MEAN CURVATURE BLOWUP IN MEAN CURVATURE FLOW

ANDREW A. COOPER

Abstract. In this note we establish that finite-time singularities of the mean curvature flow of compact Riemannian submanifolds $M_t^m \hookrightarrow (N^{m+n}, h)$ are characterised by the blow up of the mean curvature.

1. Introduction

It is well known that the mean curvature flow $\partial_t F = H$ of submanifolds $F_t : M^m \hookrightarrow \mathbb{R}^{m+n}$ has finite-time singularities characterised by the blowup of the second fundamental form II:

Theorem 1.1 (Huisken [4])**.** *Suppose $T < \infty$ is the first singular time for a compact mean curvature flow. Then $\max_{M_t} |\operatorname{II}| \to \infty$.*

We will prove that in fact it suffices to consider the mean curvature vector $H = \operatorname{tr} \operatorname{II}$:

Theorem 1.2. *Suppose $T < \infty$ is the first singular time for a mean curvature flow of compact submanifolds of a Riemannian manifold (N, h) with bounded geometry. Then $\max_{M_t} |H| \to \infty$ as $t \to T$.*

The blow-up of $|H|$ was previously known for hypersurfaces with $H > 0$, by work of Huisken and Sinestrari [3], [2] which established lower bounds on the principal curvatures in the mean-convex setting.

In [7], Šešum proved the analogous result for the Ricci flow, namely that $|\operatorname{Ric}|$ blows up at a finite first singular time. Our proof is motivated by hers.

2. Preliminaries

First we recall some evolution equations for the flow. We use indices $1 \le i, j, k, l \le m$, $m+1 \le \alpha, \beta \le m+n$. $h_{ij\alpha}$ denotes the αth component of $\operatorname{II}(\partial_i, \partial_j)$. H^α denotes the αth component of H. g_{ij} denotes the induced metric. $\overline{R}$ with four indices denotes the extrinsic Riemannian curvature, and $\overline{R}$ with two indices denotes the extrinsic Ricci curvature. ∇_i denotes the tangential covariant derivative in the direction i. We use the summation convention for upper and lower indices.

Lemma 2.1 (Huisken [4], Smoczyk [6])**.** *Along a mean curvature flow $M_t \hookrightarrow (N, h)$, we have*

(1) $\partial_t g_{ij} = -2H^\alpha h_{ij\alpha}$

(2) $\partial_t \operatorname{dvol} = -|H|^2 \operatorname{dvol}$

Key words and phrases. Mean curvature flow.

The author was partially supported by an RTG Research Training in Geometry and Topology NSF grant DMS 0353717 and as a graduate student on NSF grant DMS 06-04759.

(3) $\partial_t h_{ij\alpha} = \Delta h_{ij\alpha} - 2H^\beta h_{jk\beta} h_i{}^k{}_\alpha + h_{ik\beta} h_l{}^{k\beta} h_j{}^l{}_\alpha + \overline{R}_{il} h_j{}^l{}_\alpha - \nabla_i \overline{R}_{j\alpha} - \nabla_k \overline{R}^k{}_{ij\alpha}$

By integrating the evolution equation for $|\nabla^s \mathrm{II}|$ and using the Hölder and Morrey inequalities, one can obtain

Theorem 2.1 (Huisken [4], Smoczyk [6])**.** *Along the mean curvature flow,* $\sup_{M\times[0,T)} |\nabla^s \mathrm{II}|$ *is bounded in terms of* $\sup_{M\times[0,T)} |\mathrm{II}|$.

We also recall

Lemma 2.2 (Glickenstein [1])**.** *Suppose a 1-parameter family of complete Riemannian manifolds* $(M, g(t))$ *is uniformly continuous in* t*, that is, for any* t_0 *and any* $\epsilon > 0$ *there is* $\delta > 0$ *so that* $(1-\epsilon)g(t_0) \leq g(t) \leq (1+\epsilon)g(t_0)$ *for* $t \in [t_0, t_0+\delta]$*. Then for any* $p \in M$*,* $r > 0$*, the metric balls centred at* p *satisfy:*

