# Characterising the $D_{2}$ statistic: word matches in biological sequences 

March 22, 2021

Sylvain Forêt, Susan R. Wilson, Conrad J. Burden<br>Mathematical Sciences Institute, The Australian National University, Canberra ACT 0200, Australia

#### Abstract

Word matches are often used in sequence comparison methods, either as a measure of sequence similarity or in the first search steps of algorithms such as BLAST or BLAT. The D2 statistic is the number of matches of words of $k$ letters between two sequences. Recent advances have been made in the characterisation of this statistic and in the approximation of its distribution. Here, these results are extended to the case of approximate word matches.

We compute the exact value of the variance of the D2 statistic for the case of a uniform letter distribution, and introduce a method to provide accurate approximations of the variance in the remaining cases. This enables the distribution of D2 to be approximated for typical situations arising in biological research. We apply these results to the identification of cis-regulatory modules, and show that this method detects such sequences with a high accuracy.

The ability to approximate the distribution of D2 for both exact and approximate word matches will enable the use of this statistic in a more precise manner for sequence comparison, database searches, and identification of transcription factor binding sites.

## 1 Introduction

Alignment-free sequence comparison methods based on word matches allow sequences to be compared without assuming contiguity of homologous segments.

This is of particular interest for the comparison of biological sequences, where deletions, insertions or duplications of segments are common. Several such methods have thus been implemented (see [12], for example), and have had various applications, such as the clustering of large EST databases (for example, 6]. These applications, however, typically rely on empirical thresholds, rather than on rigorous statistical theory.

One of the statistics for alignment free sequence comparison that has received much attention is the $D_{2}$ statistic, which measures the number of words shared between two sequences. The characterisation of this statistic started with the calculation of its mean, and with approximations to the variance [26]. Later, more accurate approximations of the variance allowed asymptotic regimes of $D_{2}$ to be derived for non-uniform [19] and uniform [15] letter distributions. More recently, the exact value of the $D_{2}$ variance has been computed [16, 10]. In parallel with this theoretical effort, optimal word sizes for typical biological situations were computed [9], and practical approximations of the distribution of $D_{2}$ in these settings were proposed [10].

A more general version of the $D_{2}$ statistic is the number of approximate word matches between two sequences. After an initial characterisation of the mean of this statistic, an asymptotic distribution regime was characterised when the logarithm of the sequence size is large compared with the word size [3]. Here, we further characterise the $D_{2}$ statistic in the case of approximate word matches, by computing its variance and proposing approximations of its distribution for typical biologically relevant situations. Finally, we present an application of these results to the identification of regulatory sequences.

## 2 Results

### 2.1 Definitions

The statistic $D_{2}\left(n_{A}, n_{B}, k, t, \eta\right)$ ( $D_{2}$ henceforth) is the number of approximate word matches of length $k$ with up to $t$ mismatches between sequences $A=\left(A_{1} \ldots A_{n_{A}}\right)$ and $B=\left(B_{1} \ldots B_{n_{B}}\right)$ with $A_{i}$ and $B_{j}$ belonging to an alphabet $\mathcal{A}$ and distributed according to a letter distribution parameterised by $\eta$. As previously [10], for mathematical convenience we will impose periodic boundary conditions, that is, the letter in the first position in a sequence is assumed to follow the last letter of that sequence. Also, only the case of strand symmetric Bernoulli text will be considered, that is, sequences built from alphabets of four iid (independent and identically distributed) letters ( $\mathrm{A}, \mathrm{T}, \mathrm{G}$ and C ) with the further constraint that the probability $\xi_{a}$ of letter $a \in \mathcal{A}$ occurring is $\xi_{A}=\xi_{T}=\frac{1}{4}(1+\eta)$ and $\xi_{G}=\xi_{C}=\frac{1}{4}(1-\eta)$, where $0 \leq \eta \leq 1$. Note that the periodic boundary conditions simplify the theoretical calculations considerably, but allow the method to be used for linear as well as circular sequences by appropriate preprocessing (see Section 2.5 for example).

Defining the $t$ neighbourhood match indicator

$$
Y_{(i, j)}= \begin{cases}1 & \text { if } \Delta\left(\left(A_{i}, \ldots, A_{i+k-1}\right),\left(B_{j}, \ldots, B_{j+k-1}\right)\right) \leq t  \tag{1}\\ 0 & \text { otherwise }\end{cases}
$$

where $\Delta\left(w_{1}, w_{2}\right)$ is the number of mismatches between the words $w_{1}$ and $w_{2}$, the $D_{2}$ statistic is given by

$$
\begin{equation*}
D_{2}=\sum_{(i, j) \in I} Y_{(i, j)} \tag{2}
\end{equation*}
$$

where the index set is $I=\left\{(i, j): 1 \leq i \leq n_{A}, 1 \leq j \leq n_{B}\right\}$.

## $2.2 \quad D_{2}$ mean

The mean of $D_{2}$ was first computed for exact word matches $(t=0)$ and iid letters [26]. This was later extended to the case of letters generated by a Markov model [16]. A formula for the mean was also computed for approximate word matches $(t \geq 0)$ in the case of Bernoulli symmetric text [3] in terms of the perturbed binomial distribution [21]. In Appendix $\mathbf{A . 2}$ we derive the equivalent formula

$$
\begin{equation*}
E\left[D_{2}\right]=\frac{n_{A} n_{B}}{4^{k}} \sum_{l=0}^{t}\binom{k}{l}\left(3-\eta^{2}\right)^{l}\left(1+\eta^{2}\right)^{k-l} . \tag{3}
\end{equation*}
$$

## $2.3 \quad D_{2}$ variance

An exact formula for the variance of $D_{2}$ was derived in the case of iid letters and exact word matches using periodic boundary conditions in [10]. Another study computed the variance for exact word matches using free boundary conditions, in the cases of iid letters and of letters generated by a Markov model [16]. Here we extend these results to the case of approximate word matches for iid letters and Bernoulli symmetric text, using periodic boundary conditions. Specific details of this technical derivation are given in Appendix A.3, A brief summary is given below.

To calculate the variance of $D_{2}$ for approximate word matches and symmetric Bernoulli text, we follow the method used in [10]. First we deduce from equation (2) that:

$$
\begin{equation*}
\operatorname{Var}\left(D_{2}\right)=\operatorname{Var}\left(\sum_{(i, j) \in I} Y_{(i j)}\right)=\sum_{(i, j) \in I} \sum_{\left(i^{\prime}, j^{\prime}\right) \in I} \operatorname{Cov}\left(Y_{(i j)}, Y_{\left(i^{\prime} j^{\prime}\right)}\right) . \tag{4}
\end{equation*}
$$

We set $u=(i, j), v=\left(i^{\prime}, j^{\prime}\right)$ and for fixed $u$ split the sum over $v$ as follows. Let $J_{u}=\left\{v=\left(i^{\prime}, j^{\prime}\right):\left|i^{\prime}-i\right|<k\right.$ or $\left.\left|j^{\prime}-j\right|<k\right\}$ be the dependency neighbourhood of $Y_{u}$. For $v \notin J_{u}, \operatorname{Cov}\left(Y_{u}, Y_{v}\right)=0 . J_{u}$ is decomposed into two disjoint sets [26]: an accordion set, $J_{u}^{a}=\left\{v=\left(i^{\prime}, j^{\prime}\right):\left|i^{\prime}-i\right|<k\right.$ and $\left.\left|j^{\prime}-j\right|<k\right\}$ (when two pairs

of matching words overlap in both sequences) and a crabgrass set, $J_{u}^{c}=J_{u} \backslash J_{u}^{a}$ (when two pairs of matching words overlap in one sequence only). The accordion set is further decomposed into a diagonal part, $J_{u}^{a d}=\left\{v=\left(i^{\prime}, j^{\prime}\right):-k<i^{\prime}-i=\right.$ $\left.j^{\prime}-j<k\right\}$ and an off-diagonal part, $J_{u}^{a o}=J_{u}^{a} \backslash J_{u}^{a d}$.

