Abstract.

Explicit results for various quantum thermodynamic function (QTF) of a charged magneto-oscillator coupled to a heat bath at arbitrary temperature are demonstrated in this paper. Discernible expressions for different QTF in the two limits of very low and very high temperatures are presented for three popular heat bath models : Ohmic, single relaxation time and blackbody radiation. The central result is that the effect of magnetic field turns out to be important at low temperatures yet crucial at high temperatures. It is observed that the dissipation parameter, γ , and the cyclotron frequency, ω_c , affect the decaying or rising behaviour of various QTF in just the opposite way to each other at low temperatures. In the high temperature regime, the effect of γ is much pronounced than that of ω_c .

1. Introduction

The problem of a charged quantum particle in the presence of a constant magnetic field is of great interest in the field of quantum Hall effect [\[1\]](#page-20-0), high temperature superconductivity [\[2\]](#page-20-1), diamagnetism [\[3,](#page-20-2) [4\]](#page-20-3), plasma physics [\[5\]](#page-20-4), atomic physics [\[6\]](#page-20-5), two dimensional electronic systems [\[7\]](#page-20-6). The issue that we addres in this paper is what happens to the quantum thermodynamic functions (QTF) of a charged quantum particle in the presence of an external constant magnetic field when it is in contact with a dissipative quantum heat bath. This kind of analysis is related with the dissipative quantum mechanics, a subject that has seen a great attention through the work of Leggett and others [\[8,](#page-21-0) [9,](#page-21-1) [10\]](#page-21-2). There are several approaches for the treatment of dissipative quantum systems. The most convensional approach is system plus reservoir point of view i.e. the system of interest is coupled linearly with the environment which is represented by a collection of harmonic oscillators [\[11,](#page-21-3) [12\]](#page-21-4). Usually, one is interested in the dissipative subsystem and the reservoir variables are eliminated by projection operator or tracing procedure [\[13\]](#page-21-5). As a result of that, the reservoir enters only through few parameters. The results obtained from these kind of dissipative quantum systems are of great interest due to the recent widespread interest on the critical role of environmental effects in mesoscopic systems [\[14,](#page-21-6) [15,](#page-21-7) [16,](#page-21-8) [17,](#page-21-9) [18\]](#page-21-10), in fundamental quantum physics, and in quantum information [\[19,](#page-21-11) [20,](#page-21-12) [21,](#page-21-13) [22\]](#page-21-14). In last few years, research on the open quantum systems has questioned about validity of fundamental laws of thermodynamics [\[23,](#page-21-15) [24,](#page-21-16) [25,](#page-21-17) [26\]](#page-21-18). These subtle issues are discussed in details by several authors [\[27,](#page-21-19) [28,](#page-21-20) [29,](#page-21-21) [30,](#page-21-22) [31,](#page-21-23) [32,](#page-21-24) [33,](#page-22-0) [34\]](#page-22-1). Here, our goal is not to survey all these subtle issues, but we focus on the effect of environment and the effect of magnetic field on various thermodynamic funtions such as free enrgy, entropy, internal energy, and specific heat of a charged oscillator. By this realistic calculations, one can make direct contact with experiment on low dimensional nanostructures and quantum dots [\[7\]](#page-20-6).

Starting point of this paper is the famous Caldeira-Leggatt heat-bath model to incorporate the environmental effect in quantum and mesoscopic systems [\[8,](#page-21-0) [9\]](#page-21-1). This enables us to derive generalized quantum Langevin equation (GQLE) for the charged magneto-oscillator. Then, we use the previously derived result of Ford *et al* [\[35\]](#page-22-2) for the free energy of a charged magneto-oscillator in an arbitrary heat bath in terms of a single integral involving generalized susceptibility coming up from the generalized quantum Langevin equation [\[36,](#page-22-3) [37\]](#page-22-4). This enables us to derive the free energy of the model system at an arbitrary temperature. Using this generalized result, one can obtain free energy expression and other thermodynamic functions of the charged quantum magneto-oscillator for three popular heat bath models : Ohmic, single relaxation time and blackbody radiation heat bath or Quantum Electrodynamics (QED) model.

Now, we need to verify in which way our results are new from the previous results in literature. Ford and O'Connell discussed about the quantum thermodynamic functions for an oscillator coupled to a heat bath [\[38\]](#page-22-5). In this paper, we extend the work of Ford and O'Connell to include the presence of an external static magnetic field. We determine various quantum thermodynamic functions of the charged magneto-oscillator coupled to a heat bath. What we find that each term in the low temperature expansion of different QTF are added up by two additional magnetic field dependent terms. On the other hand, the inclusion of magnetic field in the problem is reflected in the two additional magnetic field dependent terms in each quantum thermodynamic function in the high temperature regime. In the low temperature regime, the magnetic field changes the qualitative behaviour as well as the quantitative values of different QTF for the charged magneto-oscillator from that of a free oscillator. In this low temperature regime, ω_c and γ affect deacaying or rising behaviour of various QTF in the opposite manner. It is seen that the effect of ω_c is negligible in the high temperature regime. But, the effect of γ is still crucial at high temperatures. We also plot the general expression of various QTF for the entire temperature regime by numerically evaluating equation (24).

With this preceding background, we organize the rest of the paper as follows. In section II, we describe our model and the method of deriving free energy of the system. Section III is devoted to derive various thermodynamic functions (such as entropy, internal energy, specific heat) for the low temperature as well as high temperature regime for the Ohmic heat bath. On the other hand, we derive QTF for the single relaxation time and blackbody radiation heat bath in section IV. Zero temperature results are shown in section V. We conclude in section VI.

2. Model & Free energy

The starting point of this section is the generalized Caldeira-Legget system-plusreservoir Hamiltonian for a charged particle of mass 'm' and charge 'e' in a magnetic field \vec{B} in the operator form [\[8,](#page-21-0) [9\]](#page-21-1) :

$$
\hat{H} = \frac{\left(\hat{p} - e\vec{A}/c\right)^2}{2m} + V(\hat{r}) + \sum_{j=1}^{N} \left[\frac{\hat{p}_j^2}{2m_j} + \frac{1}{2}m_j\omega_j^2 \left(q_j - \frac{c_j}{m_j\omega_j}\hat{r}\right)^2\right],\tag{1}
$$

where $\{\hat{r}, \hat{p}\}$ and $\{\hat{q}_j, \hat{p}_j\}$ are the sets of co-ordinate and momentum operators of system and bath oscillators. They follow the following commutation relations

$$
[\hat{r}_{\alpha}, \hat{p}_{\beta}] = i\hbar \delta_{\alpha\beta}, [\hat{q}_{i\alpha}, \hat{p}_{j\beta}] = i\hbar \delta_{ij} \delta_{\alpha\beta},\tag{2}
$$

where Greek indices α , β stand for three spatial directions. Eliminating the bath degrees of freedom by the Heisenberg equations of motion one can obtain the generalized quantum Langevin equation (GQLE) [\[34,](#page-22-1) [36\]](#page-22-3):