$$B_{g(t_0)}(p, \frac{r}{\sqrt{1+\epsilon}}) \subset B_{g(t)}(p, r)$$

Proof. Let $p, q \in M$. Let $\gamma : [0, S] \to M$ be a minimising geodesic from p to q for the metric $g(t_0)$. Then the distance $d_{g(t_0)}(p, q)$ in the metric $g(t_0)$ satisfies

$$\begin{aligned} d_{g(t_0)}(p,q) &= \int_0^S |\dot\gamma|_{g(t_0)}(s) ds \\ &\geq \frac{1}{\sqrt{1+\epsilon}} \int_0^S |\dot\gamma|_{g(t)}(s) ds \\ &\geq \frac{1}{\sqrt{1+\epsilon}} d_{g(t)}(p,q) \end{aligned}$$

so that $\frac{1}{\sqrt{1+\epsilon}} d_{g(t)}(p,q) \leq d_{g(t_0)}(p,q)$. This immediately implies

$$B_{g(t_0)}(p, \frac{r}{\sqrt{1+\epsilon}}) \subset B_{g(t)}(p, r)$$

□

3. The Blow Up

We will prove Theorem 1.2 by contradiction. To this end, assume $\max_M |H(t)| \leq C$ for all $t \in [0, T)$, and that the flow has a singularity at $T < \infty$.

By Theorem 1.1, we know that as $t \to T$, $\max_M |\mathrm{II}(t)| \to \infty$. Let (p_j, t_j) be a sequence in $M \times [0, T)$ with $t_j \to T$ and $\max_{t \leq t_j} |\mathrm{II}| = |\mathrm{II}(p_j, t_j)| =: Q_j^2 \to \infty$. By passing to a subsequence if necessary, we may assume that all $F(p_j, t_j)$ lie in an ambient metric ball $B^N(R)$ about some $p_0 \in N$, and choose p_0 so that $F(p_j, t_j) \to p_0$. We can assume R has radius less than the injectivity radius of (N, h).

For any $r > 0$, suppose $F(q, 0) \in B^N(r)$. Since $|\partial_t F| = |H| \leq C$, we have $F(q,t) \in B^N(CTr)$ for any $t \in [0, T)$. So $F_t(F_0^{-1}(B^N(\frac{R}{CT}))) \subset B^N(R)$. By passing to a subsequence, we may assume that all the p_j lie in one component $\tilde{M}$ of $F_0^{-1}(B^N(\frac{R}{CT}))$. The sequel only uses this smaller set $\tilde{M} \subset M$, so we will denote it by M as well.

Consider the flows given by scaling the ambient metric by Q_j and time by Q_j^{-2}:

$$F_j(p,t) = F(p, t_j + \frac{t}{Q_j^2}) : M \hookrightarrow (B^N, Q_j^2 h)$$

Lemma 3.1. *Each F_j is a mean curvature flow on $M \times [-Q_j^2 t_j, 0]$. The second fundamental form of F_j is bounded:*

$$\max_{t\leq 0} |\operatorname{II}_j| = |\operatorname{II}_j(p_j, 0)| = 1$$

Proof. Clearly $\partial_t F_j = Q_j^{-2}\partial_t F$. We need to show that by scaling the ambient metric, we induce the same scaling in H. By definition

$$\begin{aligned} H_{Q_j^2 h}(F_j) &= \operatorname{tr}_{Q_j^2 h} \operatorname{II}_{Q_j^2 h}(F_j) \\ &= (Q_j^2 h)^{pq} (\partial_p \partial_q F_j)^{\perp_{Q_j^2 h}} \end{aligned}$$

where $(Q_j^2 h)^{pq}$ is the inverse matrix of $(Q_j^2 h)(\partial_p F_j, \partial_q F_j)$ and $\perp_{Q_j^2 h}$ is the projection onto the normal bundle induced from $Q_j^2 h$.

$Q_j^2 h$ induces the same splitting into tangent and normal bundles as h, so we have

$$\begin{aligned} H_{Q_j^2 h}(F_j) &= Q_j^{-2} \left[h^{pq} (\partial_p \partial_q F_j)^{\perp_h} \right] \\ &= Q_j^{-2} \operatorname{tr}_h \operatorname{II}_h(F_j) \\ &= Q_j^{-2} H_h(F_j) \end{aligned}$$

So H scales as required.

