ABOUT THE NON-INTEGER PROPERTY OF HYPERHARMONIC NUMBERS

ISTVÁN MEZŐ

ABSTRACT. It was proven in 1915 by Leopold Theisinger that the H_n harmonic numbers are never integers. In 1996 Conway and Guy have defined the concept of hyperharmonic numbers. The question naturally arises: are there any integer hyperharmonic numbers? The author gives a partial answer to this question and conjectures that the answer is "no".

The n-th harmonic number is the n-th partial sum of the harmonic series:

$$H_n = \sum_{k=1}^n \frac{1}{k}.$$

Conway and Guy in [4] defined the harmonic numbers of higher orders, also known as the hyperharmonic numbers: $H_n^{(1)} := H_n$, and for all r > 1 let

$$H_n^{(r)} = \sum_{k=1}^n H_k^{(r-1)}$$

be the n-th harmonic number of order r. These numbers can be expressed by binomial coefficients and ordinary harmonic numbers:

$$H_n^{(r)} = \binom{n+r-1}{r-1} (H_{n+r-1} - H_{r-1}).$$

The prominent role of these numbers has been realized recently in combinatory. The $\begin{bmatrix} n \\ k \end{bmatrix}_r$ r-Stirling number is the number of the permutations of the set $\{1,\ldots,n\}$ having k disjoint, non-empty cycles, in which the elements 1 through r are restricted to appear in different cycles.

In [1] one can find the following interesting equality:

$$H_n^{(r)} = \frac{\left[\binom{n+r}{r+1} \right]_r}{n!}.$$

Let us turn our attention to the main question of this paper. It is known that any number of consecutive terms not necessarily beginning with 1 will never sum to an integer (see [7]). As a corollary, we get that the H_n harmonic numbers are never integers (n > 1). Theisinger

²⁰⁰⁰ Mathematics Subject Classification. 11B83.

Key words and phrases. harmonic numbers, hyperharmonic numbers, 2-adic norm.

proved this latter result directly in 1915 [6]. The question appears obviously: are there any integer hyperharmonic numbers?

Theisinger's main tool was the 2-adic norm. We give a short summary of his method. Every rational number $x \neq 0$ can be represented by $x = \frac{p^{\alpha}r}{s}$, where p is a fixed prime number, r and s are relative prime integers to p. α is a unique integer. We can define the p-adic norm of x by

$$|x|_p = p^{-\alpha}$$
, and let $|0|_p = 0$.

This norm fulfills the properties of the usual norms, namely

$$|x|_p = 0 \iff x = 0,$$

$$|xy|_p = |x|_p |y|_p \quad (x, y \in \mathbb{Q}),$$

$$|x + y|_p \le |x|_p + |y|_p \quad (x, y \in \mathbb{Q}).$$

Furthermore, the so-called strong triangle inequality also holds:

$$|x+y|_p \le \max\{|x|_p, |y|_p\} (\le |x|_p + |y|_p).$$

We shall use the following property of integer numbers:

$$x \in \mathbb{Z} \Longrightarrow x = p^{\alpha}r \Longrightarrow |x|_p = \frac{1}{p^{\alpha}} \le 1,$$

where r and the prime p are relative prime integers. This means that if the p-norm of a rational x is greater than 1 then x is necessarily non-integer.

Let us introduce the order of a natural number n: if $2^m \le n < 2^{m+1}$, then $\operatorname{Ord}_2(n) := m$. It is obvious that $\operatorname{Ord}_2(n) = \lfloor \log_2(n) \rfloor$.

Theorem 1.

$$|H_n|_2 = 2^{\operatorname{Ord}_2(n)} \quad (n \in \mathbb{N}),$$

that is – by our observation above – H_n is never integer.

