# Examples of rigid and flexible Seifert fibred cone-manifolds 

Alexander Kolpakov*

#### Abstract

The present paper gives an example of a rigid spherical cone-manifold and that of a flexible one which are both Seifert fibred.

Keywords cone-manifold, rigidity, flexibility, Seifert fibration MSC (2010) 53A35, 57R18, 57M25

## 1 Introduction

The theory of three-dimensional orbifolds and cone-manifolds attracts attention of many mathematicians since the original work of Thurston [29]. An introduction to the theory of orbifolds could be found in [29, Ch.13]. For a basic introduction to the geometry of three-dimensional cone-manifolds and cone-surfaces we refer the reader to [6]. The main motivation for studying three-dimensional cone-manifolds comes from Thurston's approach to geometrization of three-orbifolds: three-dimensional cone-manifolds provide a way to deform geometric orbifold structures. The orbifold theorem has been proven in full generality by M. Boileau, B. Leeb and J. Porti, see [1, 2].
One of the main questions in the theory of three-dimensional cone-manifolds is the rigidity problem. First, the rigidity property was discovered for hyperbolic manifolds (so-called Mostow-Prasad rigidity, see [19, 24]). After that, the global rigidity property for hyperbolic three-dimensional cone-manifolds with singular locus a link and cone angles less than $\pi$ was proven by S. Kojima [16]. The key result that implies global rigidity is due to Hodgson and Kerckhoff [13], who showed the local rigidity of hyperbolic cone manifolds with singularity of link or knot type and cone angles less than $2 \pi$. The de Rham rigidity for spherical orbifolds was established in [26, 27]. Detailed analysis of the rigidity property for three-dimensional cone-manifolds

[^0]was carried out in [31, 32] for hyperbolic and spherical cone-manifolds with singularity a trivalent graph and cone angles less than $\pi$.
Recently, the local rigidity for hyperbolic cone-manifolds with cone angles less than $2 \pi$ was proven in [18, 33]. However, examples of infinitesimally flexible hyperbolic cone-manifolds had already been given in [5]. For other examples of flexible cone-manifolds one may refer to [15, 21, 28].
The theorem of [32] concerning the global rigidity for spherical threedimensional cone-manifolds was proven under the condition of being not Seifert fibred. Recall that due to [22] a cone-manifold is Seifert fibred if its underlying space carries a Seifert fibration such that components of the singular stratum are leafs of the fibration. In particular, if its singular stratum is represented by a link, then the complement is a Seifert fibred three-manifold. All Seifert fibred link complements in the three-sphere are described by [4]. In the present paper, we give an explicit example of a rigid spherical cone-manifold and a flexible one which are both Seifert fibred. The singular locus for each of these cone-manifolds is a link and the underlying space is the three-sphere $\mathbb{S}^{3}$. The rigid cone-manifold given in the paper has cone-angles of both kinds, less or greater than $\pi$. The flexible one has cone-angles strictly greater than $\pi$. Deformation of its geometric structure comes essentially from those of the base cone-surface. However, hyperbolic orbifolds, which are Seifert fibred over a disc, are rigid. Their geometric structure degenerates to the minimal-perimeter hyperbolic polygon, as shown in [23]. These are uniquely determined by cone angles.
The paper is organised as follows: first, we recall some common facts concerning spherical geometry. In the second section, the geometry of the Hopf fibration is considered and a number of lemmas are proven. After that, we construct two explicit examples of Seifert fibred cone-manifolds. The first one is a globally rigid cone-manifold and its moduli space is parametrised by its cone angles only. The second one is a flexible Seifert fibred conemanifold. This means that we can deform its metric while keeping its cone angles fixed. Rigorously speaking, the following assertion is proven: the given cone-manifold has a one-parameter family of distinct spherical cone metrics with the same cone angles.

Acknowledgement. The author is grateful to Prof. J. Porti (Universitat Autònoma de Barcelona) and Prof. J.-M. Schlenker (Institut de Mathématiques de Toulouse) for their valuable comments on the paper and discussion of the subject.

## 2 Spherical geometry

Below we present several common facts concerning spherical geometry in dimension two and three.
Let us identify a point $p=(w, x, y, z)$ of the three-dimensional sphere

$$
\mathbb{S}^{3}=\left\{(w, x, y, z) \in \mathbb{R}^{4} \mid w^{2}+x^{2}+y^{2}+z^{2}=1\right\}
$$

with an $S U_{2}(\mathbb{C})$ matrix of the form

$$
P=\left(\begin{array}{cc}
w+i x & y+i z \\
-y+i z & w-i x
\end{array}\right) .
$$

Then, replace the group Isom ${ }^{+} \mathbb{S}^{3} \cong S O_{4}(\mathbb{R})$ of orientation preserving isometries with its two-fold covering $S U_{2}(\mathbb{C}) \times S U_{2}(\mathbb{C})$. Finally, define the action of $\langle A, B\rangle \in S U_{2}(\mathbb{C}) \times S U_{2}(\mathbb{C})$ on $P \in S U_{2}(\mathbb{C})$ by

$$
\langle A, B\rangle: P \longmapsto A^{t} P \bar{B} .
$$

Thus, we define the action of $S O_{4}(\mathbb{R}) \cong S U_{2}(\mathbb{C}) \times S U_{2}(\mathbb{C}) /\{ \pm \mathrm{id}\}$ on the three-sphere $\mathbb{S}^{3}$.
By assuming $w=0$, we obtain the two-dimensional sphere

$$
\mathbb{S}^{2}=\left\{(x, y, z) \in \mathbb{R}^{3} \mid x^{2}+y^{2}+z^{2}=1\right\} .
$$

Let us identify a point $(x, y, z)$ of $\mathbb{S}^{2}$ with the matrix

$$
Q=\left(\begin{array}{cc}
i x & y+i z \\
-y+i z & -i x
\end{array}\right)
$$

which represents a pure imaginary unit quaternion $Q \in \mathbf{H}$.
Instead of Isom ${ }^{+} \mathbb{S}^{2} \cong S O_{3}(\mathbb{R})$ we use its two-fold covering $S U_{2}(\mathbb{C})$ acting by

$$
A: q \longmapsto A^{t} q \bar{A}
$$

for every $A \in S U_{2}(\mathbb{C})$ and every $q \in \mathbb{S}^{2}$.
Equip each $\mathbb{S}^{3}$ and $\mathbb{S}^{2}$ with an intrinsic metric of constant sectional curvature +1 . We call the distance between two points $P$ and $Q$ of $\mathbb{S}^{n}(n=2,3)$ a real number $d(P, Q)$ uniquely defined by the conditions

$$
\begin{gathered}
0 \leq d(P, Q) \leq \pi \\
\cos d(P, Q)=\frac{1}{2} \operatorname{tr} P^{t} \bar{Q} .
\end{gathered}
$$

The next step is to describe spherical geodesic lines in $\mathbb{S}^{n}$. Let us recall the following theorem [25, Theorem 2.1.5].

Theorem 1 A function $\lambda: \mathbb{R} \rightarrow \mathbb{S}^{n}$ is a geodesic line if and only if there are orthogonal vectors $x, y$ in $\mathbb{S}^{n}$ such that

$$
\lambda(t)=(\cos t) x+(\sin t) y
$$

Taking into account the preceding discussion, we may reformulate the statement above.

Lemma 1 Every geodesic line (a great circle) in $\mathbb{S}^{3}$ (respectively, $\mathbb{S}^{2}$ ) could be represented in the form

$$
C(t)=P \cos t+Q \sin t
$$

where $P, Q \in S U_{2}(\mathbb{C})$ (respectively $P, Q \in \mathbf{H}$ ) satisfy orthogonality condition

$$
\cos d(P, Q)=0
$$

By virtue of this lemma, one may regard $P$ as the starting point of the curve $C(t)$ and $Q$ as the velocity vector at $P$, since $C(0)=P, \dot{C}(0)=\left.\frac{d}{d t} C(t)\right|_{t=0}=$ $Q$ and $d(C(0), \dot{C}(0))=\frac{\pi}{2}$ (the latter holds up to a change of the parameter sign).
Given two geodesic lines $C_{1}(t)$ and $C_{2}(t)$, define their common perpendicular $C_{12}(t)$ as a geodesic line such that there exist $0 \leq t_{1}, t_{2} \leq 2 \pi, 0 \leq \delta \leq \pi$ with the following properties:

$$
\begin{gathered}
C_{12}(0)=C_{1}\left(t_{1}\right), C_{12}(\delta)=C_{2}\left(t_{2}\right) \\
d\left(\dot{C}_{12}(0), \dot{C}_{1}\left(t_{1}\right)\right)=d\left(\dot{C}_{12}(\delta), \dot{C}_{2}\left(t_{2}\right)\right)=\frac{\pi}{2}
\end{gathered}
$$

We call $\delta$ the distance between the geodesics $C_{1}(t)$ and $C_{2}(t)$. Note, that for an arbitrary pair of geodesics their common perpendicular should not be unique.
For an additional explanation of spherical geometry we refer the reader to [25] and 31, Chapter 6.4.2].

