rf2@ieee.org

Abstract – Central Force Optimization (CFO) is a new nature-inspired deterministic multi-dimensional search and optimization metaheuristic based on the metaphor of gravitational kinematics. CFO is applied to the PBM antenna benchmark suite and the results compared to published performance data for other optimization algorithms. CFO acquires itself quite well. CFO’s gradient-like nature is discussed, and it is speculated that a “generalized hyperspace derivative” might be defined for optimization problems as a new mathematical construct based on the Unit Step function. What appears to be a sufficient but not necessary condition for local trapping, oscillation in the probe average distance curve, is discussed in the context of the theory of gravitational “resonant returns” that gives rise to strikingly similar oscillatory curves. It is suggested that the theory may be applicable to CFO as an aid to understanding trapping and to developing effective mitigation techniques, possibly based on a concept of “energy” in CFO space. It also is suggested that CFO may be re-formulated as a “total energy” model by analogizing conservation of energy for orbiting masses in physical space.

1. INTRODUCTION

Central Force Optimization (CFO) is new nature-inspired, gradient-like metaheuristic for multi-dimensional search and optimization [1-4,21]. It comprises two simple *deterministic* equations based on the metaphor of gravitational kinematics. Because the law of gravity is deterministic, so too is CFO, unlike many nature-inspired algorithms that are fundamentally stochastic. The primary purpose of this paper is to report CFO’s performance against a recognized suite of antenna benchmark problems. Its secondary purposes are (a) to describe the CFO metaheuristic and present its basic equations; (b) to suggest the possibility of a new mathematical construct, a “hyperspace directional derivative” based on the Unit step function; (c) to discuss the strikingly similar appearance of velocity curves for NEOs (Near Earth Objects) in gravitationally trapped close encounters with CFO’s average probe distance curves; (d) to suggest the possibility of using probe total “energy” as a measure of local trapping; and (e) to suggest the possibility of re-formulating CFO using a conservation of energy model.

The original paper CFO [1] introduced CFO as a new metaheuristic and applied it to two problems in applied electromagnetics (EM): designing an equalizer for the canonical Fano load, and synthesizing a linear dipole array. CFO’s results were compared to data from several other algorithms, and it also was tested against several analytic benchmark functions with known maxima. The results suggested that CFO merits further development as a promising, robust optimization methodology. CFO more recently has been used to synthesize linear and circular arrays [5], and it performed very well compared to the Quadrature Programming Method (QPM), to a Particle Swarm Optimization (PSO) algorithm, and to a Genetic Algorithm (GA). Even though CFO is a new metaheuristic that is not nearly as well developed as most of the widely used evolutionary algorithms (EAs), it nevertheless shows very robust performance at this early stage, and considerable promise for future development.

This paper provides further examples of CFO’s effectiveness by applying it to the set of “real world” antenna benchmarks developed by Pantoja, Bretones, and Martin [6] (“PBM”). Their benchmark suite is designed to objectively evaluate the performance of EAs used to solve complex EM problems, representative examples being: PSO-based array synthesis [7]; swarm intelligence optimization of layered media [8]; GA antenna modeling [9]; array design using GAs, and memetic and tabu search algorithms [10]; crack detection using a finite-difference frequency domain/PSO methodology [11]; Vee-dipole optimization using a bacteria foraging algorithm [12]; and GA-optimized MRI coil design [13]. EAs solve these problems by “evolving” solutions that are unavailable analytically or numerically. The plethora of nature-inspired EAs makes comparison difficult, if not impossible, without a standardized set of benchmarks for testing. The PBM suite, which is based on the Numerical Electromagnetics Code (NEC), addresses this need for EAs that are applied to optimized antenna design. It therefore is a useful tool for evaluating CFO.

An EA’s performance is measured by its *effectiveness* (locating global maxima accurately) and its *efficiency* (locating global maxima with minimum computational effort). An algorithm that fails to accurately locate global maxima fails to accomplish its intended purpose and consequently is ineffective. EAs that are, on a relative basis, computationally intensive are less desirable than ones requiring fewer calculations. This paper uses these performance measures to compare CFO to the four EAs discussed in [6]. The results are, for the most part, very encouraging. CFO performs very well compared to the PBM EAs, and in many cases much better. But CFO does suffer limitations, primarily a consequence of its being deterministic, which renders it prone to local trapping.

This paper is organized as follows: Section 2 provides an overview of the PBM benchmark suite and discusses NEC4 validation of the PBM data. Section 3 summarizes CFO’s performance against the PBM benchmarks. Section 4 presents the CFO gravitational metaphor and its basic equations. It also discusses some interesting indirect evidence of the metaphor’s validity drawn from the astronomy literature, the possibility of defining a CFO “energy” for trapping analysis or re-formulation of the algorithm, and it suggests the possibility of interpreting CFO as a “generalized gradient” methodology with the attendant possibility of defining a new Unit Step-based hyperspace derivative. Section 5 describes the PBM benchmark suite in detail, including antenna geometries and decision space landscapes. Section 6 discusses the CFO results in detail. Section 7 is the conclusion. Appendix A provides additional plots of the PBM benchmark topologies, including projections onto the principal planes, and sample NEC4 input/output files for each antenna. Appendix B contains pseudocode for the CFO implementation used here and Appendix C the Basic source code.

2. PBM BENCHMARKS – OVERVIEW AND NEC4 VALIDATION

2.1 The PBM Problems

The PBM benchmark suite comprises five antenna problems designed to test an EA’s effectiveness and efficiency. Table 1 lists their properties. In each case, the objective is to maximize the antenna’s directivity (“fitness”). Four of the problems are two-dimensional (2D), while the fifth is ($N_{el} - 1$) D [N_{el} is the number of dipole elements in a collinear array]. The 2D problem topologies (“landscapes”) are plotted in Section 5 to illustrate the nature and complexity of the decision space. Problems #1 and #4 are unimodal with a single global maximum. The first problem is “lumpy” with strong local maxima, whereas the fourth is “smooth.” Problem #2 is “noisy” in a complex landscape with large amplitude nearby local maxima. The third problem’s topology is extremely multimodal with four global maxima. Problem #5 is a unimodal high-dimensionality problem that optimizes the element spacing of an N_{el} -element collinear dipole array.

Table 1. Properties of the PBM Benchmark Problems.

PBM Benchmark #	Problem Characteristics (in each case objective is to maximize directivity)
1	Variable length center-fed dipole. 2D, unimodal, single global maximum, strong local maxima.
2	Uniform 10-element array of center-fed $\frac{\lambda}{2}$ -dipoles. 2D, added Gaussian noise, single global maximum, multiple strong local maxima.
3	8-element circular array of center-fed $\frac{\lambda}{2}$ -dipoles. 2D, highly multimodal, four global maxima.
4	Vee Dipole. 2D, unimodal, single global maximum, “smooth” landscape.
5	Collinear N_{el} -element array of center-fed $\frac{\lambda}{2}$ -dipoles. $(N_{el} - 1)$ D, unimodal, single global maximum.

2.1 NEC4 Validation

The PBM problems, which do not have analytic solutions, were solved numerically in [6] using NEC. The first step in evaluating CFO therefore is validation of the published PBM results. The five benchmark antennas were modeled using the Numerical Electromagnetics Code Version 4.1 Double Precision (“NEC4”) [14], which may be a different version of NEC than the one used in [6]. The segmentation and wire radii used in [6] were replicated. NEC4 input and output files are included in Appendix A. Each PBM antenna was modeled using the coordinates for the maxima reported in [6]. In several cases they were estimated from graphical data and, as a consequence, necessarily are approximate. Tables 2(a) and (b) summarize the results. x_1 and x_2 , respectively, refer to the abscissa and ordinate in the “Domain” column; λ is the wavelength; N_d is the problem’s dimensionality; and D_{\max}^{PBM} and D_{\max}^{NEC4} are the maximum directivities.

While the general conclusion is that NEC4 essentially recovers the PBM results, there are some noteworthy differences. For problems #1 and #2, NEC4’s computed directivities are slightly less than PBM’s. For problems #3 and #4, they are lower by a much wider margin. The best agreement is on problem #5 where the NEC4 and PBM data show very good agreement. What accounts for these discrepancies is not clear. There are several possible explanations, ranging from different versions of NEC to compiler differences in creating the executables to slight differences in the antenna models, for example, source modeling (NEC4 excitation was modeled following the guidelines for the “EX0” card [14, Part I, p. 48 *et seq.*]). These differences between the PBM results and NEC4 notwithstanding, the validation test shows that NEC4 can be used effectively to assess CFO’s performance against the PBM benchmarks, and that CFO should recover maxima with similar amplitudes at about the same points in the decision space.

3. CFO PERFORMANCE SUMMARY

3.1 Effectiveness

This section summarizes CFO’s performance (see §6 for detailed discussion of each run). CFO’s *effectiveness* is measured by how accurately it locates the PBM maxima (coordinates and maxima values, that is, best fitnesses). Table 3 summarizes the coordinate results and Table 4 the fitnesses (Δ is the difference in values). Inspection of these tables shows that the agreement generally is quite good.

Table 2(a). PBM and NEC4 Results for Benchmarks #1-4.

Problem #	PBM				NEC4
	Domain	x_1	x_2	D_{\max}^{PBM}	
1	$0.5\lambda \leq L \leq 3\lambda$ $0 \leq \theta \leq \frac{\pi}{2}$	2.58 λ	0.63	3.32	3.2
2	$5\lambda \leq d \leq 15\lambda$ $0 \leq \theta \leq \pi$	$\sim 5.85\lambda^{(1)}$	$\pi/2$	~ 18.3	18.11
3	$0 \leq \beta \leq 4$ $0 \leq \theta \leq \pi$	0.5, 1.5, 2.5, 3.5	$\pi/2$	~ 7.05	6.15
4	$0.5\lambda \leq L_{\text{arm}} \leq 1.5\lambda$ $\frac{\pi}{18} \leq \alpha \leq \frac{\pi}{2}$	1.5 λ	0.834	~ 5.8	4.8

Note: ⁽¹⁾ values marked with ~ are estimated from Figs. 6, 9 or 11 in [6].

Table 2(b). PBM and NEC4 Results for Benchmark #5.

Problem #	# Dipoles	N_d	Domain	d_i	D_{\max}^{PBM}	D_{\max}^{NEC4}
5	6	5	$0.5\lambda \leq d_i \leq 1.5\lambda$ $1 \leq i \leq 5$	0.99 λ	$\sim 11.25^{(1)}$	11.22
5	10	9	$0.5\lambda \leq d_i \leq 1.5\lambda$ $1 \leq i \leq 9$	0.99 λ	~ 19	19.10
5	16	15	$0.5\lambda \leq d_i \leq 1.5\lambda$ $1 \leq i \leq 15$	0.99 λ	~ 31	30.97
5	24	23	$0.5\lambda \leq d_i \leq 1.5\lambda$ $1 \leq i \leq 23$	0.99 λ	~ 47	46.88

Note: ⁽¹⁾ values marked with ~ are estimated from Fig. 13 in [6].

Turning to Table 3, for 2D problems #1 through #4, respectively, the coordinates agree to within (1.12%, 1.9%), (1.26%, 0.89%), (3.95%, 0.16%), and (0.03%, 14.75%) [relative to PBM's coordinates]. The only significant disagreements are in the abscissas for problem #3 and the ordinates for problem #4. In the

case of problem #3, the location of the global maximum at ($\beta = 0.5, \theta = \frac{\pi}{2}$) is known analytically. No

computed value was reported in [6], so that the true degree of agreement is not known. For problem #4, the discrepancy in the inner angle α may be a result of modeling differences, or possibly different versions of NEC. Of course, from a practical (read "engineering") point of view, agreement to within about 15% may be acceptable. For problem #5, the dipole separation for maximum directivity agreed to within 1% for all array sizes, which is quite good. If the 24-element array, for which $d_i = 1\lambda$, is excluded, then the agreement is even better, to within 0.7%.

Table 3. Comparison of PBM and CFO maxima coordinates.

PBM Problem #	PBM Coordinates		CFO Coordinates		Δ	
	x_1	x_2	x_1	x_2	$x_1^{PBM} - x_1^{CFO}$	$x_2^{PBM} - x_2^{CFO}$
1	2.58λ	0.63	2.55088λ	0.61805	0.02912 λ	0.01195
2a [no noise]	$\sim 5.85\lambda$	$\pi/2$	5.92359λ	1.55685	-0.07359 λ	0.01395
2b [noise]	nr ⁽¹⁾	nr	6.93601λ	1.54721	---	---
3	0.5	$\pi/2$	0.48024	1.57327	0.01976	-0.00247
4	1.5λ	0.834	1.49520λ	0.71098	0.00048 λ	0.12302
---	$d_i, i = 1, \dots, N_{el} - 1$		$d_i, i = 1, \dots, N_{el} - 1$		$MAX(d_i^{PBM} - d_i^{CFO})$	
5	0.99 λ		0.98310 λ - 1 λ		0.01 λ	

Notes: (1) not reported in [6]

Table 4 compares CFO's and PBM's best fitnesses as measured by the difference of directivities, $D_{\max}^{PBM} - D_{\max}^{CFO}$. The differences are 3.43%, 0.36%, 27.74%, and 1.47%, respectively, for problems #1 through #4 [relative to PBM's values]. The agreement is quite good, except for problem #3, which would be troublesome but for the data in Table 2(a). NEC4 returned a directivity 6.15 at the points $(\beta, \theta) = (i - 0.5, \frac{\pi}{2})$, $i = 1, \dots, 4$, instead of 7.05 as reported in [6]. If, in fact, 6.15 is the correct value, then the difference decreases to a more modest 5.47%. At a minimum, there appears to be a question concerning the accuracy of the result reported in [6], and CFO's overall performance suggests that it accurately located the first global maximum for problem #3 after all. On problem #5 the directivity values are in excellent agreement across all array sizes. The differences range from only 0.08% ($N_{el} = 16$) to 0.52% ($N_{el} = 10$). In this case CFO recovered the PBM's suite best fitnesses with very high accuracy.