Table 1 gives a summary of the components of the variance in different settings. The only case that is not analytically characterised is the off-diagonal part of the accordion for approximate word matches and non-uniform letter distribution. In this case, however, numerical tables can be assembled to approximate the entire accordion part of the variance with good accuracy. To see this, note that the accordion part takes the form $n_{A} n_{B} \Phi(k, t, \eta)$. When $n_{A}=n_{B}=2 k-1$, the only index set contributing to the variance is the accordion part. Although computing $D_{2}$ for approximate word matches requires an algorithm with complexity $o\left(n_{A} n_{B}\right)$, it is relatively inexpensive to approximate the variance of $D_{2}$ by simulation for small $n_{A}$ and $n_{B}$. Tables of the function $\Phi$ were thus approximated by simulating a large number of pairs of sequences of length $2 k-1$ for $k \leq 16$ and setting $\Phi(k, t, \eta)=\operatorname{Var}\left(D_{2}(2 k-1,2 k-1, k, t, \eta)\right) /(2 k-1)^{2}$ (see below).

## $2.4 \quad D_{2}$ distribution

It has been shown previously [10] that for exact word matches and in most biologically relevant situations, a distribution chosen ad-hoc such as the gamma distribution can provide a better estimate of the $D_{2}$ distribution than the asymptotic normal distribution. Here we provide approximations for the distribution of $D_{2}$ in the case of approximate word matches.

For convenience we have set $n_{A}=n_{B}=n$ in our numerical simulations. We
have simulated the distribution of $D_{2}$ for sequence sizes ranging from small ESTs ( $n=100$ ) to reasonably large genes $(n=3200)$, for even word sizes $k$ between 2 and 16, for every possible number of mismatches $(0 \leq t<k)$, and for both uniform $(\eta=0)$ and non-uniform $\left(\eta=\frac{1}{3}\right)$ letter distributions. For each combination of parameters, $10^{6}$ pairs of iid sequences were generated. Tables of the accordion contribution function $\Phi$ were estimated by generating $10^{9}$ pairs of iid sequences of size $n=2 k-1$, with $k$ ranging from 2 to 16 with an increment of 2. The Mersenne-Twister random number generator [20] was used, as implemented in the GNU scientific library (http://www.gnu.org/software/gsl/). The code was written in ANSI C and is available from the authors' website (http://wwwmaths.anu.edu.au/cbis/~$\left.s f / k \_w o r d s\right)$.

Previously, the gamma distribution was used to approximate the $D_{2}$ distribution in the case of exact word matches [10]. Here, the beta distribution scaled to the range $\left[0, n^{2}\right]$ is used instead of the gamma distribution. In the range of parameters assessed in our simulations, the gamma and beta distributions are mostly indistinguishable (data not shown). It might be expected, however, that the beta distribution provides better approximations for very small p-values, as it is bounded within the same domain of definition as $D_{2}\left(\left[0, n_{A} n_{B}\right]\right)$, whereas the gamma distribution is defined from zero to infinity. Histograms of our numerical simulations the $D_{2}$ statistic are compared with the density function of the beta distribution scaled to this interval, that is

$$
\begin{equation*}
\frac{1}{n_{A} n_{B}} f_{B}\left(\frac{x}{n_{A} n_{B}} ; \alpha, \beta\right) \tag{5}
\end{equation*}
$$

where $f_{B}(x ; \alpha, \beta)=\Gamma(\alpha+\beta) /(\Gamma(\alpha) \Gamma(\beta)) x^{\alpha-1}(1-x)^{1-\beta}$ is the canonical density function of the beta distribution. The parameters $\alpha$ and $\beta$ are set so that the mean and variance of the scaled beta distribution agree with the theoretical values $\mu=E\left[D_{2}\right], \sigma^{2}=\operatorname{Var}\left(D_{2}\right)$ derived in the appendix:

$$
\begin{equation*}
\alpha=\frac{\mu}{n_{A} n_{B}}\left[\frac{\mu\left(n_{A} n_{B}-\mu\right)}{\sigma^{2}}-1\right], \quad \beta=\frac{n_{A} n_{B}-\mu}{n_{A} n_{B}}\left[\frac{\mu\left(n_{A} n_{B}-\mu\right)}{\sigma^{2}}-1\right] . \tag{6}
\end{equation*}
$$

Figure 1 shows the simulated distribution of $D_{2}$ for the size typical of a small EST or a read produced by the 454 Titanium technology (sequence size $n=400$ ), in the case of non-uniform letter distributions $\left(\eta=\frac{1}{3}\right)$. The word sizes displayed in this figure are the optimal word sizes corresponding to the associated number of mismatches. We use the optimal word sizes computed previously in 9]. In brief, a word size and number mismatches combination is optimal when it best captures the relatedness between artificially evolved sequences using the $D_{2}$ statistic as a relatedness estimator.

The quantile-quantile plots between the beta and normal distributions, and the simulated $D_{2}$ distribution show unambiguously that for these parameters combinations, the beta distribution provides a closer fit to the $D_{2}$ distribution than the

Figure 1: Top row: Histograms of the simulated distribution of $D_{2}$ for sequences of size $n=400$ and non-uniformly distributed letters. The normal distribution is shown in red and the beta distribution in blue. The insert shows a close up on the far right of the tail larger than the $99^{\text {th }}$ percentile. Bottom row: quantile-quantile plots with the simulated $D_{2}$ values horizontally, and the normal (continuous red line) and beta (dashed blue line) values vertically. The vertical dashed lines represent the 0.99 and the 0.9999 quantiles.
normal distribution. Similar figures for all the simulations can be found on the authors' website (http://wwwmaths.anu.edu.au/cbis/ ${ }^{\left.\text {s } s f / k \_w o r d s\right) . ~ W e ~ o b s e r v e d ~}$ a few rare situations where the normal distribution outperformed the beta distribution, but these were cases where the number of mismatches was close to the word size, and are of little practical importance.

### 2.5 Application to the detection of regulatory sequences

We now apply the approximation of the $D_{2}$ distribution to a practical biological problem: the identification of sequences containing cis-regulatory modules (CRMs).

We use the same dataset as [16], which contains seven sets of sequences known to contain CRMs. Within each set, the CRMs are driving gene expression in one particular tissue or life stage. The sets contain between 9 and 82 sequences. For each of these 'positive' sets, a 'negative' set was constructed from randomly
chosen non-coding sequences of the same species, containing the same number of sequences and with the same sequence sizes as in the positive set.

In [16], the authors primarily assessed whether their method can capture an expected effect, namely that sequences known to contain similar (CRMs) are more related to each other than are randomly selected sequences. While they show that the $D_{2}$ based approach clearly outperforms other techniques, this approach is of limited practical use.

We chose instead to address a problem more frequently faced by practitioners: given a set of sequences known to contain CRMs, and a query sequence, can the query sequence be classified as containing similar CRMs or not? We set up the following experiment: each sequence in each positive set was selected as the query sequence and compared both to the remaining positive sequences of this set and to the corresponding negative sequences. In order that our theoretical results for the iid hypothesis null distribution could be applied, each sequence was preprocessed by (1) joining the ends to effect periodic boundary conditions and (2) removing masked tandem repeats present in the data sets and concatenating the pieces either side of the removed portion. The parameters $n_{A}$ and $n_{B}$ were taken from the preprocessed sequences and for each pairwise comparison the parameter $\eta$ estimated from the combined letter frequencies of the two sequences in question. The query sequences were then screened to accept only those for which the smallest smallest p-value of all comparisons was less than 0.01 . We used a stringent criterion, namely, a positive query sequence was considered correctly classified if the smallest p -value was obtained with another sequence of the positive set.