Similarly scaling the ambient metric by Q_j^2 scales $|\operatorname{II}|$ by Q_j^{-2}, so we have

$$\begin{aligned} \max_{t\leq 0} |\operatorname{II}_j| &= \max_{t\leq t_j} Q_j^{-2} |\operatorname{II}| \\ &= Q_j^{-2} |\operatorname{II}(p_j, t_j)| = 1 \end{aligned}$$

□

It is clear that the $(B^N, Q_j^2 h, p_0)$ converge in the Cheeger-Gromov sense to $(\mathbb{R}^{m+n}, dx^2, 0)$, where dx^2 is the Euclidean metric. In particular, we have a monotone exhausting sequence of open sets $V_j \subset \mathbb{R}^{m+n}$ and embeddings $\psi_j : (V_j, 0) \hookrightarrow (B^N, p_0)$, such that $\psi_{j+1}|_{V_j} = \psi_j$.

Let $s_0 = -Q_1^2 t_1$. Again after passing to a smaller spatial region $\tilde{M} \subset M$, we can assume $F_j(\tilde{M} \times [s_0, 0]) \subset \psi_j(V_j)$. As before, we restrict our argument to this smaller region and write M without confusion.

Define $\tilde{F}_j : M \times [s_0, 0] \to \mathbb{R}^{m+n}$ by $\tilde{F}_j = \psi_j^{-1} F_j$. Each $\tilde{F}_j$ is a mean curvature flow with respect to the metric $\psi_j^*(Q_j^2 h)$.

The second fundamental forms $\tilde{\operatorname{II}}_j$ of the $\tilde{F}_j$ are uniformly bounded, so Theorem 2.1 gives uniform bounds on the covariant derivatives of the $\tilde{\operatorname{II}}_j$. Hence we have uniform bounds on the spatial derivatives of $\tilde{F}_j$.

Since $\partial_t \tilde{F}_j = \tilde{H}_j$, we get bounds on the time derivative of $\tilde{F}_j$. In fact the evolution of H gives a bound

$$\begin{aligned} |\partial_t^2 \tilde{F}_j| = |\partial_t \tilde{H}_j| &\leq |\Delta \tilde{H}_j| + C_1 |\nabla \tilde{H}_j| + C_2 |\tilde{H}_j| |\tilde{\operatorname{II}}_j|^2 \\ &\leq |\nabla^2 \tilde{\operatorname{II}}_j| + C_1 |\nabla \tilde{\operatorname{II}}_j| + C_2 |\tilde{\operatorname{II}}_j|^3 \end{aligned}$$

and similarly, any iterated time derivative $\partial_t^s \tilde{F}_j = \partial_t^{s-1}(\tilde{H}_j)$ is controlled in terms of $|\nabla^r \tilde{\mathrm{II}}_j|$ for $r \leq 2(s-1)$. The mixed derivatives $\partial_t^r \nabla^s \tilde{\mathrm{II}}_j$ can be similarly controlled by $|\nabla^l \tilde{\mathrm{II}}_j|$ for $l \leq 2r+s$.

Thus the derivatives of $\tilde{F}_j$ are uniformly bounded. By the Arzela-Ascoli theorem we have a convergence in any C^k to a limit $F_\infty : M \times [s_0, 0] \to \mathbb{R}^{m+n}$.

Proposition 3.1. *F_∞ is a stationary mean curvature flow.*

Proof. Fix i and consider the sequence $H_{\psi_i^*(Q_i^2 h)}(\tilde{F}_j)$ of mean curvature vectors of the $\tilde{F}_j$ with respect to the metric $\psi_i^*(Q_i^2 h)$.

$$H_{\psi_i^*(Q_i^2 h)}(\tilde{F}_j) = (\psi_i^*(Q_i^2 h))^{pq}(\tilde{F}_j)(\partial_p \partial_q \tilde{F}_j)^{\perp_{\psi_i^*(Q_i^2 h)}}$$

