#### Abstract

Methods of phylogenetic inference use more and more complex models to generate trees from data. However, even simple models and their implications are not fully understood.

Here, we investigate the two-state Markov model on a tripod tree, inferring conditions under which a given set of observations gives rise to such a model. This type of investigation has been undertaken before by several scientists from different fields of research.

In contrast to other work we fully analyse the model, presenting conditions under which one can infer a model from the observation or at least get support for the tree-shaped interdependence of the leaves considered.

We also present all conditions under which the results can be extended from tripod trees to quartet trees, a step necessary to reconstruct at least a topology. Apart from finding conditions under which such an extension works we discuss example cases for which such an extension does not work.

Keywords: Phylogenetics, Identifiability, Invariant, Two-State-Model

#### 1 1. Introduction

In phylogeny, one assumes that the relationship of a set of taxonomic units (or taxa) can be visualised by a (binary) tree. The aim is to derive this tree from the observations at the taxa. From a stochastic modelling point of view, one assigns the taxa to the leaves of a (binary) tree, and assumes that the observations (which are usually considered to be i.i.d. over different sites) are the end results of a Markov process along the tree. The goal is to derive the best combination of tree and Markov model to explain the observations.

<sup>9</sup> This work regards the identifiability problem of this inference. It essentially asks <sup>10</sup> whether it is possible that infinite data sets are able to uniquely identify the transitions <sup>11</sup> on the tree and the tree completely. Note that in the present context, identifiability

<sup>\*</sup>sklaere@maths.otago.ac.nz

readily leads to consistency of various methods of estimating the parameters of the
model [see 1, Section 2.2 for an overview].

However, usually one only has an estimate of the leaf distribution such a process
induces. This leads to the question of whether one can find (simple) conditions to
determine whether a taxon distribution comes from a Markov process. In other words,
we ask whether we can validate the model, at least if there are infinitely many data
points available.

To approach this problem, we consider a very simple model. We assume that our 19 process can take only one of two states for every site, and that the tree is a tripod tree. 20 Under these restrictions, we can completely describe the map from the taxon 21 distribution to the parameters of the model, including necessary and sufficient 22 conditions on positivity of the parameters. Thereby, no conditions for reversibility of 23 the processes on the edges are needed. The analysis of the model on tripod trees has 24 immediate consequences for quartet trees. We derive these conditions to exemplify the 25 shortcomings of an extension from tripods to quartets. 26

Technically, the generic part of this work is already well-known. Initial work on the two state model from psychology can be found in Lazarsfeld and Henry [3]. Pearl and Tarsi [4] used these results in artificial intelligence to algorithmically identify the whole tree behind two-state Markov models. Note that identifiability of Markov models especially in phylogeny was studied in Allman et al. [5], Allman and Rhodes

<sup>32</sup> [6, 7], Baake [8], Chang [2]. We add to those results the analysis of the degenerate <sup>33</sup> cases, together with a complete analysis of the quartet tree model.

cases, together with a complete analysis of the quartet tree model.

The typical tool (for multi-state models) to identify a subspace of taxon distributions which might come from a Markovian tree model are phylogenetic

distributions which might come from a Markovian tree model are phylogenetic
invariants [6, 7, 9, 10, 11, 12]. Those invariants are polynomials in the taxon distribution
which are zero for those distributions that are derived from the model of interest.

<sup>38</sup> Summer et al. [13] discuss another very interesting set of invariants, the so-called

<sup>39</sup> Markov invariants. These are invariants whose value on a tree scales with the

<sup>40</sup> determinants of the Markov matrices on the edges. Thus, Markov invariants indicate

41 simple relations between the observations (the distribution of leaf states) and the model

(described by the Markov matrices), and provide conditions on the observations based
on properties of the model. We will make use of this property in this work.

In the two-state tripod case there is only one, the trivial invariant. But, not all leaf distributions are derived from the Markov model. In fact, we derive polynomials that vanish on distributions which satisfy the trivial invariant but are not identifiable

47 under the Markov model. To accommodate this observation we suggest incorporating

these polynomials into the set of invariants but with the addition that these

<sup>49</sup> polynomials do not vanish for identifiable distributions. We discuss degenerate

<sup>50</sup> distributions to describe this observation.

Although most of the leaf distributions allow for complex solutions of the model equations, in order for the solution of the algebraic equation to be parameters of a Markov model additional inequalities must be fulfilled [15, 16, 17]. The approach of <sup>54</sup> Matsen is restricted to the Cavender-Farris-Neyman model [CFN 18, 19, 20] to

<sup>55</sup> accommodate the Hadamard approach [21, 22]. Yang [17] investigated the CFN model

56 to explore conditions to obtain solutions for different optimisation problems in

<sup>57</sup> phylogeny. Extending our approach we recover the inequalities presented in Pearl and
 <sup>58</sup> Tarsi [4].

As a final step we investigate how the results for tripod trees extend to trees of four leaves. The results provide a glimpse at what we can expect from the

<sup>61</sup> reconstruction from tripods when we have no knowledge of the identifiability of the

62 given taxon distribution.

The structure of this work is as follows: In Section 2 we describe the general mutation model on a tree, with specialisation to tripod trees coming in Section 3.

<sup>65</sup> Section 4 deals with the complete solution of the two-state tripod tree model. Then, in

<sup>66</sup> Section 5 we use these results to analyse the general two-state Markov model on quartet

<sup>67</sup> trees. Section 6 discusses the relation between our work and the concept of Markov

invariants, and possible extensions of this work. ] For the sake of readability, proofs are

<sup>69</sup> presented in Appendix A.

### <sup>70</sup> 2. The Markov model of mutation along a tree

In this section we introduce the general Markov model and its properties. Pearl 71 and Tarsi [4] nicely motivate this model in the following way. Assume, one is given a set 72 L of taxa and a set of observations from a Markov process  $X: L \to \{0, 1\}$ . From these 73 observations one deduces a correlation between the taxa. The assumption is that this 74 correlation can be explained by an underlying (binary) tree T = (V, E) and an 75 extension  $Y: V \to \{0, 1\}$  of X such that for any pair of taxa there is an interior node 76 such that given the state at the interior node the two taxa are independent. See Fig. 77 A.1 for a depiction of this. 78

79

### [Figure 1 about here.]

Let us look closer at the process Y. The independence of pairs of taxa given an 80 interior node on the path between them corresponds to the so-called *directed local* 81 Markov property [e.g., 23, Chapter 2]. For this property one has to identify a node 82  $\zeta \in V$  as the root of the tree and direct all edges away from  $\zeta$ . Thus, our tree becomes 83 a directed acyclic graph, and for every node  $\beta \in V \setminus \{\zeta\}$  there is a parent node  $\alpha \in V$ 84 (with respect to the root), such that  $(\alpha, \beta) \in E$ . Further, for each node  $\beta \in V$  one 85 defines the set its descendants as those nodes  $\alpha$  for which the path from the root to  $\alpha$ 86 passes through  $\beta$ . The non-descendants are then the nodes that are neither descendants 87 nor parents. 88

The directed local Markov property states that conditioned on the state of its parent node the state of a node  $\alpha \in V$  is independent of the states of its <sup>91</sup> non-descendants. With this property the joint distribution  $\tilde{p}^Y$  has the factorisation <sup>92</sup> property, i.e. for the joint state  $\chi \in \{0, 1\}^{|V|}$  we get

$$\widetilde{p}_{\boldsymbol{\chi}}^{Y} = \Pr[Y_{\zeta} = \chi_{\zeta}] \prod_{(\alpha,\beta)\in E} \Pr[Y_{\beta} = \chi_{\beta}|Y_{\alpha} = \chi_{\alpha}] = q_{\chi_{\zeta}}^{\zeta} \prod_{(\alpha,\beta)\in E} M_{\chi_{\alpha}\chi_{\beta}}^{\alpha\beta}.$$
(1)

<sup>93</sup> Here, the marginal distribution  $q^{\zeta}$  corresponds to the initialisation of the process, i.e. <sup>94</sup>  $q_z^{\zeta}$  is the probability that the process attains state  $z \in \{0, 1\}$  at the root. The transition <sup>95</sup> matrices  $(M^e)_{e \in E}$  describe the way the process progresses along an edge. E.g., for an <sup>96</sup> edge  $(\alpha, \beta) \in E$  the term  $M_{ab}^{\alpha\beta}$  is the probability that the character a at node  $\alpha$  is <sup>97</sup> mutated into character b at node  $\beta$ .