$$
m\ddot{\hat{r}} + \int_{-\infty}^{t} dt' \gamma(t - t') \dot{\hat{r}}(t') - \frac{e}{c} \dot{\hat{r}} \times \vec{B} + \vec{\nabla} V(\hat{r}) = \hat{\theta}(t),
$$
\n(3)

where dot denotes differentiation with respect to time t . The effect of the magnetic field is solely represented by the quantum version of the Lorentz force (third term in Eq. (3)). The memory kernel $\gamma(t)$ and the operator valued random force $\theta(t)$ are unaffected

by the magnetic field. In this work, we consider the confining potential to be harmonic for which an exact analysis is possible. It is now possible to represent nonequal time anticommutator and commutator of $\hat{\theta}(t)$ as follows:

$$
\langle \{\hat{\theta}_{\alpha}(t), \hat{\theta}_{\beta}(t')\}\rangle = \delta_{\alpha\beta} \frac{\beta \hbar}{\pi} \int_0^{\infty} d\omega J(\omega) \coth\left(\frac{\beta \hbar \omega}{2}\right) \cos[\omega(t - t')],\tag{4}
$$

$$
\langle [\hat{\theta}_{\alpha}(t), \hat{\theta}_{\beta}(t')] \rangle = \delta_{\alpha\beta} \frac{\beta \hbar}{\pi} \int_0^{\infty} d\omega J(\omega) \sin \omega (t - t'), \qquad (5)
$$

where $\beta = \frac{1}{k_B}$ $\frac{1}{k_BT}$ is the inverse temperature. The memory kernel is given by

$$
\gamma(t) = \frac{2}{m\pi} \int_0^\infty d\omega \frac{J(\omega)}{\omega} \cos(\omega t). \tag{6}
$$

In equations (4)-(6), $J(\omega)$ denotes the spectral density function of the heat bath oscillators and is given by :

$$
J(\omega) = \pi \sum_{j=1}^{N} \frac{c_j^2}{2m_j \omega_j} \delta(\omega - \omega_j)
$$
\n(7)

We are interested in investigating thermodynamic behaviour of a dissipative charged magneto-oscillator at an arbitrary temperature. One can easily determine the free energy for this model system by using the remarkable formula [\[35\]](#page-22-2)

$$
F = \frac{1}{\pi} \int_0^\infty d\omega f(\omega, T) \Im \left[\frac{d}{d\omega} \ln \left(\det \alpha(\omega + i0^+) \right) \right],\tag{8}
$$

where $f(\omega, T)$ is the free energy of a single oscillator of frequency ω and is given by

$$
f(\omega, T) = k_B T \log \left[1 - \exp(-\frac{\hbar \omega}{k_B T}) \right],\tag{9}
$$

where we have ignored the zero-point contribution which is discussed in section V. Here $\alpha(\omega)$ denotes the generalized susceptibility of the model system. Since all the results presented in this paper rely on this remarkable formula, it is the cornerstone of the paper. So, we are giving a sketch of the way of deriving this notable formula. It is known that the free enrgy ascribed to the magneto-oscillator, $F(T,B)$, is the free energy of the magneto-oscillator coupled to the heat bath minus the free energy of the bath in the absence of the magneto-oscillator. To derive this free energy one can follow the following method. Using Fourier transform one can rewrite equation (3) as follows :

$$
\tilde{r}(\omega) = \alpha(\omega)\tilde{\theta}(\omega),\tag{10}
$$

where, $\tilde{r}(\omega)$ and $\tilde{\theta}(\omega)$ are the Fourier transform of the operators $\hat{r}(t)$ and $\tilde{\theta}(t)$ respectively. Now, it can be easily shown that $\alpha(\omega)$ have poles on the real axis at the normal mode frequencies, $\tilde{\omega}_j$, of the interacting system and zeroes at the bath frequencies, ω_i , in the absence of the charged magneto oscillator. Therefore, one can write

$$
\alpha(\omega) = -\frac{1}{m} \frac{\prod_i (\omega^2 - \omega_i^2)}{\prod_j (\omega^2 - \tilde{\omega}_j^2)},\tag{11}
$$

where the numerator is the product over normal modes of the free bath oscillators and the denominator is the product over those of the interacting system. From the well known formula $\frac{1}{(x+i0^+)} = P(1/x) - i\pi\delta(x)$, one can show that :

$$
\frac{1}{\pi} \Im[\frac{d}{d\omega} \ln \alpha(\omega)] = \sum_{j} [\delta(\omega - \tilde{\omega}_{j}) + \delta(\omega + \tilde{\omega}_{j})] - \sum_{i} [\delta(\omega - \omega_{i}) + \delta(\omega + \omega_{i})]. \tag{12}
$$

When this is put into equation (8), it results :

$$
F(T, B) = \sum_{j} f(\tilde{\omega}_j, T) - \sum_{i} f(\omega_i, T), \qquad (13)
$$

where, the first sum is clearly the free energy of the interacting system and second that of the free bath field. This demonstrates our assertion. Now, we can rewrite Eq. (8) as follows $|11, 12|$:

$$
F(T, B) = F(T, 0) + \Delta F(T, B),\tag{14}
$$

where

$$
F(T,0) = \frac{3}{\pi} \int_0^\infty d\omega f(\omega,T) I_1
$$
\n(15)

is the free energy of the oscillator in the absence of the magnetic field, I_1 = $\Im\left[\frac{d}{d\omega}\ln\alpha^{(0)}(\omega)\right], \alpha^{(0)}(\omega)$ is the scalar susceptibility in the absence of a magnetic field and the correction due to the magnetic field is given by

$$
\Delta F(T, B) = -\frac{1}{\pi} \int_0^\infty d\omega f(\omega, T) I_2,\tag{16}
$$

where $I_2 = \Im\left\{\frac{d}{d\omega}\ln\left[1-\left(\frac{eB\omega\alpha^{(0)}}{c}\right)\right]\right\}$ $\left[\frac{\partial a^{(0)}}{c}\right)^2$. The scalar susceptibility for a harmonic oscillator in the absence of a magnetic field is given by [\[11,](#page-21-3) [12\]](#page-21-4):

$$
\alpha^{(0)}(\omega) = \frac{1}{m(\omega_0^2 - \omega^2) - i\omega\tilde{\gamma}(\omega)},\tag{17}
$$

where

$$
\tilde{\gamma}(\omega) = \int_0^t dt' \gamma(t') e^{i\omega t'}.
$$
\n(18)

We have now all the essential ingredients to calculate thermodynamic functions. Our main task is to find free energy F . Then, one can easily derive other thermodynamic functions at an arbitrary temperature. Entropy is defined as

$$
S(T, B) = -\frac{\partial F(T, B)}{\partial T}.
$$
\n(19)

Internal energy is given by

$$
U(T, B) = F(T, B) + TS(T, B),\tag{20}
$$

and specific heat is defined as

$$
C(T, B) = T \frac{\partial S(T, B)}{\partial T}.
$$
\n(21)

Now, we can proceed for the three popular heat-bath models of our interest which are characterized by the following spectral density functions (a) Ohmic heat bath :

Figure 1. (color online) Plot of $\frac{F}{E_0}$ versus dimensionless temperature, $\frac{2\pi k_BT}{h\omega_0}$, for the charged magneto-oscillator (red filled circle) and for the free charged oscillator (blue filled square) coupled to a Ohmic or SRT heat bath (a) in the low temperature regime and (b) in the high temperature regime. To plot this figure, we use $\frac{\gamma}{\omega_0} = 0.8$, $\frac{\gamma}{\omega_c} = 1.6$, and $\frac{\omega_0}{\omega_c} = 2.0$.