## 3 Links arising from the Hopf fibration

The present section is devoted to the construction of a family of links $\mathcal{H}_{n}$ $(n \geq 2)$ which we shall use later. These links have a nice property - each of them is formed by $n \geq 2$ fibres of the Hopf fibration. Recall that the Hopf map $h: \mathbb{S}^{3} \xrightarrow{\mathbb{S}^{1}} \mathbb{S}^{2}$ has geometric nature [14, p. 654]. Our aim is to prove a number of lemmas concerning the geometry of the Hopf fibration in more detail.

### 3.1 Links $\mathcal{H}_{n}$ as fibres of the Hopf fibration

The Hopf map $h$ is defined as follows [14]: for every point $(w, x, y, z) \in \mathbb{S}^{3}$ let its image on $\mathbb{S}^{2}$ be

$$
h(w, x, y, z)=\left(2(x z+w y), 2(y z-w x), 1-2\left(x^{2}+y^{2}\right)\right) .
$$

The fibre $h^{-1}(a, b, c)$ over the point $(a, b, c) \in \mathbb{S}^{2}$ is a geodesic line in $\mathbb{S}^{3}$ of the form

$$
C(t)=\frac{1}{\sqrt{2(1+c)}}((1+c,-b, a, 0) \cos t+(0, a, b, 1+c) \sin t) .
$$

The exceptional point $(0,0,-1)$ has the fibre $(0, \cos t,-\sin t, 0)$.
The line $C(t)$ is a great circle of $\mathbb{S}^{3}$ and can be rewritten in the matrix form

$$
C(t)=P(a, b, c) \cos t+Q(a, b, c) \sin t,
$$

where

$$
\begin{gathered}
P(a, b, c)=\frac{1}{\sqrt{2(1+c)}}\left(\begin{array}{cc}
(1+c)-i b & a \\
-a & (1+c)+i b
\end{array}\right), \\
Q(a, b, c)=P(a, b, c)\left(\begin{array}{cc}
0 & i \\
i & 0
\end{array}\right) .
\end{gathered}
$$

We call

$$
F(t)=\left(\begin{array}{ll}
1 & 0 \\
0 & 1
\end{array}\right) \cos t+\left(\begin{array}{cc}
0 & i \\
i & 0
\end{array}\right) \sin t
$$

the generic fibre $h^{-1}(0,0,1)$. Moreover, every fibre $h^{-1}(a, b, c)$ can be described as a circle $C(t)=P(a, b, c) F(t)$. Note, that $P(a, b, c)$ is an $S U_{2}(\mathbb{C})$ matrix. Thus $C(t)$ could be obtained from $F(t)$ by means of the isometry $\left\langle P(a, b, c)^{t}, \mathrm{id}\right\rangle$. For the exceptional point $(0,0,-1) \in \mathbb{S}^{2}$, we set

$$
P(0,0,-1)=\left(\begin{array}{cc}
0 & 1 \\
-1 & 0
\end{array}\right) .
$$

It is known, that every pair of distinct fibres of the Hopf fibration represents simply linked circles in $\mathbb{S}^{3}$ (the Hopf link). Thus, $n$ fibres form a link $\mathcal{H}_{n}$ whose every two components form the Hopf link. One can obtain it by drawing $n$ straight vertical lines on a cylinder and identifying its ends by a rotation through the angle of $2 \pi$. Hence $\mathcal{H}_{n}$ is an $(n, n)$ torus link.
Another remark is that the $\mathcal{H}_{n}$ link could be arranged around a point in order to reveal its $n$-th order symmetry, as depicted in Fig. 1. This fact allows us to consider $n$-fold branched coverings of the corresponding conemanifolds with singular locus $\mathcal{H}_{n}$ that appear in Section 4.

Figure 1: $n$-fold branched covering of $(2,2 n)$ torus link by $\mathcal{H}_{n}$

### 3.2 Geometry of the Hopf fibration

Here and below we use the polar coordinate system $(\psi, \theta)$ on $\mathbb{S}^{2}$ instead of the Cartesian one. Suppose

$$
\begin{gathered}
a=\cos \psi \sin \theta, b=\sin \psi \sin \theta, c=\cos \theta \\
0 \leq \psi \leq 2 \pi, 0 \leq \theta \leq \pi
\end{gathered}
$$

and let

$$
M(\psi, \theta)=P(a, b, c)=\left(\begin{array}{cc}
\cos \frac{\theta}{2}-i \sin \psi \sin \frac{\theta}{2} & \cos \psi \sin \frac{\theta}{2} \\
-\cos \psi \sin \frac{\theta}{2} & \cos \frac{\theta}{2}+i \sin \psi \sin \frac{\theta}{2}
\end{array}\right)
$$

A rotation of $\mathbb{S}^{3}$ about the generic fibre $F(t)$ through angle $\omega$ has the form $\langle R(\omega), R(\omega)\rangle$, where

$$
R(\omega)=\left(\begin{array}{cc}
\cos \frac{\omega}{2} & i \sin \frac{\omega}{2} \\
i \sin \frac{\omega}{2} & \cos \frac{\omega}{2}
\end{array}\right)
$$

The image of $F(t)$ under the Hopf map $h$ is $(0,0)$ w.r.t. the polar coordinates. The following lemma shows how to obtain a rotation about the pre-image $h^{-1}(\psi, \theta)$ of an arbitrary point $(\psi, \theta)$.

Lemma $2 A$ rotation through angle $\omega$ about an axis $C(t)$ in $\mathbb{S}^{3}$ which is the pre-image of a point $(\psi, \theta) \in \mathbb{S}^{2}$ with respect to the Hopf map is

$$
\left\langle\overline{M(\psi, \theta)} R(\omega) M(\psi, \theta)^{t}, R(\omega)\right\rangle
$$

Proof. Since we have that $C(t)=M(\psi, \theta) F(t)$ and $R(\omega)^{t} F(t) \overline{R(\omega)}=F(t)$ for every $0 \leq t \leq 2 \pi$, then

$$
\begin{aligned}
\left(\overline{M(\psi, \theta)} R(\omega) M(\psi, \theta)^{t}\right)^{t} C(t) \overline{R(\omega)} & =M(\psi, \theta) R(\omega)^{t} F(t) \overline{R(\omega)}= \\
=M(\psi, \theta) F(t) & =C(t)
\end{aligned}
$$

by a straightforward computation. Here we use the fact that $M(\psi, \theta) \in$ $S U_{2}(\mathbb{C})$, and so $\overline{M(\psi, \theta)^{t}} M(\psi, \theta)=\mathrm{id}$.
Another remarkable property of the Hopf fibration is discussed below.
Lemma 3 Every two fibres $C_{1}(t)$ and $C_{2}(t)$ of the Hopf fibration are equidistant geodesic lines (great circles) in $\mathbb{S}^{3}$.
If $C_{i}(t), i \in\{1,2\}$ are pre-images of the points $\widehat{C}_{i} \in \mathbb{S}^{2}$, then the length $\delta$ of the common perpendicular for $C_{1}(t)$ and $C_{2}(t)$ equals $\frac{1}{2} d\left(\widehat{C}_{1}, \widehat{C}_{2}\right)$.