In summary, the joint probability distribution  $\tilde{p}^{Y}$  is given by the marginal distribution  $q^{\zeta}$  and the transition matrices  $(M^{e})_{e \in E}$ , and thus such a Markov process is completely characterised by these parameters. We will call  $q^{\zeta}$  and  $(M^{e})_{e \in E}$  the process parameters.

In general, the actual position of the root node  $\zeta$  is not important for (1), i.e.  $\zeta$ can be chosen arbitrarily from V, including a leaf [e.g., 7].

We only have partial knowledge on the realisations of the process Y through the process X on the leaves. The joint distribution  $p^X$  of X can then be inferred from (1) using the law of total probability. Let  $x \in \{0,1\}^{|L|}$  denote the joint state at the leaves. Then

$$p_{\boldsymbol{x}}^{X} = \sum_{\substack{\boldsymbol{\chi} \in V\\ \boldsymbol{\chi}|_{L} = \boldsymbol{x}}} \widetilde{p}_{\boldsymbol{\chi}}^{Y} = \sum_{\substack{\boldsymbol{\chi} \in V\\ \boldsymbol{\chi}|_{L} = \boldsymbol{x}}} q_{\boldsymbol{\chi}_{\zeta}}^{\zeta} \prod_{(\alpha,\beta) \in E} M_{\boldsymbol{\chi}_{\alpha}\boldsymbol{\chi}_{\beta}}^{\alpha\beta}.$$
 (2)

Note that under the assumption that X comes from a reversible Markov process YChang [2] proved that all process parameters can be recovered from all the distributions of the restrictions of X to arbitrary triples of taxa.

If we find process parameters for a joint taxon distribution p then we call p tree 111 *decomposable.* If the obtained process parameters are unique (up to model-specific 112 symmetries), we call p algebraically identifiable, and if further the process parameters 113 are marginal and transition probabilities, then p is called *stochastically identifiable*. 114 Clearly, any stochastically identifiable distribution is also algebraically identifiable. 115 Looking at (2) we realise that verifying the tree decomposability of a distribution 116 p is equivalent to solving a polynomial equation system of  $2^{|L|} - 1$  independent 117 equations in 4|L| - 5 variables. We observe that the Markov equations are 118 overdetermined for |L| > 3, i.e. the space of tree decomposable distributions is a proper 119 subspace of the space of all distributions. From this we conclude, that there are 120

<sup>121</sup> conditions that define a tree decomposable distribution. These conditions are generally <sup>122</sup> known as *invariants*, polynomials in  $2^{|L|} - 1$  variables whose roots are distributions that <sup>123</sup> are tree decomposable. One example of an invariant is

$$\sum_{\boldsymbol{x} \in \{0,1\}^{|L|}} p_{\boldsymbol{x}} = 1, \tag{3}$$

i.e. all probabilities sum to one. This is fittingly called the *trivial invariant*. Allman
and Rhodes [6] provide a complete set of invariants for trees of arbitrary size under a
two-state-model, and observe that for complete identification the knowledge of the
restrictions to six taxa are necessary.

However, as pointed out in multiple publications [e.g., 4, 16] such invariants are not sufficient to guarantee tree identifiability. In particular, additional inequalities are needed.

Here, we are not only interested in recapturing invariants and inequalities. In addition, we also investigate those distributions that are not algebraically identifiable or not tree decomposable at all to discuss their impact on invariant-based inference.

#### <sup>134</sup> 3. General properties of a Markov model on a tripod tree

The starting point of our analysis is the tripod tree T with taxa  $\alpha, \beta, \gamma$ , interior node  $\zeta$  and edges  $(\zeta, \alpha)$ ,  $(\zeta, \beta)$ ,  $(\zeta, \gamma)$  (see Fig. A.2). This is the only labeled topology for three taxa. Hence any inference will be process- and not topology-related. Allman and Rhodes [7] select a taxon as the root for their approach. We will place the root at the interior node for the symmetry this provides in the tree equations.

[Figure 2 about here.]

140

As stated in the previous section, if the joint distribution  $\boldsymbol{p}$  of  $X_{\alpha}, X_{\beta}, X_{\gamma}$  comes from a Markov process then there are parameters  $\boldsymbol{q}^{\zeta}, \boldsymbol{M}^{\alpha}, \boldsymbol{M}^{\beta}, \boldsymbol{M}^{\gamma}$  such that the Markov equations (2) are satisfied. On a tripod tree these equations are the *tripod equations* 

$$p_{abc} = q_1^{\zeta} M_{1a}^{\alpha} M_{1b}^{\beta} M_{1c}^{\gamma} + (1 - q_1^{\zeta}) M_{0a}^{\alpha} M_{0b}^{\beta} M_{0c}^{\gamma}, \quad a, b, c \in \{0, 1\}.$$

$$\tag{4}$$

As before we call *p* tree decomposable, if there are parameters, algebraically identifiable, when the parameters are unique (up to some symmetries discussed later), and stochastically identifiable if the parameters are unique and proper marginal and transition probabilities.

The works of Lazarsfeld and Henry [3] and Pearl and Tarsi [4] were mainly 149 interested in inferring conditions under which a triplet distribution is stochastically 150 identifiable. While recovering their results we also investigate tree decomposability and 151 algebraic identifiability in order to describe their impact on invariant-based inference. 152 For three taxa the only invariant is the trivial invariant. Thus, one could expect 153 that all triplet distributions are tree decomposable. As we will see later, this is not the 154 case. In fact, we will present polynomials whose roots satisfy the trivial invariant but 155 are not tree decomposable. 156

#### 157 3.1. Statistics for binary models

Following Pearl and Tarsi [4] we identify the symbols 0 and 1 with their actual integer counterparts. This permits us to introduce a set of terms that are very helpful for later steps of the analysis. We start by introducing the following abbreviations:

$$\varepsilon_{\alpha\beta\gamma} := \mathbb{E}X_{\alpha}X_{\beta}X_{\gamma} = \Pr[X_{\alpha} = 1, X_{\beta} = 1, X_{\gamma} = 1] = p_{111}, \\
\varepsilon_{\alpha\beta} := \mathbb{E}X_{\alpha}X_{\beta} = \Pr[X_{\alpha} = 1, X_{\beta} = 1] = p_{11\Sigma} = p_{110} + p_{111}, \\
\varepsilon_{\alpha} := \mathbb{E}X_{\alpha} = \Pr[X_{\alpha} = 1] = p_{1\Sigma\Sigma} = p_{100} + p_{101} + p_{110} + p_{111}.$$

The symbols  $p_{11\Sigma}$  and its modifications  $p_{1\Sigma 1}$  etc. are direct consequences of the application of the law of total probability to the equation system (4). These terms are also known as *marginalisations* leading to a removal of a random variable from consideration by summing over its states. This linear modification means we can study the tripod equations (4) also in terms of its marginalisations.