 $\tilde{\gamma}(\omega) = \gamma_0$, (b) single relaxation time : $\tilde{\gamma}(\omega) = \frac{\gamma_0}{1 - i\omega\tau}$, and (c) blackbody radiation : $\tilde{\gamma}(\omega) = \frac{2e^2\omega\Omega^2}{3c^3(\omega+i\Omega)}$ $\frac{2e^2\omega\Omega^2}{3c^3(\omega+i\Omega)}$, where γ_0 is the Ohmic friction constant, while τ is the relaxation time. Usually τ is small i.e. $\tau << \frac{\gamma_0}{m}$. Ω is the high frequency cut-off characterizing electron form factor for blackbody radiation model. One can easily express $\alpha^{(0)}(\omega)$ for all the three cases by a single expression [\[38\]](#page-22-5) :

$$
\alpha^{(0)}(\omega) = \frac{\omega + i\Omega}{m(\omega + i\Omega')(\omega_0^2 - \omega^2 - i\gamma\omega)}.\tag{22}
$$

Following Ford and O'Connell, one can write $\tau = \frac{1}{\Omega} = \frac{1}{\Omega'+\gamma}$; $\frac{\gamma_0}{m} = \gamma \frac{\Omega'^2 + \gamma \Omega' + \omega_0^2}{(\Omega'+\gamma)^2}$; $\frac{K}{m} = \omega_0^2 \frac{\Omega'}{\Omega' +}$ $\frac{\Omega'}{\Omega'+\gamma}$ for the single relaxation time model [\[38\]](#page-22-5). The Ohmic model can be represented by $\tau \to 0$, $\frac{\gamma_0}{m} \to \gamma$ and $\frac{K}{m} \to \omega_0^2$. On the other hand, for the blackbody radiation heat bath or QED model, $\frac{1}{\Omega} = \frac{1}{\Omega'} + \frac{\gamma}{\omega_c'}$ $\frac{\gamma}{\omega_0^2}$; $\frac{K}{M} = \omega_0^2 \frac{\Omega'}{\Omega' + \Omega}$ $\frac{\Omega'}{\Omega'+\gamma}; \frac{M}{m} = \frac{(\omega_0^2 + \gamma \Omega')(\Omega' + \gamma)}{\omega_0^2 \Omega'}$ $\frac{\omega_0^{2\Omega'}(\Omega'+\gamma)}{\omega_0^{2\Omega'}}$, where m is the bare mass and $M = m + \frac{2e^2\Omega}{3c^3}$ $\frac{3e^{2}\Omega}{3c^{3}}$ is the renormalized mass. In the largest value of cut-off limit $(\Omega' \to \infty)$, $m = 0$, $K = M\omega_0^2$ and $\Omega = \frac{1}{\tau_e}$, where $\tau_e = \frac{2e^2}{3Mc^3} = 6 \times 10^{-24} s$. With the general form of $\alpha^{(0)}(\omega)$ (Eq. 22) one can write free energy as follows

$$
F(T, B) = \frac{3k_B T}{\pi} \int_0^{\infty} d\omega \ln \left(1 - e^{-\frac{\hbar \omega}{k_B T}} \right) \left(-\frac{\Omega}{\omega^2 + \Omega^2} + \frac{\Omega'}{\omega^2 + \Omega'^2} \right) + \frac{k_B T}{\pi} \int_0^{\infty} d\omega \ln \left(1 - e^{-\frac{\hbar \omega}{k_B T}} \right) \left(\frac{\omega_1}{\omega^2 + \omega_1^2} + \frac{\omega_1^*}{\omega^2 + \omega_1^*^2} + \frac{\Omega_1}{\omega^2 + \Omega_1^2} + \frac{\Omega_2^*}{\omega^2 + \Omega_2^2} + \frac{\Omega_2^*}{\omega^2 + \Omega_2^2} + \frac{\Omega_2^*}{\omega^2 + \Omega_2^2} \right),
$$
(23)

where $\omega_1 = \frac{\gamma}{2} + i\sqrt{\omega_0^2 - \frac{\gamma^2}{4}}$ $\frac{\sqrt{2}}{4}$, $\Omega_1 = \left[\frac{\gamma}{2} + \left(\frac{b-a}{2}\right)\right]$ $\left[\frac{-a}{2}\right)^{\frac{1}{2}}\right]-i\left[\frac{\omega_c}{2}+\left(\frac{b+a}{2}\right)$ $\left[\frac{+a}{2}\right)^{\frac{1}{2}}\right],\,\Omega_2=\left[\frac{\gamma}{2}-\left(\frac{b-a}{2}\right)$ $\left[\frac{-a}{2}\right)^{\frac{1}{2}}\right]$ $i\left[\frac{\omega_c}{2}-\left(\frac{b+a}{2}\right.\right.$ $\left(\frac{a}{2}\right)^{\frac{1}{2}}\Big], a = \left(\frac{\omega_c}{2}\right)$ $\left(\omega_0^2-\frac{\gamma^2}{4}\right)$ $\left(\frac{\gamma^2}{4} \right)$; and $b = \left[a^2 + \left(\frac{\gamma \omega_c}{2} \right) \right]$ $\left[\frac{\omega_c}{2}\right)^2$ $\frac{1}{2}$ ω_1^* ^{*}, Ω_1^* , and Ω_2^* are

Figure 2. (color online) Plot of $\frac{U}{E_0}$ versus dimensionless temperature, $\frac{2\pi k_BT}{h\omega_0}$, for the charged magneto-oscillator (red filled circle) and for the free charged oscillator (blue filled square) coupled to a Ohmic or SRT heat bath (a) in the low temperature regime and (b) in the high temperature regime. To plot this figure, we use $\frac{\gamma}{\omega_0} = 0.8$, $\frac{\gamma}{\omega_c} = 1.6$, and $\frac{\omega_0}{\omega_c} = 2.0$.