Proof. The proof follows from the fact that the Hopf fibration is a Riemannian submersion between $\mathbb{S}^{3}$ and $\mathbb{S}_{\frac{1}{2}}^{2}=\left\{(x, y, z) \in \mathbb{R}^{3} \left\lvert\, x^{2}+y^{2}+z^{2}=\frac{1}{4}\right.\right\}$ with their standard Riemannian metrics of sectional curvature +1 and +4 respectively, see Proposition 1.1 and Proposition 1.2 of [9.
Every rotation about a fibre of the Hopf fibration induces a rotation about a point of its base.

Lemma 4 Given a rotation $\langle A, B\rangle \in S U_{2}(\mathbb{C}) \times S U_{2}(\mathbb{C})$ about a fibre $C(t)$ of the Hopf fibration, the transformation $A \in S U_{2}(\mathbb{C})$ induces a rotation of $\mathbb{S}^{2}$ about the point to which $C(t)$ projects under the Hopf map.

Proof. Rotation about the fibre $C(t)=M(\psi, \theta) F(t)$ which projects to the point $(\psi, \theta) \in \mathbb{S}^{2}$ has the form

$$
\langle A, B\rangle=\left\langle\overline{M(\psi, \theta)} R(\omega) M(\psi, \theta)^{t}, R(\omega)\right\rangle .
$$

Observe that the rotation $\langle R(\omega), R(\omega)\rangle$ fixes the geodesic $F(t)$ in $\mathbb{S}^{3}$ and $R(\omega)$ fixes the point $\widehat{F}=\left(\begin{array}{cc}0 & i \\ i & 0\end{array}\right)$ in $\mathbb{S}^{2}$. Thus $A \in S U_{2}(\mathbb{C})$ fixes the point $\widehat{C}=M(\psi, \theta) \widehat{F} \overline{M(\psi, \theta)^{t}}$. By a straightforward computation, we obtain that

$$
\widehat{C}=\left(\begin{array}{cc}
i \cos \psi \sin \theta & \sin \theta \sin \psi+i \cos \theta \\
-\sin \theta \sin \psi+i \cos \theta & -i \cos \psi \sin \theta
\end{array}\right) .
$$

The point $\widehat{C} \in \mathbb{S}^{2}$ corresponds to $(\psi, \theta)$ w.r.t. the polar coordinates.

## 4 Examples of rigidity and flexibility

In this section we work out two principal examples of Seifert fibred conemanifolds: the first represents a rigid cone-manifold, the second one is flexible.

### 4.1 Case of rigidity: the cone-manifold $\mathcal{H}_{3}(\alpha, \beta, \gamma)$

Let $\mathcal{H}_{3}(\alpha, \beta, \gamma)$ denote a three-dimensional cone-manifold with underlying space the sphere $\mathbb{S}^{3}$ and singular locus formed by the link $\mathcal{H}_{3}$ with cone angles $\alpha, \beta$ and $\gamma$ along its components. The remaining discussion is devoted to the proof of

Theorem 2 The cone-manifold $\mathcal{H}_{3}(\alpha, \beta, \gamma)$ admits a spherical structure if the following inequalities are satisfied:

$$
\begin{gathered}
2 \pi-\gamma<\alpha+\beta<2 \pi+\gamma \\
-2 \pi+\gamma<\alpha-\beta<2 \pi-\gamma .
\end{gathered}
$$

The spherical structure on $\mathcal{H}_{3}(\alpha, \beta, \gamma)$ is unique (i.e. $\mathcal{H}_{3}(\alpha, \beta, \gamma)$ is globally rigid).
The lengths $\ell_{\alpha}, \ell_{\beta}, \ell_{\gamma}$ of its singular strata are pairwise equal and the following formula holds:

$$
\ell_{\alpha}=\ell_{\beta}=\ell_{\gamma}=\frac{\alpha+\beta+\gamma}{2}-\pi .
$$

The volume of $\mathcal{H}_{3}(\alpha, \beta, \gamma)$ equals

$$
\operatorname{Vol} \mathcal{H}_{3}(\alpha, \beta, \gamma)=\frac{1}{2}\left(\frac{\alpha+\beta+\gamma}{2}-\pi\right)^{2} .
$$

Proof. First, we construct a holonomy map for $\mathcal{H}_{3}(\alpha, \beta, \gamma)$. By applying Wirtinger's algorithm, one obtains the following fundamental group presentation for the link $\mathcal{H}_{3}$ :

$$
\Gamma=\pi_{1}\left(\mathbb{S}^{3} \backslash \mathcal{H}_{3}\right)=\langle a, b, c, h \mid a c b=b a c=c b a=h, h \in Z(\Gamma)\rangle
$$

that is a central extension by $h$ of the thrice-punctured sphere group

$$
\Gamma_{0}=\pi_{1}\left(\mathbb{S}^{2} \backslash\{3 \text { points }\}\right)=\langle a, b, c \mid a c b=b a c=c b a=\mathrm{id}\rangle .
$$

Consider a holonomy map

$$
\rho: \Gamma \longmapsto \operatorname{Isom}^{+} \mathbb{S}^{3} \cong S O_{4}(\mathbb{R}) .
$$

Figure 2: The link $\mathcal{H}_{3}$

Let $\widetilde{\rho}$ denote its lift to $S U_{2}(\mathbb{C}) \times S U_{2}(\mathbb{C})$, which is a two-fold covering of $S O_{4}(\mathbb{R})$ (see [7]):

$$
\widetilde{\rho}=\left\langle\widetilde{\rho}_{1}, \widetilde{\rho}_{2}\right\rangle: \Gamma \longmapsto S U_{2}(\mathbb{C}) \times S U_{2}(\mathbb{C}) .
$$

Let us note, that if holonomy images of any two generators of $\Gamma$ commute, then the whole homomorphic image $\widetilde{\rho}(\Gamma)$ is abelian. Thus, for a representation $\widetilde{\rho}$ we have that the following three cases, up to a suitable conjugation, are possible:
(i) $\widetilde{\rho}=\left(\widetilde{\rho}_{1}, \widetilde{\rho}_{2}\right): \Gamma \rightarrow S U_{2}(\mathbb{C}) \times S U_{2}(\mathbb{C})$, both $\widetilde{\rho}_{1}$ and $\widetilde{\rho}_{2}$ are non-abelian,
(ii) $\widetilde{\rho}: \Gamma \rightarrow \mathbb{S}^{1} \times \mathbb{S}^{1}$, an abelian representation,
(iii) $\widetilde{\rho}=\left(\widetilde{\rho}_{1}, \widetilde{\rho}_{2}\right): \Gamma \rightarrow S U_{2}(\mathbb{C}) \times \mathbb{S}^{1}$, where $\widetilde{\rho}_{1}$ is non-abelian.

For case (i), let us first suppose that $\tilde{\rho}(h)$ is non-trivial. Since the holonomy images of the meridians $a, b$ and $c$ have to commute with the holonomy image of $h$, they are simultaneously diagonalisable. We arrive at case (ii). If $\widetilde{\rho}(h)$ is trivial, then we have two non-abelian representations $\widetilde{\rho}_{i}: \Gamma_{0} \rightarrow$ $S U_{2}(\mathbb{C})$. Since the holonomy images of the meridians correspond to rotations along geodesic lines in $\mathbb{S}^{3}$, it follows by [2, Lemma 9.2] that $\operatorname{tr} \widetilde{\rho}_{1}(x)=\operatorname{tr} \widetilde{\rho}_{2}(x)$ for $x \in\{a, b, c\}$. The base space of the fibred cone-manifold $\mathcal{H}_{3}(\alpha, \beta, \gamma)$ is a turnover $\mathbb{S}^{2}(\alpha, \beta, \gamma)$, with $\alpha, \beta, \gamma$ cone angles. Then, by [10, Lemma 4.1], up to a conjugation, $\widetilde{\rho}=\left(\widetilde{\rho}_{1}, \widetilde{\rho}_{1}\right)$. The representation $\rho: \Gamma \rightarrow S O(4)$ is conjugate into $S O(3)$ and the holonomy images of the meridians have a common fixed point in $\mathbb{S}^{3}$. Thus, their axis intersect, which does not
correspond to a non-degenerate spherical structure on the cone-manifold $\mathcal{H}_{3}(\alpha, \beta, \gamma)$.
For case (ii), up to a suitable conjugation, the representation $\widetilde{\rho}$ preserves the Hopf fibration. Thus, by Lemma 4 , it descends to an abelian representation of $\Gamma_{0}$, which cannot be a holonomy of a non-degenerate spherical structure on the base of the fibration.
Finally, case (iii) is left. By [2, Lemma 9.2], one has