Table 4. Comparison of PBM and CFO best fitnesses.

PBM Problem #	CFO Results			D_{\max}^{PBM}	$D_{\max}^{PBM} - D_{\max}^{CFO}$
	x_1	x_2	D_{\max}^{CFO}		
1	2.55088λ	0.61805	3.20627	3.32	0.11373
2a (without noise)	5.92359λ	1.55685	18.3654	18.3 ⁽¹⁾	-0.0654
2b (with noise)	6.93601λ	1.54721	18.6880	nr ⁽²⁾	nr
3	0.48024	1.57327	6.48634	7.05 ⁽¹⁾	0.56366
4	1.49520λ	0.71098	5.71479	5.8 ⁽¹⁾	0.08521
---	$d_i, i = 1, \dots, N_{el} - 1$		---	---	---
5 (6 el)	0.99105 λ		11.2202	$\sim 11.25^{(3)}$	0.0298
5 (7 el)	0.98310 λ		13.1826	nr	---
5 (10 el)	0.99421 λ		19.0985	$\sim 19^{(2)}$	-0.0985

5 (16 el)	0.98958 λ		30.9742	$\sim 31^{(2)}$	0.0258
5 (24 el)	1.00000 λ		46.8813	$\sim 47^{(2)}$	0.1187

Notes: ⁽¹⁾ values marked with are estimated from the figures in [6].

⁽²⁾ nr – not reported in [6].

⁽³⁾ values marked with ~ are estimated from Fig. 13 in [6].

These data show that CFO essentially accurately recovered the global maximum for every one of the five PBM benchmark problems, with the caveat that it located only one of the four maxima for problem #3. This performance is better than any of the algorithms reported in [6]. None of the algorithms in that work achieved 100% effectiveness. CFO thus is very effective against the PBM antenna benchmarks.

3.2 Efficiency

An EA's efficiency is measured by how computationally intensive it is. As the detailed results in §6 show, CFO generally converges quickly, at least to the vicinity of a global maximum if trapping has not occurred. After its usually rapid rise, the best fitness often continues to increase, but much more slowly with only slight additional gains.

Efficiency is measured by the total number of calculations (objective function evaluations) required for the best fitness to saturate. The PBM paper examines four algorithms: **GA-FPC**, **μ GA**, **GA-RC**, and **PSO** (see [6] for details). The first three are GA variants, while the fourth is a particle swarm. Because these algorithms are stochastic, each one was run twenty times to develop statistics. The “mean hit time” in Table II in [6] is the average generation number at which the global maximum was located. Thus the *average* number of function evaluations is the product of mean hit time and the population size. Table 5 shows this measure for the PBM algorithms, along with the total number of objective function evaluations for saturation of CFO's best fitness [$N_{eval} = (j^* + 1)N_p$, where j^* is the step at which the fitness saturated, and N_p is the number of CFO “probes” (see §4.2)]. In Table 5 the best values are shown in bold red font, and the second best in bold blue.

On problem #1 CFO performed much better than all the other algorithms, requiring only 60 calculations to locate the global maximum compared to 1530 for the next best algorithm, **PSO**. On problem #2, without and with noise, CFO did not perform as well as **GA-FPC** and **μ GA** by a factor of about 2 to 3; it was on a par with **GA-RC**; and it did substantially better than **PSO**. For problem #3, CFO out-performed all the algorithms except **PSO**, whose performance was about 17% better. Two different CFO initial probe distributions were used on problem #4, with the result that CFO's performance was comparable to **GA-FPC**'s, and quite a bit better than **μ GA**'s and **GA-RC**'s, by at least a factor of 2. Compared to **PSO**, however, CFO did not do as well by a factor of about 3. Problems #5a and 5b in [6, Table II] are 7 and 13 element collinear arrays, respectively [6 @ p.1119]. For problem #5a CFO was nearly 15 times more efficient than the next most efficient algorithm, **PSO**. On problem #5b, CFO was more than 12 times more efficient, again compared to **PSO**.

Thus, CFO more than holds its own in terms of computational efficiency, especially for an algorithm that is not highly developed. Out of six problems, CFO performed the best on three, outperforming the other algorithms by a very wide margin. On problem #3, CFO turned in the second best result, but it was close to the best efficiency. On problem #4, CFO was the second best performer. And on problem #2 it was the third most efficient algorithm. Across the six problems, CFO was best on three and second best on two. **PSO** turned in the next best overall performance, placing first on two problems and second on three. On the one problem where CFO did not finish in the top two, it was the third best. Even in its infancy, CFO has proven to be very competitive in terms of efficiency.

Table 5. CFO Efficiency (# function evaluations).

Problem #	CFO N_{eval}	Results from PBM Paper [6], Table II (mean hit time x population)			
		GA-FPC	μGA	GA-RC	PSO
1	60	3140	5065	8920	1530
2a [no noise]	1320	360	450	1400	2280
2b [with noise]	768				
3	1050	1940	1685	5040	900
4	1488 ⁽¹⁾ 1155	1300	3125	3800	330

5b	144	3480	5695	nr	1770

Notes: ⁽¹⁾ different initial probe distributions.

⁽²⁾ not reported in [6].

4. THE CFO METAPHOR

There are many nature-inspired search and optimization EAs, for example, metaheuristics based on animal and insect behaviour, human population behaviour, or physical processes such as water drop pooling. Most of these algorithms are fundamentally stochastic because the processes they analogize are inherently random. In fact, their ability to locate maxima derives from this inherent randomness. Without it, these EAs cannot function.

Central Force Optimization, by contrast, is completely deterministic because it is based on the metaphor of gravitational kinematics, the branch of physics that computes the motion of masses moving solely under the influence of gravity. Because gravity is deterministic, so too is CFO. This feature is a significant improvement over stochastic algorithms. Every CFO run with the same setup parameters returns precisely the same results. But, of course, as with all deterministic methodologies, the downside is a tendency for CFO to become trapped at local maxima. In fact, the two major issues in CFO's further development appear to be (1) finding effective ways of mitigating trapping and (2) establishing a precise methodology for specifying run parameters. This section describes CFO's basic equations and discusses these issues, in particular oscillation in D_{avg} (defined below) as a harbinger of trapping and recent results in the astronomy literature that may be useful in understanding this phenomenon.

Even though CFO is fundamentally deterministic, the algorithm designer is free to inject some randomness if doing so improves performance. When local trapping occurs, stochastic perturbation of CFO's "probe" distribution may mitigate the trapping. The judicious injection of some measure of randomness has not been investigated here, but it has been used in other CFO implementations with very good results [5]. The author emphasizes CFO's deterministic nature because CFO is one of very few algorithms that provide true reproducibility and control over computed results. This characteristic may be especially useful in parameter-tuning implementations in which CFO's run parameters are adjusted using real-time feedback. Nevertheless, some CFO implementations may benefit from a stochastic component, and that possibility certainly merits consideration.

4.1 CFO, NEOs and Energy

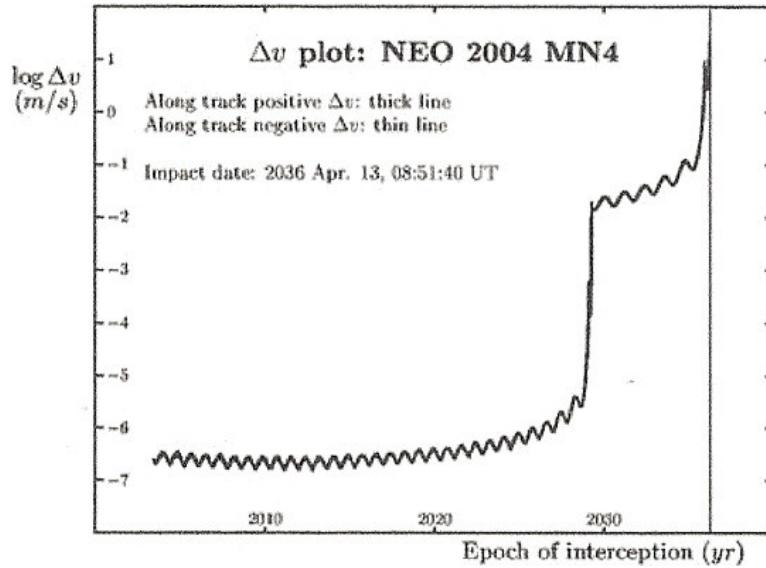

Near Earth Objects (NEOs) approaching our planet can become gravitationally "trapped" for a while. As a general rule, in the absence of friction or some other energy dissipation mechanism, an object's trajectory will depend only upon its (constant) total energy. Recent work on gravitational "resonant returns" [15], however, shows that small objects closely approaching Earth can exchange energy with the planet without dissipation and, for some time at least, become gravitationally trapped in a tight orbit. A consequence of this type of encounter is the plot in Figure 2 of [16], which is reproduced below with permission. The curve plots the velocity change Δv required to modify the trajectory of NEO asteroid Apophis to avoid a collision with Earth as a function of when the encounter occurs.

The Apophis Δv plot is particularly interesting because of its unusual structure, the two plateau-like regions with superimposed oscillation separated by a rapid rise in Δv . The oscillatory behaviour is a direct result of actual gravitational trapping in the physical Universe. For comparison, Figure 32(b) from the original CFO paper [1] also is reproduced below. It plots the average distance, D_{avg} , between CFO's probe with the best fitness and all the other probes for the 2D Step Function.

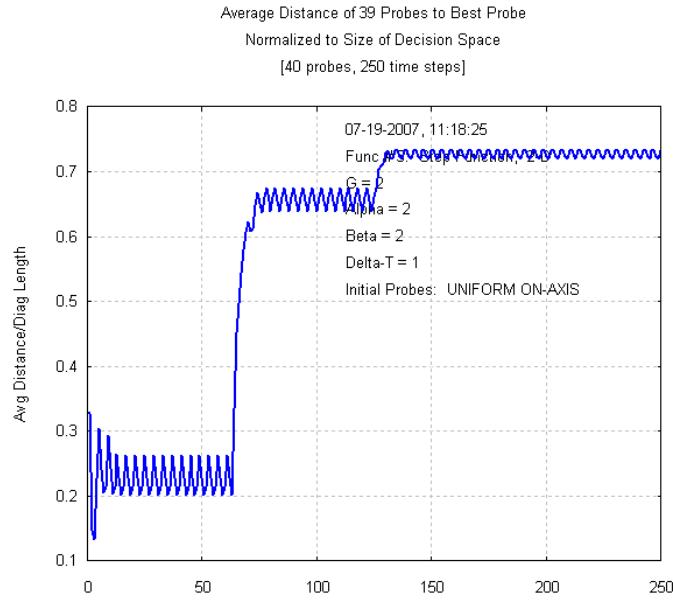

Not only is the structural similarity between the Apophis Δv plot and CFO's D_{avg} self-evident, it is quite remarkable. It is difficult to imagine that the Apophis curve, which is based on actual NEO gravitational trapping, and the CFO D_{avg} curve, which is based on the metaphor of gravitational kinematics, are not different manifestations of the same or, at a minimum, a very similar underlying phenomenon. Although admittedly speculative, the author believes that this similarity is compelling evidence of the validity of CFO's gravitational metaphor, and that it might point the way to techniques for

mitigating trapping. In particular, the analysis of Valsecchi *et al.* [15] may be directly applicable to improving CFO so that it avoids local trapping.

Another possible application of conservative energy exchange between a small object and a larger gravitating mass in a trapping encounter is using the object's total energy, E_{tot} , as a measure of trapping. This suggestion, too, is speculative in nature, but it reflects what hopefully is strong correlation between real gravitational kinematics and CFO's metaphorical search methodology. If the effect of gravitational trapping is to modify E_{tot} , then with a suitable definition of energy in CFO space E_{tot} may become a key factor in signalling trapping and possibly providing a mitigation mechanism simply by increasing its value. It may also be possible to re-formulate the basic CFO equations in terms of an energy model. Whether or not this approach has any merit is a question for researchers far more capable than the author, one that he hopes will be pursued.

Reproduction of Figure 32(b) in the original CFO Paper [1].

4.2 The CFO Equations

CFO addresses the following problem: Locate the global maxima of the objective function $f(x_1, x_2, \dots, x_{N_d})$ defined on the decision space $x_i^{\min} \leq x_i \leq x_i^{\max}$, $1 \leq i \leq N_d$, the x_i being *decision variables*, where i the coordinate number, and N_d the space's dimensionality (number of coordinates). *Fitness* refers to the value of $f(\vec{x})$ at the point \vec{x} . The objective function's topology, which is unknown, may be continuous or discontinuous, highly multimodal or unimodal, and possibly subject to a set of constraints Ω among the decision variables. While many optimization algorithms search for minima, CFO searches for maxima [which, of course, is the same as minimizing $-f(\vec{x})$].