Proof. First, let n be even. Since $|x|_2 = |-x|_2$ for all $x \in \mathbb{Q}$, by the strong triangle inequality we get

$$\max\{|H_n|_2, |1|_2\} = \max\left\{|H_n|_2, |1|_2, \left|\frac{1}{3}\right|_2, \left|\frac{1}{5}\right|_2, \dots, \left|\frac{1}{n-1}\right|_2\right\} \ge$$

$$\ge \left|H_n - 1 - \frac{1}{3} - \frac{1}{5} - \dots - \frac{1}{n-1}\right|_2 =$$

$$= \left|\frac{1}{2} + \frac{1}{4} + \dots + \frac{1}{n-2} + \frac{1}{n}\right|_2 =$$

$$= \left|\frac{1}{2}\right|_2 \left|1 + \frac{1}{2} + \frac{1}{3} + \dots + \frac{1}{n/2}\right|_2 = 2\left|H_{n/2}\right|_2.$$

If n is odd, the situation is the same:

$$\max\{|H_n|_2, |1|_2\} \ge 2 |H_{(n-1)/2}|_2.$$

The reader may verify it.

So we get that the 2-adic norm of the harmonic numbers is monotone increasing. Since $|H_2|_2 = \left|\frac{3}{2}\right|_2 = 2$, the 2-adic norm of all the harmonic numbers are greater than 1. As a corollary, this means that the harmonic numbers are not integers because of the property of the 2-adic norm mentioned above.

We can continue the calculations on $H_{n/2}$ (or on $H_{(n-1)/2}$) instead of H_n . For instance let us consider that n/2 is even. Then the method described above gives that

$$|H_{n/2}|_2 \ge \left|\frac{1}{2}\right|_2 |H_{n/4}|_2 = 2|H_{n/4}|_2.$$

This and the previous estimation implies that

$$|H_n|_2 \ge \left|\frac{1}{2}\right|_2 |H_{n/2}|_2 \ge \left|\frac{1}{2}\right|_2 \left|\frac{1}{2}\right|_2 |H_{n/4}|_2 = 4|H_{n/4}|_2.$$

And so on. If n/2 is odd then we choose (n/2 - 1)/2 instead of n/4. We can perform these steps exactly $Ord_2(n)$ times.

After all, we shall have the following:

$$|H_n|_2 \ge \left| \frac{1}{2^{\text{Ord}_2(n)}} \right|_2 |H_1|_2 = 2^{\text{Ord}_2(n)}.$$

On the other hand,

$$|H_n|_2 \le \max\left\{|1|_2, \left|\frac{1}{2}\right|_2, \cdots, \left|\frac{1}{n}\right|_2\right\} = \left|\frac{1}{2^{\text{Ord}_2(n)}}\right|_2 = 2^{\text{Ord}_2(n)},$$

because the greatest 2-power occurring between 1 and n is $\operatorname{Ord}_2(n)$. The inequalities detailed above give the statement.

A different approach can be found in [5], [2] and in their references. The next proof comes from these sources.

Proof. Let us fix the order of n, i.e.: $\operatorname{Ord}_2(n) := m$. This implies that the denominator of $\frac{2^{m-1}}{n}$ is odd, unless $n = 2^m$. We get that the number

$$2^{m-1}H_n - \frac{1}{2}$$

can be represented by the sum of rationals with odd denominators. For example,

$$2^{m-1}H_n - \frac{1}{2} = \frac{a_1}{b_1} + \dots + \frac{a_s}{b_s} = \frac{c}{\operatorname{lcm}(b_1, \dots, b_s)},$$

where b_i is odd for all $i=1,\ldots,s$. It means that $b:=\operatorname{lcm}(b_1,\ldots,b_s)$ is odd. The last formula gives the result

$$H_n = \frac{\frac{c}{b} + \frac{1}{2}}{2^{m-1}} = \frac{2c + b}{2^m b}.$$

Let us turn our attention to hyperharmonic numbers. We need a lemma which can be found in [3]:

Lemma 2.

$$|n!|_n = p^{(A_p(n)-n)/(p-1)}$$

where $A_p(n)$ is the sum of the digits of the p-adic expansion of n.