Figure 3. (color online) Plot of $\frac{S}{k_B}$ versus dimensionless temperature, $\frac{2\pi k_B T}{h\omega_0}$, for the charged magneto-oscillator (red filled circle) and for the free charged oscillator (blue filled square) coupled to a Ohmic or SRT heat bath (a) in the low temperature regime and (b) in the high temperature regime. To plot this figure, we use $\frac{\gamma}{\omega_0} = 0.8$, $\frac{\gamma}{\omega_c} = 1.6$, and $\frac{\omega_0}{\omega_c} = 2.0$.

complex conjugate of ω_1 , Ω_1 and Ω_2 respectively and $\omega_c = eB/mc$ is the cyclotron frequency. One can rewrite Eq. (23) in terms of Stieltjes function $(J(z))$ as follows :

$$
F(T,B) = 3k_B T \Big[J\Big(\frac{\hbar\Omega}{2\pi k_B T}\Big) - J\Big(\frac{\hbar\Omega'}{2\pi k_B T}\Big) \Big] - k_B T \Big[J\Big(\frac{\hbar\omega_1}{2\pi k_B T}\Big) + J\Big(\frac{\hbar\omega_1^*}{2\pi k_B T}\Big) + J\Big(\frac{\hbar\Omega_1}{2\pi k_B T}\Big) + J\Big(\frac{\hbar\Omega_2^*}{2\pi k_B T}\Big) + J\Big(\frac{\hbar\Omega_2^*}{2\pi k_B T}\Big) + J\Big(\frac{\hbar\Omega_2^*}{2\pi k_B T}\Big) \Big], \quad (24)
$$

Figure 4. (color online) Plot of $\frac{C}{k_B}$ versus dimensionless temperature, $\frac{2\pi k_B T}{h\omega_0}$, for the charged magneto-oscillator (red filled circle) and for the free charged oscillator (blue filled square) coupled to a Ohmic or SRT heat bath (a) in the low temperature regime and (b) in the high temperature regime. To plot this figure, we use $\frac{\gamma}{\omega_0} = 0.8$, $\frac{\gamma}{\omega_c} = 1.6$, and $\frac{\omega_0}{\omega_c} = 2.0$.

Figure 5. (color online) Plot of (a) $\frac{F}{E_0}$, (b) $\frac{U}{E_0}$, (c) $\frac{S}{k_B}$, and (d) $\frac{C}{k_B}$, versus dimensionless temperature, $\frac{2\pi k_BT}{\hbar\omega_0}$, for the charged magneto-oscillator coupled to a Ohmic heat bath in the low temperature regime for different values of dissipation parameter, γ , blue filled square ($\gamma/\omega_0 = 0.25$), red filled circle ($\gamma/\omega_0 = 0.5$), pink upward triangle ($\gamma/\omega_0 = 0.75$) and black dowanward triangle ($\gamma/\omega_0 = 1.0$). To plot this figure, we also use $\frac{\omega_0}{\omega_c} = 2.0$.

where Stieltjes J function is given by [\[39\]](#page-22-6)

$$
J(z) = -\frac{1}{\pi} \int_0^\infty dt \ln\left(1 - e^{-2\pi t}\right) \frac{z}{t^2 + z^2}.
$$
 (25)

Figure 6. (color online) Plot of (a) $\frac{F}{E_0}$, (b) $\frac{U}{E_0}$, (c) $\frac{S}{k_B}$, and (d) $\frac{C}{k_B}$, versus dimensionless temperature, $\frac{2\pi k_BT}{h\omega_0}$, for the charged magneto-oscillator coupled to a radiation heat bath in the low temperature regime for different values of dissipation parameter, γ , blue filled square ($\gamma/\omega_0 = 0.25$), red filled circle ($\gamma/\omega_0 = 0.5$), pink upward triangle $(\gamma/\omega_0 = 0.75)$ and black dowanward triangle $(\gamma/\omega_0 = 1.0)$. To plot this figure, we also use $\frac{\omega_0}{\omega_c} = 2.0$.

Now, we have all the ingredients to calculate the thermodynamic functions for the charged magneto-oscillator in contact with a heat bath. In the next section, we discuss about the Ohmic heat bath model.

3. Ohmic Model

In this section, we discuss the QTF of the charged magneto-oscillator in contact with a Ohmic heat bath in the low temperature as well as high temperature regime. For the Ohmic model, $\Omega \to \infty$, $\tau \to 0$, $\frac{\tau_0}{m} \to \gamma$, $\frac{K}{m} \to \omega_0^2$ and hence

$$
F(T,B) = -k_B T \Big[J\Big(\frac{\hbar\omega_1}{2\pi k_B T}\Big) + J\Big(\frac{\hbar\omega_1^*}{2\pi k_B T}\Big) + J\Big(\frac{\hbar\Omega_1}{2\pi k_B T}\Big) + J\Big(\frac{\hbar\Omega_1^*}{2\pi k_B T}\Big) + J\Big(\frac{\hbar\Omega_2}{2\pi k_B T}\Big) + J\Big(\frac{\hbar\Omega_2^*}{2\pi k_B T}\Big)\Big].
$$
 (26)

3.1. Low-temperature expansion $(k_BT << \hbar\omega_0)$

In the low-temperature case, we use the asymptotic expansion for $J(z)$:

$$
J(z) = \sum_{n=0}^{\infty} \frac{D_{2n+2}}{(2n+1)(2n+2)} \frac{1}{z^{2n+1}},
$$
\n(27)

Figure 7. (color online) Plot of (a) $\frac{F}{E_0}$, (b) $\frac{U}{E_0}$, (c) $\frac{S}{k_B}$, and (d) $\frac{C}{k_B}$, versus dimensionless temperature, $\frac{2\pi k_BT}{\hbar\omega_0}$, for the charged magneto-oscillator coupled to a Ohmic heat bath in the high temperature regime for different values of dissipation parameter, γ , red filled circle ($\gamma/\omega_0 = 0.25$), blue filled square ($\gamma/\omega_0 = 0.5$), pink upward triangle $(\gamma/\omega_0 = 0.75)$ and black dowanward triangle $(\gamma/\omega_0 = 1.0)$. To plot this figure, we also use $\frac{\omega_0}{\omega_c} = 2.0$

expansion, the free energy becomes :

$$
F(T,B) = -\left[\frac{\pi (k_B T)^2 \gamma}{2\hbar \omega_0^2} + \frac{\pi^3 (k_B T)^4}{45\hbar^3 \omega_0^6} (A_1 + A_2 + A_3) + \frac{8\pi^5 (k_B T)^6 (B_1 + B_2 + B_3)}{315\hbar^5 \omega_0^{10}} + ..\right],
$$
\n(28)

where $A_1 = \gamma(3\omega_0^2 - \gamma^2), A_2 = (3\Gamma_1^2\lambda_1 - \Lambda_1^3), A_3 = (3\Gamma_2^2\lambda_2 - \Lambda_2^3), B_1 = \gamma(5\omega_0^4 - 5\gamma^2\omega_0^2 + \gamma^4),$ $B_2 = (\lambda_1^5 - 10\lambda_1^3\Gamma_1^2 + 5\lambda_1\Gamma_1^4), B_3 = (\lambda_2^5 - 10\lambda_2^3\Gamma_2^2 + 5\lambda_2\Gamma_2^4), \Gamma_{1,2} = \frac{\omega_c}{2} \pm \sqrt{\frac{b+a}{2}}$ $\frac{+a}{2}$; $\lambda_{1,2}=\frac{\gamma}{2}\pm\sqrt{\frac{b+a}{2}}$ $\frac{1}{2}a$; and $\Lambda_{1,2} = \gamma \pm \sqrt{2(b-a)}$. Entropy can be written as

$$
S(T,B) = k_B \left[\frac{\pi k_B T \gamma}{\hbar \omega_0^2} + \frac{4\pi^3 (k_B T)^3}{45 \hbar^3 \omega_0^6} (A_1 + A_2 + A_3) + \frac{16\pi^5 (k_B T)^5 (B_1 + B_2 + B_3)}{105 \hbar^5 \omega_0^{10}} + \ldots \right].
$$
\n(29)