CFO “flies” a group of “probes” through the decision space. Their trajectories are computed from the *equations of motion* for each probe’s acceleration and position vector. These equations are derived by generalizing Newton’s universal law of gravitation and law of motion from three-dimensional physical space to metaphorical N_d -dimensional “CFO space.” The resulting equations are [1-4]:

$$\vec{a}_{j-1}^p = G \sum_{\substack{k=1 \\ k \neq p}}^{N_p} U(M_{j-1}^k - M_{j-1}^p) \cdot (M_{j-1}^k - M_{j-1}^p)^\alpha \times \frac{(\vec{R}_{j-1}^k - \vec{R}_{j-1}^p)}{\|\vec{R}_{j-1}^k - \vec{R}_{j-1}^p\|^\beta} \quad (1)$$

$$\vec{R}_j^p = \vec{R}_{j-1}^p + \frac{1}{2} \vec{a}_{j-1}^p \Delta t^2, \quad j \geq 1 \quad (2)$$

The probe number is $1 \leq p \leq N_p$, and the time step (iteration) number is $0 \leq j \leq N_t$, where N_p and N_t are the *total* number of probes and the *total* number of time steps, respectively. \vec{a}_{j-1}^p is “probe” p ’s

acceleration at time step (iteration) $j-1$. $\vec{R}_j^p = \sum_{k=1}^{N_d} x_k^{p,j} \hat{e}_k$ is its position vector at step j , where the

$x_k^{p,j}$ are probe p ’s coordinates at step j , and \hat{e}_k is the unit vector along the x_k axis. Note that the version of eq. (2) in [1] contains a “velocity” term not included in the CFO formulation in [2]. The velocity term was dropped because including it actually impeded convergence (reasons unknown). In [1], however, this term already had been set to zero as a matter of convenience, so that from the outset it never was required, and consequently is no longer included.

CFO “flies” its N_p probes through the decision space as a function of time (iteration number) along trajectories calculated using equations (1) and (2). A new probe distribution is computed at each step, and at the location of each probe the objective function’s fitness is computed. For example, at time step $j-1$ at probe p ’s location, the fitness is $M_{j-1}^p = f(x_1^{p,j-1}, x_2^{p,j-1}, \dots, x_{N_d}^{p,j-1})$. Note that M does *not* mean “mass” (see [1] for a discussion of the symbology). Each of the other probes has a fitness M_{j-1}^k , $k = 1, \dots, p-1, p+1, \dots, N_p$, associated with it at step $j-1$.

The function $U(\cdot)$ in eq. (1) is the Unit Step function, $U(z) = \begin{cases} 1, & z \geq 0 \\ 0, & \text{otherwise} \end{cases}$. Following

standard notation, the magnitude of vector \vec{B} is $\|\vec{B}\| = \left(\sum_{i=1}^{N_d} b_i^2 \right)^{\frac{1}{2}}$, where the b_i are its scalar

components. G is CFO’s “gravitational constant,” and Δt the “time” interval between steps during which the acceleration is constant. It is important to remember that this terminology is chosen solely to reflect CFO’s gravitational metaphor, as is the factor $\frac{1}{2}$ in eq. (2), and beyond that there is no significance to the

nomenclature. α and β are the CFO exponents. While G and Δt have direct analogs in the equations of motion for gravitationally controlled real masses moving through physical space, there is no analog in Nature for α and β . They are included to provide added flexibility in how CFO is implemented by giving the algorithm designer the freedom to change how CFO’s “gravity” varies with mass or distance, or both, in order to achieve a more effective algorithm. Of course, α and β are perfectly acceptable parameters in metaphorical “CFO space,” because there gravity can be whatever the designer wants it to be.

The Unit Step function in eq. (1) is extremely important because it creates positive-definite CFO mass. Under the gravitational analogy on which CFO is based objects in CFO space have “mass” just as they do in the physical Universe. But unlike real objects, mass in CFO space is a *user-defined* function of the objective function’s fitness (not necessarily the fitness value itself). The problem is, depending on how the user defines that function, that the mass can be positive or negative. And negative mass leads to serious problems!

In this paper CFO “mass,” by definition, is $U(M_{j-1}^k - M_{j-1}^p) \cdot (M_{j-1}^k - M_{j-1}^p)^\alpha$, that is, the difference in fitness values raised to the α power multiplied by the Unit Step. The *difference* of fitnesses intuitively seems to be a good measure of how much “gravitational” influence the value of the objective function at one point in the decision space should have on a probe at another point in the space, but other choices certainly are possible. The exponent α is optional, giving the algorithm designer added flexibility as discussed above. In marked contrast, with the difference of fitnesses definition, the Unit Step is an essential element, because without it the mass could be negative depending on which fitness is greater. In the real world, gravity always is attractive because mass is positive. Negative mass creates a repulsive gravitational force that flies probes away from maxima, instead of the positive gravitational force required to fly probes toward them. This is just the opposite of what CFO is intended to do. The Unit Step solves the negative mass problem by creating positive-definite CFO mass and, consequently, a positive gravitational force that always is attractive.

A frequently used measure of how well CFO’s probes have clustered at a maximum is the average distance between the probe with the best fitness and all the other probes, normalized to the size of the decision space (length of the principal diagonal), that is,

$$D_{avg} = \frac{1}{L \cdot (N_p - 1)} \sum_{p=1}^{N_p} \sqrt{\sum_{i=1}^{N_d} (x_i^{p,j} - x_i^{p*,j})^2} \quad \text{where } p^* \text{ is the number of the probe with the best fitness, } L = \sqrt{\sum_{i=1}^{N_d} (x_i^{\max} - x_i^{\min})^2} \text{ is the diagonal length, and } \vec{R}_j^p = \sum_{k=1}^{N_d} x_k^{p,j} \hat{e}_k \text{ is probe } p \text{'s position vector at step } j.$$

Plotting D_{avg} as a function of the time step is helpful in showing how the probe distribution evolves. As pointed out in §4.1, oscillation in D_{avg} appears to be a sufficient but not necessary condition for local trapping of CFO’s probe with the best fitness.

4.3 A New “Hyperspace Directional Derivative”?

The Unit Step introduced in the definition of mass in §4.2 may be important in another, purely mathematical way. It may be the basis for defining a new type of “hyperspace directional derivative.” In

Nature, gravity is a conservative vector force field that produces “action at a distance.” While its fundamental equations are vector in nature, gravity also can be calculated as the gradient of a scalar potential function, just as the electric field is derived from an electric potential. The general notion of a “gradient” also applies in CFO space, but to some degree its utility depends on how mass is defined. For example, in this CFO implementation with $\alpha = \beta = 2$, the difference in fitness values divided by the distance between probes is essentially the square of the average slope, that is, the square of a derivative. When the Unit Step is included, this term, in a general sense, may be thought of as a sort of “generalized derivative.” However, with entirely different CFO mass definitions, or the present definition with different exponent values, this generalization may not be as apparent or compelling; but in this case it seems both clear and appropriate. This observation suggests the possibility of defining a new mathematical construct, a “hyperspace directional derivative,” that includes the Unit Step so that it always points towards an objective function’s maxima. The author makes this suggestion entirely on a speculative basis. As with the “energy” notions discussed in §4.1, whether or not this suggestion makes any sense is a question left to the mathematicians who hopefully will pursue CFO’s further development.

4.4 CFO Parameters

The CFO implementation described in this paper uses seven run parameters: α , β , G , Δt , N_t , N_p , and F_{rep} . They are all defined above, except F_{rep} , the “repositioning factor.” [Note that probe initial acceleration could be used as an eighth parameter, but it is zero for all runs reported here.] F_{rep} is an algorithmic element and has nothing to do with fundamental CFO theory. For the specific CFO implementation used in this paper, F_{rep} addresses the problem of errant probes. When equations (1) and (2) in §4.2 are used to compute a probe distribution, some “errant” probes may end up with coordinates outside the decision space domain. When that happens the question is, how to get them back? There are many possibilities. For example, the decision space boundary could be made “reflecting” (probes bouncing back into the decision space) or “absorbing” (probes extinguished and replaced with a new ones), and so on. A simple empirical scheme is used here.

On a coordinate-by-coordinate basis, probes flying out of the decision space are placed a fraction, F_{rep} , of the distance between the probe’s starting coordinate and the corresponding boundary coordinate. But because there is no obvious way to assign a value to $0 \leq F_{rep} \leq 1$, the following simple, deterministic (somewhat clumsy, but workable) approach was taken. At each step, the current and previous 4 fitness values were stored in a 5-element array. F_{rep} started at a value of 0.5 and was incremented by 0.005 whenever the absolute value of the difference between 5th array element and the average value of elements 3, 4, and 5 differed by less than 0.0005. If incrementing F_{rep} in this manner resulted in $F_{rep} \geq 1$, then it was reset to the starting value, and this procedure was repeated with the then current probe distribution. If the data reported here are used for validation, it is important to note that the 5 saved fitness values are not necessarily sequential because of how the array index was computed (see pseudocode in Appendix B for details), which then affects when F_{rep} is incremented. F_{rep} ’s starting value and increment, and the fitness tolerance were determined empirically, that is, on a trial and error basis, as are all CFO parameters used in this and the other CFO papers.

Of all the CFO parameters, F_{rep} and N_p seem to have the greatest effect by far on the algorithm’s performance. The sensitivity to F_{rep} is what led to the empirical scheme described above. Changing F_{rep} generally improves convergence, because doing so avoids or terminates local trapping (this effect discovered empirically). The number of probes, N_p , determines how well the decision space is sampled, that is, how much information CFO has about the objective function at the start of a run.

Numerical testing shows that CFO's convergence frequently is a sensitive function of how many initial probes are deployed. Another related non-numerical factor is where the initial probes are placed. As some of the cases in §6 show, changing the initial probe distribution may make the difference between capturing the global maximum or missing it.

The question of how best to assign values to CFO's run parameters is extremely important, yet it remains unanswered because CFO is in its infancy. At this point there is no methodology. Like most EAs, actually using the algorithm for a specific problem or class of problems, that is, setting up and making many runs, results in the user's learning how to make best use of the algorithm. Some parameter values work better than others, and the experience gained by making many runs is reflected in the user's choice of parameters in subsequent ones. Of course, the result is that the user *de facto* becomes a part of the algorithm because every run includes a degree of subjectivity. Needless to say, EAs should be implemented using an objective methodology to determine run parameters, but there presently is none for CFO, and, for that matter, for most EAs. One advantage CFO offers is its being deterministic. Results that are reproducible from one run to the next, coupled with CFO's frequently rapid convergence, even if to a local maximum, lend CFO to implementations that perform real-time parameter adjustments in response to a feedback mechanism. This sort of *Reactive Search* is proposed in [17], and it may be particularly appropriate for CFO because the algorithm is fast and deterministic.

5. PBM BENCHMARKS – ANTENNA GEOMETRIES & LANDSCAPE PLOTS

This section describes each PBM benchmark antenna and, for the 2D cases, its decision space using a perspective view of the topology. Additional perspective plots and projections onto the decision space's principal planes are included in Appendix A, as are samples of the NEC4 input/output files used to generate the plots and to validate NEC4.

5.1 Benchmark #1: Variable Length Center-Fed Dipole

The antenna geometry for Problem #1 is shown in Fig. 1. The objective is to maximize a center-fed dipole's directivity, D , as a function of its total length, L , and the polar angle, θ . A perspective view of the 2D landscape appears in Fig. 2, with additional plots in Appendix A. The topology is smoothly varying with a single global maximum and two local maxima of similar amplitude.

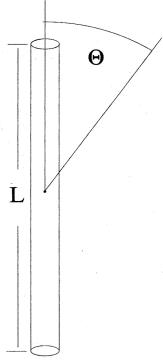

Fig. 1. Dipole.

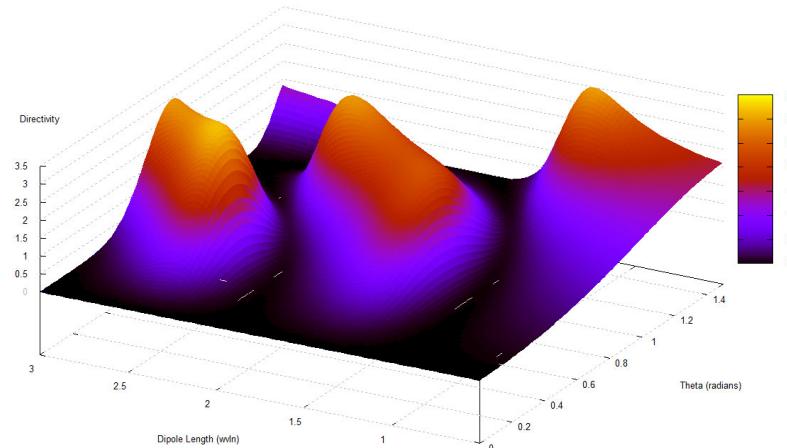

Fig. 2. Benchmark #1 topology, perspective view.

5.2 Benchmark #2: Uniform Dipole Array

The problem #2 antenna is the uniform array of half-wave dipoles shown in Fig. 3. All elements are center-fed with in-phase equal amplitude sources. The standard right-handed Cartesian coordinate system used by NEC4 also is shown, as are the polar angle θ and azimuth angle ϕ . The objective is to maximize

directivity $D(d, \theta)$ in the plane $\phi = 90^\circ$ as a function of element separation d and polar angle θ in the presence of additive Gaussian noise. Fig. 4(a) shows the landscape without noise, and Fig. 4(b) with it. Following [6], noise is generated by adding to the NEC4-computed directivity a normally distributed zero-mean, 0.2-variance random variable z , here computed using the Box Muller method [18,19] as:

$$z = \mu + \sigma \sqrt{-2 \ln(s)} \cos(2\pi t)$$
, where μ and σ , respectively, are the mean (zero) and standard deviation (0.4472), and s and t are random variables uniformly distributed on $[0,1]$. s and t are generated using the compiler's internal RND function [20] seeded with the CFO run's start time.