$$
\begin{aligned}
\widetilde{\rho}(a) & =\left\langle m_{a}^{t} R(\alpha) \overline{m_{a}}, R(\alpha)\right\rangle, \\
\widetilde{\rho}(b) & =\left\langle m_{b}^{t} R(\beta) \overline{m_{b}}, R(\beta)\right\rangle, \\
\widetilde{\rho}(c) & =\left\langle m_{c}^{t} R(\gamma) \overline{m_{c}}, R(\gamma)\right\rangle
\end{aligned}
$$

for $m_{a}, m_{b}, m_{c} \in S U_{2}(\mathbb{C})$.
Note, that every matrix $m \in S U_{2}(\mathbb{C})$ is of the form $m=R(\tau) M(\psi, \theta)$ for suitable $0 \leq \psi \leq \pi, 0 \leq \theta, \tau \leq 2 \pi$. Then we obtain that the image of every meridian in $\Gamma=\pi_{1}\left(\mathbb{S}^{3} \backslash \mathcal{H}_{3}\right)$ has the form

$$
\begin{gathered}
\left\langle m^{t} R(\omega) \bar{m}, R(\omega)\right\rangle=\left\langle M^{t}(\psi, \theta) R^{t}(\tau) R(\omega) \overline{R(\tau)} \overline{M(\psi, \tau)}, R(\omega)\right\rangle= \\
\left\langle M^{t}(\psi, \theta) R(\omega) \overline{M(\psi, \theta)}, R(\omega)\right\rangle
\end{gathered}
$$

since $R(\omega)$ and $R(\tau)$ commute. Hence, Lemma 2 implies that every meridian is mapped by $\widetilde{\rho}$ to a rotation about an appropriate fibre of the Hopf fibration. By Propositions 2.1 and 2.2 of [9], the holonomy preserves the fibration structure.
Let $A=\widetilde{\rho}(a), B=\widetilde{\rho}(b), C=\widetilde{\rho}(c)$ be holonomy images of the generators $a$, $b, c$ for $\Gamma=\pi_{1}\left(\mathbb{S}^{3} \backslash \mathcal{H}_{3}\right)$.
After a suitable conjugation in $S U_{2}(\mathbb{C}) \times S U_{2}(\mathbb{C})$, we obtain

$$
\begin{gathered}
A=\left\langle A_{l}, A_{r}\right\rangle=\langle R(\alpha), R(\alpha)\rangle, \\
B=\left\langle B_{l}, B_{r}\right\rangle=\left\langle\overline{M(0, \phi)} R(\beta) M(0, \phi)^{t}, R(\beta)\right\rangle, \\
C=\left\langle C_{l}, C_{r}\right\rangle=\left\langle\overline{M(\psi, \theta)} R(\gamma) M(\psi, \theta)^{t}, R(\gamma)\right\rangle .
\end{gathered}
$$

In order for the holonomy map $\widetilde{\rho}$ to be a homomorphism, the following relations should hold:

$$
\begin{gathered}
A_{l} C_{l} B_{l}=B_{l} A_{l} C_{l}=C_{l} B_{l} A_{l} \\
A_{r} C_{r} B_{r}=B_{r} A_{r} C_{r}=C_{r} B_{r} A_{r}
\end{gathered}
$$

The latter of them are satisfied by the construction of $\widetilde{\rho}: \Gamma \rightarrow S U_{2}(\mathbb{C}) \times \mathbb{S}^{1}$. Let us consider the former relations. By Lemma 4, the elements $A_{l}, B_{l}$ and $C_{l}$ are rotations of $\mathbb{S}^{2}$ about the points $\widehat{F}_{a}=(0,0), \widehat{F}_{b}=(0, \phi)$ and $\widehat{F}_{c}=(\psi, \theta)$, respectively. Since $\widehat{F}_{a}, \widehat{F}_{b}, \widehat{F}_{c}$ form a triangle on $\mathbb{S}^{2}$ and the base space of $\mathcal{H}_{3}(\alpha, \beta, \gamma)$ is a turnover with $\alpha, \beta, \gamma$ cone angles, one may expect the following

Lemma 5 The points $\widehat{F}_{a}=(0,0), \widehat{F}_{b}=(0, \phi)$ and $\widehat{F}_{c}=(\psi, \theta)$ form a triangle with angles $\frac{\alpha}{2}, \frac{\beta}{2}$ and $\frac{\gamma}{2}$ at the corresponding vertices.

Proof. By a straightforward computation, we obtain that

$$
\begin{aligned}
& A_{l} C_{l} B_{l}-B_{l} A_{l} C_{l}=\left(\begin{array}{cc}
i R_{1} & R_{2}+i R_{3} \\
-R_{2}+i R_{3} & -i R_{1}
\end{array}\right), \\
& C_{l} B_{l} A_{l}-B_{l} A_{l} C_{l}=\left(\begin{array}{cc}
i R_{4} & R_{5}+i R_{3} \\
-R_{5}+i R_{3} & -i R_{4}
\end{array}\right),
\end{aligned}
$$

where

$$
\begin{gathered}
R_{1}=2 \sin \frac{\beta}{2} \sin \frac{\gamma}{2} \sin \theta \cos \phi \sin \left(\frac{\alpha}{2}-\psi\right) \\
R_{2}=2 \sin \frac{\beta}{2}\left(\cos \frac{\gamma}{2} \sin \frac{\alpha}{2} \sin \phi+\sin \frac{\gamma}{2}\left(-\cos \phi \cos \left(\frac{\alpha}{2}-\psi\right) \sin \theta+\right.\right. \\
\left.\left.\cos \frac{\alpha}{2} \cos \theta \sin \phi\right)\right) \\
R_{3}=-2 \sin \frac{\beta}{2} \sin \frac{\gamma}{2} \sin \theta \sin \phi \sin \left(\frac{\alpha}{2}-\psi\right) \\
R_{4}=2 \sin \frac{\gamma}{2}\left(\cos \theta \sin \frac{\alpha}{2} \sin \frac{\beta}{2} \sin \phi-\left(\cos \frac{\beta}{2} \sin \frac{\alpha}{2}+\right.\right. \\
\left.\left.\cos \frac{\alpha}{2} \sin \frac{\beta}{2} \cos \phi\right) \sin \theta \sin \psi\right) \\
R_{5}=2 \sin \frac{\gamma}{2}\left(\cos \frac{\beta}{2} \cos \psi \sin \frac{\alpha}{2} \sin \theta+\right. \\
\left.\cos \frac{\alpha}{2} \sin \frac{\beta}{2}(\cos \phi \cos \psi \sin \theta-\cos \theta \sin \phi)\right)
\end{gathered}
$$

In order to determine the parameters $\phi, \psi$ and $\theta$, one can proceed as follows: these are determined by the system of equations $R_{k}=0, k \in\{1, \ldots, 5\}$
under the restrictions $0<\alpha, \beta, \gamma<2 \pi$ and $0<\psi \leq 2 \pi, 0<\theta \leq \pi$. Thus, the common solutions to $R_{1}$ and $R_{3}$ are $\psi=\frac{\alpha}{2}$ and $\psi=\frac{\alpha}{2} \pm \pi$. We claim that the cone angles in the base space of $\mathcal{H}_{3}(\alpha, \beta, \gamma)$ and along its fibres are the same, and choose $\psi=\frac{\alpha}{2}$.
Taking into account that $0<\alpha, \beta, \gamma<2 \pi$ (this implies that the sine functions of half cone angles are non-zero), turn the set of relations $R_{k}$, $k \in\{1, \ldots, 5\}$ into a new one:

$$
\begin{aligned}
& \widetilde{R}_{1}=-\cos \phi \sin \frac{\gamma}{2} \sin \theta+\left(\sin \frac{\alpha}{2} \cos \frac{\gamma}{2}+\cos \frac{\alpha}{2} \sin \frac{\gamma}{2} \cos \theta\right) \sin \phi, \\
& \widetilde{R}_{2}=-\cos \theta \sin \frac{\beta}{2} \sin \phi+\left(\sin \frac{\alpha}{2} \cos \frac{\beta}{2}+\cos \frac{\alpha}{2} \sin \frac{\beta}{2} \cos \phi\right) \sin \theta .
\end{aligned}
$$