Figure 2 shows the results of this experiment. A good sensitivity is achieved in most datasets, with typically $80 \%$ or more of the sequences correctly classified for at least one parameter combination using this stringent criterion. The optimal parameters vary from one condition to another. This may reflect different properties of the underlying CRMs, in terms of size, letter composition and level of conservation that they require in order to be functional. The problem of choosing optimal parameters is easily solved by using the above approach, namely by determining a set of positive sequences and using these to estimate appropriate parameters before comparing the query sequence(s) to them.

The percentage of correctly classified negative sequences based on the smallest p-value was typically around $50 \%$ (data not shown). This suggests that while this method can successfully identify candidates, further validation of the candidates would be needed.

## 3 Discussion

In this study we present exact values and approximations of the variance of $D_{2}$ for pairs of symmetric Bernoulli texts. These results enable the distribution of $D_{2}$ to be approximated with or without mismatches for most situations occurring in biological research.

Figure 2: Percentage of times that a sequence containing CRMs is correctly classified: each subplot corresponds to a type of CRM, and the numbers in parentheses are the number of positive control sequences in each set. Percentages are only plotted if at least 4 query sequences survived the screening requirement that the minimum p-value should be less than 0.01 .

We illustrate the application of these results by using the $D_{2}$ statistic to identify sequences containing regulatory modules. Our results show that this method can be used to identify candidate regulatory sequences for further experimental validation, or in combination with other prediction methods.

A remaining theoretical problem is evaluation of the variance and distribution of the $D_{2}$ statistic in the case of approximate word matches for strings that are not symmetric Bernoulli texts, such as proteins. This lack of theory could be partially circumvented by using exact word matches for protein searches, but using alphabet reduction to account for most common substitutions. A similar alphabet reduction resulted in increased accuracy in the construction of phylogenetic trees with an alignment free method [14.

## Appendix

## A Derivation of D2 mean and variance

Define the statistic $D_{2}$ to be the number of $k$-word matches with up to $t$ mismatches $(t=0, \ldots, k)$ between sequences A and B of letters drawn from an alphabet $\mathcal{A}$. Let the sequence lengths be $n_{A}$ and $n_{B}$ respectively, and assume each sequence to consist of i.i.d. random letters with probability $\xi_{a}$ of letter $a \in \mathcal{A}$ occurring at any given location, where $\sum_{a \in \mathcal{A}} \xi_{a}=1$. Also assume periodic boundary conditions on both sequences, that is, the letter in the first position in sequence A is assumed to follow the letter in the $n_{A}{ }^{\text {th }}$ position, and the letter in the first position in sequence $B$ is assumed to follow the letter in the $n_{B}{ }^{\text {th }}$ position.

In general, we restrict ourselves to the case of strand symmetric Bernoulli texts of nucleotide sequences, that is, i.i.d. sequences for which $\xi_{C}=\xi_{G}=\frac{1}{4}(1-\eta), \xi_{A}=$ $\xi_{T}=\frac{1}{4}(1+\eta)$, where $0 \leq \eta \leq 1$, and write the $D_{2}$ statistic as $D_{2}\left(n_{A}, n_{B}, k, t, \eta\right)$.

## A. 1 Preliminaries

We use the following terminology adapted from [3]:

1. For $m=1,2, \ldots$, define $p_{m}=\sum_{a \in \mathcal{A}} \xi_{a}{ }^{m}$. For strand symmetric Bernoulli texts, $p_{2}=\left(1+\eta^{2}\right) / 4$.
2. Define $\Delta\left(\mathbf{W}_{1}, \mathbf{W}_{2}\right)$ to be a random variable equal to the number of mismatches between the two random $k$-words $\mathbf{W}_{1}$ and $\mathbf{W}_{2}$. When there is no possibility of confusion, we simply write $\Delta(k)$ for the number of mismatches between the two random $k$-words. One easily checks that $\Delta(k)$ is a binomial
random variable:

$$
\begin{align*}
\operatorname{Pr}(\Delta(k)=l) & =\operatorname{Pr}(\text { Exactly } l \text { mismatches and } k-l \text { matches }) \\
& =\binom{k}{l}(\text { prob. of mismatch })^{l}(\text { prob. of match })^{k-l} \\
& =\binom{k}{l}\left(1-p_{2}\right)^{l} p_{2}^{k-l} \\
& =\binom{k}{l} \frac{1}{4^{k}}\left(3-\eta^{2}\right)^{l}\left(1+\eta^{2}\right)^{k-l} . \tag{7}
\end{align*}
$$

3. $Y_{(i, j)}=Y_{u}=$ the approximate word match indicator, taking the value 1 if the number of mismatches between $k$-word at $i$ in $A$ and the $k$-word at $j$ in $B$ is at most $t$. That is:

$$
Y_{(i, j)}= \begin{cases}1 & \text { if } \Delta\left(\left(A_{1}, \ldots, A_{i+k-1}\right),\left(B_{1}, \ldots, B_{j+k-1}\right)\right) \leq t  \tag{8}\\ 0 & \text { otherwise }\end{cases}
$$

Note that $D_{2}=\sum_{i=1}^{n_{A}} \sum_{j=1}^{n_{B}} Y_{(i, j)}$.
4. $g_{t}(k, \eta, c), G_{t}(k, \eta, c)$, probability and cumulative distribution functions of the perturbed binomial distribution [21]. Given a fixed $k$-word with CGcontent $c(c=0, \ldots, k), g_{t}(k, \eta, c)$ (resp. $\left.G_{t}(k, \eta, c)\right)$ is the probability that the number of mismatches between that word and a random $k$-word will be equal to (resp. at most) $t$. Specifically:

$$
\begin{align*}
G_{t}(k, \eta, c) & =\sum_{r=0}^{t} g_{r}(k, \eta, c)  \tag{9}\\
g_{t}(k, \eta, c) & =h(k, \eta, c) u_{t}(k, \eta, c) \tag{10}
\end{align*}
$$

where $0 \leq c, t \leq k$ are integers, and

$$
\begin{align*}
h(k, \eta, c) & =\frac{1}{4^{k}}(1-\eta)^{c}(1+\eta)^{k-c}  \tag{11}\\
u_{t}(k, \eta, c) & =\sum_{i=0}^{k-t}\binom{c}{i}\binom{k-c}{k-t-i} v_{t}(i, \eta, c)  \tag{12}\\
v_{t}(i, \eta, c) & =\left(\frac{3+\eta}{1-\eta}\right)^{c-i}\left(\frac{3-\eta}{1+\eta}\right)^{t-c+i} \tag{13}
\end{align*}
$$

In the above definition, we follow a convention that $\binom{n}{a}=0$ if $a<0$ or $a>n$.
5. We set $I=\left\{(i, j): 1 \leq i \leq n_{A}, 1 \leq j \leq n_{B}\right\}$. Given $u=(i, j) \in I$, the dependency neighbourhood of $u$ is defined as:

$$
\begin{equation*}
J_{u}=\left\{v=\left(i^{\prime}, j^{\prime}\right):\left|i^{\prime}-i\right|<k \text { or }\left|j^{\prime}-j\right|<k\right\} . \tag{14}
\end{equation*}
$$