Since the ψ_i agree, every $\psi_i^*(Q_i^2 h)$ is conformal to $\psi_k^*(Q_k^2 h)$ on V_k for $k \leq i$. Hence splitting into normal and tangent bundles is the same for each $\psi_i^*(Q_i^2 h)$. Since the $\psi_i^*(Q_i^2 h) \to dx^2$, this splitting is the same as the one from dx^2. Now letting first $j \to \infty$ and then $i \to \infty$, we have

$$\begin{aligned}
\lim_i \lim_j H_{\psi_i^*(Q_i^2 h)}(\tilde{F}_j) &= \lim_i (\partial_p \partial_q (\lim_j \tilde{F}_j))^{\perp_{dx^2}} (\psi_i^*(Q_i^2 h))^{pq} (\lim_j \tilde{F}_j) \\
&= (\partial_p \partial_q F_\infty)^{\perp_{dx^2}} \lim_i (\psi_i^*(Q_i^2 h))^{pq}(F_\infty) \\
&= (\partial_p \partial_q F_\infty)^{\perp_{dx^2}} (dx^2)^{pq}(F_\infty) \\
&= H_{dx^2}(F_\infty)
\end{aligned}$$

In particular, $\lim_j H_{\psi_j^*(Q_j^2 h)}(\tilde{F}_j) = H_{dx^2}(F_\infty)$. On the other hand, since $\tilde{F}_j$ is a mean curvature flow with respect to $\psi_j^*(Q_j^2 h)$,

$$\begin{aligned}
\lim_j H_{\psi_j^*(Q_j^2 h)}(\tilde{F}_j) &= \lim_j \partial_t \tilde{F}_j \\
&= \partial_t \lim_j \tilde{F}_j = \partial_t F_\infty
\end{aligned}$$

Thus F_∞ is a mean curvature flow.

The rescaled $\tilde{H}_j = H_{\psi_j^*(Q_j^2 h)}(\tilde{F}_j)$ have $|\tilde{H}_j| \leq \frac{C}{Q_j^2}$, so in the limit $H_{dx^2}(F_\infty)$ vanishes. Hence the flow is stationary. □

Since the limit flow is stationary, we will abuse notation and write $F_\infty : M \hookrightarrow \mathbb{R}^{m+n}$ for $F_\infty(\cdot, 0)$.

Adapting the ideas of [7], we consider the growth of balls in $F_\infty(M)$.

Definition 3.1. We say that the submanifold $F : M^m \hookrightarrow \mathbb{R}^{m+n}$ has euclidean extrinsic volume growth at $p \in \mathbb{R}^{m+n}$ if $\mathrm{vol}(F(M) \cap \overline{B}(p, r)) = r^m \omega_m$ for all $r > 0$, where $\overline{B}$ is the ball in $\mathbb{R}^{m+n}$ with centre p and radius r and ω_m is the volume of the unit Euclidean m-ball.

Proposition 3.2. *$F_\infty : M \hookrightarrow \mathbb{R}^{m+n}$ has euclidean extrinsic volume growth at 0.*

Proof. Let us make the following convention for intersections with extrinsic balls. $\overline{B}_\infty(\rho)$ will denote the metric ball in $(\mathbb{R}^{m+n}, dx^2)$ centred at $0 \in \mathbb{R}^{m+n}$. $\overline{B}_j(\rho)$ will denote the metric ball in $(N, Q_j^2 h)$ centred at $F_j(p_j, 0)$. $\overline{B}_{t_j}(\rho)$ will denote the metric ball in (N, h) centred at $F(p_j, t_j)$. Note that $\overline{B}_j(\rho) = \overline{B}_{t_j}(\frac{\rho}{Q_j})$.

Let vol_∞, vol_j, and vol_{t_j} denote the volumes induced from the embeddings F_∞, $F_j(\cdot,0)$, and $F(\cdot,t_j)$ respectively. We also use vol_{t_j} to denote the pullback volume $F_{t_j}^*\,\mathrm{vol}_{t_j}$ on the domain manifold M.