Note, that the conditions of Theorem 2 concerning cone angles are exactly the existence conditions for a spherical triangle with angles $\frac{\alpha}{2}, \frac{\beta}{2}$ and $\frac{\gamma}{2}$. For the latter, the following trigonometric identities (spherical cosine and sine rules) are satisfied [25, Theorems 2.5.2 and 2.5.4]:

$$
\begin{gathered}
\cos \phi=\frac{\cos \frac{\gamma}{2}+\cos \frac{\alpha}{2} \cos \frac{\beta}{2}}{\sin \frac{\alpha}{2} \sin \frac{\beta}{2}}, \\
\cos \theta=\frac{\cos \frac{\beta}{2}+\cos \frac{\alpha}{2} \cos \frac{\gamma}{2}}{\sin \frac{\alpha}{2} \sin \frac{\gamma}{2}}, \\
\frac{\sin \phi}{\sin \frac{\gamma}{2}}=\frac{\sin \theta}{\sin \frac{\beta}{2}} .
\end{gathered}
$$

These identities state that the points $\widehat{F}_{a}, \widehat{F}_{b}$ and $\widehat{F}_{c}$ form a triangle on $\mathbb{S}^{2}$ with angles $\frac{\alpha}{2}, \frac{\beta}{2}$ and $\frac{\gamma}{2}$ at the corresponding vertices. Its double provides the base turnover with cone angles $\alpha, \beta$ and $\gamma$ for the fibred cone-manifold $\mathcal{H}_{3}(\alpha, \beta, \gamma)$.
On substituting the expressions for $\cos \phi$ and $\cos \psi$ above in the relations $\widetilde{R}_{k}$, $k \in\{1,2\}$ and taking into account the sine rule, one obtains that $\widetilde{R}_{k}=0$, $k \in\{1,2\}$. The lemma is proven.
Let $\mathcal{S}$ denote the domain of cone angles indicated in the statement of the theorem:

$$
\mathcal{S}=\left\{\begin{array}{l|l}
\vec{\alpha}=(\alpha, \beta, \gamma) \left\lvert\, \begin{array}{r}
2 \pi-\gamma<\alpha+\beta<2 \pi+\gamma \\
-2 \pi+\gamma<\alpha-\beta<2 \pi-\gamma
\end{array}\right.
\end{array}\right\} .
$$

Let $\mathcal{S}^{*}$ denote the subset of $\mathcal{S}$, such that for every triple of cone angles $\vec{\alpha}=(\alpha, \beta, \gamma) \in \mathcal{S}^{*}$ there exists a spherical structure on $\mathcal{H}_{3}(\vec{\alpha})$. Our next step is to show that $\mathcal{S}^{*}$ coincides with $\mathcal{S}$.

The set $\mathcal{S}^{*}$ is non-empty. From [8], it follows that $\mathcal{H}_{3}(\pi, \pi, \pi)$ has a spherical structure. The orbifold $\mathcal{H}_{3}(\pi, \pi, \pi)$ is Seifert fibred and its base is a turnover with cone angles equal to $\pi$. Thus, the point $(\pi, \pi, \pi) \in \mathcal{S}$ belongs to $\mathcal{S}^{*}$.
The set $\mathcal{S}^{*}$ is open, because a deformation of the holonomy induces a deformation of the structure [20].
In order to prove that the set $\mathcal{S}^{*}$ is closed, we consider a sequence $\vec{\alpha}_{n}=$ $\left(\alpha_{n}, \beta_{n}, \gamma_{n}\right)$ in $\mathcal{S}^{*}$ converging to $\vec{\alpha}_{\infty}=\left(\alpha_{\infty}, \beta_{\infty}, \gamma_{\infty}\right)$ in $\mathcal{S}$. Since every spherical cone-manifold with cone angles $\leq 2 \pi$ is an Alexandrov space with curvature $\geq 1[3]$, we obtain that the diameter of $\mathcal{H}_{3}\left(\vec{\alpha}_{n}\right)$ is bounded above: $\operatorname{diam} \mathcal{H}_{3}\left(\vec{\alpha}_{n}\right) \leq \pi$.
Let dist $\mathcal{H}_{3}\left(\vec{\alpha}_{n}\right)$ denote the minimum of the mutual distances between the axis of rotations $A, B$ and $C$. Since $\vec{\alpha}_{\infty} \in \mathcal{S}$, we have by Lemma 5 that the turnover $\mathbb{S}^{2}\left(\vec{\alpha}_{\infty}\right)$ is non-degenerate. By making use of Lemma 3, one obtains that (restricting to a subsequence, if needed) for every $\vec{\alpha}_{n} \in \mathcal{S}$, $n=1,2, \ldots$ the function $\operatorname{dist} \mathcal{H}_{3}\left(\vec{\alpha}_{n}\right)$ is uniformly bounded below away from zero:

$$
\text { dist } \mathcal{H}_{3}\left(\vec{\alpha}_{n}\right) \geq d_{0}>0, \quad n=1,2, \ldots
$$

Then we use the following facts [3]:

1. The Gromov-Hausdorff limit of Alexandrov spaces with curvature $\geq 1$, dimension $=3$ and bounded diameter is an Alexandrov space with curvature $\geq 1$ and dimension $\leq 3$,
2. Dimension of an Alexandrov space with curvature $\geq 1$ holds the same at every point (the word "dimension" means Hausdorff or topological dimension, which are equal in the case of curvature $\geq 1$ ).

Since dist $\mathcal{H}_{3}\left(\vec{\alpha}_{n}\right) \geq d_{0}>0$, the sequence $\mathcal{H}_{3}\left(\vec{\alpha}_{n}\right)$ does not collapse. Thus, the cone-manifold $\mathcal{H}_{3}\left(\vec{\alpha}_{\infty}\right)$ has a non-degenerate spherical structure and $\vec{\alpha}_{\infty} \in \mathcal{S}^{*}$.
The subset $\mathcal{S}^{*} \subset \mathcal{S}$ is non-empty, as well as both closed and open. This implies $\mathcal{S}^{*}=\mathcal{S}$.
Finally, we claim the following fact concerning the geometric characteristics of $\mathcal{H}_{3}(\alpha, \beta, \gamma)$ cone-manifold:

Lemma 6 Let $\ell_{\alpha}, \ell_{\beta}, \ell_{\gamma}$ denote the lengths of the singular strata for $\mathcal{H}_{3}(\alpha, \beta, \gamma)$ cone-manifold with cone angles $\alpha, \beta$ and $\gamma$. Then

$$
\ell_{\alpha}=\ell_{\beta}=\ell_{\gamma}=\frac{\alpha+\beta+\gamma}{2}-\pi .
$$

The volume of $\mathcal{H}_{3}(\alpha, \beta, \gamma)$ is

$$
\operatorname{Vol} \mathcal{H}_{3}(\alpha, \beta, \gamma)=\frac{1}{2}\left(\frac{\alpha+\beta+\gamma}{2}-\pi\right)^{2}
$$