In the case of the binary model the above symbols  $\varepsilon_A$  for all  $A \in L$  correspond to the joint mean of the random variables for the taxa in A. Using these definitions we can introduce simple terms which correspond to the covariances between the set of random variables:

$$\tau_{\alpha\beta} := \operatorname{Cov}[X_{\alpha}, X_{\beta}] = \mathbb{E}X_{\alpha}X_{\beta} - \mathbb{E}X_{\alpha}\mathbb{E}X_{\beta},$$

with equivalent definitions for  $\tau_{\alpha\gamma}$  and  $\tau_{\beta\gamma}$ . Of further interest are the following terms ( $c \in \{0, 1\}$ )

$$\tau_{\alpha\beta|c} := p_{11c} p_{\Sigma\Sigma c} - p_{1\Sigma c} p_{\Sigma 1 c},$$

with equivalent definitions for  $\tau_{\alpha\gamma|b}$ ,  $b \in \{0, 1\}$  and  $\tau_{\beta\gamma|a}$ ,  $a \in \{0, 1\}$ . These terms are actually multiples of the conditional covariances,  $\operatorname{Cov}[X_{\alpha}, X_{\beta}|X_{\gamma} = c] = \tau_{\alpha\beta|c}/p_{\Sigma\Sigma c}$ . Finally, we also introduce the three-way covariances

$$\tau_{\alpha\beta\gamma} := \operatorname{Cov}[X_{\alpha}, X_{\beta}, X_{\gamma}] = \mathbb{E}(X_{\alpha} - \mathbb{E}X_{\alpha})(X_{\beta} - \mathbb{E}X_{\beta})(X_{\gamma} - \mathbb{E}X_{\gamma})$$
$$= \varepsilon_{\alpha\beta\gamma} - \varepsilon_{\alpha}\varepsilon_{\beta\gamma} - \varepsilon_{\beta}\varepsilon_{\alpha\gamma} - \varepsilon_{\gamma}\varepsilon_{\alpha\beta} + 2\varepsilon_{\alpha}\varepsilon_{\beta}\varepsilon_{\gamma}.$$

For a review on covariance for more than two random variables see e.g. Rayner and Beh [24]. The term  $\tau_{\alpha\beta\gamma}$  describes the interactions of the three leaves considered. Summer et al. [13] call this term a *stangle*, a stochastic tangle, highlighting its relation to entangled states of qbits in quantum mechanics. The three-way covariances are zero in the case of symmetric models like CFN, which also reflects the findings in Baake [8]. However, for more complex models the three-way covariances are needed as indicated by the findings of Chang [2].

Since covariances are a measure of interdependence of random variables, and because the identification of a tree and a Markov model is an interpretation of the interdependence in terms of hidden variables and conditional independence, looking at these covariances is a very logical way to verify whether or not such an interpretation is admissible. Using these terms we can immediately propose a useful property. Lemma 1. Let p denote the joint probability for binary random variables  $X_{\alpha}$ ,  $X_{\beta}$  and X<sub>\gamma</sub>. If we flip the state in one taxon, then we flip the signs in its pairwise covariances. E.g., if  $X_{\alpha} \mapsto 1 - X_{\alpha}$ , then  $\tau_{\alpha\beta} \mapsto -\tau_{\alpha\beta}$ ,  $\tau_{\alpha\gamma} \mapsto -\tau_{\alpha\gamma} \tau_{\beta\gamma} \mapsto \tau_{\beta\gamma}$ .

One immediate consequence of this observation is that the product  $\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma}$ always has the same sign no matter how much we flip states.

<sup>192</sup> 3.2. Tree properties

In this section we assume that p is tree decomposable and regard some immediate consequences. We will later see that these conditions are necessary for identifiability but not sufficient. Nevertheless, these conditions provide some immediate insights for it.

Lemma 2. 1. If a triplet distribution  $\mathbf{p}$  is tree decomposable on T with  $\tau_{\alpha\beta} = 0$ , then also  $\tau_{\alpha\beta\gamma} = 0$  and  $\tau_{\alpha\gamma} = 0$  or  $\tau_{\beta\gamma} = 0$ .

<sup>198</sup> 2. If a triplet distribution  $\mathbf{p}$  is stochastically identifiable then the product  $\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma}$  is <sup>199</sup> non-negative.

The non-negativity of the product has already been verified by Lazarsfeld and Henry [3]. With Lemma 1 it is not complicated to derive that on a star tree (with arbitrary number of leaves) there always is a state flipping such that all pairs of leaves are positively correlated.

Corollary 3. Suppose we are given a stochastically identifiable distribution  $\mathbf{p}$  on a tree with finite leaf set L such that the pairwise covariances do not vanish, i.e.,  $\tau_{\alpha\beta} \neq 0$  for all  $\alpha, \beta \in L$ . Then there exists a set of leaves  $L_0 \subset L$  such that flipping the states of the leaves in  $L_0$  yields all covariances  $\tau_{\alpha\beta}, \alpha, \beta \in L$ , being positive.

Lemma 2(1) occurs exactly if  $X_{\alpha}$  or  $X_{\beta}$  is independent of the remaining random variables. It also implies the following:

**Corollary 4.** A triplet distribution  $\mathbf{p}$  with  $\tau_{\alpha\beta} = 0$  but  $\tau_{\alpha\gamma} \neq 0$  and  $\tau_{\beta\gamma} \neq 0$  is not tree decomposable.

Thus we already see, that the trivial invariant does not characterise tree decomposable distributions in this setting. The following example shows that such cases can be easily constructed.

<sup>215</sup> Example 1. Triplet distributions of type

$$\boldsymbol{p} = (p_{000}, p_{001}, p_{010}, p_{011}, p_{100}, p_{101}, p_{110}, p_{111}) = (4 - x, x, 2, 2, 2, 2, 2, 2, 2)/16, \quad x \in [0, 4] \setminus \{2\},$$

yield  $\tau_{\alpha\beta} = 0$  but  $\tau_{\alpha\gamma} = \tau_{\beta\gamma} = (2 - x)/32$  and hence are not tree decomposable. In fact, for binary variables a much more complicated graphical model with more "inner" nodes and edges is needed to explain theses covariances.

#### 219 4. Solving the tripod equations

In this section we are given a triplet distribution p and infer conditions under which it is algebraically identifiable. For each case we will present an example.

#### 222 4.1. The algebraic solution

As has been pointed out multiple times, the only invariant in the tripod case is 223 the trivial invariant. In other words, the "set" of invariants for a tripod tree is satisfied 224 by all triplet distributions. However, as we have seen in Corollary 4 there are triplet 225 distributions that are not tree decomposable even though they satisfy the trivial 226 invariant. Thus executing the actual decomposition, i.e. finding a solution for the 227 tripod equations not only provides complete forms for the parameters but is also helpful 228 to identify further cases. The first task is to clarify up to which level of uniqueness the 229 decomposition of a triplet distribution can be attained. To do this we look at the 230 implications of a state-flip at the root. 231

Lemma 5. If a triplet distribution  $\boldsymbol{p}$  is tree decomposable with parameters  $\boldsymbol{q}^{\zeta}, \boldsymbol{M}^{\alpha}, \boldsymbol{M}^{\beta}, \boldsymbol{M}^{\gamma}$  then it is also tree decomposable for parameters  $\widetilde{\boldsymbol{q}}^{\zeta}, \widetilde{\boldsymbol{M}}^{\alpha}, \widetilde{\boldsymbol{M}}^{\beta}, \widetilde{\boldsymbol{M}}^{\gamma}$ with  $\widetilde{q}_{z}^{\zeta} = q_{1-z}^{\zeta}, \widetilde{M}_{za}^{\alpha} = M_{(1-z)a}^{\alpha}, \widetilde{M}_{zb}^{\beta} = M_{(1-z)b}^{\alpha}, \widetilde{M}_{zc}^{\gamma} = M_{(1-z)c}^{\gamma}$ .