We have, for any $r>0$,

$$\begin{aligned}\frac{\mathrm{vol}_\infty(F_\infty(M)\cap\overline{B}_\infty(r))}{r^m} &= \lim_j \frac{\mathrm{vol}_j(F_j(M)\cap\overline{B}_j(r))}{r^m}\\ &= \lim_j \frac{\mathrm{vol}_{t_j}(F_{t_j}(M)\cap\overline{B}_{t_j}(\frac{r}{Q_j}))}{(\frac{r}{Q_j})^m}\end{aligned} \tag{1}$$

Since $|\partial_t F| = |H| \le C$, we have that $|F(\cdot,t)-F(\cdot,t_0)|\le C|t-t_0|$. Thus F is uniformly continuous in time. In particular, for any $\epsilon>0$ there is $\delta>0$ so that $F(q,t)\in\overline{B}(F(q,t_0),\epsilon)$ for all $t\in[t_0,t_0+\delta], q\in M$.

Then we have, for such ϵ,δ,t,t_0, that

$$F_{t_j}^{-1}(\overline{B}_{t_j}(\rho))\subset F_{t_0}^{-1}(\overline{B}_{t_0}((1+\epsilon)\rho))$$

which implies

$$\mathrm{vol}_{t_j}(F_{t_j}^{-1}(\overline{B}_{t_j}(\frac{r}{Q_j}))) \le \mathrm{vol}_{t_j}(F_{t_0}^{-1}(\overline{B}_{t_0}((1+\epsilon)\frac{r}{Q_j})))$$

Since $t_j\to T$, we can take some j_0 so large that, for our given ϵ, all the t_j with $j\ge j_0$ are δ-close. So we can estimate (1) by:

$$\lim_j \frac{\mathrm{vol}_{t_j}(F_{t_j}(M)\cap\overline{B}_{t_j}(\frac{r}{Q_j}))}{(\frac{r}{Q_j})^m} \le \lim_j \frac{\mathrm{vol}_{t_j}(F_{t_{j_0}}^{-1}(\overline{B}_{t_{j_0}}((1+\epsilon)\frac{r}{Q_j})))}{(\frac{r}{Q_j})^m} \tag{2}$$

The evolution of the volume form shows that the flow is volume-reducing. So $\mathrm{vol}_{t_j}\le\mathrm{vol}_{t_{j_0}}$ for $j\ge j_0$. Thus we can estimate (2) by

$$\begin{aligned}\lim_j \frac{\mathrm{vol}_{t_j}(F_{t_{j_0}}^{-1}(\overline{B}_{t_{j_0}}((1+\epsilon)\frac{r}{Q_j})))}{(\frac{r}{Q_j})^m} &\le \lim_j \frac{\mathrm{vol}_{t_{j_0}}(F_{t_{j_0}}^{-1}(\overline{B}_{t_{j_0}}((1+\epsilon)\frac{r}{Q_j})))}{(\frac{r}{Q_j})^m}\\ &= \lim_j \frac{\mathrm{vol}_{t_{j_0}}(F_{t_{j_0}}(M)\cap\overline{B}_{t_{j_0}}((1+\epsilon)\frac{r}{Q_j}))}{(\frac{r}{Q_j})^m}\\ &= \lim_j (1+\epsilon)^m \frac{\mathrm{vol}_{t_{j_0}}(F_{t_{j_0}}(M)\cap\overline{B}_{t_{j_0}}((1+\epsilon)\frac{r}{Q_j}))}{((1+\epsilon)\frac{r}{Q_j})^m}\end{aligned}$$

so that the only dependence of the right hand side on j is in the Q_j.

Since $F_{t_{j_0}}(M)$ is a submanifold, we have $\lim_{\rho\to0}\dfrac{\mathrm{vol}_{t_{j_0}}(F_{t_{j_0}}(M)\cap\overline{B}_{t_{j_0}}(\rho))}{\rho^m}=\omega_m$. Since $Q_j\to\infty$, we may take $\rho=(1+\epsilon)\frac{r}{Q_j}\to0$. So we have shown

$$\frac{\mathrm{vol}_\infty(F_\infty(M)\cap\overline{B}_\infty(r))}{r^m}\le(1+\epsilon)^m\omega_m$$

Since ϵ was arbitrary, it follows that $\mathrm{vol}_\infty(F_\infty(M)\cap\overline{B}(r))\le r^m\omega_m$.