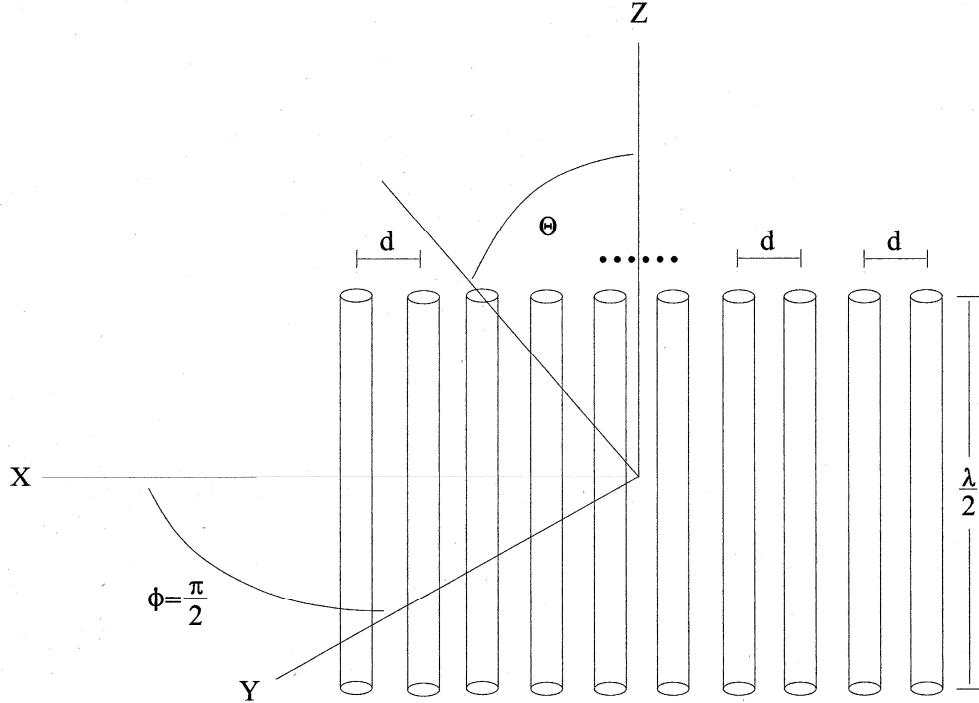

Fig. 3. Uniform Array of Half-Wave Center-Fed In-Phase Dipoles.

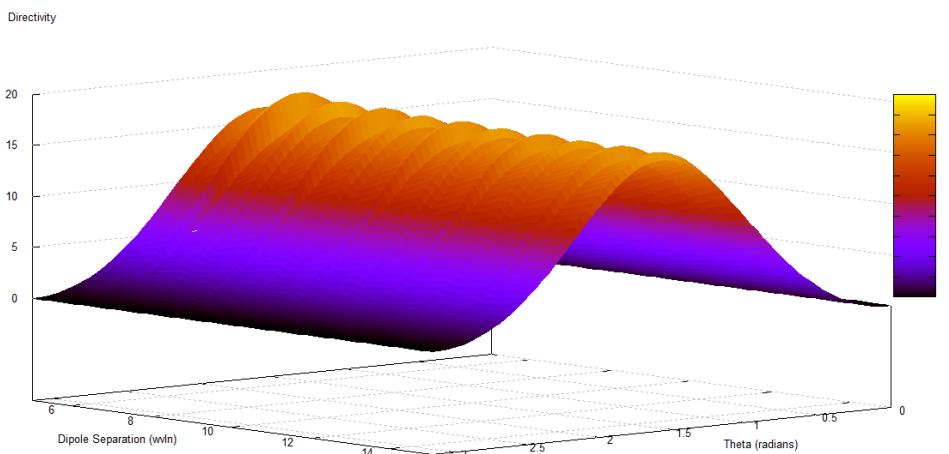

Fig. 4(a). Uniform half-wave dipole array without noise, perspective view.

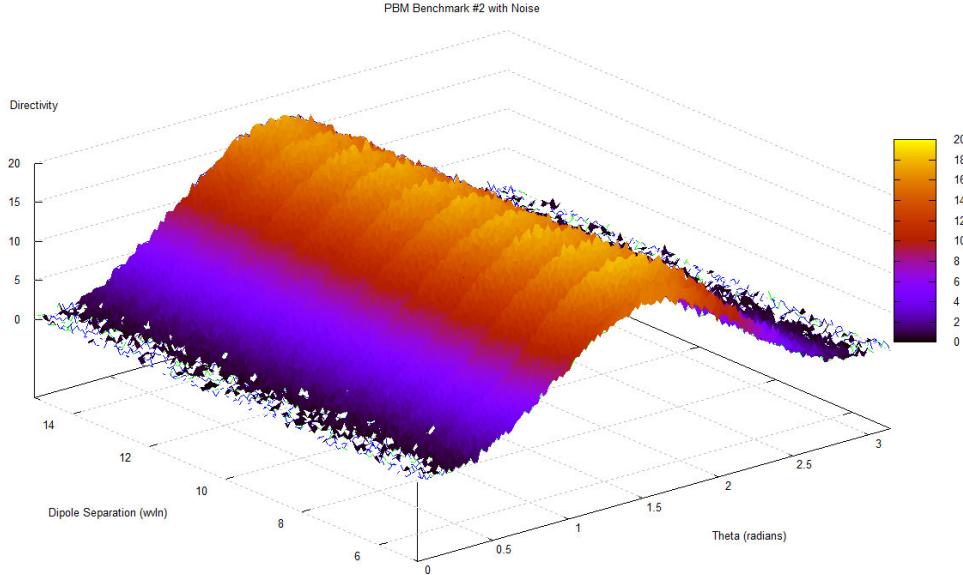

Fig. 4(a). Uniform dipole array with additive Gaussian noise, perspective view.

5.3 Benchmark #3: Circular Array of Half-Wave Dipoles

The antenna for problem #3 is the circular array of half-wave dipoles shown in Fig. 5. The array comprises eight dipoles parallel to the z-axis uniformly deployed on a one-wavelength radius circle. All elements are center-fed by equal-amplitude sources; but, following [6], the phase varies as $\alpha_n = -\cos[2\pi\beta(n-1)]$, $n = 1, \dots, 8$. The unit-amplitude excitation therefore is $V_n = \cos\alpha_n + j\sin\alpha_n$. The objective is to maximize the directivity $D(\beta, \theta)$ in the plane $\phi = 0^\circ$ as a function of the dimensionless phase parameter $0 \leq \beta \leq 4$ and the polar angle θ . The range for β produces the four global maxima at $(\beta_i = i - 0.5, i = 1, \dots, 4; \theta = \frac{\pi}{2})$ seen in the perspective topology plot in Fig. 6.

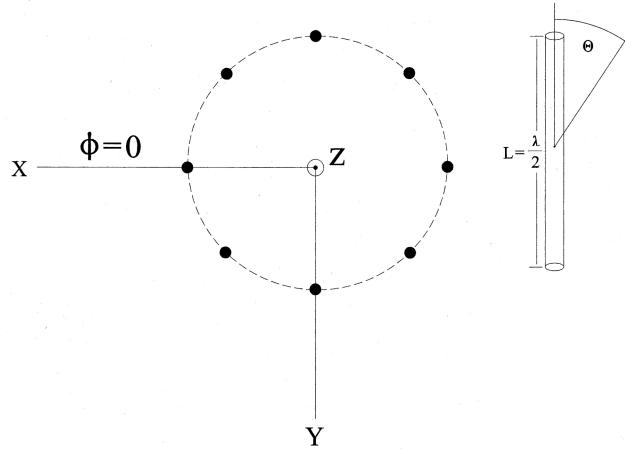

Fig. 5. Circular Array of Half-Wave Dipoles (1λ radius)

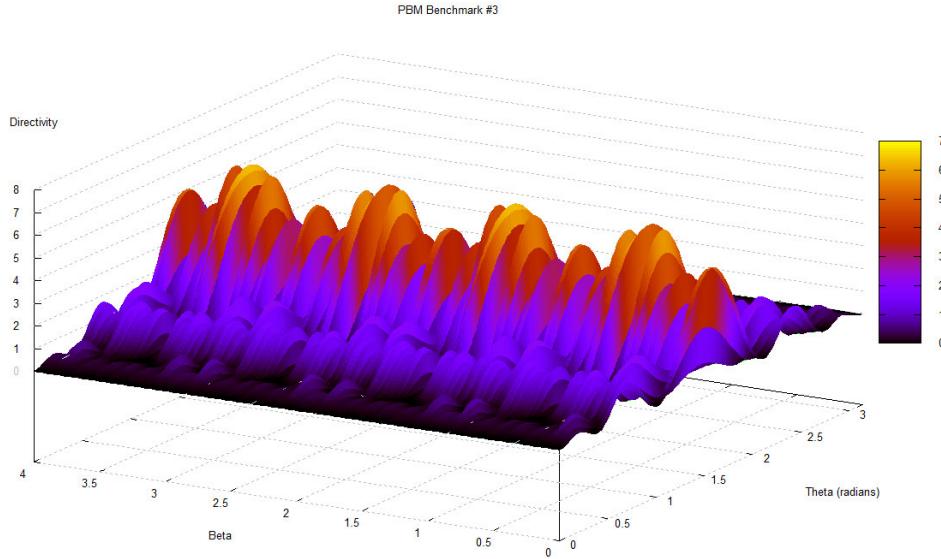

Fig. 6. Circular array landscape, perspective view.

5.4. Benchmark #4: Vee Dipole

The Vee-dipole antenna for benchmark #4 is shown in Fig. 7. The antenna comprises two arms of length L_{arm} with inner angle 2α connected by a feed segment of length $2L_{feed}$ fed at its midpoint. The objective is to maximize the directivity $D(L_{total}, \alpha)$ along the +X-axis as a function of the total dipole length $0.5\lambda \leq L_{total} = 2L_{arm} + 2L_{feed} \leq 1.5\lambda$ and the inner half-angle $\frac{\pi}{18} \leq \alpha \leq \frac{\pi}{2}$ with $L_{feed} = 0.01\lambda$. Topology of benchmark #4's

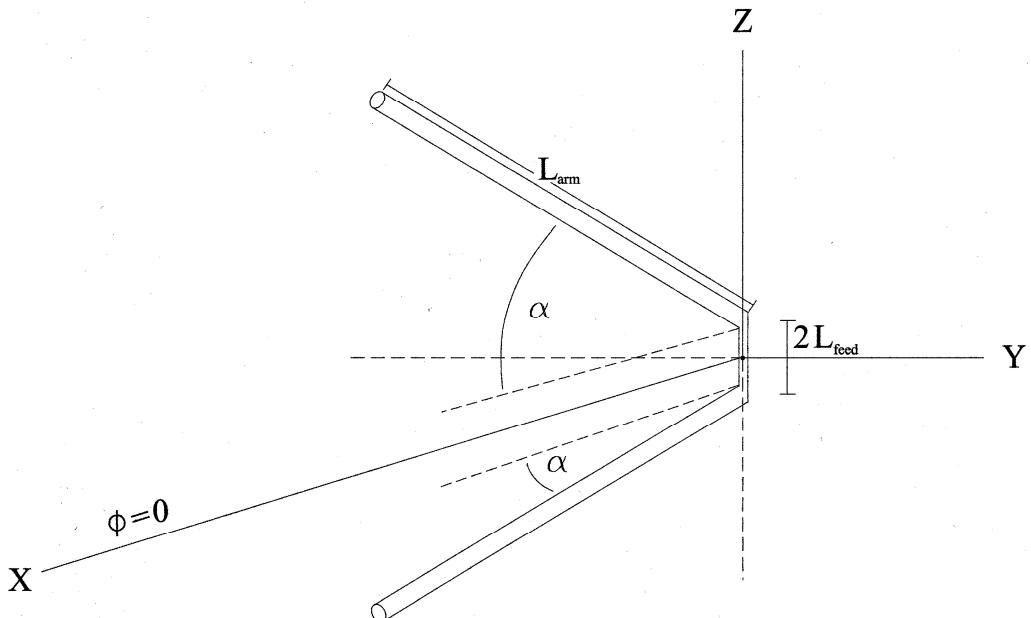

Fig. 7. Vee Dipole

decision space appears in Fig. 8. This objective function is unimodal with a single global maximum at $D(L_{total}, \alpha) = (1.5\lambda, 0.834)$. The surface is smoothly varying without pronounced local maxima.

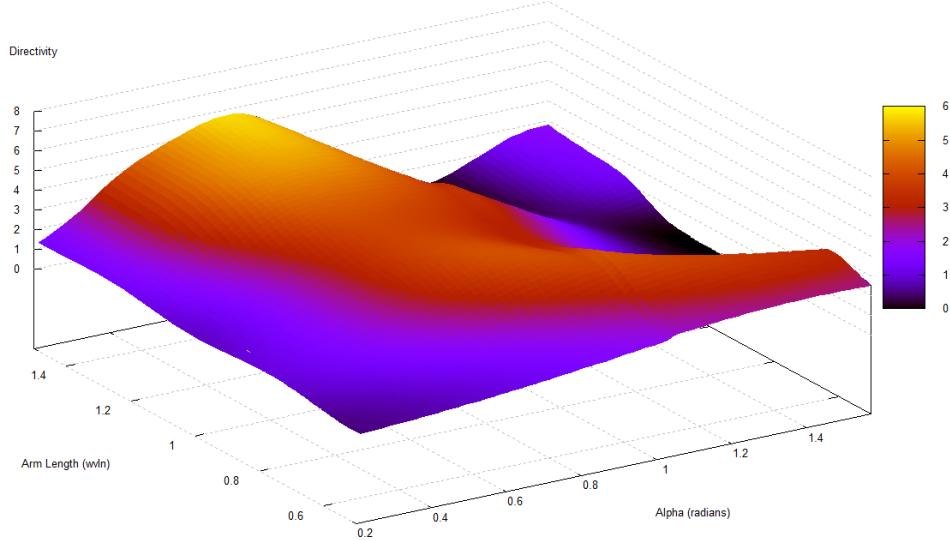

Fig. 8. Vee dipole decision space topology, perspective view.