Note that for $v \notin J_{u}, \operatorname{Cov}\left(Y_{u}, Y_{v}\right)=0$. $J_{u}$ is divided into two parts, accordion $J_{u}^{a}$ and crabgrass $J_{u}^{c}$ defined by

$$
\begin{align*}
J_{u}^{a} & =\left\{v=\left(i^{\prime}, j^{\prime}\right) \in J_{u}:\left|i^{\prime}-i\right|<k \text { and }\left|j^{\prime}-j\right|<k\right\} \\
J_{u}^{c} & =J_{u} \backslash J_{u}^{a} . \tag{15}
\end{align*}
$$

The accordion set is further decomposed into a diagonal part, $J_{u}^{a d}$ and an off-diagonal part, $J_{u}^{a o}$ :

$$
\begin{align*}
J_{u}^{a d} & =\left\{v=\left(i^{\prime}, j^{\prime}\right):-k<i^{\prime}-i=j^{\prime}-j<k\right\}  \tag{16}\\
J_{u}^{a o} & =J_{u}^{a} \backslash J_{u}^{a d} . \tag{17}
\end{align*}
$$

## A. 2 Mean of $D_{2}$

An equivalent and more concise formula for $E\left[D_{2}\right]$ to that given in [3] is

$$
\begin{align*}
E\left[D_{2}\left(n_{A}, n_{B}, k, t, \eta\right)\right] & =\sum_{(i, j) \in I} E\left[Y_{(i, j)}\right] \\
& =n_{A} n_{B} \sum_{l=0}^{t} \operatorname{Pr}(\Delta(k)=l) \\
& =n_{A} n_{B} \sum_{l=0}^{t}\binom{k}{l}\left(1-p_{2}\right)^{l} p_{2}^{k-l} \\
& =\frac{n_{A} n_{B}}{4^{k}} \sum_{l=0}^{t}\binom{k}{l}\left(3-\eta^{2}\right)^{l}\left(1+\eta^{2}\right)^{k-l} . \tag{18}
\end{align*}
$$

## A. 3 Variance of $D_{2}$

An exact formula for the variance of $D_{2}\left(n_{A}, n_{B}, k, 0, \eta\right)$ (i.e. the case of exact word matches) has previously been given by [10. The case of approximate word matches, $0 \leq t \leq k$, is dealt with here. We have

$$
\begin{align*}
\operatorname{Var}\left(D_{2}\left(n_{A}, n_{B}, k, t, \eta\right)\right) & =\operatorname{Var}\left(\sum_{u \in I} Y_{u}\right) \\
& =\sum_{u \in I} \sum_{v \in J_{u}^{c}} \operatorname{Cov}\left(Y_{u}, Y_{v}\right)+\sum_{u \in I} \sum_{v \in J_{u}^{a}} \operatorname{Cov}\left(Y_{u}, Y_{v}\right) \\
& =\left.\operatorname{Var}\left(D_{2}\right)\right|_{\text {crabgrass }}+\left.\operatorname{Var}\left(D_{2}\right)\right|_{\text {accordion }} . \tag{19}
\end{align*}
$$

Below we give an exact formula for the crabgrass part. A convenient exact formula for the accordion part remains intractable in general, and we give below a practical alternate numerical method for its evaluation. For the case of a uniform letter distribution, $\eta=0$, we demonstrate below (in section A.4) that only the diagonal part of the accordion contributes to the variance of $D_{2}$, and give an exact formula for this case.

## A.3.1 Crabgrass contribution to $\operatorname{Var}\left(D_{2}\right)$

From Eqs. (6) and (7) on page 9 of [3], the crabgrass contribution is given by

$$
\begin{align*}
\left.\operatorname{Var}\left(D_{2}\right)\right|_{\text {crabgrass }} & =\sum_{u \in I} \sum_{v \in J_{u}^{c}} \operatorname{Cov}\left(Y_{u}, Y_{v}\right) \\
& =n_{A} n_{B}\left(n_{A}+n_{B}-4 k+2\right) \sum_{r=-k+1}^{k-1} \operatorname{Var}\left(f_{|r|}(\mathbf{W})\right), \tag{20}
\end{align*}
$$

where, for a given $(k-r)$-word $\mathbf{w} \in \mathcal{A}^{k-r}$,

$$
\begin{align*}
f_{r}(\mathbf{w}) & =\sum_{l=0}^{\min (r, t)} \operatorname{Pr}(\Delta(r)=l) G_{t-l}\left(k-r, \eta, c_{\mathbf{w}}\right) \\
& =\sum_{l=0}^{\min (r, t)}\binom{r}{l}\left(1-p_{2}\right)^{l} p_{2}^{r-l} G_{t-l}\left(k-r, \eta, c_{\mathbf{w}}\right) \\
& =\sum_{l=0}^{\min (r, t)}\binom{r}{l} \frac{\left(3-\eta^{2}\right)^{l}\left(1+\eta^{2}\right)^{r-l}}{4^{r}} G_{t-l}\left(k-r, \eta, c_{\mathbf{w}}\right), \tag{21}
\end{align*}
$$

where $c_{\mathbf{w}}$ is the GC-content of $\mathbf{w}$. The variance with respect to the random $(k-r)-$ word $\mathbf{W}$ is calculated using

$$
\begin{equation*}
\operatorname{Var}\left(f_{r}(\mathbf{W})\right)=E\left[f_{r}(\mathbf{W})^{2}\right]-E\left[f_{r}(\mathbf{W})\right]^{2} \tag{22}
\end{equation*}
$$

Since the $\mathbf{w}$-dependence of the function $f_{r}$ is only via the GC-content of $\mathbf{w}$, the expectation values are calculated using

$$
\begin{align*}
E\left[\phi\left(c_{\mathbf{W}}\right)\right] & =\sum_{c=0}^{k-r} \operatorname{Pr}\left(c_{\mathbf{W}}=c\right) \phi(c) \\
& =\sum_{c=0}^{k-r}\binom{k-r}{c}\left(\xi_{C}+\xi_{G}\right)^{c}\left(\xi_{A}+\xi_{T}\right)^{k-r-c} \phi(c) \\
& =\sum_{c=0}^{k-r}\binom{k-r}{c} \frac{1}{2^{k-r}}(1-\eta)^{c}(1+\eta)^{k-r-c} \phi(c) . \tag{23}
\end{align*}
$$

## A.3.2 Accordion contribution to $\operatorname{Var}\left(D_{2}\right)$

The accordion part is

$$
\begin{align*}
\left.\operatorname{Var}\left(D_{2}\right)\right|_{\text {accordion }} & =\sum_{u \in I} \sum_{v \in J_{u}^{a}} \operatorname{Cov}\left(Y_{u}, Y_{v}\right), \\
& =n_{A} n_{B} \Phi(k, t, \eta) \tag{24}
\end{align*}
$$

where

$$
\begin{equation*}
\Phi(k, t, \eta)=\sum_{r=-k+1}^{k-1} \sum_{s=-k+1}^{k-1} \operatorname{Cov}\left(Y_{u}, Y_{u+(r, s)}\right) \tag{25}
\end{equation*}
$$

is independent of $n_{A}$ and $n_{B}$. For the case $n_{A}=n_{B}=2 k-1$, Eq. (20) implies $\left.\operatorname{Var}\left(D_{2}\right)\right|_{\text {crabgrass }}=0$, giving

$$
\begin{equation*}
\Phi(k, t, \eta)=\frac{\operatorname{Var}\left(D_{2}(2 k-1,2 k-1, k, t, \eta)\right)}{(2 k-1)^{2}} \tag{26}
\end{equation*}
$$

which can be estimated numerically by measuring the variance of $D_{2}$ for a large sample of pairs of sequences of length $2 k-1$. Tables of $\Phi(k, t, \eta)$ can be assembled for a range of parameters to provide a practical way of numerically calculating the accordion contribution.

