An urn model asso
iated with the Ja
obi polynomials

F. Alberto Grünbaum

Abstra
t. We onsider an urn model leading to a random walk that can be solved explicitly in terms of the well known Jacobi polynomials.

1. Urn models and orthogonal polynomials

There are two simple and classical models in statistical mechani
s whi
h have re
ently been asso
iated to very important lasses of orthogonal polynomials. The oldest one of this models is due to D. Bernoulli (1770) and S. Laplace (1810), while the more recent model is due to Paul and Tatiana Ehrenfest (1907). While both of these models are featured in very lassi
al texts in probability theory, su
h as [F], the connection with orthogonal polynomials is of much more reent vintage. In fa
t, the polynomials in question due to Krawt
houk and Hahn had not been recognized as basic objects with rich properties till around 1950. For a few pertinent and useful referen
es see $[A, AAR, Ch, DS, E, G1, ILMV, K, KMcG1].$ $[A, AAR, Ch, DS, E, G1, ILMV, K, KMcG1].$ $[A, AAR, Ch, DS, E, G1, ILMV, K, KMcG1].$ $[A, AAR, Ch, DS, E, G1, ILMV, K, KMcG1].$ $[A, AAR, Ch, DS, E, G1, ILMV, K, KMcG1].$ $[A, AAR, Ch, DS, E, G1, ILMV, K, KMcG1].$ $[A, AAR, Ch, DS, E, G1, ILMV, K, KMcG1].$ $[A, AAR, Ch, DS, E, G1, ILMV, K, KMcG1].$ $[A, AAR, Ch, DS, E, G1, ILMV, K, KMcG1].$ $[A, AAR, Ch, DS, E, G1, ILMV, K, KMcG1].$ $[A, AAR, Ch, DS, E, G1, ILMV, K, KMcG1].$ $[A, AAR, Ch, DS, E, G1, ILMV, K, KMcG1].$ $[A, AAR, Ch, DS, E, G1, ILMV, K, KMcG1].$ $[A, AAR, Ch, DS, E, G1, ILMV, K, KMcG1].$ $[A, AAR, Ch, DS, E, G1, ILMV, K, KMcG1].$ $[A, AAR, Ch, DS, E, G1, ILMV, K, KMcG1].$

From the omments above one ould get the impression that the relations between orthogonal polynomials -specially some well known classes of them- is only a matter of historical interest. Nothing could be further from the truth: there are several areas of probability and mathemati
al physi
s where re
ent important progress hinges on the onne
tions with orthogonal polynomials.

²⁰⁰⁰ Mathematics Subject Classification. 33C45, 60G99, 60J10.

Key words and phrases. Random walks, urn models, Jacobi polynomials, orthogonal polynomials.

The author was supported in part by NSF Grant DMS-0603901.

The entire area of Random Matrix theory starts with the work of E. Wigner and F. Dyson and rea
hes a new stage in the hands of M. Mehta who brought in the power of orthogonal polynomials into the pi
ture.

In the area of Random growth processes the seminal work of K. Johansson depends heavily on orthogonal polynomials, specifically Laguerre and Meixner ones, in [J].

The onne
tion between birth-and-death pro
esses and orthogonal polynomials has many parents but the people that made the most of it are S. Karlin and J. McGregor, see [KMcG]. We will have a chance to go ba
k to their work in onne
tion with our model here. One should remark that the ideas of using the spe
tral analysis of the orresponding one step transition matrix have been pushed recently in the case of quantum random walks, an area where physi
s, omputer s
ien
e and mathematics could make important contributions. See [\[CGMV,](#page-8-12) Ko].

The study of the so called ASEP (asymmetric simple exclusion pro- ϵ cesses) going back to F. Spitzer, see [S], and very much connected with the work of K. Johansson mentioned earlier, has recently profited from onne
tions with the Askey-Wilson polynomials. All of this has important and deep onne
tions with ombinatori
s and a host of other areas of mathematics. There are many other examples that one could mention, but we just add here the study of noninterse
ting or nonolliding random process which goes back to F. Dyson.

There are lots of interrelations among these areas. For one example: the Hahn polynomials that were mentioned in onne
tion with the Bernoulli-Lapla
e model were studied by Karlin and M
Gregor in connection with a model in genetics due to Moran, see [KMcG1]. They have also been found to be useful in discussing random processes with non-intersecting paths, see $[G]$.

All of these areas are pla
es where orthogonal polynomials have been put to very good use. For a very good review of several of these items see [K]. Orthogonal polynomials of several variables, as well as matrix valued orthogonal polynomials have re
ently been onne
ted to certain random walks. For two samples see $[G2, G3]$ $[G2, G3]$.

2. The Ja
obi polynomials

The lassi
al Ja
obi polynomials are usually onsidered either in the interval $[-1, 1]$ or, as will do, in the interval $[0, 1]$

These polynomials are orthogonal with respect to the weight function

$$
W(x) = x^{\alpha}(1-x)^{\beta}.
$$

Here we assume that $\alpha, \beta > -1$, in fact it will be assumed throughout that α, β are non-negative integers.