Internal energy can be written as follows :

$$
U(T,B) = \frac{\pi (k_B T)^2 \gamma}{2\hbar \omega_0^2} + \frac{\pi^3 (k_B T)^4 (A_1 + A_2 + A_3)}{45\hbar^3 \omega_0^6} + \frac{40\pi^5 (k_B T)^5 (B_1 + B_2 + B_3)}{315\hbar^5 \omega_0^{10}} + \dots
$$
\n(30)

Figure 8. (color online) Plot of (a) $\frac{F}{E_0}$, (b) $\frac{U}{E_0}$, (c) $\frac{S}{k_B}$, and (d) $\frac{C}{k_B}$, versus dimensionless temperature, $\frac{2\pi k_BT}{h\omega_0}$, for the charged magneto-oscillator coupled to a radiation heat bath in the high temperature regime for different values of dissipation parameter, γ , red filled circle ($\gamma/\omega_0 = 0.25$), blue filled square ($\gamma/\omega_0 = 0.5$), pink upward triangle $(\gamma/\omega_0 = 0.75)$ and black dowanward triangle $(\gamma/\omega_0 = 1.0)$. To plot this figure, we also use $\frac{\omega_0}{\omega_c} = 2.0$

Finally, specific heat of the system is given by

$$
C(T,B) = k_B \left[\frac{\pi k_B T \gamma}{\hbar \omega_0^2} + \frac{4\pi^3 (k_B T)^3}{15 \hbar^3 \omega_0^6} (A_1 + A_2 + A_3) + \frac{16\pi^5 (k_B T)^5 (B_1 + B_2 + B_3)}{21 \hbar^5 \omega_0^{10}} + \ldots \right]
$$
\n(31)

3.2. High-temperature expansion $(k_BT >> \hbar\omega_0)$

In the high temperature regime, we use the small arguement expansion for $J(z)$:

$$
J(z) = -\frac{1}{2}\ln(2\pi) - (z + \frac{1}{2})\ln z + (1 - \gamma_E)z + \sum_{n=2}^{\infty} \frac{(-1)^n \zeta(n)}{n} z^n, \qquad (32)
$$

where $\gamma_E = 0.577215$ is Euler's constant and $\zeta(n)$ is the Riemann Zeta function. Using Eq. (32), one can write down the free energy of the system in the high temperature regime as follows:

$$
F(T,B) = -3k_B T \ln\left(\frac{k_B T}{\hbar \omega_0}\right) - \frac{3\hbar \gamma}{2\pi} \ln\left(\frac{2\pi k_B T}{\hbar \omega_0}\right) - \frac{\hbar \omega_1'}{\pi} \phi - \frac{3\hbar \gamma (1 - \gamma_E)}{2\pi}
$$

$$
-\frac{2\hbar \omega_c}{\pi} \theta - 2k_B T \Big[\sum_{n=2}^{\infty} (-1)^n \frac{\zeta(n)}{n} \Big(\frac{\hbar \omega_0}{2\pi k_B T} \Big)^n \Big(\tan(n\phi) + 2\tan(n\theta) \Big) \Big],\tag{33}
$$

Figure 9. (color online) Plot of (a) $\frac{F}{E_0}$, (b) $\frac{U}{E_0}$, (c) $\frac{S}{k_B}$, and (d) $\frac{C}{k_B}$, versus dimensionless temperature, $\frac{2\pi k_BT}{\hbar\omega_0}$, for the charged magneto-oscillator coupled to a Ohmic heat bath in the low temperature regime for different values of cyclotron frequency, ω_c , red filled circle ($\omega_c/\omega_0 = 0.25$), blue filled square ($\omega_c/\omega_0 = 0.5$), pink upward triangle $(\omega_c/\omega_0 = 0.75)$ and black dowanward triangle $(\omega_c/\omega_0 = 1.0)$. To plot this figure, we also use $\frac{\gamma}{\omega_0} = 0.8$.

where $\theta = \tan^{-1} P$, $P =$ $\sqrt{2(b+a)}$ $\frac{(\overline{b} + \overline{a})}{\gamma}$, $\phi = \tan^{-1}(\frac{2\omega'_1}{\gamma})$, and $\omega'_1 = \sqrt{\omega_0^2 - \frac{\gamma^2}{4}}$ $rac{\gamma^2}{4}$. The entropy is given by

$$
S(T,B) = 3k_B \left(\ln \frac{k_B T}{\hbar \omega_0} + 1\right) - 4k_B \sum_{n=2}^{\infty} (-1)^n \frac{(n-1)\zeta(n)}{n} \left(\frac{\hbar \omega_0}{2\pi k_B T}\right)^n \tan(n\theta)
$$

$$
+ \frac{3\hbar \gamma}{2\pi T} - 2k_B \sum_{n=2}^{\infty} (-1)^n \frac{(n-1)\zeta(n)}{n} \left(\frac{\hbar \omega_0}{2\pi k_B T}\right)^n \tan(n\phi).
$$
(34)

On the other hand, internal energy is given by

$$
U(T, B) = 3k_B T - \frac{3\hbar\gamma}{2\pi} \ln\left(\frac{2\pi k_B T}{\hbar\omega_0}\right) - \frac{\hbar\omega_1'}{\pi}\phi + \frac{3\hbar\gamma\gamma_E}{2\pi} - \frac{2\hbar\omega_c}{\pi}\theta
$$

$$
-4k_B T \sum_{n=2}^{\infty} (-1)^n \frac{(n-1)\zeta(n)}{n} \left(\frac{\hbar\omega_0}{2\pi k_B T}\right)^n \tan(n\phi)
$$

$$
-8k_B T \sum_{n=2}^{\infty} (-1)^n \frac{\zeta(n)}{n} \left(\frac{\hbar\omega_0}{2\pi k_B T}\right)^n \tan(n\theta).
$$
(35)

Finally, specific heat is given by

$$
C(T, B) = 3k_B - \frac{3\hbar\gamma}{2\pi T} + 4k_B \sum_{n=2}^{\infty} (-1)^n (n-1)\zeta(n) \left(\frac{\hbar\omega_0}{2\pi k_B T}\right)^n \tan(n\theta) + 2k_B \sum_{n=2}^{\infty} (-1)^n (n-1)\zeta(n) \left(\frac{\hbar\omega_0}{2\pi k_B T}\right)^n \tan(n\phi).
$$
 (36)

Figure 10. (color online) Plot of (a) $\frac{F}{E_0}$, (b) $\frac{U}{E_0}$, (c) $\frac{S}{k_B}$, and (d) $\frac{C}{k_B}$, versus dimensionless temperature, $\frac{2\pi k_BT}{h\omega_0}$, for the charged magneto-oscillator coupled to a radiation heat bath in the low temperature regime for different values of cyclotron frequency, ω_c , red filled circle ($\omega_c/\omega_0 = 0.25$), blue filled square ($\omega_c/\omega_0 = 0.5$), pink upward triangle ($\omega_c/\omega_0 = 0.75$) and black dowanward triangle ($\omega_c/\omega_0 = 1.0$). To plot this figure, we also use $\frac{\gamma}{\omega_0} = 0.8$.