## A. $4 \operatorname{Var}\left(D_{2}\right)$ for a uniform letter distribution

For the case of a uniform letter distribution, $\xi_{a}=1 / d$ for all $a \in \mathcal{A}$ where $d=|\mathcal{A}|$ is the alphabet size, we find that the crabgrass and off-diagonal part of the accordion contribution to $\operatorname{Var}\left(D_{2}\right)$ are zero, and that an analytic formula for the remaining, diagonal-accordion, contribution, can easily be found.

## A.4.1 Crabgrass contribution, $\eta=0$

When $\eta=0$, the perturbed binomial distribution reduces to the ordinary binomial distribution, independent of $c$ 21]:

$$
\begin{equation*}
g_{t}(k, 0, c)=\binom{k}{t}\left(\frac{1}{4}\right)^{t}\left(\frac{3}{4}\right)^{k-t} \tag{27}
\end{equation*}
$$

Accordingly, the function $f_{r}(\mathbf{W})$ in Eq. 20 is independent of the random word $\mathbf{W}$, its variance is zero, and thus $\left.\operatorname{Var}\left(D_{2}\left(n_{A}, n_{B}, k, t, 0\right)\right)\right|_{\text {crabgrass }}=0$.

## A.4.2 Diagonal-accordion contribution

For arbitrary $\eta$ we have (see Fig. 3)

$$
\begin{align*}
\left.\operatorname{Var}\left(D_{2}\right)\right|_{\text {diag.accordion }} & =\sum_{u \in I} \sum_{v \in J_{u}^{a d}} \operatorname{Cov}\left(Y_{u}, Y_{v}\right) \\
& =n_{A} n_{B} \sum_{r=-k+1}^{k-1} \operatorname{Cov}\left(Y_{u}, Y_{u+(r, r)}\right) \\
& =n_{A} n_{B}\left[\operatorname{Cov}\left(Y_{u}, Y_{u}\right)+2 \sum_{r=1}^{k-1} \operatorname{Cov}\left(Y_{u}, Y_{u+(r, r)}\right)\right] . \tag{28}
\end{align*}
$$

The covariance is

$$
\begin{equation*}
\operatorname{Cov}\left(Y_{u}, Y_{u+(r, r)}\right)=E\left[Y_{u}, Y_{u+(r, r)}\right]-E\left[Y_{u}\right]^{2}, \tag{29}
\end{equation*}
$$

where

$$
\begin{align*}
E\left[Y_{u}, Y_{u+(r, r)}\right] & =\operatorname{Pr}\left(Y_{u}=1, Y_{u+(r, r)}=1\right) \\
& =\sum_{l=0}^{\min (k-r, t)} \operatorname{Pr}(\Delta(k-r)=l) \sum_{s_{1}=0}^{t-l} \operatorname{Pr}\left(\Delta(r)=s_{1}\right) \sum_{s_{2}=0}^{t-l} \operatorname{Pr}\left(\Delta(r)=s_{2}\right) \\
& =\sum_{l=0}^{\min (k-r, t)}\binom{k-r}{l}\left(1-p_{2}\right)^{l} p_{2}^{k-r-l}\left[\sum_{s=0}^{t-l}\binom{r}{s}\left(1-p_{2}\right)^{s} p_{2}^{r-s}\right]^{2} \tag{30}
\end{align*}
$$

and

$$
\begin{equation*}
E\left[Y_{u}\right]=\operatorname{Pr}\left(Y_{u}=1\right)=\sum_{l=0}^{t} \operatorname{Pr}(\Delta(k)=l)=\sum_{l=0}^{t}\binom{k}{l}\left(1-p_{2}\right)^{l} p_{2}^{k-l} . \tag{31}
\end{equation*}
$$

The $l^{\text {th }}$ term in Eq. (30) accounts for the event that there are up to $t-l$ mismatches between $\left(A_{i}, \ldots, A_{i+r-1}\right)$ and ( $B_{j}, \ldots, B_{j+r-1}$ ), exactly $l$ mismatches between $\left(A_{i+r}, \ldots, A_{i+k-1}\right)$ and ( $B_{j+r}, \ldots, B_{j+k-1}$ ) and up to $t-l$ mismatches between $\left(A_{i+k}, \ldots, A_{i+k+r-1}\right)$ and $\left(B_{j+k}, \ldots, B_{j+k+r-1}\right)$.

For the case of a uniform letter distribution, one simply sets $p_{2}=1 / d$ in Eqs. (30) and (31).

## A.4.3 Off-diagonal-accordion contribution, $\eta=0$

The proof that $\left.\operatorname{Var}\left(D_{2}\right)\right|_{\text {off-diag.accordion }}=0$ for a uniform letter distribution is non-trivial. First we establish some general results about the distance function $\Delta\left(\mathbf{W}_{1}, \mathbf{W}_{2}\right)$, equal to the number of mismatches between two random $k$-words $\mathbf{W}_{1}$ and $\mathbf{W}_{2}$.

For a uniform letter distribution, and for two independent (i.e. non-overlapping) words $\mathbf{W}_{1}$ and $\mathbf{W}_{2}$, we have from Eq. (7)

$$
\begin{equation*}
\operatorname{Pr}\left(\Delta\left(\mathbf{W}_{1}, \mathbf{W}_{2}\right)=l\right)=\binom{k}{l}\left(1-p_{2}\right)^{l} p_{2}^{k-l}=\binom{k}{l} \frac{(d-1)^{l}}{d^{k}} \tag{32}
\end{equation*}
$$

If one of the words is fixed to be $\mathbf{w}$, one easily checks that the conditional probability is also binomial:

$$
\begin{equation*}
\operatorname{Pr}\left(\Delta\left(\mathbf{W}_{1}, \mathbf{W}_{2}\right)=l \mid \mathbf{W}_{2}=\mathbf{w}\right)=\binom{k}{l} \frac{(d-1)^{l}}{d^{k}}=\operatorname{Pr}\left(\Delta\left(\mathbf{W}_{1}, \mathbf{W}_{2}\right)=l\right) . \tag{33}
\end{equation*}
$$

Thus $\Delta\left(\mathbf{W}_{1}, \mathbf{W}_{2}\right)$ and $\mathbf{W}_{2}$ are independent random variables.

Now consider the case of three independent random words $\mathbf{W}_{1}, \mathbf{W}_{2}$ and $\mathbf{W}_{3}$. Then

$$
\begin{align*}
& \operatorname{Pr}\left(\Delta\left(\mathbf{W}_{1}, \mathbf{W}_{2}\right)=l_{1}, \Delta\left(\mathbf{W}_{2}, \mathbf{W}_{3}\right)=l_{2}\right) \\
&= \sum_{\mathbf{w} \in \mathcal{A}^{k}} \operatorname{Pr}\left(\Delta\left(\mathbf{W}_{1}, \mathbf{W}_{2}\right)=l_{1} \mid \mathbf{W}_{2}=\mathbf{w}\right) \\
& \quad \times \operatorname{Pr}\left(\Delta\left(\mathbf{W}_{2}, \mathbf{W}_{3}\right)=l_{2} \mid \mathbf{W}_{2}=\mathbf{w}\right) \operatorname{Pr}\left(\mathbf{W}_{2}=\mathbf{w}\right) \\
&= \sum_{\mathbf{w} \in \mathcal{A}^{k}} \operatorname{Pr}\left(\Delta\left(\mathbf{W}_{1}, \mathbf{W}_{2}\right)=l_{1}\right) \operatorname{Pr}\left(\Delta\left(\mathbf{W}_{2}, \mathbf{W}_{3}\right)=l_{2}\right) \frac{1}{d^{k}} \\
&= \operatorname{Pr}\left(\Delta\left(\mathbf{W}_{1}, \mathbf{W}_{2}\right)=l_{1}\right) \operatorname{Pr}\left(\Delta\left(\mathbf{W}_{2}, \mathbf{W}_{3}\right)=l_{2}\right) \tag{34}
\end{align*}
$$

where we have used the fact that, once $\mathbf{W}_{2}$ is fixed, $\Delta\left(\mathbf{W}_{1}, \mathbf{W}_{2}\right)$ and $\Delta\left(\mathbf{W}_{2}, \mathbf{W}_{3}\right)$ depend only on $\mathbf{W}_{1}$ and $\mathbf{W}_{3}$ respectively, and so are effectively independent.