These polynomials are eigenfunctions of the differential operator

$$
x(1-x)\frac{d^2}{dx^2} + (\alpha+1+x(\alpha+\beta+2))\frac{d}{dx}
$$

a fact that will not play any role in our discussion but which is crucial in most of the physical and/or geometrical applications of Jacobi polynomials. These applications cover a vast spectrum including potential theory, electromagnetism and quantum mechanics.

Neither the orthogonality, nor the fact that our polynomials are eigenfunctions of this differential operator are enough to determine them uniquely. One can multiply each polynomial by a constant and preserve these properties. We hose to normalize our polynomials by the ondition

$$
Q_n(1)=1.
$$

For us it will be important that these polynomials satisfy (in fa
t are defined by) the three term recursion relation

 $xQ_n(x) = A_nQ_{n+1}(x) + B_nQ_n(x) + C_nQ_{n-1}(x)$ with $Q_0 = 1$ and $Q_{-1} = 0$.

The coefficients A_n, B_n, C_n given by

$$
A_n = \frac{(n + \beta + 1)(n + \alpha + \beta + 1)}{(2n + \alpha + \beta + 1)(2n + \alpha + \beta + 2)}, \quad n \ge 0
$$

\n
$$
B_n = 1 + \frac{n(n + \beta)}{2n + \alpha + \beta} - \frac{(n + 1)(n + \beta + 1)}{2n + \alpha + \beta + 2}, \quad n \ge 0
$$

\n
$$
C_n = \frac{n(n + \alpha)}{(2n + \alpha + \beta)(2n + \alpha + \beta + 1)}, \quad n \ge 1,
$$

The coefficient B_n can be rewritten as

$$
B_n = \frac{2n(n+\alpha+\beta+1) + (\alpha+1)\beta + \alpha(\alpha+1)}{(2n+\alpha+\beta)(2n+\alpha+\beta+2)}
$$

which makes it clear that, along with the other coefficients, it is nonnegative.

Since we insist on the condition $Q_n(1) = 1$ we can see, for instance by induction and using the recursion relation, that

$$
A_n + B_n + C_n = 1.
$$

There are, of course, several explicit expressions for the different variants of the Jacobi polynomials and they can be used for instance in omputing the integrals that appear in the last se
tion.

The normalization above is natural when one thinks of these polynomials (at least for some values of α, β) as the spherical functions for some appropriate symmetric space, and insists that these functions take the value 1 at the North pole of the orresponding sphere. The simplest of all cases is the one with $\alpha = \beta = 0$ when one gets the Legendre polynomials and the usual two dimensional sphere sitting in \mathbb{R}^3 . The reader may want to see [VK].

The fact that the coefficients are nonnegative and add up to one cries out for a probabilistic interpretation of these quantities. This is the purpose of this paper. We have not seen in the literature concrete models of random walks where the Jacobi polynomials play this role.

3. The model

Here we onsider a dis
rete time random walk on the non-negative integers whose one step transition probability matrix coincides with the one that gives the three-term recursion relation satisfied by the Jacobi polynomials.

At times $t = 0, 1, 2, \dots$ an urn contains n blue balls and this determines the state of our random walk on $\mathbb{Z} \geq 0$.

The urn sits in a "bath" consisting of an infinite number of red balls. The transition me
hanism is made up of a few steps whi
h are des
ribed now, leaving some of the details for later.

In the first step a certain number of red balls from the surrounding bath are mixed with the n blue balls in the urn.

In the second step a ball is selected (with uniform distribution) from among the balls in the urn. This "chosen ball" can be blue or red. In either ase an experiment is performed in a parallel world, using an appropriate "auxiliary urn", to determine if this hosen ball will retain its olor or have it hanged (from red to blue or vi
eversa).

Once this is settled, and the possible change of color has taken place, the main urn contains the initial n balls plus a certain number of balls taken form the bath in the first step, and we are ready for the

third and last step. This final step consists of having all red balls in the urn removed and dropped in the bath.

The state of the system at time $t+1$ is given by the number of blue balls in the urn after these three step are ompleted. Clearly the new state can take any of the values $n-1, n, n+1$.

A more detailed des
ription of the three steps above is given in the next section.

4. The details of the model

If at time t the urn contains n blue balls, with $n = 0, 1, 2, ...$ we pi
k

$$
n+\alpha+\beta+1
$$

red balls from the bath to get a total of $2n + \alpha + \beta + 1$ balls in the urn at the end of step one.