The monotonicity formula for minimal submanifolds [5] asserts that $\frac{\mathrm{vol}_\infty(F_\infty(M)\cap\overline{B}_\infty(r))}{r^m}$ is decreasing as $r\to 0$. Since $F_\infty(M)$ is a submanifold,

$$\lim_{r\to 0}\frac{\mathrm{vol}_\infty(F_\infty(M)\cap\overline{B}_\infty(r))}{r^m}=\omega_m$$

Hence $\frac{\mathrm{vol}_\infty(F_\infty(M)\cap\overline{B}_\infty(r))}{r^m}\searrow\omega_m$ as $r\to 0$. In particular

$$\mathrm{vol}_\infty(F_\infty(M)\cap\overline{B}_\infty(r))\geq r^m\omega_m$$

Thus we have established that F_∞ has euclidean extrinsic volume growth at 0. □

Now we consider intrinsic metric balls $B_\infty\subset M$ induced from F_∞.

Proposition 3.3. *M_∞ has supereuclidean intrinsic volume growth at 0, that is,* $\mathrm{vol}_\infty(B_\infty(0,r))\geq r^m\omega_m$.

Proof. This claim is proved essentially identically to the corresponding claim in the proof of Theorem 2 from [7].

Consider the flow of rescaled metrics $g_j(t)$ induced from the rescaled $F_j(\cdot,t)$. Their evolution is given by

$$\partial_t g_j=-2H_j\cdot\mathrm{II}_j$$

where H_j is the rescaled mean curvature vector and II_j is the rescaled second fundamental form. By choice of rescaling, $|\,\mathrm{II}_j\,|\leq 1$ and $|H_j|\leq\frac{C}{Q_j^2}$. In particular, $|\partial_t g_j|\leq 2C$, so the $g_j(t)$ are uniformly continuous in t in the sense of Lemma 2.2, with no dependence on j.

The uniform continuity of each g_j implies the uniform continuity of the original metric $g(t)$. To see this, simply compute the rescaled metrics. We have

$$\begin{aligned}(1-\epsilon)g_j(t_0)\leq&g_j(t)\leq(1+\epsilon)g_j(t_0)\\(1-\epsilon)g(t_j+\frac{t_0}{Q_j^2})\leq&g(t_j+\frac{t}{Q_j^2})\leq(1+\epsilon)g(t_j+\frac{t_0}{Q_j^2})\end{aligned}$$

where $t\in[t_0,t_0+\delta]$. This inequality appears to depend on j, but in fact we may choose one j (say $j=1$) and obtain that g is uniformly continuous in t.

Thus we may apply Lemma 2.2 to estimate the metric balls at any time t_j by the metric ball at time t_{j_0}, so long as $t_j-t_{j_0}\leq\delta$. Since $t_j\to T$, we can pick a j_0 so that this condition holds for all $j\leq j_0$. Let B_∞, B_j, and B_{t_j} denote the intrinsic metric balls induced by the embeddings F_∞, $F_j(\cdot,0)$, and $F(\cdot,t_j)$ respectively, considered as subsets of the domain M.

$$\begin{aligned}\frac{\mathrm{vol}_\infty(B_\infty(r))}{r^m}&=\lim_j\frac{\mathrm{vol}_j(B_j(r))}{r^m}\\&=\lim_j\frac{\mathrm{vol}_{t_j}(B_{t_j}(\frac{r}{Q_j}))}{(\frac{r}{Q_j})^m}\\&\geq\lim_j(1+\epsilon)^{-\frac{m}{2}}\frac{\mathrm{vol}_{t_j}(B_{t_{j_0}}(\frac{r}{\sqrt{1+\epsilon}Q_j}))}{(\frac{r}{\sqrt{1+\epsilon}Q_j})^m}\end{aligned}\tag{3}$$