5.5. Benchmark #5: *N*-element Collinear Dipole Array

Benchmark #5 is a collinear array of N_{el} half-wave dipoles as shown in Fig. 9. All elements are center-fed in-phase with equal amplitudes sources. The objective is to maximize directivity $D(d_i, i = 1, \dots, N_{el} - 1)$ in the plane $\phi = 0^\circ$ as a function of the element center-to-center spacings $0.5\lambda \leq d_i \leq 1.5\lambda$. Because there are $N_{el} - 1$ spacings in an N_{el} array, the dimensionality of this problem is $(N_{el} - 1) D$, unlike the previous four benchmarks each of which is 2D. As discussed at length in [6], maximum directivity occurs at $d_i = 0.99\lambda, \forall i$ independent of the number of elements, that is, with all dipoles spaced 0.99λ regardless of the array size. Of course, the value of the directivity does depend on the array size, increasing approximately in proportion to the length.

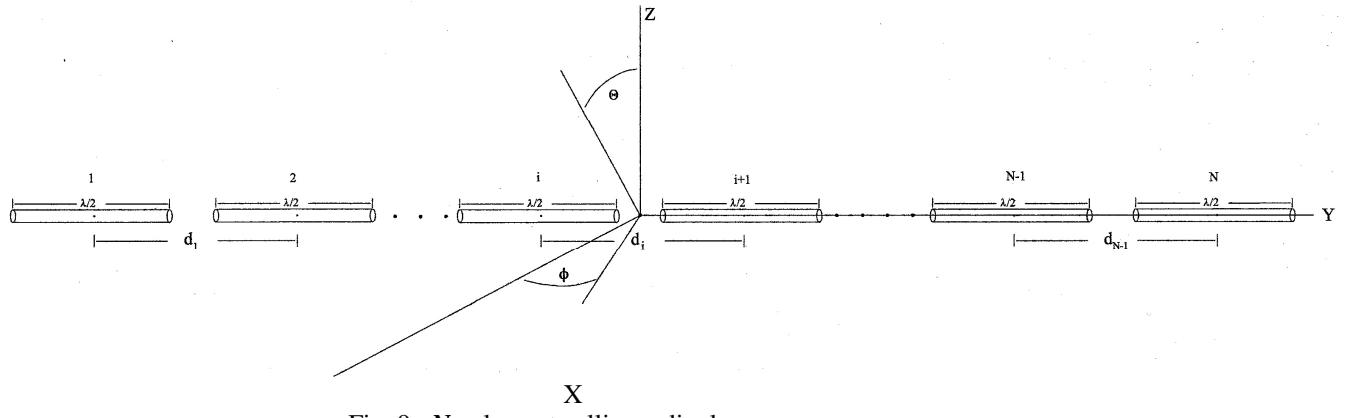

Fig. 9. N_{el} -element collinear dipole array.

6. CFO PERFORMANCE AGAINST PBM BENCHMARKS IN DETAIL

This section discusses in detail CFO's performance against the PBM benchmark suite. The following parameter values were used for all runs reported here: $\alpha = 2$, $\beta = 2$, $G = 2$, $\Delta t = 1$. The numbers of time steps and probes, N_t and N_p , respectively, vary from run to run. And the important repositioning factor, F_{rep} , is variable as described in §4.4 and Appendix B. *All CFO run parameters are determined empirically because at this time there is no methodology for assigning parameter values.*

6.1 Benchmark #1: Variable Length, Center-Fed Dipole

The CFO run was made with $N_t = 100$ and $N_p = 4$. The initial probes were located symmetrically in the (L, θ) -plane at $(1.333\lambda, \frac{\pi}{4})$, $(2.167\lambda, \frac{\pi}{4})$, $(1.75\lambda, \frac{\pi}{6})$, $(1.75\lambda, \frac{\pi}{3})$ as shown in Fig. 10. The best fitness value of 3.2062693 was returned at step #14 at the point $(L, \theta) = (2.55088\lambda, 0.618046)$. While the PBM paper [6] reports a maximum directivity of 3.32 at $(L, \theta) = (2.58\lambda, 0.63)$, the directivity computed at that point by NEC4 is 3.2. CFO's returned value thus appears to be the actual maximum value that is computed by NEC4.

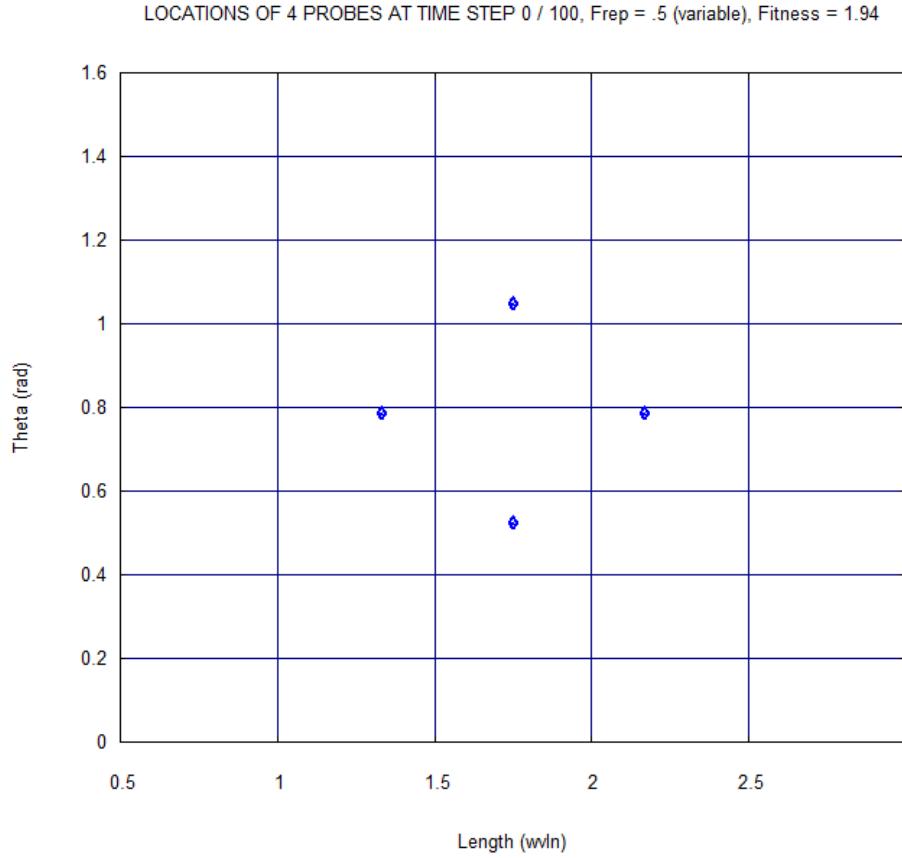

Fig. 10. Initial probe distribution for benchmark #1.

Table 6 shows the best fitness values at time steps when they changed. Saturation occurred at step #14, after only $N_{eval} = 60$ function evaluations [$N_{eval} = (j+1)N_p$ where j is the time step number]. The run was terminated at step #100, and there was no change in fitness through that step. Figures 11(a)

and (b) plot as a function of time step the best fitness and average distance between the probe with the best fitness and all other probes. In this case the best fitness increases in a step-wise fashion, whereas in many other CFO runs the increase is smoother. The plateau between steps #0 and 1 is a consequence of zero initial acceleration (it also will appear in all subsequent plots). Because the acceleration is zero, the probe distribution does not change. The D_{avg} curve shows an erratic gradual decrease with a spike near step #70 followed by what visually appears to be complete coalescence of the probes thereafter. Inspection of the plot data, which are not tabulated here, shows that D_{avg} is, in fact, constant at 0.001255 between steps #84 and 100, inclusive. Thus, all four probes have converged on the maximum, and it is reasonable to expect that the probe distribution at that point is static.

Table 6. Best fitnesses for benchmark #1.

Step #	Fitness	N_{eval}
0	1.9364220	4
1	1.9364220	8
3	2.7352687	16
7	3.0338912	32
14	3.2062693	60
100	3.2062693	404

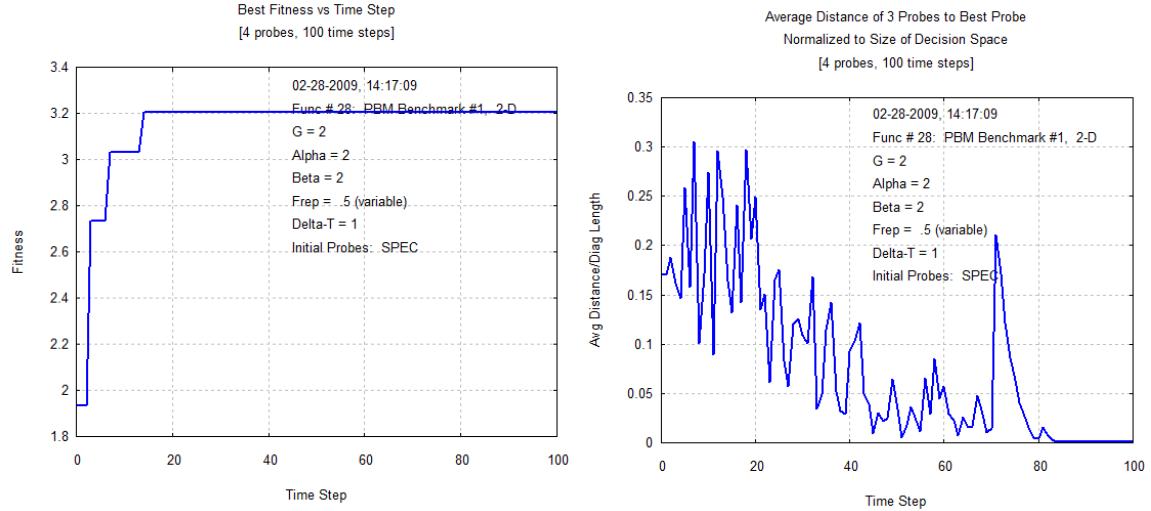

Fig. 11(a). Prob. #1 best fitness

Fig. 11(b). Prob. #1 D_{avg}

6.2. Benchmark #2: Uniform Dipole Array, Added Noise

Two CFO runs were made for problem #2, the first without noise, the second with additive Gaussian noise (see §5.2). $N_p = 24$ for both runs with initial probes deployed in the (d, θ) -plane in a 6x4 grid as shown in Fig. 12. $N_t = 250$ for the noiseless run. Figs. 14(a) and (b) plot the evolution of the best fitness and D_{avg} , respectively. The fitness values at steps where they changed appear in Table 7. The best fitness was 18.3653834 at step #207 at $(d, \theta) = (5.92359\lambda, 1.55685)$. It increased very quickly through step 10 and slowly thereafter. The probe distribution at step #250 appears in Fig. 13, and it shows that by then almost all the probes have coalesced on the maximum. But at least one probe appears to be

stuck at $(0.5\lambda, 0)$. The reason for this behavior (which has occurred in other CFO runs) is not understood. The D_{avg} curve in Fig. 14(b) clearly exhibits the oscillatory behavior that seems to be characteristic of local trapping, this time at the global maximum. Comparing these results to the PBM data show that CFO has successfully located the global maximum when the landscape is quiet.

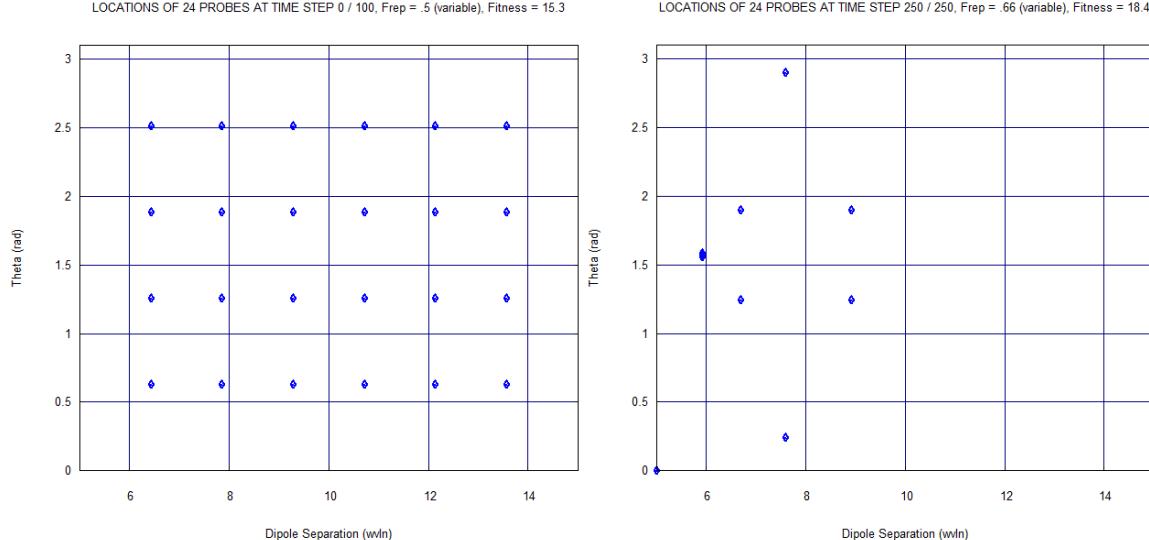

Fig. 12. Prob. #2 initial probes.

Fig. 13. Probes at step #250, no noise.