Proof. Let us calculate the geometric parameters explicitly, using the holonomy map defined above. First, we introduce two notions suitable for the further discussion. Given an element $M=\left\langle M_{l}, M_{r}\right\rangle \in S U_{2}(\mathbb{C}) \times S U_{2}(\mathbb{C})$, one may assume that the pair of matrices $\left\langle M_{l}, M_{r}\right\rangle$ is conjugated, by means of a certain element $\left\langle C_{l}, C_{r}\right\rangle \in S U_{2}(\mathbb{C}) \times S U_{2}(\mathbb{C})$, to the pair of diagonal matrices

$$
\left\langle\left(\begin{array}{cc}
e^{i \gamma} & 0 \\
0 & e^{-i \gamma}
\end{array}\right),\left(\begin{array}{cc}
e^{i \varphi} & 0 \\
0 & e^{-i \varphi}
\end{array}\right)\right\rangle
$$

with $0 \leq \gamma, \varphi \leq \pi$.
Then call the translation length of $M$ the quantity $\delta(M):=\varphi-\gamma$ and call the "jump" of $M$ the quantity $\nu(M):=\varphi+\gamma$, see [11] and [31, Ch.6.4.2]. We suppose that $\varphi>\gamma$, otherwise changing $\gamma, \varphi$ for $2 \pi-\gamma$ and $\pi-\varphi$ makes the considered tuple to have the desired form.
Recall that the representation of $\Gamma=\pi_{1}\left(\mathbb{S}^{3} \backslash \mathcal{H}_{3}\right)$ is

$$
\Gamma=\langle a, b, c, h \mid a c b=b a c=c b a=h, h \in Z(\Gamma)\rangle,
$$

where $a, b, c$ are meridians and $h$ is a longitudinal loop that represents a fibre. Denote by $H$ the image of $h$ under the holonomy map $\widetilde{\rho}$. Then we obtain

$$
\ell_{\alpha}=\ell_{\beta}=\ell_{\gamma}=\delta(H) .
$$

Since $A=\widetilde{\rho}(a)$ and $H=\widetilde{\rho}(h)$ commute, there exists an element $C=\left\langle C_{l}, C_{r}\right\rangle$ of $S U_{2}(\mathbb{C}) \times S U_{2}(\mathbb{C})$ such that

$$
\begin{gathered}
C A C^{-1}=\left\langle\left(\begin{array}{cc}
e^{i \frac{\alpha}{2}} & 0 \\
0 & e^{-i \frac{\alpha}{2}}
\end{array}\right),\left(\begin{array}{cc}
e^{i \frac{\alpha}{2}} & 0 \\
0 & e^{-i \frac{\alpha}{2}}
\end{array}\right)\right\rangle, \\
C H C^{-1}=\left\langle\left(\begin{array}{cc}
e^{i \gamma(H)} & 0 \\
0 & e^{-i \gamma(H)}
\end{array}\right),\left(\begin{array}{cc}
e^{i \varphi(H)} & 0 \\
0 & e^{-i \varphi(H)}
\end{array}\right)\right\rangle .
\end{gathered}
$$

By a straightforward computation similar to that in Lemma 5, one obtains

$$
2 \cos \gamma(H)=\operatorname{tr} H_{l}=\operatorname{tr} A_{l} C_{l} B_{l}=\operatorname{tr}(-\mathrm{id})=2 \cos \pi
$$

and

$$
2 \cos \varphi(H)=\operatorname{tr} H_{r}=\operatorname{tr} A_{r} C_{r} B_{r}=2 \cos \frac{\alpha+\beta+\gamma}{2} .
$$

From the foregoing discussion, the singular stratum's length is

$$
\ell_{\alpha}=\delta(H)=\frac{\alpha+\beta+\gamma}{2}-\pi .
$$

An analogous equality holds for $\ell_{\beta}$ and $\ell_{\gamma}$. By the Schläfli formula [12], the following relation holds:

$$
2 \mathrm{dVol} \mathcal{H}_{3}(\alpha, \beta, \gamma)=\ell_{\alpha} \mathrm{d} \alpha+\ell_{\beta} \mathrm{d} \beta+\ell_{\gamma} \mathrm{d} \gamma .
$$

Solving this differential equality, we obtain that

$$
\operatorname{Vol} \mathcal{H}_{3}(\alpha, \beta, \gamma)=\frac{1}{2}\left(\frac{\alpha+\beta+\gamma}{2}-\pi\right)^{2}+\mathrm{Vol}_{0}
$$

where $\mathrm{Vol}_{0}$ is an arbitrary constant. Since the geometric structure on the base space of the fibration (consequently, on the whole $\mathcal{H}_{3}(\alpha, \beta, \gamma)$ conemanifold) degenerates when $\alpha+\beta+\gamma \longrightarrow 2 \pi$, the equality $\operatorname{Vol}_{0}=0$ follows from the volume function continuity.
Consider a holonomy $\widetilde{\rho}=\left\langle\widetilde{\rho}_{1}, \widetilde{\rho}_{2}\right\rangle: \Gamma=\pi_{1}\left(\mathbb{S}^{3} \backslash \mathcal{H}_{3}\right) \rightarrow S U_{2}(\mathbb{C}) \times S U_{2}(\mathbb{C})$ for $\mathcal{H}_{3}(\alpha, \beta, \gamma)$ cone-manifold. As we already know from the preceding discussion, one has $\widetilde{\rho}: \Gamma \rightarrow S U_{2}(\mathbb{C}) \times \mathbb{S}^{1}$ essentially, and $\widetilde{\rho}_{1}$ determines $\widetilde{\rho}_{2}$ up to a conjugation by means of the equality $\operatorname{tr} \widetilde{\rho}_{1}(m)=\operatorname{tr} \widetilde{\rho}_{2}(m)$ for meridians in $\Gamma$. So any deformation of $\widetilde{\rho}$ is a deformation of $\widetilde{\rho}_{1}$. In the case of $\mathcal{H}_{3}(\alpha, \beta, \gamma)$, the map $\widetilde{\rho}_{1}$ is a non-abelian representation of the base turnover group. Spherical turnover is rigid, that means $\widetilde{\rho}_{1}$ is determined only by the corresponding cone angles. Thus $\mathcal{H}_{3}(\alpha, \beta, \gamma)$ is locally rigid.
The global rigidity follows from the fact that every $\mathcal{H}_{3}(\alpha, \beta, \gamma)$ cone-manifold could be deformed to the orbifold $\mathcal{H}_{3}(\pi, \pi, \pi)$ by a continuous path through locally rigid structures. This assertion holds since $\mathcal{S}^{*}$ contains the point $(\pi, \pi, \pi)$ and $\mathcal{S}^{*}$ is convex. The global rigidity of $\mathcal{H}_{3}(\pi, \pi, \pi)$ spherical orbifold follows from [26, 27] and implies the global rigidity of $\mathcal{H}_{3}(\alpha, \beta, \gamma)$ by means of deforming the orbifold structure backwards to the considered conemanifold one.

### 4.2 Case of flexibility: the cone-manifold $\mathcal{H}_{4}(\alpha)$

Let $\mathcal{H}_{4}(\alpha)$ denote a three-dimensional cone-manifold with underlying space the sphere $\mathbb{S}^{3}$ and singular locus formed by the link $\mathcal{H}_{4}$ with cone angle $\alpha$ along all its components.
The following theorem provides an example of a flexible cone-manifold which is Seifert fibred.

Figure 3: The link $\mathcal{H}_{4}$
Theorem 3 The cone-manifold $\mathcal{H}_{4}(\alpha)$ admits a spherical structure if

$$
\pi<\alpha<2 \pi
$$

This structure is not unique (i.e. $\mathcal{H}_{4}(\alpha)$ is not globally, nor locally rigid). The deformation space contains an open interval, that provides a oneparameter family of distinct spherical cone-metrics on $\mathbb{S}^{3}$.
The length of each singular stratum is

$$
\ell=2(\alpha-\pi) .
$$

The volume of $\mathcal{H}_{4}(\alpha)$ equals

$$
\operatorname{Vol} \mathcal{H}_{4}(\alpha)=2(\alpha-\pi)^{2}
$$

Proof. The following lemma precedes the proof of the theorem.
Lemma 7 Given a quadrangle $Q$ on $\mathbb{S}^{2}$ with three right angles and one angle $\frac{\alpha}{2}$ (see Fig. [4), the following statements hold:

1. The quadrangle $Q$ exists if $\pi<\alpha<2 \pi$,
2. $\sin \ell_{1} \sin \ell_{2}=-\cos \frac{\alpha}{2}$,
3. $\cos \phi=\frac{\cos \ell_{1} \cos \ell_{2}}{\sin \frac{\alpha}{2}}$,
4. $\cos \psi=\tan \ell_{1} \cot \phi$,
5. $0 \leq \ell_{1}, \ell_{2}, \phi, \psi \leq \frac{\pi}{2}$.

Proof. We refer the reader to [30, §3.2] for a detailed proof of the statements above.