Since $|H| \leq C$, we have using the evolution of dvol that

$$\mathrm{dvol}_t \geq e^{-C^2|t-t_0|}\,\mathrm{dvol}_{t_0}$$

Since the $t_j \to T$, we can take j_0 large enough that $\mathrm{vol}_{t_j} \geq (1-\epsilon)\,\mathrm{vol}_{t_{j_0}}$ for $j > j_0$. Then we may continue (3):

$$\begin{aligned}\lim_j (1+\epsilon)^{-\frac{m}{2}} \frac{\mathrm{vol}_{t_j}(B_{t_{j_0}}(\frac{r}{\sqrt{1+\epsilon}Q_j}))}{(\frac{r}{\sqrt{1+\epsilon}Q_j})^m} &\geq \lim_j (1-\epsilon)(1+\epsilon)^{-\frac{m}{2}} \frac{\mathrm{vol}_{t_{j_0}}(B_{t_{j_0}}(\frac{r}{\sqrt{1+\epsilon}Q_j}))}{(\frac{r}{\sqrt{1+\epsilon}Q_j})^m} \\ &= \frac{1-\epsilon}{(1+\epsilon)^{\frac{m}{2}}}\omega_m\end{aligned}$$

for any $\epsilon > 0$. Thus $\mathrm{vol}_\infty(B_\infty(r)) \geq r^m\omega_m$. □

We also need an elementary fact about continuous functions.

Lemma 3.2. *Let ϕ, ψ be continuous, nonnegative real functions on a measure space (X, μ), such that*

(1) $\mu(U) > 0$ for any nonempty open U.
(2) $\phi \leq \psi$
(3) For any $R \in \mathbb{R}$, the sublevel sets $D_\phi(R) = \{x \in X | \phi(x) \leq R\}$ and $D_\psi(R) = \{x \in X | \psi(x) \leq R\}$ have the same finite measure.

Then $\phi \equiv \psi$.

Proof. Since $\phi \leq \psi$, we have for each R that $D_\psi(R) \subset D_\phi(R)$.

Hence $\mu(D_\phi(R) \setminus D_\psi(R)) = \mu(D_\phi(R)) - \mu(D_\psi(R)) = 0$.

Consider $V = \{x \in X | \phi(x) < \psi(x)\}$. For each $x \in V$, we can find a rational R so that $\phi(x) \leq R < \psi(x)$. Then $x \in D_\phi(R) \setminus D_\psi(R)$. Thus we have

$$V \subset \bigcup_{R \in \mathbb{Q}} D_\phi(R) \setminus D_\psi(R)$$

Thus $\mu(V) \leq \sum_{R \in \mathbb{Q}} \mu(D_\phi(R) \setminus D_\psi(R)) = 0$. On the other hand, V is open since ϕ and ψ are continuous. Then the assumption on μ implies that V must be empty, i.e. $\phi \equiv \psi$. □

Now we combine these lemmas to finish the proof of Theorem 1.2.

Proof of Theorem 1.2. Propositions 3.2 and 3.3 give

$$r^m\omega_m \leq \mathrm{vol}_\infty(B_\infty(r)) \leq \mathrm{vol}_\infty(F_\infty(M) \cap \overline{B}(r)) = r^m\omega_m$$

Thus $\mathrm{vol}_\infty(F_\infty(M) \cap \overline{B_\infty}(r)) = \mathrm{vol}_\infty(B_\infty(R))$.

Let $d(p)$ denote the intrinsic distance in $F_\infty(M)$ from 0 to p and $\overline{d}(p)$ denote the extrinsic distance. Then $d \geq \overline{d}$. By Lemma 3.2, we have in fact $d \equiv \overline{d}$. So $F_\infty(M)$-minimising geodesics at 0 are $\mathbb{R}^{m+n}$-minimising geodesics at 0. That is, $F_\infty(M)$ is totally geodesic at 0.

Hence $\mathrm{II}_\infty(0,0) = 0$.

This is the desired contradiction, for $|\mathrm{II}_\infty(0,0)| = 1$ by construction. □

Remark. There are two major differences between the argument we give here and that in [7].

First, the blow-up argument in Šešum's work makes use of Perelman's non-collapsing theorem to get an injectivity radius bound, and uses Cheeger-Gromov convergence of the rescaled Ricci flows. We note that our argument could be stated in terms of the Cheeger-Gromov limit of $(M, F_j^*(Q_j^2 h), p_j)$. Uniform bounds on the second fundamental forms $\tilde{\mathrm{II}}_j$ immediately imply a uniform injectivity radius bound, so this approach would not require a result analogous to Perelman's.

Second, where Šešum's argument employs the Bishop volume comparison for Ricci-nonnegative Riemannian manifolds, we use the monotonicity theorem for minimal submanifolds.