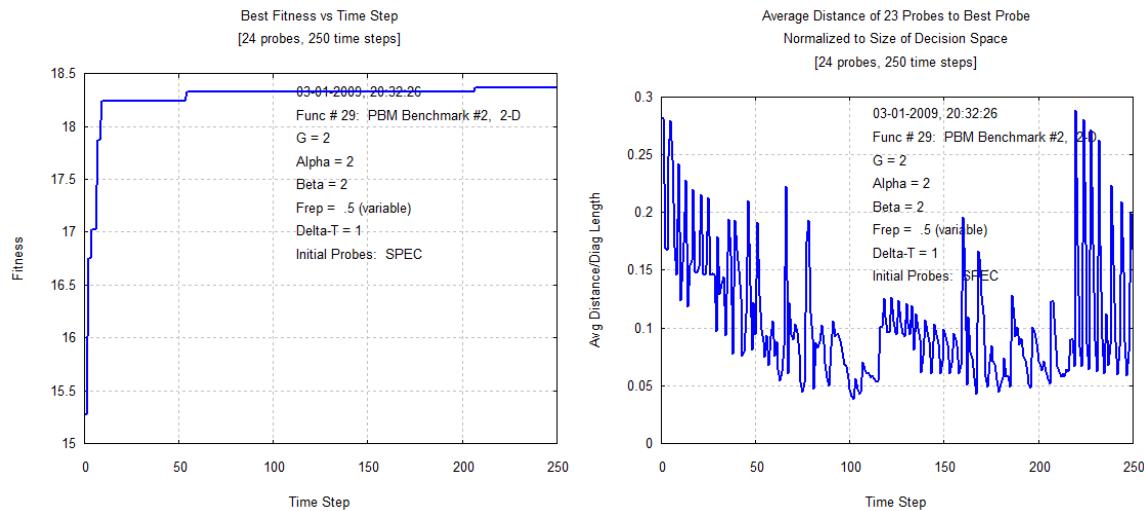

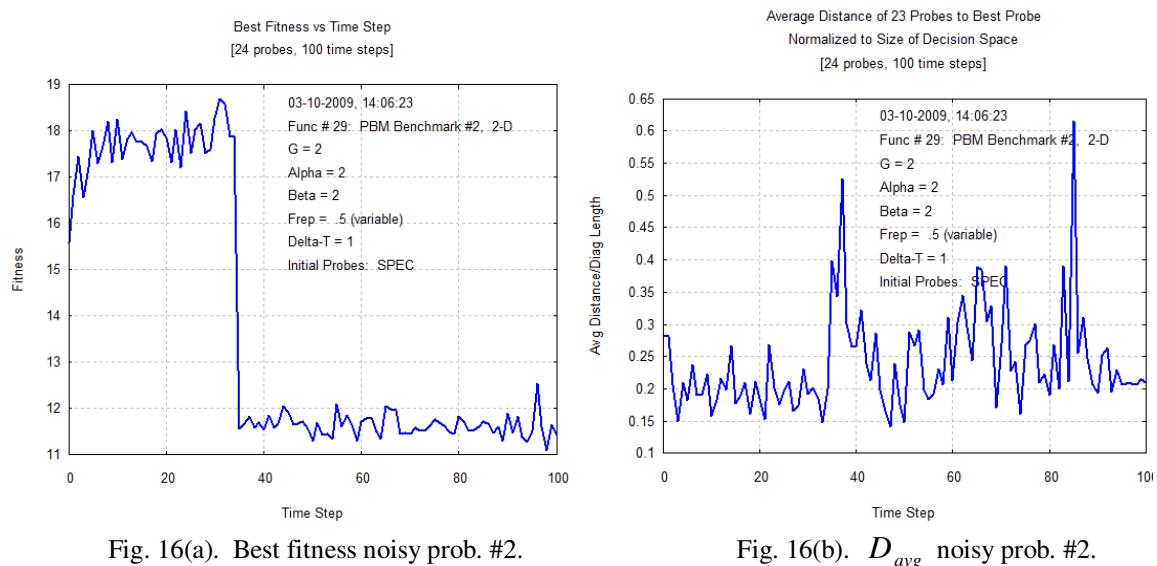

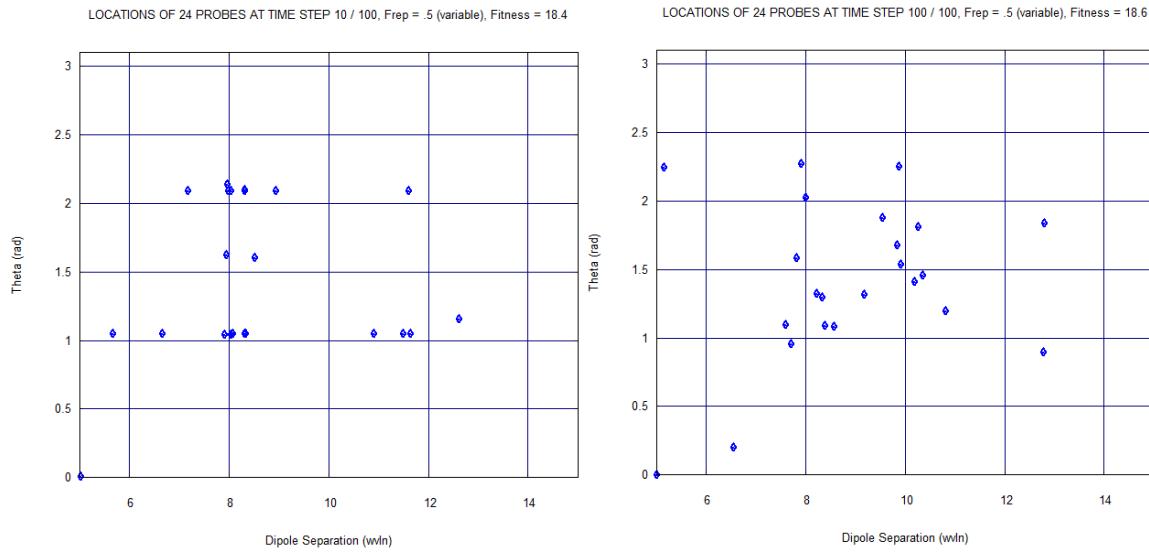

Fig. 14(a). Prob. #2 best fitness, no noise.

Fig. 14(b). Prob. #2 D_{avg} , no noise.

Table 7. Best fitnesses for benchmark #2 without noise.

Step #	Fitness	N_{eval}
0	15.2756606	24
1	15.2756606	48
2	16.7494288	72
4	17.0215851	120
7	17.8648757	192
9	18.2389570	240
54	18.3231442	1320
207	18.3653834	4992
250	18.3653834	6024

The second, noisy run was made with $N_t = 100$. Because of the additive noise, the best fitness changed at every time step. Inspection of the tabulated data (not shown) reveals that no two successive fitness values were the same. This result is expected because the normally distributed noise was added to the returned fitness at each calculation of the objective function's value. The best fitness occurred at step #31 with a value of 18.6880533 at $(d, \theta) = (6.93601\lambda, 1.54721)$. Consistent with the noisy landscape, the probe distributions fluctuate from step to step. Figs. 15(a) and (b) show the probe locations in the (d, θ) -plane at steps 10 and 100, respectively, and neither plot has probes clustered near the maximum. Interestingly, the probe “stuck” at $(0.5\lambda, 0)$ is still evident. The evolution of the best fitness and D_{avg} are plotted in Figs. 16(a) and (b), respectively.

The fitness curve is quite interesting. There is an erratic increase to the global maximum at step #31, but there appears to be a clear upward trend in the data. Within a few steps of locating the maximum, the

fitness drops precipitously, followed by an erratic variation around a value of about 11.5. The D_{avg} curve also fluctuates erratically. Through step #31 the variation is around an “eyeball average” just below 0.2, and after that the variability increases substantially with no “average” value being evident. These behaviors in the best fitness and D_{avg} do not have obvious explanations. Nevertheless, it is clear that CFO did successfully locate the global maximum even in the noisy decision space.

6.3 Benchmark #3: Circular Array of Half-Wave Dipoles

The CFO run for problem #3 was made with $N_t = 300$ and $N_p = 10$ probes initially placed on the β, θ -axes as shown in Fig. 17(a). Five probes were equally spaced on each of the decision space coordinate axes. Clustering of the probes at step #300 is shown in Fig. 17(b). One of the four global maxima was found at step #104 with a value of 6.4863443 at $(\beta, \theta) = (0.480235, 1.57327)$. The returned coordinates are close to the known first maximum’s location of $(0.5, \frac{\pi}{2})$. But CFO did not locate the other three global maxima, a result that perhaps is not too surprising in view of the small number of probes and their initial deployment.

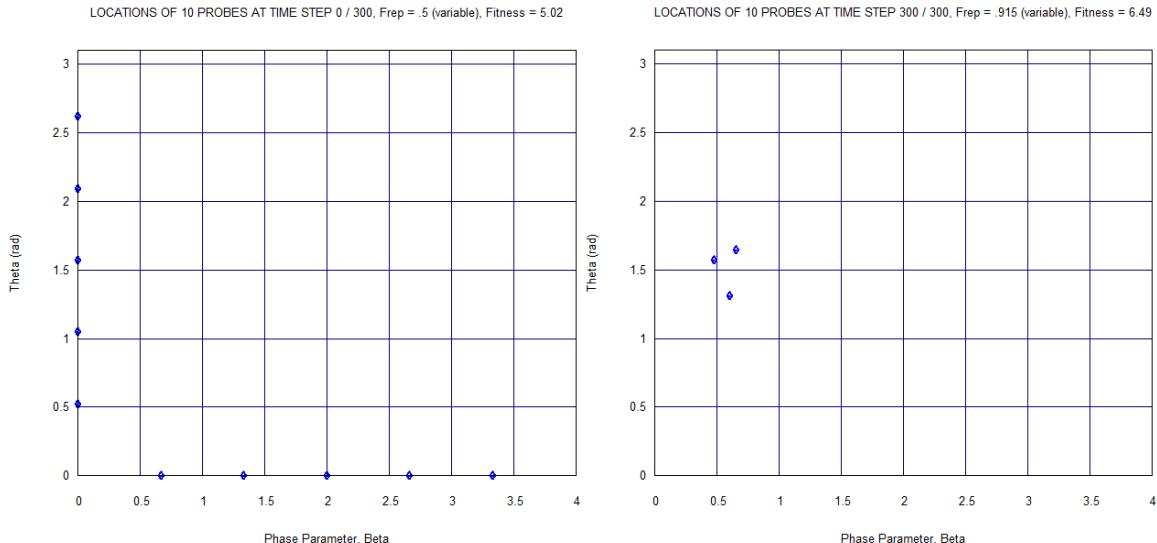

Fig. 17(a). Prob. #3 initial probes.

Fig. 17(b). Prob. #3 probes at step #300.

Figs. 18(a) and (b) plot the fitness and D_{avg} evolution, respectively, and Table 8 lists the fitness values at time steps when they changed. As is often the case, CFO’s best fitness increased very quickly through the first four steps, thereafter increasing much more slowly. The fitness saturated at step #104. The D_{avg} curve is a good example of the oscillatory behavior that signals local trapping. Several distinct regions are evident in the plot, and each one presumably corresponds to a more or less stable oscillatory probe distribution. But the regions do not exhibit any obvious correlation to the plateaus in the fitness curve.

This problem provides a good example of how important the initial probe distribution can be in adequately sampling the objective function’s topology. Because only one of the four global maxima was found, a second run was made with a much denser initial probe distribution, 100 probes instead of 10,

deployed in a uniform 10×10 grid with $(\Delta\beta = 0.3636, \Delta\theta = \frac{\pi}{11})$, with the other run parameters unchanged.

However, the run length was necessarily short, $N_t = 20$, because of excessive runtime. CFO failed to locate a global maximum. It returned a best fitness of 5.7543994 at the point $(\beta, \theta) = (1.63636, 1.68534)$ after only three steps. It appears that the initial probe distribution trapped CFO at a local maximum almost from the beginning of the run, and that only a very much longer run would determine whether or not a better fitness would evolve.

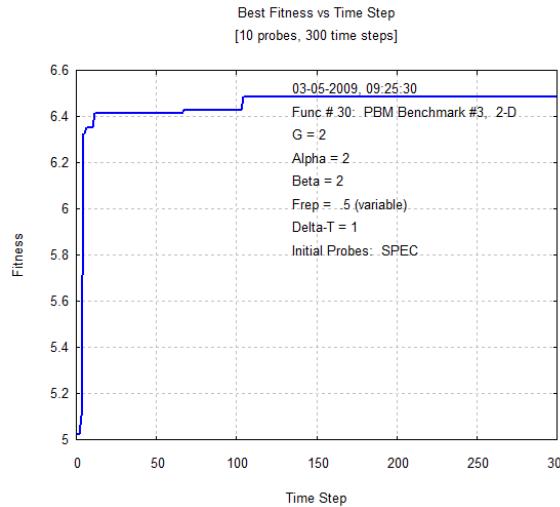

Fig. 18(a). Best fitness, prob. #3.

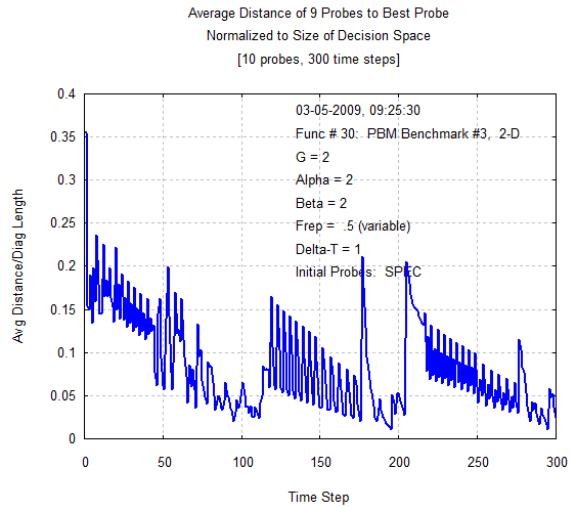

Fig. 18(b). D_{avg} , prob. #3.