Hence, except for the case where everything is equal to 1/2, there will always be 235 at least two sets of parameters that decompose a triplet distribution  $\boldsymbol{p}$ . In terms of 236 molecular evolution one can view these solutions as having either few mutations 237  $(M_{z(1-z)}^{\delta} < M_{zz}^{\delta}, \delta \text{ leaf})$  or many mutations  $(M_{z(1-z)}^{\delta} > M_{zz}^{\delta}, \delta \text{ leaf})$  for the other. Change 238 [2] addressed the problem of symmetric solutions by introducing matrix categories that 239 are reconstructible from rows. One such class consists of diagonally dominant matrices, 240 i.e.  $M_{zz}^{\delta} > M_{z(1-z)}^{\delta}$  for all leaves and  $z \in \{0,1\}$ . If only these two sets of parameters exist 241 then we will regard the associated distribution as algebraically identifiable. It should be 242 noted that the set of symmetric solutions increases with the number of parameters, i.e. 243 each possible permutation of the states at the root yields a new solution. This fact has 244 also been observed by Chang [2] in the case of the time-continuous Markov model. 245

Next, we present conditions under which p is algebraically identifiable and present the closed form for the parameters.

<sup>248</sup> Theorem 6. Let p denote a triplet distribution and assume

$$\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma} \neq 0, \quad \tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma} \neq -\left(\frac{\tau_{\alpha\beta\gamma}}{2}\right)^2.$$
 (5)

 $_{249}$  Then p is algebraically identifiable. The associated parameters have the following form:

$$q_{1}^{\zeta} = \frac{1}{2} - \frac{\tau_{\alpha\beta\gamma}}{2\sqrt{\chi}},$$

$$M_{01}^{\alpha} = \varepsilon_{\alpha} + \frac{\tau_{\alpha\beta\gamma} - \sqrt{\chi}}{2\tau_{\beta\gamma}}, \quad M_{01}^{\beta} = \varepsilon_{\beta} + \frac{\tau_{\alpha\beta\gamma} - \sqrt{\chi}}{2\tau_{\alpha\gamma}}, \quad M_{01}^{\gamma} = \varepsilon_{\gamma} + \frac{\tau_{\alpha\beta\gamma} - \sqrt{\chi}}{2\tau_{\alpha\beta}}, \quad (6)$$

$$M_{11}^{\alpha} = \varepsilon_{\alpha} + \frac{\tau_{\alpha\beta\gamma} + \sqrt{\chi}}{2\tau_{\beta\gamma}}, \quad M_{11}^{\beta} = \varepsilon_{\beta} + \frac{\tau_{\alpha\beta\gamma} + \sqrt{\chi}}{2\tau_{\alpha\gamma}}, \quad M_{11}^{\gamma} = \varepsilon_{\gamma} + \frac{\tau_{\alpha\beta\gamma} + \sqrt{\chi}}{2\tau_{\alpha\beta}},$$

where  $\chi = \tau_{\alpha\beta\gamma}^2 + 4\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma}$ . 250

Note that Pearl and Tarsi [4] presented a similar solution for the parameters. 251 Looking at the parameters in (6) we see that algebraically the conditions in (5) prevent 252 division by zero. Together with the trivial invariant we can thus claim that the space of 253 algebraically identifiable triplet distributions is given by  $\mathcal{S} \setminus (\mathcal{S}_0 \cup \mathcal{S}_1)$  with 254

$$S := \{ \boldsymbol{p} \in \mathbb{R}^8_+ : p_{000} + \dots + p_{111} = 1 \}, \\ S_0 := \{ \boldsymbol{p} \in S : \tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma} = 0 \}, \\ S_1 := \{ \boldsymbol{p} \in S : \tau^2_{\alpha\beta\gamma} + 4\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma} = 0 \}.$$

Considering (5) and Lemma 2(2) we see that triplet distributions with 255  $\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma} < 0$  are only algebraically, but not stochastically identifiable. In fact, for 256  $-\tau_{\alpha\beta\gamma}^2 < 4\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma} < 0$  we get real-valued parameters, and for  $4\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma} < -\tau_{\alpha\beta\gamma}^2$  we 257 get a set of complex-valued parameters. 258

The following example presents such distributions. 259

**Example 2.** Regard the distributions 260

$$p_1 = (6, 7, 2, 1, 1, 1, 4, 5)/27, \quad p_2 = (6, 7, 1, 2, 1, 1, 4, 5)/27, \quad p_3 = (6, 6, 2, 2, 1, 1, 4, 5)/27.$$

All three distributions satisfy the conditions (5), i.e. they are algebraically identifiable. 261

For  $p_1$  the covariance  $\tau_{\beta\gamma}$  is negative and the other two positive, while for  $p_2$  we have 262  $\tau_{\alpha\gamma}$  negative and the other two positive. The distribution  $p_3$  has only positive pairwise 263 covariances. 264

The parameters for  $p_1$  are real-valued, the parameters for  $p_2$  are complex-valued 265 and  $p_3$  is stochastically identifiable. 266

Though this example is artificial it indicates just how sensitive the model is to 267 misreads in alignments. E.g., the difference between  $p_1$  and  $p_3$  could be seen as reading 268 the pattern 011 under  $p_3$  as pattern 001 under  $p_1$ . 269

#### 4.2. Stochastically identifiable distributions 270

The next step is to determine conditions under which a distribution satisfying (5) 271 is stochastically identifiable. These conditions should correspond to the conditions 272 given by Pearl and Tarsi [4, Theorem 1]. 273

Example 2 dealt with  $\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma} < 0$ . However, as the following example shows, 274 positivity of the product does not necessarily yield stochastic identifiability. 275

**Example 3.** The tripod distribution 276

p = (68, 0, 20, 12, 20, 12, 17, 51)/200

yields positive covariances for all three pairs but also  $M_{01}^{\gamma} = -1/20$ , i.e. not a 277 probability. 278

The example contains a pattern of expected zero occurrence. From the tripod equations we conclude that a stochastically identifiable distribution is strictly positive, thus this example is slightly contrived. However, as Example 1 showed, a strictly positive triplet distribution is not necessarily stochastically identifiable either.

In order to get necessary and sufficient conditions on a triplet distribution to be stochastically identifiable we need to go back to the parameters in (6) and bound them accordingly. This yields:

Theorem 7. A triplet distribution p is stochastically identifiable if and only if after suitable state flips the following inequalities hold

$$\tau_{\alpha\beta} > 0, \quad \tau_{\alpha\beta|0} \ge 0, \quad \tau_{\alpha\beta|1} \ge 0,$$
  

$$\tau_{\alpha\gamma} > 0, \quad \tau_{\alpha\gamma|0} \ge 0, \quad \tau_{\alpha\gamma|1} \ge 0,$$
  

$$\tau_{\beta\gamma} > 0, \quad \tau_{\beta\gamma|0} \ge 0, \quad \tau_{\beta\gamma|1} \ge 0.$$
(7)

In other words, the direction of the correlation between a pair of leaves shall not be influenced by the third leaf. With this we can summarise that a triplet distribution is stochastically identifiable if it is in  $S \setminus (S_0 \cup S_1)$  and there is a state flip such that (7) is satisfied.

Example 4. The tripod distribution p from Example 3 has positive pairwise and conditional covariances except for  $\tau_{\alpha\beta|1} = -9/2500$ . Thus it does not satisfy (7).

#### 294 4.3. Non-identifiable cases

The above considerations dealt with cases where a given triplet distribution p is algebraically identifiable. The final step of the tripod analysis is to regard those distributions that violate the conditions (5). Corollary 4 already discussed the case where one pairwise covariance is zero while the other two are not and we found that they were not tree decomposable. In the following we look at the remaining cases.