We now generalise Eqs. (33) and (34) to the following proposition $P_{N}$, which will be proved by induction:
For given $N \geq 2$, let $\mathbf{W}_{1}, \ldots, \mathbf{W}_{N+1}$ be mutually independent $k$-words, and define

$$
\begin{equation*}
\Delta_{i}=\Delta\left(\mathbf{W}_{i}, \mathbf{W}_{j}\right), \quad i=1, \ldots, N . \tag{35}
\end{equation*}
$$

Then for any $\mathbf{w} \in \mathcal{A}^{k}$,

$$
\begin{align*}
& \operatorname{Pr}\left(\Delta_{1}=l_{1}, \ldots, \Delta_{N-1}=l_{N-1} \mid \mathbf{W}_{N}=\mathbf{w}\right) \\
& \quad=\operatorname{Pr}\left(\Delta_{1}=l_{1}, \ldots, \Delta_{N-1}=l_{N-1}\right) \tag{36}
\end{align*}
$$

and

$$
\begin{align*}
& \operatorname{Pr}\left(\Delta_{1}=l_{1}, \ldots, \Delta_{N}=l_{N}\right) \\
& \quad=\operatorname{Pr}\left(\Delta_{1}=l_{1}, \ldots, \Delta_{N-1}=l_{N-1}\right) \operatorname{Pr}\left(\Delta_{N}=l_{N}\right) . \tag{37}
\end{align*}
$$

Note that Eq. (36) could equivalently be written as

$$
\begin{align*}
& \operatorname{Pr}\left(\Delta_{1}=l_{1}, \ldots, \Delta_{N-1}=l_{N-1} \mid \mathbf{W}_{N} \in R\right) \\
& \quad=\operatorname{Pr}\left(\Delta_{1}=l_{1}, \ldots, \Delta_{N-1}=l_{N-1}\right), \tag{38}
\end{align*}
$$

where $R \subset \mathcal{A}^{k}$ is any restricted set of $k$-words. Note also that combining Eq. (37) for the propositions $P_{2}$ to $P_{N}$ implies

$$
\begin{equation*}
\operatorname{Pr}\left(\Delta_{1}=l_{1}, \ldots, \Delta_{N}=l_{N}\right)=\operatorname{Pr}\left(\Delta_{1}=l_{1}\right) \times \ldots \times \operatorname{Pr}\left(\Delta_{N}=l_{N}\right) \tag{39}
\end{equation*}
$$

The proposition $P_{2}$ is proved by Eqs.(33) and (34). It remains to prove that $P_{N}$ implies $P_{N+1}$. Define $S(\mathbf{w}, l)=\left\{\mathbf{x} \in \mathcal{A}^{k} \mid \Delta(\mathbf{x}, \mathbf{w})=l\right\}$. Starting with the left
hand side of Eq. (36) with $N$ replaced by $N+1$, we have

$$
\begin{aligned}
\operatorname{Pr}\left(\Delta_{1}=\right. & \left.l_{1}, \ldots, \Delta_{N}=l_{N} \mid \mathbf{W}_{N+1}=\mathbf{w}\right) \\
= & \operatorname{Pr}\left(\Delta_{1}=l_{1}, \ldots, \Delta_{N}=l_{N} \mid \mathbf{W}_{N+1}=\mathbf{w}, \mathbf{W}_{N} \in S\left(\mathbf{w}, l_{N}\right)\right) \\
& \times \operatorname{Pr}\left(\mathbf{W}_{N} \in S\left(\mathbf{w}, l_{N}\right)\right) \\
+ & \operatorname{Pr}\left(\Delta_{1}=l_{1}, \ldots, \Delta_{N}=l_{N} \mid \mathbf{W}_{N+1}=\mathbf{w}, \mathbf{W}_{N} \notin S\left(\mathbf{w}, l_{N}\right)\right) \\
& \times \operatorname{Pr}\left(\mathbf{W}_{N} \notin S\left(\mathbf{w}, l_{N}\right)\right) \\
= & \operatorname{Pr}\left(\Delta_{1}=l_{1}, \ldots, \Delta_{N-1}=l_{N-1} \mid \mathbf{W}_{N+1}=\mathbf{w}, \mathbf{W}_{N} \in S\left(\mathbf{w}, l_{N}\right)\right) \\
& \times \operatorname{Pr}\left(\mathbf{W}_{N} \in S\left(\mathbf{w}, l_{N}\right)\right)
\end{aligned}
$$

where the second term is zero since " $\Delta_{N}=l_{N}$ " and " $\mathbf{W}_{N} \notin S\left(\mathbf{w}, l_{N}\right)$ " are mutually exclusive events, and the requirement " $\Delta_{N}=l_{N}$ " has been dropped from the first term since it is automatically satisfied by the condition " $\mathbf{W}_{N+1}=\mathbf{w}$ and $\mathbf{W}_{N} \in S\left(\mathbf{w}, l_{N}\right)$ ". Then, since $\Delta_{1}, \ldots, \Delta_{N-1}$ are independent of $\mathbf{W}_{N+1}$, and rewriting the second factor, we have

$$
\begin{align*}
\operatorname{Pr} & \left(\Delta_{1}=l_{1}, \ldots, \Delta_{N}=l_{N} \mid \mathbf{W}_{N+1}=\mathbf{w}\right) \\
= & \operatorname{Pr}\left(\Delta_{1}=l_{1}, \ldots, \Delta_{N-1}=l_{N-1} \mid \mathbf{W}_{N} \in S\left(\mathbf{w}, l_{N}\right)\right) \\
& \times \operatorname{Pr}\left(\Delta_{N}=l_{N} \mid \mathbf{W}_{N+1}=\mathbf{w}\right) \\
= & \operatorname{Pr}\left(\Delta_{1}=l_{1}, \ldots, \Delta_{N-1}=l_{N-1}\right) \operatorname{Pr}\left(\Delta_{N}=l_{N}\right) \quad \text { by Eqs.(33) and (38) } \\
= & \operatorname{Pr}\left(\Delta_{1}=l_{1}, \ldots, \Delta_{N}=l_{N}\right) \quad \text { by Eq. (37) } \tag{40}
\end{align*}
$$

which establishes the first part of proposition $P_{N+1}$. Starting with the left hand side of Eq. (37) with $N$ replaced $N+1$,