Table 8. Best fitnesses for benchmark #3.

Step #	Fitness	N_{eval}
0	5.0234259	10
1	5.0234259	20
3	5.1050500	40
4	6.3241185	50
6	6.3533093	70
11	6.4120958	120
67	6.4268772	680
104	6.4863443	1050
300	6.4863443	3000

6.4. Benchmark #4: Vee Dipole

Problem #4 provides another interesting example of the importance of the initial probe distribution. Two runs were made with different distributions as shown below. Both converged on the single global maximum, but one was slightly more accurate. The first run was made with $N_t = 250$ and $N_p = 12$. The initial 3×4 probe grid and the probes at step #250 appear in Figs. 19(a) and (b), respectively. The global maximum was located at the point $(L_{arm}, \alpha) = (1.48104\lambda, 0.708983)$ with a value of 5.6885293 saturating at step #61 (see Table 9 for fitness values when they changed). The fitness evolution plot in Fig. 20(a) shows a very rapid initial increase through step #3 followed by step-wise increases

through step #61. The D_{avg} plot in Fig. 20(b) is quite erratic and shows no sign of the oscillation associated with trapping.

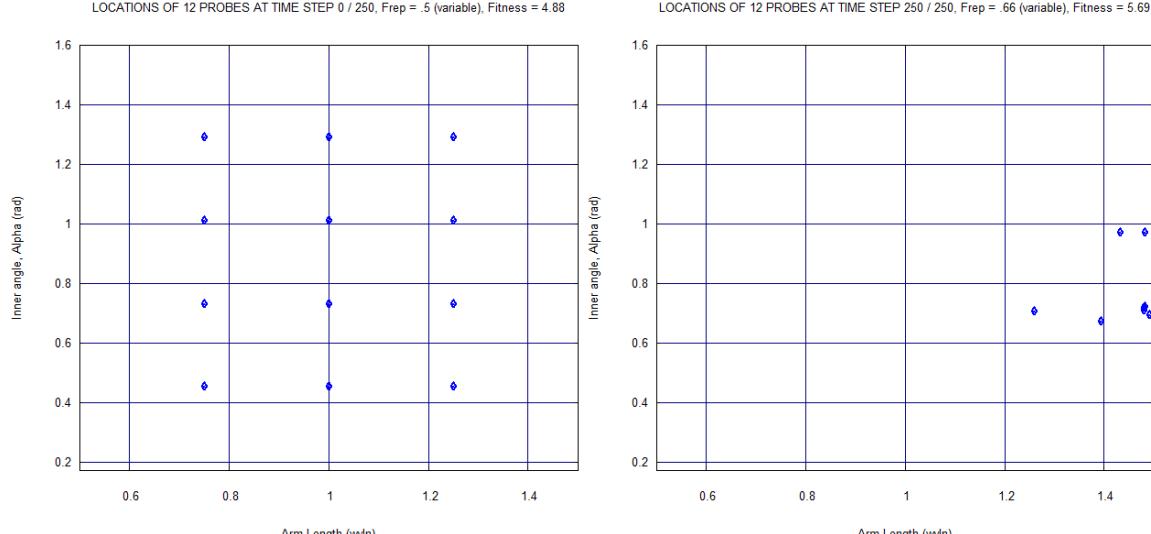

Fig. 19(a). Prob. #4 initial probes.

Fig. 19(b). Prob. #4 probes at step #250.

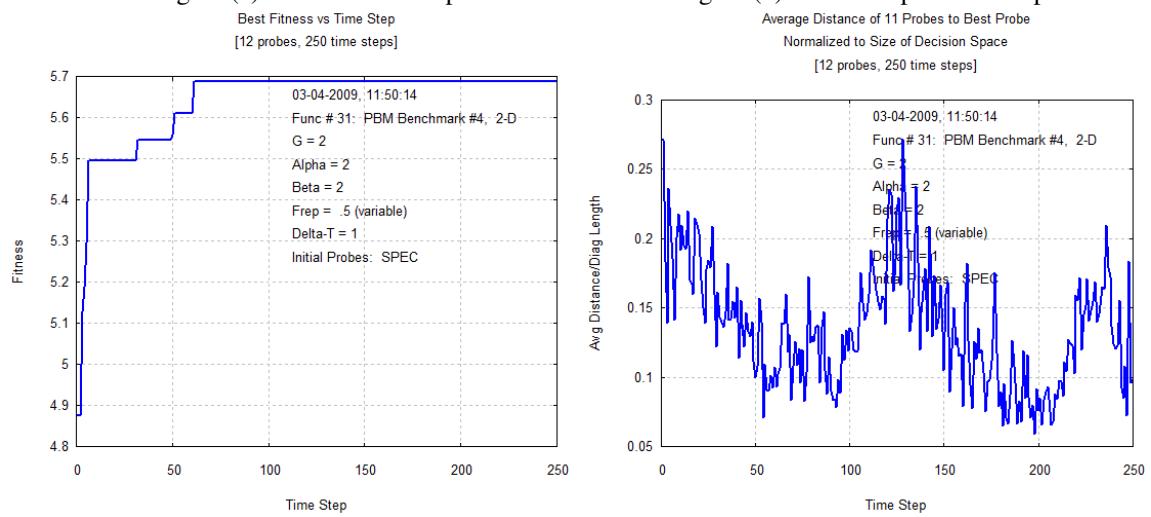

Fig. 20(a). Best fitness, prob. #4.

Fig. 20(b). D_{avg} , prob. #4.

Table 9 Best fitnesses for benchmark #4, run 1.

Step #	Fitness	N_{eval}
0	4.8752849	12
1	4.8752849	24
3	5.1286138	96
4	5.1880004	120
5	5.2966344	144
6	5.4954087	168
32	5.5462571	792
50	5.5590426	1224
51	5.6104798	1248
61	5.6885293	1488
250	5.6885293	6024

The second run was made for the same number of time steps ($N_t = 250$), but with fewer probes ($N_p = 7$). Three probes were placed on the L_{arm} -axis, and four on the α -axis as shown in Fig. 21(a). The final probe distribution appears in Fig. 21(b), and, interestingly, it includes a probe “stuck” in the lower left corner at $(L_{arm}, \alpha) = (0.5\lambda, \frac{\pi}{18})$. The global maximum was somewhat greater than the previous run’s at 5.7147684 located at the point $(L_{arm}, \alpha) = (1.4952\lambda, 0.710984)$. Convergence on the maximum was slower with saturation at step #164 (Table 10 lists fitness values when they changed), which seems reasonable in view of the smaller number of probes initially placed very far from the maximum. Figs. 22(a) and (b) plot the best fitness and D_{avg} vs. time step. The fitness increase is very rapid through step #5, followed by a slower step-wise increase as seen in the first run. The D_{avg} curve is less erratic than in the first run. Visually it seems to contain an oscillatory tendency, but the oscillation is not well-developed as in previous cases.

250	5.7147864	1757

6.5. Benchmark #5: *N*-element Collinear Dipole Array

Benchmark #5 is an N_{el} -element array of collinear $\frac{\lambda}{2}$ dipoles. The problem is run with several array sizes, from 6 to 24 elements following [6], in order to create decision spaces of high dimensionality, $N_d = N_{el} - 1$. As discussed in [6], maximum directivity occurs when the dipole center-to-center spacing is $d_i = 0.99\lambda, i = 1, \dots, N_d$, $0.5\lambda \leq d_i \leq 1.5\lambda$, that is, all dipoles are uniformly separated by just less than one wavelength. The objective of this benchmark is to recover that spacing over a range of array sizes. CFO runs were made with $N_p = 2N_d$ initial probes on the principal diagonal at $\vec{R}_0^p = \sum_{i=1}^{N_d} (0.5 + \frac{p}{3}) \hat{e}_i$, $1 \leq p \leq N_p$ (note that “axis” in Figs. 23-29 refers to the diagonal, not coordinate axes).

CFO’s performance is summarized in Table 11. In each case except $N_{el} = 24, 30$, CFO recovers the PBM maximum as expected. The returned values of d_i are all the same and range from a minimum of 0.983095λ to a maximum of 0.996288λ . For $N_{el} = 24$, however, CFO returns an optimum spacing of precisely 1λ , and an explanation of this result is not apparent. The step at which fitness saturation takes place appears in column 5, and in every case it is extremely rapid, never more than 6 steps.

Table 11. Best fitness coordinates and values for benchmark #5.

# Dipoles N_{el}	N_d	N_p	N_t	Step #for Saturation	N_{eval}	d_i ($i = 1, \dots, N_d$)	D_{max}
6	5	10	100	6	70	0.991050λ	11.2202
7	6	12	10	5	72	0.983095λ	13.1826
10	9	18	50	5	108	0.994210λ	19.0985
13	12	24	16	5	144	0.996288λ	25.0611
16	15	30	30	3	120	0.989583λ	30.9742
24	23	46	10	3 ⁽⁴⁾	184	1.000000λ	46.8813
30	29	58	10	4 ⁽⁴⁾	290	1.000000λ	58.8844

Notes:

- 1. For all runs: probes on-diagonal, 2 probes per dimension.
- 2. Same value was returned for all coordinates of global maximum
- 3. 7 & 13 element arrays are cases 5a & 5b in [6, Table II].
- 4. Best fitness decreases at step #6

Figs. 23 through 29 plot the evolution of the best fitnesses [(a) plots] and D_{avg} [(b) plots] for each of the arrays in Table 11. The results are consistent with other typical CFO results. In each case except $N_{el} = 24$, the fitness increases very quickly followed by saturation and a plateau. The D_{avg} curves exhibit correspondingly rapid decreases followed by essentially flat plateaus indicating a stable, tight probe distribution. There is no sign of the oscillation that indicates local trapping. The fitness curve for the $N_{el} = 24$ array [Fig. 28(a)] is somewhat unusual because the best fitness plateaus at its maximum between step #3 and #5, decreases at step #6, and then begins to gradually increase. This behavior is not understood. While this behavior appears to be a rare occurrence, a similar precipitous drop in fitness was seen in the 2D Goldstein-Price function in [4]. But in that case it was accompanied by a corresponding increase in D_{avg} , while none is seen here. In order to rule out the possibility of an artifact in the 24-element case, another run was made with 30-elements (not one of the PBM problems) as shown in Table 11. The returned optimal dipole spacing was the same as for the 24-element array, *viz.*, 1λ (all 29 coordinates). The best fitness and D_{avg} curves (Fig. 29) are similar. The fitness also decreases at step 6, but the drop is not as great. This case suggests that there is not artifact peculiar to the 24-element array, and that the results in that case are correct.

7. CONCLUSION

This paper describes Central Force Optimization as a new, deterministic, Nature-inspired search and optimization metaheuristic that embraces the metaphor of gravitational kinematics. It reports the results of testing CFO against the PBM suite of antenna benchmarks. CFO's performs quite well, in many respects better than the more established algorithms analyzed in PBM. CFO located all global maxima, even in a noisy decision landscape, and it did so with excellent efficiency. CFO generally performed better than the algorithms reported by PBM. This paper also highlights the striking similarity between velocity curves for Near Earth Objects in close encounters with planet Earth and CFO's average distance curves in the presence of local trapping. The nature of these plots suggests that oscillation is a sufficient but not necessary condition for local trapping, and that the recently developed theory of gravitational "resonant returns" might be of use in better understanding and perhaps mitigating trapping. The concept of "energy" in the gravitational metaphor was discussed, and suggestions made for its use as a test for local trapping and possibly a trapping mitigation mechanism. Also discussed was the possibility that CFO could be reformulated on the basis of a "total energy" model. Finally, this paper suggests the possibility of a new mathematical construct, a hyperspace "directional derivative" based on the Unit Step function that always points towards a function's maxima.

ACKNOWLEDGMENT

The author wishes to acknowledge and express his gratitude to the following individuals who in various ways have helped bring CFO to the attention of the optimization community. If CFO realizes what appears to be its considerable potential, in no small measure it will be due to their interest and encouragement: Professor Mario Pavone, Department of Mathematics, University of Catania, Sicily, Italy; Professor Zhihua Cui, Taiyuan University of Science and Technology, Division of System Simulation and Computer Application, Taiyuan, Shanxi, China; Professor Kusum Deep, Department of Mathematics, Indian Institute of Technology, Roorkee, India; Professor Nihad Dib, Department of Electrical Engineering, Jordan University of Science and Technology, Irbid, Jordan. If, on the other hand, CFO fails to meet this expectation, then the responsibility is entirely the author's.

25 March 2009, Brewster, Massachusetts; Revised 16 December 2009.

APPENDIX A. ADDITIONAL BENCHMARK PLOTS & SAMPLE NEC4 FILES

This Appendix includes additional topology plots for each of the 2D benchmarks. In some cases additional perspective views are included, and in all cases projections of the objective function's surface onto the decision space principal planes are included. Sample NEC4 input and output files using the maxima coordinates reported in or estimated from [6] are included after the plots. To save space, the lengthy NEC4 output files are truncated to show only relevant data.

APPENDIX B. CFO PSEUDOCODE

A CFO run requires seven user-specified parameters: N_t , N_p , G , α , β , Δt , and F_{rep} , some of which are much more important than others. A possible eighth parameter is the initial probe acceleration, which is set to zero for all runs reported here and consequently not included in the parameter list. Constant values for G and Δt combine multiplicatively in a single coefficient, but there is the possibility that these parameters could be varied during a run. For the CFO runs reported here, $\alpha = \beta = 2$ because this value seems to provide good results for many test functions (it may, in fact, be a good default value). Note that in this paper there is no change in fitness value or average probe distance between steps 0 and 1 because the initial acceleration has been set to zero.