Proposition 8. Assume that a triplet distribution  $\mathbf{p}$  obeys  $\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma} = -(\tau_{\alpha\beta\gamma}/2)^2$  but  $\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma} \neq 0$ . Then  $\mathbf{p}$  is not tree decomposable.

In other words, we found another set of triplet distributions that are not tree decomposable.

304 Example 5. The distribution

$$\boldsymbol{p} = (16, 5, 8, 15, 14, 5, 2, 15)/80$$

yields  $\tau_{\alpha\beta} = -1/80$ ,  $\tau_{\alpha\gamma} = 1/40$  and  $\tau_{\beta\gamma} = 1/8$  but  $\chi = 0$  and hence has no factorisation in the sense of (4). As in Example 1 we point out here that there seems to be no simple graphical structure which explains the observed covariances adequately. On the other hand, similarly to Example 2 the simple act of moving 1/80 from pattern 100 to pattern 110 yields algebraic identifiability. This indicates the level of care required when inferring meaning from observed covariances.

Together with Corollary 4 this covers the distributions that are not tree 311 decomposable. The remaining cases are triplet distributions that are tree decomposable 312 but not algebraically identifiable. 313

**Proposition 9.** Let p be a triplet distribution with  $\tau_{\alpha\beta} = 0$  and  $\tau_{\alpha\gamma} = 0$ . Then p is tree 314 decomposable with infinitely many parameter sets. 315

The parameter sets are identified by one of the following compositions: 316

(i)  $\tau_{\beta\gamma} \neq 0$ . Then  $M_{0a}^{\alpha} = M_{1a}^{\alpha} = p_{a\Sigma\Sigma}, a \in \{0, 1\}, and for any <math>u, b, c \in \{0, 1\}$ : 317

$$q_{1}^{\zeta} = \frac{p_{\Sigma\Sigma c} - M_{1c}^{\gamma}}{M_{0c}^{\gamma} - M_{1c}^{\gamma}}, \quad M_{ub}^{\beta} = \frac{p_{\Sigma bc} - p_{\Sigma b\Sigma} M_{(1-u)c}^{\prime}}{p_{\Sigma\Sigma c} - M_{(1-u)c}^{\gamma}}$$
(8)

with free parameters  $M_{0c}^{\gamma} \neq M_{1c}^{\gamma}$ . 318

(ii)  $\tau_{\beta\gamma} = 0$ . Then for all  $a, b, c \in \{0, 1\}$  the free parameters can be distributed as 319 follows: 320

321 (a) 
$$M_{0a}^{\alpha} = M_{1a}^{\alpha} = p_{a\Sigma\Sigma}, \ M_{0b}^{\beta} = M_{1b}^{\beta} = p_{\Sigma b\Sigma} \ and$$

$$q_1^{\zeta} = \frac{p_{\Sigma\Sigma c} - M_{0c}^{\gamma}}{M_{1c}^{\gamma} - M_{0c}^{\gamma}},\tag{9}$$

parameters

with free parameters  $M_{0z}^{\gamma} \neq M_{1z}^{\gamma}$ . 322

(b) 
$$M_{0a}^{\alpha} = M_{1a}^{\alpha} = p_{a\Sigma\Sigma}, \ M_{0b}^{\beta} = M_{1b}^{\beta} = p_{\Sigma b\Sigma}, \ M_{0c}^{\gamma} = M_{1c}^{\gamma} = p_{\Sigma\Sigma c} \ with \ free \ parameter \ q_{1}^{\zeta}.$$

32 326

In other words, the distribution is tree decomposable because process parameters 327 exist but it is not algebraically identifiable because we have no means to recover the 328 true parameters or more precisely, there are infinitely many parameters that yield the 329 same distribution. 330

**Example 6.** The triplet distribution 331

$$p = (2, 2, 2, 2, 2, 2, 2, 2)/16$$

yields complete independence of the leaves  $\tau_{\alpha\beta} = \tau_{\alpha\gamma} = \tau_{\beta\gamma} = 0$ , i.e. the case (ii) in 332 Proposition 9 is to be regarded here. It is not too surprising that such a distribution 333 yields an infinite number of solutions since the state at the root is completely 334 undetermined. 335

Looking again at the cases listed above, we see that  $X_{\alpha}$  is not only pairwise 336 independent from  $(X_{\beta}, X_{\gamma})$  (induced by  $\tau_{\alpha\beta} = \tau_{\alpha\gamma} = 0$ ), but even completely 337 independent. Then the multiple solutions come from the fact that we can place the root 338 arbitrarily between  $\beta$  and  $\gamma$ . 339

The good news is, that the non-identifiable cases form a small subset among all 340 triplet distributions. In fact: 341

Proposition 10. Non-identifiable triplet distributions, i.e. distributions violating the
 conditions (5) form a Lebesgue zero set in the set of all possible triplet distributions.

This concludes our analysis of the tripod case. We identified the subset of triplet distributions that are uniquely algebraically and stochastically identifiable, and those that are tree decomposable but not algebraically identifiable, or not tree decomposable at all.

#### <sup>348</sup> 5. Extension to quartet trees

In this section we will explore the implications of extending the results for three taxa to four taxa. For this section we look at the quartet tree Q = (V, E) with

$$V = \{\zeta, \psi, \alpha, \beta, \gamma, \delta\}, \quad E = \{(\zeta, \psi), (\zeta, \alpha), (\zeta, \beta), (\psi, \gamma), (\psi, \delta)\}.$$

Fig. A.3 provides an illustration including the four tripod restrictions  $\overline{T} = T_{\alpha\beta\gamma}, \ \widetilde{T} = T_{\alpha\beta\delta}, \ \widehat{T} = T_{\alpha\gamma\delta} \ \text{and} \ \check{T} = T_{\beta\gamma\delta}.$ 

Regard the quartet distribution  $\pi = (\pi_{abcd})_{a,b,c,d \in \{0,1\}}$  describing the joint distribution for  $\alpha$ ,  $\beta$ ,  $\gamma$  and  $\delta$ . If  $\pi$  is stochastically identifiable and reversible then it can be reconstructed from the *marginalisations* on its four tripods [2], i.e. computing the parameters for all tripods will immediately return the full process. However, the converse is not necessarily true. As Example 7 below shows, there are cases where each tripod marginalisation is stochastically identifiable but no quartet tree can be reconstructed.

360

Pearl and Tarsi [4] presented an algorithm to reconstruct the topology for an arbitrary number of taxa. Their algorithm employs the condition that tripods that share an interior node in the (unknown) tree topology must have the same marginal distribution at this interior node. Their approach yields an invariant, which for Qamounts to

$$f_1(\boldsymbol{\pi}) = \tau_{\alpha\delta}\tau_{\beta\gamma} - \tau_{\alpha\gamma}\tau_{\beta\delta}.$$
(10)

This invariant is related to the four-point-condition [e.g., 26, p. 146] and thus topologically informative, i.e. it is particular to topology Q. If a distribution  $\pi$  is from another tree than  $f_1(\pi) \neq 0$ .

To reconstruct the process parameters as well, more invariants are needed. In particular, for  $\pi$  to be algebraically identifiable on Q the parameters obtained from the tripod marginalisations must satisfy the following properties:

- 1. The parameters for edges  $(\zeta, \alpha)$ ,  $(\zeta, \beta)$  and  $q^{\zeta}$  obtained from triplet distributions  $\overline{p}$  and  $\tilde{p}$ , respectively, must be equal.
- 2. The parameters for edges  $(\psi, \gamma)$ ,  $(\psi, \delta)$  and  $q^{\psi}$  obtained from triplet distributions  $\hat{p}$  and  $\check{p}$ , respectively, must be equal.