$$
\begin{align*}
& \operatorname{Pr}\left(\Delta_{1}=l_{1}, \ldots, \Delta_{N+1}=l_{N+1}\right) \\
& =\sum_{\mathbf{w} \in \mathcal{A}^{k}} \operatorname{Pr}\left(\Delta_{1}=l_{1}, \ldots, \Delta_{N}=l_{N} \mid \mathbf{W}_{N+1}=\mathbf{w}\right) \\
& \quad \times \operatorname{Pr}\left(\Delta_{N+1}=l_{N+1} \mid \mathbf{W}_{N+1}=\mathbf{w}\right) \operatorname{Pr}\left(\mathbf{W}_{N+1}=\mathbf{w}\right) \\
& =\sum_{\mathbf{w} \in \mathcal{A}^{k}} \operatorname{Pr}\left(\Delta_{1}=l_{1}, \ldots, \Delta_{N}=l_{N}\right) \operatorname{Pr}\left(\Delta_{N+1}=l_{N+1}\right) \frac{1}{d^{k}} \quad \text { by Eq. (40) } \\
& =  \tag{41}\\
& \operatorname{Pr}\left(\Delta_{1}=l_{1}, \ldots, \Delta_{N}=l_{N}\right) \operatorname{Pr}\left(\Delta_{N+1}=l_{N+1}\right)
\end{align*}
$$

which establishes the second half of proposition $P_{N+1} .{ }^{1}$
We are now in a position to calculate

$$
\begin{equation*}
\left.\operatorname{Var}\left(D_{2}\right)\right|_{\text {off-diag.accordion }}=\sum_{u \in I} \sum_{v \in J_{u}^{a o}} \operatorname{Cov}\left(Y_{u}, Y_{v}\right) \tag{42}
\end{equation*}
$$

Writing $u=(i, j), v=(i+r, j+s) \in J_{u}^{a o}$, the off-diagonal part $J_{u}^{a o}$ can be subdivided into six parts illustrated in Fig. 3, namely

[^0]

Figure 3: The main diagonal and off-diagonal regions I to VI of $J_{u}^{a}$.

I: $0 \leq s<r \leq k-1$;
II: $-k+1 \leq s<r \leq 0 ;$
III: $-k+1 \leq r<s \leq 0$;
IV: $0 \leq r<s \leq k-1$;
$\mathrm{V}: 1 \leq r \leq k-1,-k+1 \leq s \leq-1 ;$
VI: $1 \leq s \leq k-1,-k+1 \leq r \leq-1$.
We proceed to prove that $\operatorname{Cov}\left(Y_{u}, Y_{v}\right)$ vanishes for each of the six cases.
Case I is illustrated in Fig. [(a). The union of the overlapping words $\mathbf{W}_{u}^{A}=$ $\left(A_{i}, \ldots, A_{i+k-1}\right)$ and $\mathbf{W}_{v}^{A}=\left(A_{i+r}, \ldots, A_{i+k+r-1}\right)$ is subdivided into the shaded pieces $\mathbf{W}_{0}^{A, L}=\left(A_{i}, \ldots, A_{i+s-1}\right)$ and $\mathbf{W}_{0}^{A, R}=\left(A_{i+k+r-s}, \ldots, A_{i+k+r-1}\right)$ each of length $s$, and a set of and a set of single-letter words $\mathbf{W}_{\alpha}^{A}=\left(A_{i+s+\alpha-1}\right), \alpha=$ $1, \ldots, k+r-2 s$.

Similarly, the union of the overlapping words $\mathbf{W}_{u}^{B}=\left(B_{j}, \ldots, B_{j+k-1}\right)$ and $\mathbf{W}_{v}^{B}=\left(B_{j+s}, \ldots, B_{j+k+s-1}\right)$ is subdivided into the shaded pieces $\mathbf{W}_{0}^{B, L}=\left(B_{i}, \ldots, B_{j+s-1}\right)$ and $\mathbf{W}_{0}^{B, R}=\left(B_{j+k}, \ldots, B_{j+k+s-1}\right)$ each of length $s$, and a set of and a set of single-letter words $\mathbf{W}_{\alpha}^{B}=\left(B_{j+s+\alpha-1}\right), \alpha=1, \ldots, k-s$.

$$
\begin{aligned}
& \text { Define } \quad \Delta_{0}^{L}=\Delta\left(\mathbf{W}_{0}^{A, L}, \mathbf{W}_{0}^{B, L}\right), \quad \Delta_{0}^{R}=\Delta\left(\mathbf{W}_{0}^{B, R}, \mathbf{W}_{0}^{A, R}\right) \\
& \Delta_{\alpha}^{L}=\Delta\left(\mathbf{W}_{\alpha}^{A}, \mathbf{W}_{\alpha}^{B}\right), \quad \Delta_{\alpha}^{R}=\Delta\left(\mathbf{W}_{\alpha}^{B}, \mathbf{W}_{\alpha+r-s}^{A}\right), \quad \alpha=1, \ldots, k-s .
\end{aligned}
$$

Figure 4: (a) Case I of the off-diagonal accordion contribution to $\operatorname{Var}\left(D_{2}\right)$. Cases II, III and IV are obtained by reflection or by interchanging the roles of $A$ and $B$. (b) Case V of the off-diagonal contribution. Case VI is obtained by interchanging the roles of $A$ and $B$.

Then

$$
\begin{equation*}
\Delta\left(\mathbf{W}_{u}^{A}, \mathbf{W}_{u}^{B}\right)=\sum_{\alpha=0}^{k-s} \Delta_{\alpha}^{L}, \quad \Delta\left(\mathbf{W}_{v}^{A}, \mathbf{W}_{v}^{B}\right)=\sum_{\alpha=0}^{k-s} \Delta_{\alpha}^{R} \tag{43}
\end{equation*}
$$

With the indicator variables $Y_{u}$ and $Y_{v}$ defined as above, we have

$$
\begin{align*}
& E\left(Y_{u}, Y_{v}\right)=\operatorname{Pr}\left(Y_{u}=1, Y_{v}=1\right) \\
& =\operatorname{Pr}\left(\Delta\left(\mathbf{W}_{u}^{A}, \mathbf{W}_{u}^{B}\right) \leq t, \Delta\left(\mathbf{W}_{v}^{A}, \mathbf{W}_{v}^{B}\right) \leq t\right) \\
& =\sum_{\left\{m_{0}, \ldots, m_{k-s}\right\} \in I_{t}} \sum_{\left\{l_{0}, \ldots, l_{k-s}\right\} \in I_{t}} \operatorname{Pr}\left(\Delta_{0}^{L}=m_{0}, \ldots\right. \\
& \left.\quad \ldots, \Delta_{k-s}^{L}=m_{k-s}, \Delta_{0}^{R}=l_{0}, \ldots, \Delta_{k-s}^{R}=l_{k-s}\right), \tag{44}
\end{align*}
$$

where the index set summed over is

$$
\begin{equation*}
I_{t}=\left\{l_{0}, \ldots, l_{k-s} \mid 0 \leq l_{0} \leq s, 0 \leq l_{1}, \ldots, l_{k-s} \leq 1, \sum_{\alpha=0}^{k-s} l_{\alpha} \leq t\right\} \tag{45}
\end{equation*}
$$

The set $\left\{\Delta_{1}^{L}, \ldots, \Delta_{k-s}^{L}, \Delta_{1}^{R}, \ldots, \Delta_{k-s}^{R}\right\}$ partitions into a collection of disjoint subsets of the form $\left\{\Delta_{\alpha}^{L}, \Delta_{\alpha}^{R}, \Delta_{\alpha+r-s}^{L}, \Delta_{\alpha+r-s}^{R}, \Delta_{\alpha+2(r-s)}^{L}, \ldots\right\}, \alpha=1, \ldots, r-s$ (indicated by the zig-zag line in Fig. 4(a)), each of which satisfies the conditions of the proposition $P_{N}$ for some $N$. Also, these subsets are independent of one another and of $\Delta_{0}^{L}$ and $\Delta_{0}^{R}$, since they contain random variables which are functions of corresponding disjoint subsets of letters.