CFO is a simple algorithm that is easily implemented. The basic steps are: **(a)** compute initial probe positions and corresponding objective function fitnesses; assign initial accelerations; **(b)** successively compute each probe's new position using equation (2) §4.2 based on previously computed accelerations using equation (1) §4.2; **(c)** verify that each probe is located inside the decision space, making corrections as required; **(d)** update fitness at each new probe position; **(e)** compute accelerations for the next time step using new positions; and **(f)** loop over time steps or until a termination criterion is met.

The initial acceleration was set to zero for runs reported here; a non-zero value “flies” probes in the directions of the accelerations at step 0 which may or may not improve performance. Because CFO may “fly” probes outside the decision space domain into regions of unallowable solutions, any errant probes should be returned to the decision space. There are many possible retrieval schemes, and the one used here is simple and deterministic as described below and in §4.4. The repositioning factor, F_{rep} , which is used to return errant probes, in fact is one of CFO’s most important parameters. When and how it should be changed are unanswered questions. The simple approach below seems to provide good results, and it was chosen solely for that reason.

Note that all CFO parameters presently are chosen on an empirical basis, that is, by “trial and error” because there is no methodology for specifying their values. This question remains one of the most pressing in CFO’s further development. The parameter values that have been used provide good results for the purpose of demonstrating CFO’s effectiveness and efficiency as an optimization metaheuristic, but these are not necessarily the best values.

CFO pseudocode is as follows (values for N_{saved} , TOL_{fit} , F_{rep}^{init} and ΔF_{rep} are those used in this paper):

(1) DATA STRUCTURES

(A) Create arrays $R(p, i, j)$ [position vectors], $A(p, i, j)$ [accelerations], $1 \leq p \leq N_p$, $1 \leq i \leq N_d$,

$$0 \leq j \leq N_t \text{ [probe #, coordinate #, time step #]}$$

(B) Create fitness array $M(p, j) = f(R(p, i, j))$

(C) Create array of last N_{saved} best fitnesses $M_{best}(q)$, $1 \leq q \leq N_{saved}$

(2) INITIALIZATION

At time step $j = 0$:

(A)(i) Uniform probes on each coordinate axis (note: $\frac{N_p}{N_d}$, # probes/dimension, user-specified).

For $i = 1$ to N_d , $n = 1$ to $\frac{N_p}{N_d}$:

$$p = n + \frac{(i-1)N_p}{N_d}, \quad R(p, i, 0) = x_i^{\min} + \frac{(n-1)(x_i^{\max} - x_i^{\min})}{\frac{N_p}{N_d} - 1}.$$

(A)(ii) Probes slightly off decision space diagonal

For $p = 1$ to N_p , $i = 1$ to N_d :

$$R(p, i, 0) = x_i^{\min} + \frac{(n-1)(x_i^{\max} - x_i^{\min})[N_d(p-1) + i - 1]}{N_p N_d - 1}.$$

(A)(iii) Uniform 2D grid

$$\Delta x_1 = \frac{x_1^{\max} - x_1^{\min}}{\frac{N_p}{N_d} - 1}, \quad \Delta x_2 = \frac{x_2^{\max} - x_2^{\min}}{\frac{N_p}{N_d} - 1}; \quad \text{For } k = 1 \text{ to } \frac{N_p}{N_d}, m = 1 \text{ to } \frac{N_p}{N_d}:$$

$$p = \frac{N_p}{N_d}(k-1) + m, \quad R(p,1,0) = x_1^{\min} + (k-1)\Delta x_1, \quad R(p,2,0) = x_2^{\min} + (m-1)\Delta x_2$$

(A)(iv) Other user-specified probe distribution [Note - This option used for this paper]

(B) Initial acceleration

$$A(p,i,0) = 0, \quad 1 \leq p \leq N_p, \quad 1 \leq i \leq N_d$$

(C) Initial fitness

$$M(p,0) = f(R(p,i,0)), \quad 1 \leq p \leq N_p, \quad 1 \leq i \leq N_d,$$

$$\text{Best Fitness} = \text{MAX}(M(p,0), 1 \leq p \leq N_p)$$

(D) Saved Fitnesses & Fitness Tolerance

$$N_{\text{saved}} = 5, \quad N_{\text{sat}} = 3, \quad TOL_{\text{fit}} = 0.0005$$

(E) Initial Reposition Factor & Increment

$$F_{\text{rep}}^{\text{init}} = 0.5, \quad \Delta F_{\text{rep}} = 0.005, \quad F_{\text{rep}} = F_{\text{rep}}^{\text{init}}$$

(3) TIME LOOP ($0 \leq j \leq N_t$)

(A) Saved Fitness Array Index: $s = j \text{ MOD } N_{\text{saved}}$; If $s = 0$ then $s = N_{\text{saved}}$

IMPORTANT NOTE: Saved fitnesses are not necessarily sequential as a result of how s is calculated, which affects when F_{rep} is incremented. See discussion in §4.4.

New Probe Positions

For $p = 1$ to N_p , $i = 1$ to N_d :

$$(a) \quad R(p,i,j) = R(p,i,j-1) + \frac{1}{2} A(p,i,j-1) \Delta t^2, \quad \Delta t^2 = 1$$

(b) Retrieve errant probes as required (Note: For Repositioning Factor, $0 \leq F_{\text{rep}} \leq 1$, see Formato [2-4])

$$\text{If } R(p,i,j) < x_i^{\min} \text{ then } R(p,i,j) = x_i^{\min} + F_{\text{rep}} \cdot (R(p,i,j-1) - x_i^{\min})$$

$$\text{If } R(p,i,j) > x_i^{\max} \text{ then } R(p,i,j) = x_i^{\max} - F_{\text{rep}} \cdot (x_i^{\max} - R(p,i,j-1))$$

(B) Update Fitness Matrix

For $p = 1$ to N_p :

$$M(p,j) = f(R(p,i,j))$$

If $M(p,j) \geq \text{Best Fitness}$ then $\text{Best Fitness} = M(p,j)$ & $M_{\text{best}}(s) = M(p,j)$

(C) Update Reposition Factor

$$\text{If } \left| M_{\text{best}}(N_{\text{saved}}) - \frac{1}{N_{\text{sat}}} \sum_{q=s}^{N_{\text{saved}}} M_{\text{best}}(q) \right| \leq TOL_{\text{fit}}, \quad s = N_{\text{saved}} - N_{\text{sat}} + 1, \text{ then}$$

$$F_{\text{rep}} = F_{\text{rep}} + \Delta F_{\text{rep}}$$

$$\text{If } F_{\text{rep}} \geq 1 \text{ then } F_{\text{rep}} = F_{\text{rep}}^{\text{init}}$$

(D) *Update Accelerations*

For $p = 1$ to N_p , $i = 1$ to N_d :

$$A(p, i, j) = G \sum_{\substack{k=1 \\ k \neq p}}^{N_p} U(M(k, j) - M(p, j)) \times \\ (M(k, j) - M(p, j))^{\alpha} \times \frac{R(k, i, j) - R(p, i, j)}{\left| \vec{R}_j^k - \vec{R}_j^p \right|^{\beta}},$$

$$\text{where } \left| \vec{R}_j^k - \vec{R}_j^p \right| = \sqrt{\sum_{m=1}^{N_d} (R(k, m, j) - R(p, m, j))^2}$$

(E) Increment $j \rightarrow j + 1$, and repeat from (3)(A) until $j = N_t$ or other stopping criterion has been met.

'-----
'1. "Central Force Optimization: A New Metaheuristic with Applications in Applied Electromagnetics,"
'   Progress in Electromagnetics Research, PIER 77, 425-491, 2007 (online).
'Abstract - Central Force Optimization (CFO) is a new deterministic multi-dimensional search
'metaheuristic based on the metaphor of gravitational kinematics. It models "probes" that "fly"
'through the decision space by analogy to masses moving under the influence of gravity. Equations
'are developed for the probes' positions and accelerations using the analogy of particle motion
'in a gravitational field. In the physical universe, objects traveling through three-dimensional
'space become trapped in close orbits around highly gravitating masses, which is analogous to
'locating the maximum value of an objective function. In the CFO metaphor, "mass" is a user-defined
'function of the value of the objective function to be maximized. CFO is readily implemented in a
'compact computer program, and sample pseudocode is presented. As tests of CFO's effectiveness,
'an equalizer is designed for the well-known Fano load, and a 32-element linear array is synthesized.
'CFO results are compared to several other optimization methods.
'2. "Central Force Optimization: A New Nature Inspired Computational Framework for Multidimensional
'   Search and Optimization," Studies in Computational Intelligence (SCI), vol. 129, 221-238 (2008),
'   www.springerlink.com, Springer-Verlag Berlin Heidelberg 2008.
'Abstract - This paper presents Central Force Optimization, a novel, nature inspired, deterministic
'search metaheuristic for constrained multi-dimensional optimization. CFO is based on the metaphor
'of gravitational kinematics. Equations are presented for the positions and accelerations experienced
'by "probes" that "fly" through the decision space by analogy to masses moving under the influence of
'gravity. In the physical universe, probe satellites become trapped in close orbits around highly
'gravitating masses. In the CFO analogy, "mass" corresponds to user-defined function of the value
'of an objective function to be maximized. CFO is a simple algorithm that is easily implemented in
'a compact computer program. A typical CFO implementation is applied to several test functions.
'CFO exhibits very good performance, suggesting that it merits further study.
'3. "Central Force Optimisation: A New Gradient-Like Metaheuristic for Multidimensional Search and
'   Optimisation," International Journal of Bio-Inspired Computation, vol. 1, no. 4, 217-238 (2009),
'Abstract: This paper introduces Central Force Optimization, a novel, Nature-inspired, deterministic
```

```

'search metaheuristic for constrained multidimensional optimization in highly multimodal, smooth, or
'discontinuous decision spaces. CFO is based on the metaphor of gravitational kinematics. The
'algorithim searches a decision space by "flying" its "probes" through the space by analogy to masses
'moving through physical space under the influence of gravity. Equations are developed for the probes'
'positions and accelerations using the gravitational metaphor. Small objects in our Universe can become
'trapped in close orbits around highly gravitating masses. In "CFO space" probes are attracted to "masses"
'created by a user-defined function of the value of an objective function to be maximized. CFO may be
'thought of in terms of a vector "force field" or, loosely, as a "generalized gradient" methodology
'because the force of gravity can be computed as the gradient of a scalar potential. The CFO algorithm
'is simple and easily implemented in a compact computer program. Its effectiveness is demonstrated by
'running CFO against several widely used benchmark functions. The algorithm exhibits very good performance,
'suggesting that it merits further study.
'4. "Central Force Optimization: A New Gradient-Like Optimization Metaheuristic," OPSEARCH, Journal
'   of the Operational Research Society of India, vol. 46, no. 1, 25-51, 2009, Springer India.
'Abstract: This paper introduces Central Force Optimization as a new, Nature-inspired metaheuristic
'for multidimensional search and optimization based on the metaphor of gravitational kinematics. CFO is a
'"gradient-like" deterministic algorithm that explores a decision space by "flying" a group of "probes"
'whose trajectories are governed by equations analogous to the equations of gravitational motion in the
'physical Universe. This paper suggests the possibility of creating a new "hyperspace directional derivative"
'using the Unit Step function t7o create positive-definite "masses" in "CFO space." A simple CFO implementation
'is tested against several recognized benchmark functions with excellent results, suggesting that CFO merits
'further investigation.
'5. "Synthesis of Antenna Arrays Using Central Force Optimization," Mosharaka International Conference
'   on Communications, Computers and Applications, MIC-CPE 2009.
'Abstract: Central force optimization (CFO) technique is a new deterministic multi-dimensional
'search metaheuristic based on an analogy to classical particle kinematics in a gravitational
'field. CFO is a simple technique and is still in its infancy. To enhance its global search
'ability while keeping its simplicity, a new selection part is introduced in this paper. CFO
'is briefly presented and applied in the design of linear antenna array and the modified CFO
'is applied to the design of circular array. The results are compared with those obtained using
'other evolutionary optimization techniques.
'6. "Central Force Optimization and NEOs - First Cousins?" Journal of Multiple Valued Logic and Soft
'   Computing (to be published)
'Abstract: Central Force Optimization is a new deterministic multidimensional search and optimization algorithm
'based on the metaphor of gravitational kinematics. This paper describes CFO and suggests some possible
'directions for its future development. Because CFO is deterministic, it is more computationally efficient
'than stochastic algorithms and may lend itself well to "parameter tuning" implementations. But, like
'all deterministic algorithms, CFO is prone to local trapping. Oscillation in CFO's Davg curve appears to
'be a reliable harbinger of trapping. And there seems to be a reasonable basis for believing that
'trapping can be handled deterministically using the theory of gravitationally trapped Near Earth Objects.
'Deterministic mitigation of local trapping would be a major step forward in optimization theory. Finally,
'CFO may be thought of as a "gradient-like" algorithm utilizing the Unit Step function as a critical element,
'and it is suggested that a useful, new derivative-like mathematical construct might be defined based on the Unit
'Step.
'7. "Array Synthesis and Antenna Benchmark Performance Using Central Force Optimization," IET (UK)
'   (in review)
'Abstract: Central force optimization (CFO) is a new deterministic multi-dimensional search metaheuristic
'based on an analogy to classical particle kinematics in a gravitational field. CFO is a simple technique
'that is still in its infancy. This paper evaluates CFO's performance and provides further examples of its
'effectiveness by applying it to a set of "real world" antenna benchmarks and to pattern synthesis for linear
'and circular array antennas. A new selection scheme is introduced that enhances CFO's global search ability
'while maintaining its simplicity. The improved CFO algorithm is applied to the design of a circular array
'with very good results. CFO's performance on the antenna benchmarks and the synthesis problems is compared
'to that of other evolutionary optimization techniques.