Figure 4: The quadrangle $Q$
Given a quadrangle $Q$ from Lemma 7 (so-called Saccheri's quadrangle) one can construct another one, depicted in Fig5, by reflecting $Q$ in its sides incident to the vertex $O$. We may regard $O$ to be the point $(0,0) \in \mathbb{S}^{2}$. Thus, the fibres over the corresponding vertices are

$$
\begin{gathered}
F_{a}(t)=M(\psi, \phi) F(t), \\
F_{b}(t)=M(\pi-\psi, \phi) F(t), \\
F_{c}(t)=M(\pi+\psi, \phi) F(t), \\
F_{d}(t)=M(2 \pi-\psi, \phi) F(t) .
\end{gathered}
$$

Let $A=\left\langle A_{l}, A_{r}\right\rangle, B=\left\langle B_{l}, B_{r}\right\rangle, C=\left\langle C_{l}, C_{r}\right\rangle, D=\left\langle D_{l}, D_{r}\right\rangle$ denote the respective rotations through angle $\alpha$ about the axis $F_{a}, F_{b}, F_{c}$ and $F_{d}$. From Lemma 2, one obtains

$$
\begin{gathered}
A_{l}=\overline{M(\psi, \phi)} R(\alpha) M(\psi, \phi)^{t}, A_{r}=R(\alpha) ; \\
B_{l}=\overline{M(\pi-\psi, \phi)} R(\alpha) M(\pi-\psi, \phi)^{t}, B_{r}=R(\alpha) ; \\
C_{l}=\overline{M(\pi+\psi, \phi)} R(\alpha) M(\pi+\psi, \phi)^{t}, B_{r}=R(\alpha) ; \\
D_{l}=\overline{M(2 \pi-\psi, \phi)} R(\alpha) M(2 \pi-\psi, \phi)^{t}, D_{r}=R(\alpha) .
\end{gathered}
$$

We assume that $\ell_{1}, \ell_{2}, \phi$ and $\psi$ satisfy the identities of Lemma 7

Figure 5: The base quadrangle $P$ for $\mathcal{H}_{4}(\alpha)$
The fundamental group of $\pi_{1}\left(\mathbb{S}^{3} \backslash \mathcal{H}_{4}\right)$ has the presentation

$$
\Gamma=\pi_{1}\left(\mathbb{S}^{3} \backslash \mathcal{H}_{4}\right)=\langle a, b, c, d, h \mid a d c b=b a d c=c b a d=d c b a=h, h \in Z(\Gamma)\rangle
$$

Let us construct a lift of the holonomy map $\tilde{\rho}: \Gamma \rightarrow S U_{2}(\mathbb{C}) \times S U_{2}(\mathbb{C})$ as follows:

$$
\widetilde{\rho}(a)=A, \widetilde{\rho}(b)=B, \widetilde{\rho}(c)=C, \widetilde{\rho}(d)=D .
$$

Here we choose $\widetilde{\rho}: \Gamma \rightarrow S U_{2}(\mathbb{C}) \times \mathbb{S}^{1}$ by the same reason as in Theorem 2, In order to show that the map $\widetilde{\rho}$ is a homomorphism, one has to check whether the following relations are satisfied:

$$
\begin{gathered}
A_{l} D_{l} C_{l} B_{l}=B_{l} A_{l} D_{l} C_{l}=C_{l} B_{l} A_{l} D_{l}=D_{l} C_{l} B_{l} A_{l} \\
A_{r} D_{r} C_{r} B_{r}=B_{r} A_{r} D_{r} C_{r}=C_{r} B_{r} A_{r} D_{r}=D_{r} C_{r} B_{r} A_{r}
\end{gathered}
$$

The latter relations hold in view of the fact that the matrices $A_{r}, B_{r}, C_{r}$ and $D_{r}$ pairwise commute. Then, we show that the following equality holds:

$$
A_{l} D_{l} C_{l} B_{l}=\mathrm{id} .
$$

To do this, split the quadrangle $P$ into two triangles by drawing a geodesic line from $B$ to $D$. Since $A_{l}, B_{l}, C_{l}$ and $D_{l}$ are rotations about the vertices of the quadrangle depicted in Fig. 66, let us decompose the rotations $B_{l}=B_{l}^{\prime} B_{l}^{\prime \prime}$ and $D_{l}=D_{l}^{\prime} D_{l}^{\prime \prime}$ into the products of rotations $B_{l}^{\prime}, B_{l}^{\prime \prime}$ through angles $\beta_{1}$,

Figure 6: Section of P by the line joining vertices $B$ and $D$
$\beta_{2}$ and the rotations $D_{l}^{\prime}, D_{l}^{\prime \prime}$ through angles $\delta_{1}$ and $\delta_{2}$, respectively. The following equalities hold: $\beta_{1}+\beta_{2}=\frac{\alpha}{2}$ and $\delta_{1}+\delta_{2}=\frac{\alpha}{2}$. Thus, the triples $D_{l}^{\prime \prime}, C_{l}, B_{l}^{\prime}$ and $A_{l}, D_{l}^{\prime}, B_{l}^{\prime \prime}$ consist of rotations about the vertices of two disjoint triangles depicted in Fig. 6. Similar to the computation of Lemma 6, we have

$$
D_{l}^{\prime \prime} C_{l} B_{l}^{\prime}=-\mathrm{id}
$$

and

$$
A_{l} D_{l}^{\prime} B_{l}^{\prime \prime}=-\mathrm{id} .
$$

From the identities above, it follows that

$$
A_{l} D_{l} C_{l} B_{l}=A_{l} D_{l}^{\prime} D_{l}^{\prime \prime} C_{l} B_{l}^{\prime} B_{l}^{\prime \prime}=-A_{l} D_{l}^{\prime} B_{l}^{\prime \prime}=\mathrm{id} .
$$

The statement holds under a cyclic permutation of the factors. Thus,

$$
A_{l} D_{l} C_{l} B_{l}=B_{l} A_{l} D_{l} C_{l}=C_{l} B_{l} A_{l} D_{l}=D_{l} C_{l} B_{l} A_{l}=\mathrm{id}
$$

Below we shall consider the side-length $\ell_{1}$ as a parameter. Let $\ell_{1}:=\tau$. Then by Lemma 7 one has that $\sin \ell_{2}=-\frac{\cos \frac{\alpha}{2}}{\sin \tau}$ and $\ell_{2}:=\ell_{2}(\tau)$ is a well-defined continuous function of $\tau$. The quadrangle $P$ depends on the parameter $\tau$ continuously while keeping the angles in its vertices equal to $\frac{\alpha}{2}$.
Let $\mathcal{H}_{4}(\alpha ; \tau)$ denote a three-dimensional cone-manifold with underlying space the sphere $\mathbb{S}^{3}$ and singular locus the link $\mathcal{H}_{4}$ with cone angle $\alpha$ along its components. Furthermore, its holonomy map is determined by the quadrangle $P$ described above (see Fig. (5) depending on the parameter $\tau$. This means that the double of $P$ forms a "pillowcase" cone-surface with all cone angles equal to $\alpha$, which is the base space for the fibred cone-manifold $\mathcal{H}_{4}(\alpha ; \tau)$.

Let $\mathbb{L}_{n}(\alpha, \beta)$ be a cone-manifold with underlying space the sphere $\mathbb{S}^{3}$ and singular locus a torus link of the type $(2,2 n)$ with cone angles $\alpha$ and $\beta$ along its components. Torus links of the type $(2,2 n)$ are two-bridge links. The corresponding cone-manifolds were previously considered in [17, 22]. Since the cone-manifold $\mathcal{H}_{4}(\alpha)$ forms a 4 -fold branched covering of the conemanifold $\mathbb{L}_{4}\left(\alpha, \frac{\pi}{2}\right)$, from [17, Theorem 2] we obtain that $\mathcal{H}_{4}(\alpha)$ has a spherical structure if $\pi<\alpha<2 \pi$. The length of each singular stratum equals to $\ell=2(\alpha-\pi)$ and the volume is $\operatorname{Vol} \mathcal{H}_{4}(\alpha)=2(\alpha-\pi)^{2}$.
Under the assumption that $\ell_{1}=\ell_{2}$, the base quadrangle depicted in Fig. 5 appears to have a four order symmetry. Moreover, by making use of Lemma 7. one may derive the following equalities: $\psi=\frac{\pi}{4}, \cos \phi=\cot \frac{\alpha}{4}$. The general formulas for the holonomy of $\mathcal{H}_{4}(\alpha)$ cone-manifold derived above subject to the condition $\ell_{1}=\ell_{2}$ (equivalently, the cone-manifold $\mathcal{H}_{4}(\alpha)$ has a four order symmetry) give the holonomy map induced by the covering. Thus $\mathcal{H}_{4}(\alpha) \cong \mathcal{H}_{4}\left(\alpha ; \arccos \left(\sqrt{2} \cos \frac{\alpha}{4}\right)\right)$ is a spherical cone-manifold.
We claim that one can vary the parameter $\tau$ in certain ranges while keeping spherical structure on $\mathcal{H}_{4}(\alpha ; \tau)$ non-degenerate.