#### 376 3. The parameters $M^{\psi}$ for the interior edge $(\zeta, \psi)$ are obtained from the equations

$$\overline{M}_{01}^{\gamma} = (1 - M_{01}^{\psi})\widehat{M}_{01}^{\gamma} + M_{01}^{\psi}\widehat{M}_{11}^{\gamma}, 
\overline{M}_{11}^{\gamma} = (1 - M_{11}^{\psi})\widehat{M}_{01}^{\gamma} + M_{11}^{\psi}\widehat{M}_{11}^{\gamma}.$$
(11)

These equations must hold equivalently when  $\gamma$  is replaced by  $\delta$  and the parameters come from tripod  $\widetilde{T}$  instead of  $\widehat{M}$ .

These conditions imply further restrictions on  $\pi$ . An indicator for the minimal number of such conditions is the observation that a quartet distribution  $\pi$  has 15 degrees of freedom, but there are only 11 process parameters on Q, two for each edge and one for the root distribution. Thus we need at least four additional conditions or rather invariants. We will use the above observations to derive an equivalent set of invariants.

Proposition 11. A quartet distribution  $\pi$  is algebraically identifiable on Q if its tripod marginalisations satisfy conditions (5) and the following invariants vanish on  $\pi$ :

$$\begin{split} f_0(\boldsymbol{\pi}) &= \varepsilon_{\alpha\beta\gamma\delta}\tau_{\alpha\gamma} - \varepsilon_{\alpha\beta\gamma}\varepsilon_{\alpha\gamma\delta} + \varepsilon_{\gamma}\varepsilon_{\alpha\beta}\varepsilon_{\alpha\gamma\delta} + \varepsilon_{\alpha}\varepsilon_{\gamma\delta}\varepsilon_{\alpha\beta\gamma} - \varepsilon_{\alpha\beta}\varepsilon_{\alpha\gamma}\varepsilon_{\gamma\delta} \\ f_1(\boldsymbol{\pi}) &= \tau_{\alpha\delta}\tau_{\beta\gamma} - \tau_{\alpha\gamma}\tau_{\beta\delta}, \\ f_2(\boldsymbol{\pi}) &= \tau_{\alpha\gamma}\tau_{\beta\gamma\delta} - \tau_{\beta\gamma}\tau_{\alpha\gamma\delta}, \\ f_3(\boldsymbol{\pi}) &= \tau_{\alpha\gamma}\tau_{\alpha\beta\delta} - \tau_{\alpha\delta}\tau_{\alpha\beta\gamma}. \end{split}$$

The parameters unique up to state flip at the interior nodes are then given by Theorem 6 and

$$M_{01}^{\psi} = \frac{1}{2} + \frac{\tau_{\alpha\delta}\tau_{\alpha\beta\gamma} - \tau_{\alpha\beta}\tau_{\alpha\gamma\delta} - \tau_{\alpha\delta}\sqrt{\chi_{\alpha\beta\gamma}}}{2\tau_{\alpha\beta}\sqrt{\chi_{\alpha\gamma\delta}}},$$

$$M_{11}^{\psi} = \frac{1}{2} + \frac{\tau_{\alpha\delta}\tau_{\alpha\beta\gamma} - \tau_{\alpha\beta}\tau_{\alpha\gamma\delta} + \tau_{\alpha\delta}\sqrt{\chi_{\alpha\beta\gamma}}}{2\tau_{\alpha\beta}\sqrt{\chi_{\alpha\gamma\delta}}}.$$
(12)

The existence of these invariants means that tree decomposable quartet distributions form a Lebesgue zero set in the set of all quartet distributions for the same reason that the non-identifiable sets are a Lebesgue zero set in the set of all tree decomposable distributions.

Invariant  $f_1$  comes from the equality of the marginal distributions at the interior nodes, as proposed by Pearl and Tarsi [4]. Invariants  $f_2$  and  $f_3$  come from the equality of edge transition matrices. Hence, distributions for which  $f_1$ ,  $f_2$  and  $f_3$  vanish will uniquely identify topology Q. Therefore,  $f_1$  to  $f_3$  are topologically informative.

However, only distributions for which  $f_0$  vanishes will be subject to the inferred parameters. In other words, in the set of zero points for  $f_1$  to  $f_3$  there is a set of distributions that returns the same set of parameters for Q, but only for one of these distributions  $f_0$  vanishes. It would be interesting to investigate how this distribution relates to the set it projects from, e.g. if it is related to the possible maximum
likelihood optimum.

<sup>403</sup> Despite the fact that  $f_1$  to  $f_3$  are sufficient to infer a topology,  $f_0$  is also <sup>404</sup> topologically informative in that it will not vanish for distributions coming from <sup>405</sup> another tree.

In the case of the CFN model, all triplet covariances vanish. Hence, only invariants  $f_0$  and  $f_1$  are of interest in that case. Therefore, either invariant is sufficient to identify the associated tree topology.

The parameters for the interior edge do not add more non-identifiable cases. However, as in the tripod case, further conditions are needed to guarantee quartet identifiability.

Proposition 12. A quartet distribution is stochastically identifiable if and only if every
 triplet marginalisations satisfies both Theorem 7 and the following inequalities

$$\tau_{\alpha\delta}\sqrt{\chi_{\alpha\beta\gamma}} - \tau_{\alpha\beta}\sqrt{\chi_{\alpha\gamma\delta}} \le \tau_{\alpha\beta}\tau_{\alpha\gamma\delta} - \tau_{\alpha\delta}\tau_{\alpha\beta\gamma} \le \tau_{\alpha\beta}\sqrt{\chi_{\alpha\gamma\delta}} - \tau_{\alpha\delta}\sqrt{\chi_{\alpha\beta\gamma}}.$$
 (13)

All other relations are covered due to the fact that the quartet distribution pneeds to satisfy the invariants  $f_0 - f_3$ . The following example provides a very nice case in which reconstruction is not possible but offers a very interesting challenge.

**Example 7.** Chor et al. [27] discussed several examples of distributions with multiple maxima of the likelihood function. These examples relate to the CFN model, i.e.,  $p_{abcd} = p_{(1-a)(1-b)(1-c)(1-d)}$  so that the Hadamard approach can be used. Regard the symmetric distribution

$$\boldsymbol{p} = (14, 0, 0, 3, 0, 2, 1, 0, 0, 1, 2, 0, 3, 0, 0, 14)/40.$$
(14)

<sup>421</sup> Retrieving the statistics yields:

$$\tau_{\alpha\beta} = 7/40 = \tau_{\gamma\delta}, \quad \tau_{\alpha\gamma} = 3/20 = \tau_{\beta\delta}, \quad \tau_{\alpha\delta} = 1/8 = \tau_{\beta\gamma},$$
  
$$\tau_{\alpha\beta\gamma} = \tau_{\alpha\beta\delta} = \tau_{\alpha\gamma\delta} = \tau_{\beta\gamma\delta} = 0.$$

The last equality immediately shows, that the above distribution will trivially satisfy invariants  $f_2$  and  $f_3$ . However, we get  $f_1 = -11/1600$  and  $f_0 = -23/375$ , i.e. our observations do not come from the quartet tree defined by the bipartition  $\alpha\beta|\gamma\delta$ .

<sup>425</sup> Looking at the alternative invariants for  $f_1$ , i.e. at

$$f_1^{\alpha\delta|\beta\gamma} = \tau_{\alpha\beta}\tau_{\gamma\delta} - \tau_{\alpha\gamma}\tau_{\beta\delta} = 13/1600,$$
  
$$f_1^{\alpha\gamma|\beta\delta} = \tau_{\alpha\beta}\tau_{\gamma\delta} - \tau_{\alpha\delta}\tau_{\beta\gamma} = 3/200,$$

<sup>426</sup> we see that this distribution comes from none of the available quartet trees.