Example 3. Let p = 2 and n = 11. Then $n = 1011_2$, that is, $A_2(n) = 3$

$$|n!|_2 = |39916800|_2 = |256 \cdot 155925|_2 = |256|_2|155925|_2 = |2^8|_2 \cdot 1 = 2^{-8}.$$

We can apply the lemma: $A_2(n) - n = 3 - 11 = -8$, whence $|n!|_2 = 2^{-8}$.

Theorem 4. If $\operatorname{Ord}_2(n+r-1) > \operatorname{Ord}_2(r-1)$ then

$$|H_n^{(r)}|_2 = 2^{A_2(n+r-1)-A_2(n)-A_2(r-1)+\operatorname{Ord}_2(n+r-1)}$$

else

$$|H_n^{(r)}|_2 = 2^{A_2(n+r-1)-A_2(n)-A_2(r-1)+\max\left\{\left|\frac{1}{r}\right|_2,\left|\frac{1}{r+1}\right|_2,\dots,\left|\frac{1}{n+r-1}\right|_2\right\}}.$$

Proof.

$$\begin{aligned} & \left| H_{n}^{(r)} \right|_{2} = \left| \binom{n+r-1}{r-1} (H_{n+r-1} - H_{r-1}) \right|_{2} = \\ & = \left| \binom{n+r-1}{r-1} \right|_{2} \left| \frac{a}{2^{\operatorname{Ord}_{2}(n+r-1)}b} - \frac{c}{2^{\operatorname{Ord}_{2}(r-1)}d} \right|_{2} = \\ & = \left| \binom{n+r-1}{r-1} \right|_{2} \left| \frac{2^{\operatorname{Ord}_{2}(r-1)}ad - 2^{\operatorname{Ord}_{2}(n+r-1)}bc}{2^{\operatorname{Ord}_{2}(n+r-1) + \operatorname{Ord}_{2}(r-1)}bd} \right|_{2}. \end{aligned}$$

Because of the condition $\operatorname{Ord}_2(n+r-1) > \operatorname{Ord}_2(r-1)$ we get

$$|H_n^{(r)}|_2 = \left| \binom{n+r-1}{r-1} \right|_2 \left| \frac{ad - 2^{\operatorname{Ord}_2(n+r-1) - \operatorname{Ord}_2(r-1)}bc}{2^{\operatorname{Ord}_2(n+r-1)}bd} \right|_2.$$

Since the nominator is odd, we get the following:

$$\left| \frac{ad - 2^{\operatorname{Ord}_2(n+r-1) - \operatorname{Ord}_2(r-1)}bc}{2^{\operatorname{Ord}_2(n+r-1)}bd} \right|_2 = 2^{\operatorname{Ord}_2(n+r-1)}.$$

To compute the 2-adic norm of the binomial coefficient, we use the previous lemma.

This, and the previous equality give the result with respect to the condition $\operatorname{Ord}_2(n+r-1) > \operatorname{Ord}_2(r-1)$.

Let us fix an arbitrary n for which $Ord_2(n+r-1) = Ord_2(r-1)$.

$$H_{n+r-1} - H_{r-1} = \frac{1}{r} + \frac{1}{r+1} + \dots + \frac{1}{n+r-1}.$$

Let us substract all of the fractions with odd denominators. Then we can take $\frac{1}{2}$ out of the remainder and continue the recursive method described in the first proof of Theorem 1. We can make such substraction steps

$$\max\left\{ \left| \frac{1}{r} \right|_2, \left| \frac{1}{r+1} \right|_2, \dots, \left| \frac{1}{n+r-1} \right|_2 \right\}$$

times. The result:

$$|H_{n+r-1} - H_{r-1}|_2 \ge \max\left\{ \left| \frac{1}{r} \right|_2, \left| \frac{1}{r+1} \right|_2, \dots, \left| \frac{1}{n+r-1} \right|_2 \right\}.$$