4. Single relaxation time and QED model

Free energy for the single relaxation time and QED model is given by

$$
F(T,B) = F_{ohmic}(T,B) + 3k_B T \Big[J\Big(\frac{\hbar\Omega}{2\pi k_B T}\Big) - J\Big(\frac{\hbar\Omega'}{2\pi k_B T}\Big) \Big].
$$
 (37)

As Ω and Ω' are always large compared with k_BT , so retaining only the first term of the low temperature expansion of $J(z)$; one can write

$$
F(T,B) = F_{ohmic}(T,B) + \frac{\pi (k_B T)^2}{2\hbar} \Big(\frac{1}{\Omega} - \frac{1}{\Omega'}\Big). \tag{38}
$$

For single relaxation time model, $\frac{1}{\Omega} = \frac{1}{\Omega'+\gamma}$ and $\Omega' >> \gamma$. Hence, the second term in Eq. (38) is negligibly small and

$$
F_{SRT}(T, B) \simeq F_{Ohmic}(T, B),\tag{39}
$$

where subscript SRT stands for single relaxation time. On the other hand, for QED, $\frac{1}{\Omega}-\frac{1}{\Omega'}=\frac{\gamma}{\omega_0^2}$ $\frac{\gamma}{\omega_0^2}$. Thus,

$$
F_{QED}(T,B) = F_{Ohmic}(T,B) + \frac{\pi (k_B T)^2 \gamma}{2\hbar \omega_0^2}.
$$
\n
$$
(40)
$$

Figure 11. (color online) Plot of (a) $\frac{F}{E_0}$, (b) $\frac{U}{E_0}$, (c) $\frac{S}{k_B}$, and (d) $\frac{C}{k_B}$, versus dimensionless temperature, $\frac{2\pi k_BT}{h\omega_0}$, for the charged magneto-oscillator coupled to a Ohmic heat bath in the high temperature regime for different values of cyclotron frequency, ω_c , red filled circle ($\omega_c/\omega_0 = 0.25$), blue filled square ($\omega_c/\omega_0 = 0.5$), pink upward triangle ($\omega_c/\omega_0 = 0.75$) and black dowanward triangle ($\omega_c/\omega_0 = 1.0$). To plot this figure, we also use $\frac{\gamma}{\omega_0} = 0.8$.

4.1. *QED* : Low temperature expansion $(k_BT << \hbar\omega_0)$

Using the low temperature expansion of $J(z)$, one can obtain

$$
F_{QED}(T, B) = -\left[\frac{\pi^3 (k_B T)^4 (A_1 + A_2 + A_3)}{45 \hbar^3 \omega_0^6} + \frac{8 \pi^5 (k_B T)^6 (B_1 + B_2 + B_3)}{315 \hbar^5 \omega_0^{10}} + \dots\right].
$$
\n(41)

The leading term in the expansion of $F_{Ohmic}(T, B)$ exactly cancels the second term in Eq. (40) and hence, the leading term is the $O(T⁴)$. Entropy of the system is given by

$$
S_{QED}(T,B) = k_B \left[\frac{4\pi^3 (k_B T)^3 (A_1 + A_2 + A_3)}{45\hbar^3 \omega_0^6} + \frac{16\pi^5 (k_B T)^5 (B_1 + B_2 + B_3)}{105\hbar^5 \omega_0^{10}} + \ldots \right]
$$
(42)

Internal energy is given by

$$
U_{QED}(T,B) = \frac{\pi^3 (k_B T)^4 (A_1 + A_2 + A_3)}{15 \hbar^3 \omega_0^6} + \frac{8 \pi^5 (k_B T)^6 (B_1 + B_2 + B_3)}{63 \hbar^5 \omega_0^{10}} + \dots
$$
 (43)

Finally, specific heat of the system is given by

Figure 12. (color online) Plot of (a) $\frac{F}{E_0}$, (b) $\frac{U}{E_0}$, (c) $\frac{S}{k_B}$, and (d) $\frac{C}{k_B}$, versus dimensionless temperature, $\frac{2\pi k_BT}{h\omega_0}$, for the charged magneto-oscillator coupled to a radiation heat bath in the high temperature regime for different values of cyclotron frequency, ω_c , red filled circle ($\omega_c/\omega_0 = 0.25$), blue filled square ($\omega_c/\omega_0 = 0.5$), pink upward triangle ($\omega_c/\omega_0 = 0.75$) and black dowanward triangle ($\omega_c/\omega_0 = 1.0$). To plot this figure, we also use $\frac{\gamma}{\omega_0} = 0.8$.

Figure 13. (color online) Plot of $\frac{F}{E_0}$ versus dimensionless temperature, $\frac{2\pi k_BT}{h\omega_0}$, for the charged magneto-oscillator (red filled circle) and for the free charged oscillator (blue filled square) coupled to a blackbody radiation heat bath (a) in the low temperature regime and (b) in the high temperature regime. To plot this figure, we use $\frac{\gamma}{\omega_0} = 0.8$, $\frac{\gamma}{\omega_c} = 1.6$, and $\frac{\omega_0}{\omega_c} = 2.0$.

$$
C_{QED}(T, B) = k_B \left[\frac{4\pi^3 (k_B T)^3 (A_1 + A_2 + A_3)}{15\hbar^3 \omega_0^6} + \frac{16\pi^5 (k_B T)^5 (B_1 + B_2 + B_3)}{21\hbar^5 \omega_0^{10}} + \dots \right].
$$
\n(44)

Figure 14. (color online) Plot of $\frac{U}{E_0}$ versus dimensionless temperature, $\frac{2\pi k_BT}{h\omega_0}$, for the charged magneto-oscillator (red filled circle) and for the free charged oscillator (blue filled square) coupled to a blackbody radiation heat bath (a) in the low temperature regime and (b) in the high temperature regime. To plot this figure, we use $\frac{\gamma}{\omega_0} = 0.8$, $\frac{\gamma}{\omega_c} = 1.6$, and $\frac{\omega_0}{\omega_c} = 2.0$.