<sup>427</sup> Nevertheless, we shall have a look at the parameters. Note that the symmetry of <sup>428</sup> the distribution  $\boldsymbol{p}$  implies  $M_{01}^{\alpha} = 1 - M_{11}^{\alpha} =: \overline{M}_{\alpha}$ . Looking at the numerical values for <sup>429</sup> the parameters for every tripod tree we find surprising similarities: [Table 1 about here.]

<sup>431</sup> These parameters permit us to infer parameters  $M_{\zeta} = 1/14$  and  $M_{\psi} = 1/7$  such <sup>432</sup> that e.g. the parameters for  $\alpha$  on the tripod trees  $\alpha\beta\delta$  and  $\alpha\gamma\delta$  can be obtained from <sup>433</sup> the parameter for tripod tree  $\alpha\beta\gamma$  by

$$\widetilde{M}_{\alpha} = M_{\zeta}(1 - \overline{M}_{\alpha}) + (1 - M_{\zeta})\overline{M}_{\alpha}, \quad \widehat{M}_{\alpha} = M_{\psi}(1 - \overline{M}_{\alpha}) + (1 - M_{\psi})\overline{M}_{\alpha},$$

with analogue assignments for the other leaves. These computations can be visualised by the network in Fig. A.4. The assignment of probabilities for each split permits to justify the observations for each of the four tripod trees. However, the visualisation is misleading because the factorisation of the system does not follow the edges in the network [e.g., ? ? 28].

#### 440 6. The connection with Markov invariants

This section investigates the connection between the work presented here and the concept of Markov invariants as coined by Sumner et al. [13]. To show these relations we will look back at our covariances and investigate their relationship with the parameters. Following Allman and Rhodes [6] one can write the three-way-probabilities as a  $2 \times 2 \times 2$  tensor  $\boldsymbol{P}^{\alpha\beta\gamma}$  such that

$$\boldsymbol{P}^{\alpha\beta|0} = \begin{pmatrix} p_{000} & p_{010} \\ p_{100} & p_{110} \end{pmatrix}, \quad \boldsymbol{P}^{\alpha\beta|1} = \begin{pmatrix} p_{001} & p_{011} \\ p_{101} & p_{111} \end{pmatrix}$$

With this as a basis we easily infer our pairwise covariances in terms of determinants of dimensional restrictions of  $\mathbf{P}^{\alpha\beta\gamma}$ . E.g., a marginalisation over  $\gamma$  corresponds to  $\mathbf{P}^{\alpha\beta\Sigma} = \mathbf{P}^{\alpha\beta|0} + \mathbf{P}^{\alpha\beta|1}$ . The determinant of this matrix then corresponds to

$$\det \mathbf{P}^{\alpha\beta\Sigma} = p_{00\Sigma}p_{11\Sigma} - p_{01\Sigma}p_{10\Sigma}$$
  
=  $p_{11\Sigma}(p_{00\Sigma} + p_{11\Sigma} + p_{01\Sigma} + p_{10\Sigma}) - (p_{10\Sigma} + p_{11\Sigma})(p_{01\Sigma} + p_{11\Sigma})$   
=  $p_{11\Sigma} - p_{1\Sigma\Sigma}p_{\Sigma1\Sigma} = \tau_{\alpha\beta}.$ 

Thus, we have invariably obtained an alternative way to compute the covariances. In a similar fashion, if we take the determinant of the conditional kernels  $\mathbf{P}^{\alpha\beta|c}$ ,  $c \in \{0, 1\}$ , we arrive at the (not normalised) conditional covariance  $\tau_{\alpha\beta|c}$ :

det 
$$\mathbf{P}^{\alpha\beta|c} = p_{00c}p_{11c} - p_{01c}p_{10c}$$
  
=  $p_{11c}(p_{\Sigma\Sigma c} - p_{01c} - p_{10c} - p_{11c}) - (p_{\Sigma1c} - p_{11c})(p_{1\Sigma c} - p_{11c})$   
=  $p_{11c}p_{\Sigma\Sigma c} - p_{\Sigma1c}p_{1\Sigma c} = \tau_{\alpha\beta|c}$ .

15

430

It must be noted that the determinant has been used earlier in connection with LogDet families [e.g., 25]. In order to relate these findings to the process parameter, let us denote by  $\Pi = \text{diag}(q^{\zeta})$  the diagonal matrix of the marginal distribution at the root, and with

$$\boldsymbol{M}^{\alpha} = \begin{pmatrix} M_{00}^{\alpha} & M_{01}^{\alpha} \\ M_{10}^{\alpha} & M_{11}^{\alpha} \end{pmatrix}$$

the transition matrix for leaf  $\alpha$ . Then the marginalisation of Equation (2) can be written as

$$\boldsymbol{P}^{\alpha\beta\Sigma} = (\boldsymbol{M}^{\alpha})^{\mathrm{T}} \overline{\boldsymbol{\Pi}} \boldsymbol{M}^{\beta}, \qquad (15)$$

where  $\Pi$  is the marginal distribution at the most recent common ancestor of  $\alpha$  and  $\beta$ . If  $\mathcal{E}_{\alpha\beta}$  is defined as the set of edges connecting the root of the tree and the most recent common ancestor of  $\alpha$  and  $\beta$  then we compute  $\overline{\Pi}$  by

$$\overline{\Pi} = \Pi \prod_{e \in \mathcal{E}_{lphaeta}} M^e$$

 $_{461}$  If we take the determinant on both sides of Eq. (15) we get

$$\det \boldsymbol{P}^{lphaeta\Sigma} = \det \boldsymbol{M}^lpha \det \boldsymbol{M}^eta \det \boldsymbol{\Pi} \prod_{e\in \mathcal{E}_{lphaeta}} \det \boldsymbol{M}^e.$$

<sup>462</sup> We further observe that the determinant in the two-state-case is equal to

$$\det \mathbf{M}^{\alpha} = 1 - M_{00}^{\alpha} - M_{11}^{\alpha} = -(M_{11}^{\alpha} - M_{01}^{\alpha})$$

463 Going back to a tripod tree under the two-state-model this yields the relation

$$\tau_{\alpha\beta} = (M_{11}^{\alpha} - M_{01}^{\alpha})(M_{11}^{\beta} - M_{01}^{\beta})q_1^{\zeta}(1 - q_1^{\zeta}).$$
(16)

<sup>464</sup> This relation has been observed in Steel [25] and forms the basis for LogDet inference.

- <sup>465</sup> The covariances  $\tau_{\alpha\beta}$  also form the simplest form of *Markov invariants*. Summer et al.
- <sup>466</sup> [13] define these terms in general by:

$$f(\boldsymbol{p}) = g(\hat{\boldsymbol{p}}) \prod_{e \in E} (\det \boldsymbol{M}^e)^{k_e}, \qquad (17)$$

with  $k_e \in \mathbb{Z}$  denoting the exponent for edge  $e \in E$ . The term  $g(\hat{p})$  describes a function depicting the relationship of a reduced structure in the tree. Summer et al. [13] give one example of such a reduced structure as the tree for which the pendant edges have been reduced to length zero. In the case of the tripod tree this reduced structure corresponds to the interior node  $\zeta$ , and hence the distribution  $\hat{p}$  is equivalent to  $q^{\zeta}$  only. In this setting, Markov invariants are one-dimensional "representations" of the stochastic <sup>473</sup> models used for inference, such that the complex structure of these models is retained <sup>474</sup> [14].