Lemma 8 If $\tau$ varies over $\left(\frac{\alpha-\pi}{2}, \frac{\pi}{2}\right)$, the cone-manifold $\mathcal{H}_{4}(\alpha ; \tau)$ has a nondegenerate spherical structure.

Proof. The proof has much in common with the proof of the spherical structure existence on $\mathcal{H}_{3}(\alpha, \beta, \gamma)$ cone-manifold given in Theorem 2, Let us express the identities of Lemma 7 in terms of the parameter $\ell_{1}:=\tau$. We obtain

$$
\begin{gathered}
\cos \phi=\cos \tau \sqrt{1-\cot ^{2} \frac{\alpha}{2} \cot ^{2} \tau}, \\
\cos \psi=\sqrt{\frac{1-\cot ^{2} \frac{\alpha}{2} \cot ^{2} \tau}{1+\cot ^{2} \frac{\alpha}{2} \cot ^{4} \tau}}, \\
\sin \ell_{2}=-\frac{\cos \frac{\alpha}{2}}{\sin \tau} .
\end{gathered}
$$

Since Lemma 7 states that $0 \leq \phi, \psi, \ell_{2} \leq \frac{\pi}{2}$, the functions $\phi:=\phi(\tau)$, $\psi:=\psi(\tau), \ell_{2}:=\ell_{2}(\tau)$ are well-defined and depend continuously on $\tau$.
Moreover, the following relations hold:

$$
\begin{gathered}
\cos b_{1}=\frac{\cos \phi}{\cos \ell_{2}}=\cos \tau \sqrt{\frac{\sin ^{2} \tau-\cot ^{2} \frac{\alpha}{2} \cos ^{2} \tau}{\sin ^{2} \tau-\cos ^{2} \frac{\alpha}{2}}} \\
\cos b_{2}=\frac{\cos \phi}{\cos \tau}=\sqrt{1-\cot ^{2} \frac{\alpha}{2} \cot ^{2} \tau}
\end{gathered}
$$

If one sets the centre $O$ of the quadrangle $P$ to $(0,0) \in \mathbb{S}^{2}$, the whole quadrangle is situated in the upper hemisphere provided $\phi<\frac{\pi}{2}$. From the fact that $\cos b_{1} \geq \cos \phi$ and $\cos b_{2} \geq \cos \phi$, it follows $b_{1}, b_{2} \leq \phi$. Thus $b_{1}, b_{2} \leq \frac{\pi}{2}$ and the functions $b_{1}:=b_{1}(\tau), b_{2}:=b_{2}(\tau)$ are well-defined and continuous with respect to $\tau$.
Observe that if the condition $\frac{\alpha-\pi}{2}<\tau<\frac{\pi}{2}$ is satisfied, then the required inequality $\phi<\frac{\pi}{2}$ holds.
Let $\mathcal{S}_{\alpha}^{*}$ denote the subset of $\mathcal{S}_{\alpha}=\left\{\tau \left\lvert\, \frac{\alpha-\pi}{2}<\tau<\frac{\pi}{2}\right.\right\}$ that consists of the points $\tau \in \mathcal{S}_{\alpha}$ such that the cone-manifold $\mathcal{H}_{4}(\alpha ; \tau)$ has a non-degenerate spherical structure. We show $\mathcal{S}_{\alpha}^{*}=\mathcal{S}_{\alpha}$ by means of the fact that $\mathcal{S}_{\alpha}^{*}$ is both open and closed non-empty subset of $\mathcal{S}_{\alpha}$.
As noticed above, $\tau=\arccos \left(\sqrt{2} \cos \frac{\alpha}{4}\right)$ belongs to $\mathcal{S}_{\alpha}^{*}$. Hence the set $\mathcal{S}_{\alpha}^{*}$ is non-empty.
The set $\mathcal{S}_{\alpha}^{*}$ is open by the fact that a deformation of the holonomy implies a deformation of the structure [20]. To prove that $\mathcal{S}_{\alpha}^{*}$ is closed, consider a sequence $\tau_{n}$ converging in $\mathcal{S}_{\alpha}^{*}$ to $\tau_{\infty} \in \mathcal{S}_{\alpha}$.
The lengths of common perpendiculars between the axis of rotations $A, B$, $C$ and $D$ defined above equal respectively $b_{1}, b_{2}$ and $\phi$.
Since $\tau_{\infty}$ corresponds to a non-degenerated quadrangle, every cone-manifold $\mathcal{H}_{4}\left(\alpha ; \tau_{n}\right)$ has the quantities $b_{1}\left(\tau_{n}\right), b_{2}\left(\tau_{n}\right)$ and $\phi\left(\tau_{n}\right)$ uniformly bounded below away from zero. By the arguments similar to those of Theorem 2, we obtain that $\mathcal{H}_{4}\left(\alpha ; \tau_{\infty}\right)$ is a non-degenerate spherical cone-manifold. Thus $\tau_{\infty}$ belongs to $\mathcal{S}_{\alpha}^{*}$. Hence $\mathcal{S}_{\alpha}^{*}$ is closed.
Finally, we obtain that $\mathcal{S}_{\alpha}^{*}=\mathcal{S}_{\alpha}$. Thus, while $\tau$ varies over $\left(\frac{\alpha-\pi}{2}, \frac{\pi}{2}\right)$ the cone-manifold $\mathcal{H}_{4}(\alpha ; \tau)$ does not collapse.
The following lemma shows that the interval $\left(\frac{\alpha-\pi}{2}, \frac{\pi}{2}\right)$ represents a part of the deformation space for possible spherical structures on $\mathcal{H}_{4}(\alpha ; \tau)$.
Lemma 9 The cone-manifolds $\mathcal{H}_{4}\left(\alpha ; \tau_{1}\right)$ and $\mathcal{H}_{4}\left(\alpha ; \tau_{2}\right)$ with $\pi<\alpha<2 \pi$ and $\frac{\alpha-\pi}{2}<\tau_{1}, \tau_{2}<\frac{\pi}{2}$ are not isometric if $\tau_{1} \neq \tau_{2}$.
Proof. If the cone-manifolds $\mathcal{H}_{4}\left(\alpha ; \tau_{1}\right)$ and $\mathcal{H}_{4}\left(\alpha ; \tau_{2}\right)$ were isometric, then their holonomy maps $\widetilde{\rho}_{i}, i=1,2$ would be conjugated representations of $\Gamma=\pi_{1}\left(\mathbb{S}^{3} \backslash \mathcal{H}_{4}\right)$ into $S U_{2}(\mathbb{C}) \times S U_{2}(\mathbb{C})$. Then the mutual distances between the axis of rotations $A_{i}, B_{i}, C_{i}$ and $D_{i}, i=1,2$, coming from the holonomy maps $\widetilde{\rho}_{1}$ and $\widetilde{\rho}_{2}$ would be equal for the corresponding pairs. From Lemma3, it follows that the common perpendicular length for the given fibres $C_{1}$ and $C_{2}$ is half the distance between the images of $C_{1}$ and $C_{2}$ under the Hopf map. By applying Lemmas 3 and 8 to the base quadrangle $P$ of $\mathcal{H}_{4}\left(\alpha ; \tau_{i}\right)$, $i=1,2$ one makes sure that the inequality $\tau_{1} \neq \tau_{2}$ implies the inequality for the lengths of corresponding common perpendiculars.

Note, that by the Schläfli formula the volume of $\mathcal{H}_{4}(\alpha)$ remains the same under any deformation preserving cone angles. Then the formulas for the volume and the singular stratum length follow from the covering properties of $\mathcal{H}_{4}(\alpha) \xrightarrow{4: 1} \mathbb{L}_{4}\left(\alpha, \frac{\pi}{2}\right)$ and Theorem 2 of [17]. Thus, Theorem 3 is proven.