Figure 15. (color online) Plot of $\frac{S}{k_B}$ versus dimensionless temperature, $\frac{2\pi k_B T}{h\omega_0}$, for the charged magneto-oscillator (red filled circle) and for the free charged oscillator (blue filled square) coupled to a blackbody radiation heat bath (a) in the low temperature regime and (b) in the high temperature regime. To plot this figure, we use $\frac{\gamma}{\omega_0} = 0.8$, $\frac{\gamma}{\omega_c} = 1.6$, and $\frac{\omega_0}{\omega_c} = 2.0$.

4.2. *QED* : High temperature expansion $(k_BT >> \hbar\omega_0)$

In this subsection, the high temperature thermodynamic propertis for the QED model are discussed in details. One can show that free energy for this model is

$$
F_{QED}(T,B) = F_{Ohmic}^{HT} + \frac{\pi (k_B T)^2 \gamma}{2\hbar \omega_0^2},\tag{45}
$$

where F_{Ohmic}^{HT} is the high temperature free energy for the Ohmic model (Eq. 33). Entropy

Figure 16. (color online)Plot of $\frac{C}{k_B}$ versus dimensionless temperature, $\frac{2\pi k_B T}{h\omega_0}$, for the charged magneto-oscillator (red filled circle) and for the free charged oscillator (blue filled square) coupled to a blackbody radiation heat bath (a) in the low temperature regime and (b) in the high temperature regime. To plot this figure, we use $\frac{\gamma}{\omega_0} = 0.8$, $\frac{\gamma}{\omega_c} = 1.6$, and $\frac{\omega_0}{\omega_c} = 2.0$.

in the high temperature regime is given by

$$
S_{QED}(T,B) = S_{Ohmic}^{HT}(T,B) - \frac{\pi (k_B^2 T)\gamma}{\hbar \omega_0^2},\tag{46}
$$

where, the high temperature specific heat for the Ohmic model $(S_{Ohmic}^{HT}(T, B))$ is given by equation (34). Internal energy of the system is given by

$$
U_{QED}(T,B) = U_{Ohmic}^{HT}(T,B) - \frac{\pi (k_B T)^2 \gamma}{2\hbar \omega_0^2},\tag{47}
$$

where $U_{Ohmic}^{HT}(T, B)$ is given by equation (35). Finally, specific heat of the system in the high temperature regime for the QED model is given by

$$
C_{QED}(T, B) = C_{Ohmic}^{HT}(T, B) - \frac{\pi k_B^2 T \gamma}{\hbar \omega_0^2},\tag{48}
$$

and $C_{Ohmic}^{HT}(T, B)$ is the specific heat for the Ohmic model in the high temperature regime (see equation 36).

To explicitly demonstrate the distinguishing behaviour of different thermodynamic functions for three different heat bath models, we plot different thermodynamic quantities as a function of dimensionless temperature $(\frac{2\pi k_BT}{\hbar\omega_0})$ in different figures for the low temperature regime as well as for the high temperature regime. The results for different values of dissipation, γ , as well as for different values of ω_c , are also analyzed here. We compare our results for various QTF of a charged magneto-oscillator with that of a free oscillator. From our analysis, one can conclude that the qualitative behaviour of different QTF for the charged magneto-oscillator in the high temperature regime is same as that of a free oscillator. Even, the quantitative values do not differ much from each other in the high temperature regime (see figures $1(b)-4(b)$) and figures $13(b)-16(b)$

Figure 17. (color online) Plot of (a) $\frac{F}{E_0}$, (b) $\frac{U}{E_0}$, (c) $\frac{S}{k_B}$, and (d) $\frac{C}{k_B}$, versus dimensionless temperature, $\frac{2\pi k_BT}{h\omega_0}$, for the charged magneto-oscillator coupled to a Ohmic heat bath for the entire temperature regime with different values of dissipation parameter, γ , red filled circle ($\gamma/\omega_0 = 0.4$), blue filled square ($\gamma/\omega_0 = 0.8$), pink upward triangle ($\gamma/\omega_0 = 1.2$). To plot this figure, we also use $\frac{\omega_c}{\omega_0} = 0.5$.

Figure 18. (color online) Plot of (a) $\frac{F}{E_0}$, (b) $\frac{U}{E_0}$, (c) $\frac{S}{k_B}$, and (d) $\frac{C}{k_B}$, versus dimensionless temperature, $\frac{2\pi k_BT}{h\omega_0}$, for the charged magneto-oscillator coupled to a Ohmic heat bath for the entire temperature regime with different values of cyclotron frequency, ω_c , red filled circle ($\omega_c/\omega_0 = 0.25$), blue filled square ($\omega_c/\omega_0 = 0.5$), pink upward triangle ($\omega_c/\omega_0 = 0.75$). To plot this figure, we also use $\frac{\gamma}{\omega_0} = 1.0$.

). In the low temperature regime, the free energy of the charged magneto-oscillator

decays faster than that of the free oscillator for the Ohmic heat bath as well as for the QED model. On the other hand, the other QTF like internal energy (U) , entropy (S) , and specific heat (C) for the magneto-oscillator rises faster than that of the free oscillator in the low temperature regime (see figures $1(a)-4(a)$ and figures $13(a)-16(a)$). It has been observed that ω_c and γ affect different QTF in the opposite manner. In the low temperature regime, U, S and C rise and F decays much faster for higher values of γ (see figure (5) and figure (6)) whereas they (U, S and C) rise or F decays much faster for lower values of ω_c (see figure (9) and figure (10)). In the high temperature regime, different QTF do not vary much for different values of ω_c (see figure (11) and figure (12)). But, the effect of different values of dissipation parameter, γ , is pronounced in the high temperature regime also. In this regime, U , S and C rise and F decays much faster for higher values of γ (see figure (7) and figure (8)).

We also plot general result for different quantum thermodynamic functions for the entire temperature regime by using equation (24) which is expressed in terms of Stieltjes J function (see figure (17) and figure (18)). For the numerical computation, we use the Lanczos formula for the Stieltjes J function $[?, 41]$ $[?, 41]$:

$$
J(z) = (z + \frac{1}{2}) \ln \frac{z + \gamma_1 + 1/2}{z} - \gamma_1 - 1/2 + \ln \left[d_0 + \sum_{n=1}^{N} \frac{d_n}{z + n} \right], \quad \Re z > 0, \text{(49)}
$$

where $N = 6$, $\gamma_1 = 5$, $d_0 = 1.00$, $d_1 = 76.18$, $d_2 = -86.51$, $d_3 = 24.01$, $d_4 = -1.23$, $d_5 = 0.001$, and $d_6 = 0.0$. It is seen that both at very high temperatures and at very low temperatures, the numerical results fairly match with the analytical expressions. Also, it is seen that the effect of dissipation parameter is pronounced in the entire temperature regime of our interest.