We now perform step two: this gives us a blue ball with probability

$$
\frac{n}{2n+\alpha+\beta+1}
$$

and a red ball with probability

$$
\frac{n+\alpha+\beta+1}{2n+\alpha+\beta+1}
$$

If the chosen ball is blue then in a "auxiliary urn" with n blue balls we throw in α blue balls and $n + \beta$ read balls, mix all these balls and pi
k one with uniform distribution. We imagine the auxiliary urn surrounded by a bath of an infinite number of blue and red balls which are used to augment the n blue balls in this auxiliary urn.

The probability of getting a blue ball in the auxiliary urn is

$$
\frac{n+\alpha}{2n+\alpha+\beta}
$$

and if this is the out
ome the "
hosen ball" in the main urn has its olor hanged (from blue to red). If we get a red ball in this auxiliary urn then the hosen ball retains its blue olor.

On the other hand, if in step two we had hosen a red ball then in a different "auxiliary urn" with n blue balls we throw in $\alpha + 1$ blue balls and $n + \beta + 1$ red balls. This auxiliary urn is also surrounded by a bath of an infinite number of blue and red balls.

These balls are mixed and one is hosen with the uniform distribution. The probability that this ball in the auxiliary urn is red is given by

$$
\frac{n+\beta+1}{2n+\alpha+\beta+2}
$$

and if this is the case the chosen ball in the main urn has its color hanged (from red to blue). Otherwise the hosen ball retains its red olor.

Notice that the chosen ball in the main urn has a change of color only when we get a match of colors for the balls drawn in the main and an auxiliary urn: blue followed by blue or red followed by red.

In either case once the possible changes of color of the chosen ball in the main urn has been de
ided upon, we remove all the red balls form the main urn.

We see that the state of the system goes from n to $n-1$ when the chosen ball is blue and then its color gets changed into red. This event has probability

$$
\frac{n}{2n+\alpha+\beta+1}
$$

multiplied by

$$
\frac{n+\alpha}{2n+\alpha+\beta}
$$

Observe that this coincides with the value of C_n in the recursion relation satisfied by our version of the Jacobi polynomials.

The state increases from *n* to $n+1$ if the chosen ball is red and its olor gets hanged into blue. This event has probability

$$
\frac{n+\alpha+\beta+1}{2n+\alpha+\beta+1}
$$

multiplied by

$$
\frac{n+\beta+1}{2n+\alpha+\beta+2}
$$

Observe that this coincides with the values of A_n given earlier.

As we noticed earlier, when the chosen ball is blue and the ball in the orresponding auxiliary ball is red then the hosen ball retains its color. Likewise if the chosen ball is red and the ball in the corresponding auxiliary urn is blue then the chosen one retains its color. In either case

the total number of blue balls in the main urn remains un
hanged and the state goes from n to n .

Recall the basic property of the coefficients A_n, B_n, C_n , namely

$$
A_n + B_n + C_n = 1
$$

This shows that the probabilty of going from state n to state n is given by B_n .

In summary we have built a random walk whose one step transition probability is the one given by the three term relation satisfied by our version of the Ja
obi polynomials.

5. Birth-and-death pro
esses and orthogonal polynomials

A Markov hain with state spa
e given by the non-negative integers and a tridiagonal one step transition probability matrix $\mathbb P$ is called a birth-and-death process. Our model given above, clearly fits in this framework.

One of the most important connections between orthogonal polynomials and birth-and-death processes, such as the one considered here is given by the Karlin-McGregor formula $[KMcG]$.

If the polynomials satisfy

$$
\pi_j \int_0^1 Q_i(x) Q_j(x) W(x) dx = \delta_{ij}
$$

one gets the following representation formula for the entries of the powers of the one-step transition probability matrix

$$
(\mathbb{P}^n)_{ij} = \pi_j \int_0^1 x^n Q_i(x) Q_j(x) W(x) dx.
$$

This ompa
t expression gives the solution to the dynami
s of our random walk and allows for the study of many of its properties.

In the case of our version of the Jacobi polynomials the squares of the norms of the polynomials Q_i are given by

$$
\frac{\Gamma(i+1)\Gamma(i+\alpha+1)\Gamma(\beta+1)^2}{\Gamma(i+\beta+1)\Gamma(i+\alpha+\beta+1)(2i+\alpha+\beta+1)}
$$

In our case when α, β are assumed to be nonnegative integers this expression can, of course, be written without any reference to the Gamma fun
tion.

We close this paper by recalling how one can compute in the case of our transition matrix P its invariant (stationary) distribution, i.e. the (unique up to s
alars) row ve
tor

$$
\boldsymbol{\pi}=(\pi_0,\pi_1,\pi_2,\dots)
$$

such that

$$
\pi P = \pi.
$$

It is a simple matter of using the recursion relation for the polynomials Q_i to show that the components π_i are given, up to a common multipli
ative onstants by the inverses of the integrals

$$
\int_0^1 Q_i^2(x)W(x)dx.
$$

mentioned above. This justifies the notation π_i for these two apparently unrelated quantities, and in our case furnishes an explicit expression for an invariant distribution.
