{0}, \rho_{1}\right\}$, by Theorem 2 (iii).

Conversely, let $E_{\rho} \otimes n$ be the generalized conditional expectation $B\left(\mathcal{H}^{\otimes n}\right) \rightarrow$ $M_{0}^{\otimes n}$. It is easy to see that for any invertible density matrix $\rho, E_{\rho \otimes n}=E_{\rho}^{\otimes n}$, so that if $E_{\rho_{0}}=E_{\rho_{1}}$, then $E_{\rho_{0}^{\otimes n}}=E_{\rho_{1}^{\otimes n}}$ for all $n$. Hence if $M_{0}$ is sufficient for $\left\{\rho_{0}, \rho_{1}\right\}$, then $M_{0}^{\otimes n}$ is sufficient for $\left\{\rho_{0}^{\otimes n}, \rho_{1}^{\otimes n}\right\}$ for all $n$, this implies (i).