5. Zero point energy

For the sake of completeness, we are giving here zero point energy contribution of the charged magneto oscillator for the above mentioned three popular heat bath models. It is known that free energy $F = U + TS$. Hence, the zero-point free energy is identical with zero-point energy. The zero-point free energy is obtained by replacing $f(\omega,T) \to \frac{\hbar \omega}{2}$ in Eq. (11) and in Eq. (12). Thus,

$$
F(0, B) = \frac{\hbar}{2\pi} \Big[3\Big(\Omega \ln \Omega - \Omega' \ln \Omega'\Big) - \omega_1 \ln \omega_1 - \omega_1^* \ln \omega_1^* - \Omega_1 \ln \Omega_1 - \Omega_1^* \ln \Omega_1^* - \Omega_2 \ln \Omega_2 - \Omega_2^* \ln \Omega_2^* \Big].
$$
\n(50)

For single relaxation time model, the zero point free energy becomes

$$
F(0,B) = \frac{\hbar}{2\pi} \Big[3\Big((\Omega' + \gamma) \ln(\Omega' + \gamma) - \Omega' \ln \Omega' \Big) - \gamma \ln \omega_0 + 2\omega'_1 \tan^{-1} \Big(\frac{2\omega'_1}{\gamma} \Big) -\lambda_1 \ln(\lambda_1^2 + \Gamma_1^2) - \lambda_2 \ln(\lambda_2^2 + \Gamma_2^2) + 2\Gamma_1 \tan^{-1} \Big(\frac{\Gamma_1}{\lambda_1} \Big) + 2\Gamma_2 \tan^{-1} \Big(\frac{\Gamma_2}{\lambda_2} \Big) \Big],
$$
 (51)

Quantum thermodynamics of a charged magneto-oscillator coupled to a heat bath. 20

where $\lambda_{1,2} = \frac{\gamma}{2} \pm \left(\frac{b-a}{2}\right)$ $\left(\frac{-a}{2}\right)^{\frac{1}{2}}$, and $\Gamma_{1,2} = \frac{\omega_c}{2} \pm \left(\frac{b+a}{2}\right)$ $\left(\frac{1}{2}a\right)^{\frac{1}{2}}$. On the other hand, the zero point contribution in the free energy for the Ohmic model is given by

$$
F(0,B) = \frac{\hbar}{2\pi} \Big[3\gamma \Big(1 - \ln(\omega_0 \tau) \Big) + 2\gamma \ln \omega_0 - \lambda_1 \ln(\lambda_1^2 + \Gamma_1^2) - \lambda_2 \ln(\lambda_2^2 + \Gamma_2^2) + 2\omega_1' \tan^{-1} \Big(\frac{2\omega_1'}{\gamma} \Big) + 2\Gamma_1 \tan^{-1} \Big(\frac{\Gamma_1}{\lambda_1} \Big) + 2\Gamma_2 \tan^{-1} \Big(\frac{\Gamma_2}{\lambda_2} \Big) \Big].
$$
 (52)

Finally, the zero point free energy for the QED model is given by

$$
F(0,B) = \frac{\hbar}{2\pi} \Big[3 \Big\{ \Big(\frac{\Omega' \omega_0^2}{\omega_0^2 + \gamma \Omega'} \Big) \ln \Big(\frac{\Omega' \omega_0^2}{\omega_0^2 + \gamma \Omega'} \Big) - \Omega' \ln \Omega' \Big\}
$$

- $\lambda_1 \ln(\lambda_1^2 + \Gamma_1^2) - \lambda_2 \ln(\lambda_2^2 + \Gamma_2^2) + 2\omega'_1 \tan^{-1} \Big(\frac{2\omega'_1}{\gamma} \Big)$
+ $2\Gamma_1 \tan^{-1} \Big(\frac{\Gamma_1}{\lambda_1} \Big) + 2\Gamma_2 \tan^{-1} \Big(\frac{\Gamma_2}{\lambda_2} \Big) - \gamma \ln \omega_0 \Big].$ (53)

6. Conclusions

Recent observations have suggested that small quantum systems are particularly sensitive to environmental effects [\[14,](#page-21-6) [15\]](#page-21-7). Dissipation and fluctuation effects often play a crucial role on the behaviour of such small systems. The influence of an external magnetic field on such small systems like quantum dots, quantum wires, and two dimensional electronic systems are of great interest in the fields of nanostructures. This fact has led to motivate us to study the quantum thermodynamic behaviour of a charged magneto-oscillator in an arbitrary heat bath at arbitrary temperature. Results for both high temperature and low temperature are shown explicitly in this paper.

We use the "remarkable formula" of Ford et al [\[35\]](#page-22-2) for the free energy of the charged magneto-oscillator which involves single integral. This is an exact results for the free enrgy of a charged magneto-oscillator which takes into account interaction effects. Starting form this remarkable formula, we calculate several thermodynamic functions like free energy, entropy, internal energy, and specific heat for three different popular models like Ohmic, single relaxation time, and radiation heat bath or QED model. Explicit results are presented for the high temperature as well as for low temperatures. The central result of this analysis is that the qualitative behaviour as well as quantitative values of different thermodynamic quantities for the charged magneto oscillator differs from that of the free oscillator in the low temperature regime. The effect of ω_c and γ are also investigated. They affect the rising or decay behaviour of different QTF just in the opposite manner to each other in the low temperature regime. In the high temperature regime, the effect of ω_c is not so significant. On the other hand, the effect of different γ on the rising or decaying behaviour of different QTF is significant even in the high temperature regime. We have also shown the general results of various QTF by numerically evaluating equation (24). The numerical results obtained from the general expression fairly matches with the analytical expressions in the two limits of very high temperatures and very low temperatures. The experimentalist can make an estimation

of change in values of different QTF from our study.

The application of this kind of analysis is manifold. Recent nanofabrication allows to create very small systems of few atoms in which environmental effects play an important role. This analysis is helpful in understanding environmental effects on small systems [\[7\]](#page-20-6). The effect of magnetic field on the properties of two-dimensional quantum system in contact with a quantum heat bath is of great importance in the field of nanophysics [\[42\]](#page-22-8), quantum information theory [\[19,](#page-21-11) [20,](#page-21-12) [21,](#page-21-13) [22\]](#page-21-14), atomic and nuclear physics [\[5,](#page-20-4) [6\]](#page-20-5). In that sense, our study will be helpful in analyzing different thermodynamic properties of small quantum systems like quantum dots, quantum wires, two dimensional electronic systems in contact with a heat bath in the presence of a constant magnetic field. Recently Jordan and Büttiker discussed about the entanglement energetics of quantum system at zero temperature [\[43\]](#page-22-9). So, following our method one can think of extending the study of entanglement enrgetics at finite temperature in the presence of an external magnetic field. Also Ratchov *et al* discussed about decrease in coherence length of Aharonov-Bohm like interferrometer due to the interaction with a zero temperature environment. Again, one can think of extending this work by following the method used in this paper for the finite temperature analysis [\[44\]](#page-22-10). Apart from that, one can think of another area in which thermodynamics plays a crucial role. Following the previous research of several authors [\[45,](#page-22-11) [46,](#page-22-12) [47\]](#page-22-13), one can think of developing microscopic theory for the entropy of black holes. Thus, it is worthwhile to apply this approach to the study of thermodynamic properties of black holes.