Thus we can factor the probability in Eq.(44) and rearrange the sum to obtain

$$
\begin{align*}
E\left(Y_{u}, Y_{v}\right)= & \sum_{\left\{m_{0}, \ldots, m_{k-s}\right\} \in I_{t}} \operatorname{Pr}\left(\Delta_{0}^{L}=m_{0}\right) \ldots \operatorname{Pr}\left(\Delta_{k-s}^{L}=m_{k-s}\right) \\
& \times \sum_{\left\{l_{0}, \ldots, l_{k-s}\right\} \in I_{t}} \operatorname{Pr}\left(\Delta_{0}^{R}=l_{0}\right) \ldots \operatorname{Pr}\left(\Delta_{k-s}^{R}=l_{k-s}\right) \\
= & \sum_{\left\{m_{0}, \ldots, m_{k-s}\right\} \in I_{t}} \operatorname{Pr}\left(\Delta_{0}^{L}=m_{0}, \ldots, \Delta_{k-s}^{L}=m_{k-s}\right) \\
& \times \sum_{\left\{l_{0}, \ldots, l_{k-s}\right\} \in I_{t}} \operatorname{Pr}\left(\Delta_{0}^{R}=l_{0}, \ldots, \Delta_{k-s}^{R}=l_{k-s}\right) \\
= & \operatorname{Pr}\left(\Delta\left(\mathbf{W}_{u}^{A}, \mathbf{W}_{u}^{B}\right) \leq t\right) \operatorname{Pr}\left(\Delta\left(\mathbf{W}_{v}^{A}, \mathbf{W}_{v}^{B}\right) \leq t\right) \\
= & E\left(Y_{u}\right) E\left(Y_{v}\right) . \tag{46}
\end{align*}
$$

Thus $\operatorname{Cov}\left(Y_{u}, Y_{v}\right)=0$ for $v$ in the Case I part of $J_{u}^{a o}$. Cases II, III and IV can be similarly dealt with by reversing the order of both sequences, interchanging the roles of sequences $A$ and $B$, or both.

Case V is illustrated in Fig. 4(b). This time the union of the overlapping words $\mathbf{W}_{u}^{A}$ and $\mathbf{W}_{v}^{A}$ is subdivided into the set of single-letter words $\mathbf{W}_{\alpha}^{A}=\left(A_{i+\alpha-1}\right)$,
$\alpha=1, \ldots, k+r$, and the union of the overlapping words $\mathbf{W}_{u}^{B}$ and $\mathbf{W}_{v}^{B}$ is subdivided into the set of single-letter words $\mathbf{W}_{\alpha}^{B}=\left(B_{j-|s|+\alpha-1}\right), \alpha=1, \ldots, k+|s|$. We define

$$
\Delta_{\alpha}^{L}=\Delta\left(\mathbf{W}_{\alpha}^{A}, \mathbf{W}_{\alpha+|s|}^{B}\right), \quad \Delta_{\alpha}^{R}=\Delta\left(\mathbf{W}_{\alpha}^{B}, \mathbf{W}_{\alpha+r}^{A}\right), \quad \alpha=1, \ldots, k
$$

Then

$$
\begin{equation*}
\Delta\left(\mathbf{W}_{u}^{A}, \mathbf{W}_{u}^{B}\right)=\sum_{\alpha=1}^{k} \Delta_{\alpha}^{L}, \quad \Delta\left(\mathbf{W}_{v}^{A}, \mathbf{W}_{v}^{B}\right)=\sum_{\alpha=1}^{k} \Delta_{\alpha}^{R} \tag{47}
\end{equation*}
$$

and

$$
\begin{align*}
E\left(Y_{u}, Y_{v}\right)= & \operatorname{Pr}\left(Y_{u}=1, Y_{v}=1\right) \\
= & \operatorname{Pr}\left(\Delta\left(\mathbf{W}_{u}^{A}, \mathbf{W}_{u}^{B}\right) \leq t, \Delta\left(\mathbf{W}_{v}^{A}, \mathbf{W}_{v}^{B}\right) \leq t\right) \\
= & \sum_{\left\{m_{1}, \ldots, m_{k}\right\} \in I_{t}} \sum_{\left\{l_{1}, \ldots, l_{k}\right\} \in I_{t}} \operatorname{Pr}\left(\Delta_{1}^{L}=m_{1}, \ldots\right. \\
& \left.\quad \ldots, \Delta_{k}^{L}=m_{k}, \Delta_{1}^{R}=l_{1}, \ldots, \Delta_{k}^{R}=l_{k}\right), \tag{48}
\end{align*}
$$

where the index set is now

$$
\begin{equation*}
I_{t}=\left\{l_{0}, \ldots, l_{k} \mid 0 \leq l_{1}, \ldots, l_{k} \leq 1, \sum_{\alpha=1}^{k} l_{\alpha} \leq t\right\} \tag{49}
\end{equation*}
$$

The set $\left\{\Delta_{1}^{L}, \ldots, \Delta_{k}^{L}, \Delta_{1}^{R}, \ldots, \Delta_{k}^{R}\right\}$ partitions into a collection of disjoint subsets of the form $\left\{\Delta_{\alpha}^{L}, \Delta_{\alpha+|s|}^{R}, \Delta_{\alpha+r+|s|}^{L}, \ldots\right\}, \alpha=1, \ldots, r$, or
$\left\{\Delta_{\alpha}^{R}, \Delta_{\alpha+|s|}^{L}, \Delta_{\alpha+r+|s|}^{R}, \ldots\right\}, \alpha=1, \ldots,|s|$ (indicated by the zig-zag line in Fig. [4(b)), each of which satisfies the conditions of the proposition $P_{N}$ for some $N$, and which are mutually independent. Thus we can factor the probability in Eq.(48), rearrange the sum and recombine the probabilities to obtain

$$
\begin{align*}
E\left(Y_{u}, Y_{v}\right)= & \sum_{\left\{m_{1}, \ldots, m_{k}\right\} \in I_{t}} \operatorname{Pr}\left(\Delta_{1}^{L}=m_{1}, \ldots, \Delta_{k}^{L}=m_{k}\right) \\
& \times \sum_{\left\{l_{1}, \ldots, l_{k}\right\} \in I_{t}} \operatorname{Pr}\left(\Delta_{1}^{R}=l_{1}, \ldots, \Delta_{k}^{R}=l_{k}\right) \\
= & \operatorname{Pr}\left(\Delta\left(\mathbf{W}_{u}^{A}, \mathbf{W}_{u}^{B}\right) \leq t\right) \operatorname{Pr}\left(\Delta\left(\mathbf{W}_{v}^{A}, \mathbf{W}_{v}^{B}\right) \leq t\right) \\
= & E\left(Y_{u}\right) E\left(Y_{v}\right) \tag{50}
\end{align*}
$$

giving $\operatorname{Cov}\left(Y_{u}, Y_{v}\right)=0$ for $v$ in the Case V part of $J_{u}^{a o}$. Case VI can be similarly dealt with by interchanging the roles of sequences $A$ and $B$.

## Acknowledgement

We thank Joerg Arndt for help with optimising the code of the simulations. We also would like to express our thanks to anonymous referees for valuable suggestions which have improved the content of this paper. This work was funded in part by ARC discovery grant DP0559260.

[^0]:    ${ }^{1}$ Aside: For an alternate proof that $\left.\operatorname{Var}\left(D_{2}\left(n_{A}, n_{B}, k, t, 0\right)\right)\right|_{\text {crabgrass }}=0$ one can apply the above proposition to the third line of Eq. (5) of [3].