On the other hand, by the strong triangle inequality

$$|H_{n+r-1} - H_{r-1}|_2 \le \max \left\{ \left| \frac{1}{r} \right|_2, \left| \frac{1}{r+1} \right|_2, \dots, \left| \frac{1}{n+r-1} \right|_2 \right\}.$$

Corollary 5. The sum of the harmonic numbers cannot be integer:

$$H_1 + H_2 + \dots + H_n \notin \mathbb{N} \quad (n > 1).$$

Or, which is the same,

$$H_n^{(2)} \not\in \mathbb{N} \quad (n > 1).$$

Proof. $H_1 + H_2 + \cdots + H_n = H_n^{(2)}$. The condition with respect to the order of n and r holds because $\operatorname{Ord}_2(n+2-1) > \operatorname{Ord}_2(2-1) = 0$ for all $n \geq 1$. Furthermore,

$$|H_n^{(2)}|_2 = 2^{A_2(n+1)-A_2(n)-A_2(1)+\operatorname{Ord}_2(n+1)}$$
.

Let $m = \operatorname{Ord}_2(n+1)$. Our goal is to minimize the power of 2. $\operatorname{Ord}_2(n+1) = m$ implies that $n+1 < 2^{m+1}$, therefore $1 \le A_2(n+1) \le m+1$ and $1 \le A_2(n) \le m$. The minimum in the power is taken when $A_2(n) = m$ and $A_2(n+1) = 1$. It is possible if and only if $n = 2^m - 1$. In this case

$$A_2(n+1) - A_2(n) - A_2(1) + \operatorname{Ord}_2(n+1) = 1 - m - 1 + m = 0.$$

We get that if $n \neq 2^m - 1$ for some m, then $|H_n^{(2)}|_2 > 1$, that is, $H_n^{(2)} \notin \mathbb{N}$. On the other hand, let us assume that n has the form $2^m - 1$. This implies that

$$H_n^{(2)} = {n+2-1 \choose 2-1} (H_{n+2-1} - H_{2-1}) =$$

$$= (n+1)(H_{n+1} - 1) = 2^m \left(\frac{a}{2^{\text{Ord}_2(n+1)}b} - 1\right) = \frac{a}{b} - 2^m \notin \mathbb{N}.$$

One can easily prove the following, using the method in the previous proof.

Corollary 6. $H_n^{(3)} \notin \mathbb{N}$ for all n > 1.

As we can see, the method to prove the non-integer property of harmonic numbers does not work for hyperharmonic numbers, because there are n and r integers for which $|H_n^{(r)}|_2 = 1$. In spite of this fact, we believe that Theisinger's theorem holds for all hyperharmonic numbers, too.

Conjecture 7. None of the hyperharmonic numbers can be integers (r, n > 2).

Example 8. We demonstrate that the theorem described above simplifies the calculation of the 2-norm of hyperharmonic numbers.

For instance,

$$H_{18}^{(8)} = {18+8-1 \choose 8-1} (H_{18+8-1} - H_{8-1}) =$$

$$= 480700 \left(\frac{34052522467}{8923714800} - \frac{363}{140} \right) = \frac{10914604807}{18564}.$$

Since $|18564|_2 = 2^{-2}$, we get that $|H_{18}^{(8)}|_2 = 2^2 = 4$. On the other hand, $A_2(18+8-1) = A_2(16+8+1) = 3$, $A_2(8-1) =$ $A_2(4+2+1) = 3$, $A_2(18) = A_2(16+2) = 2$ and $Ord_2(18+8-1) =$ $Ord_2(16 + 9) = 4$. By theorem 5,

$$|H_{18}^{(8)}|_2 = 2^{3-3-2+4} = 2^2 = 4.$$

Finally, we pose an interesting question:

Problem 9. For which $n_1 \neq n_2$ and $r_1 \neq r_2$ does the equality

$$H_{n_1}^{(r_1)} = H_{n_2}^{(r_2)}$$

stand?