In our framework, we rediscover more Markov invariants of type (17) when

<sup>476</sup> investigating how the remaining covariances are related to the process parameters under <sup>477</sup> the tripod equations (4). In fact, we find:

$$\tau_{\alpha\beta\gamma} = (M_{11}^{\alpha} - M_{01}^{\alpha})(M_{11}^{\beta} - M_{01}^{\beta})(M_{11}^{\gamma} - M_{01}^{\gamma})q_{1}^{\zeta}(1 - q_{1}^{\zeta})(1 - 2q_{1}^{\zeta}), \qquad (18)$$

$$\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma} = (M_{11}^{\alpha} - M_{01}^{\alpha})^2 (M_{11}^{\beta} - M_{01}^{\beta})^2 (M_{11}^{\gamma} - M_{01}^{\gamma})^2 (q_1^{\zeta})^3 (1 - q_1^{\zeta})^3,$$
(19)

$$\chi = (M_{11}^{\alpha} - M_{01}^{\alpha})^2 (M_{11}^{\beta} - M_{01}^{\beta})^2 (M_{11}^{\gamma} - M_{01}^{\gamma})^2 (q_1^{\zeta})^2 (1 - q_1^{\zeta})^2.$$
(20)

with equivalent terms for the other covariances. These equivalences permit a different way to prove Theorem 6 from the one we present in Appendix A.

It should be noted that our interpretation of the above Markov invariants as covariances only works for the two state model. On the other hand, the form of the Markov invariants stays valid, even though they might not be as immediately apparent from the model as in the cases discussed here. However, in the case of the two-state model using the notion of covariance permits a good interpretation of the findings. We observe for the (not normalised) conditional covariances

$$\tau_{\alpha\beta|c} = (M_{11}^{\alpha} - M_{01}^{\alpha})(M_{11}^{\beta} - M_{01}^{\beta})M_{0c}^{\gamma}M_{1c}^{\gamma}q_{1}^{\zeta}(1 - q_{1}^{\zeta}), \qquad (21)$$

i.e., the transition matrix for leaf  $\gamma$  shall be included into the term  $g(\hat{p})$  for (17) to be valid. On the other hand, remember that we did not use these covariances to solve the tripod equations (4). We need them only to formulate the positivity constraints in Theorem 7. This property is beyond the purely algebraic framework.

In summary, Markov invariants are very useful when investigating properties of and conditions on leaf distributions p. Especially, they explore the relationship of process parameters and leaf distribution such that phylogenetic invariants like  $f_1$  to  $f_3$ from Proposition 11 can be easily extracted. We will employ these relationships to prove the results of Section 3.

#### 495 7. Discussion

Acknowledgements. We thank Elizabeth S. Allman and John A. Rhodes for stimulating
the finalization of the manuscript as well as for sharing their thoughts on this subject
with us. Further, we owe much to the discussions with David Bryant, Mike Steel, and
Arndt von Haeseler. Suggestions from Jessica Leigh and three anonymous referees are
greatly appreciated.

#### 583 Appendix A. Proofs

Proof of Lemma 1. A state flip replaces the probabilities at leaf  $\alpha$  implies a "new" distribution  $\hat{p}$  with  $\hat{p}_{abc} = p_{(1-a)bc}$ ,  $a, b, c \in \{0, 1\}$ . This has the following implications to

586 the covariances.

$$\tau_{\alpha\beta} = p_{11\Sigma} - p_{1\Sigma\Sigma}p_{\Sigma1\Sigma} = (p_{\Sigma1\Sigma} - p_{01\Sigma}) - p_{1\Sigma\Sigma}p_{\Sigma1\Sigma}$$
$$= -p_{01\Sigma} + p_{\Sigma1\Sigma}(1 - p_{1\Sigma\Sigma}) = -(p_{01\Sigma} - p_{0\Sigma\Sigma}p_{\Sigma1\Sigma})$$
$$= -(\hat{p}_{11\Sigma} - \hat{p}_{1\Sigma\Sigma}\hat{p}_{\Sigma1\Sigma}) = -\hat{\tau}_{\alpha\beta}.$$

and analogously  $\hat{\tau}_{\alpha\gamma} = -\tau_{\alpha\gamma}$  and  $\hat{\tau}_{\beta\gamma} = \tau_{\beta\gamma}$ . Thus, if  $\tau_{\alpha\beta}$  and  $\tau_{\alpha\gamma}$  are smaller than zero, then a state flip produces positive covariances and the sign for the overall product remains the same.

Proof of Lemma 2. Using the Markov invariants from Section 6 we immediately see, that if  $\tau_{\alpha\beta} = 0$  due to  $M_{01}^{\alpha} - M_{11}^{\alpha} = 0$  then also  $\tau_{\alpha\gamma} = 0$  and  $\tau_{\alpha\beta\gamma} = 0$ . If  $q_1^{\zeta} \in \{0, 1\}$  then all four covariances are zero.

<sup>593</sup> For point 2 regard (19). But this term will be non-negative as long as  $q_1^{\zeta}$  is a <sup>594</sup> probability, which is a model condition. This completes the proof.

<sup>595</sup> Proof of Corollary 3. Select one leaf  $\alpha \in L$  and define  $L_0 = \{\beta : \tau_{\alpha\beta} < 0\}$ . Flipping the <sup>596</sup> states in  $L_0$  gives us  $\tau_{\alpha\beta} > 0$  for all  $\beta \in L, \beta \neq \alpha$  by Lemma 1. Fix now

<sup>597</sup>  $\beta \neq \beta' \in L \setminus \{\alpha\}$ . Then  $\alpha, \beta, \beta'$ , together with the root  $\zeta$  of the tree, define uniquely a <sup>598</sup> tripod tree and the restriction of p to  $\alpha, \beta, \beta'$  must obey the tripod equations. Using <sup>599</sup> Lemma 2(2), on this tripod tree shows now that  $\tau_{\alpha\beta}\tau_{\alpha\beta'}\tau_{\beta\beta'} > 0$ . This implies that  $\tau_{\beta\beta'}$ <sup>600</sup> is positive, too.

- 601 Proof of Corollary 4. A triplet distribution p for which only one covariance is zero does
- $_{602}$  not satisfy Lemma 2(1) and hence is not tripod decomposable. Further, by looking at
- (16) we see that there is also no real- or complex-valued parameter set that would yield
- <sup>604</sup> only one zero covariance. Hence, such a triplet distribution would also not be
- <sup>605</sup> algebraically decomposable.

606 Proof of Lemma 5. We insert the refined parameters into the tripod equations to get:

$$p_{abc} = q_1^{\zeta} M_{1a}^{\alpha} M_{1b}^{\beta} M_{1c}^{\gamma} + (1 - q_1^{\zeta}) M_{0a}^{\alpha} M_{0b}^{\beta} M_{0c}^{\gamma}$$
$$= \widehat{q}_0^{\zeta} \widehat{M}_{0a}^{\alpha} \widehat{M}_{0b}^{\beta} \widehat{M}_{0c}^{\gamma} + (1 - \widehat{q}_0^{\zeta}) \widehat{M}_{1a}^{\alpha} \widehat{M}_{1b}^{\beta} \widehat{M}_{1c}^{\gamma}$$
$$= (1 - \widehat{q}_1^{\zeta}) \widehat{M}_{0a}^{\alpha} \widehat{M}_{0b}^{\beta} \widehat{M}_{0c}^{\gamma} + \widehat{q}_1^{\zeta} \widehat{M}_{1a}^{\alpha} \widehat{M}_{1b}^{\beta} \widehat{M}_{1c}^{\gamma},$$

i.e. the tripod equations are recovered with flipped parameters. This completes theproof.

609 Proof of Theorem 6. We derive the parameters from the tripod equations. As

- 610 mentioned in Section 3.1 there is a linear relationship between p and its
- 611 marginalisations. Thus, finding a solution for the tripod equations is equivalent to
- 612 finding the solution for the following set of equations

$$\varepsilon_{\alpha\beta\gamma} = q_1^{\zeta} M_{11}^{\alpha} M_{11}^{\beta} M_{11}^{\gamma} + (1 - q_1^{\zeta}) M_{01}^{\alpha} M_{01}^{\beta} M_{01}^{\gamma}, \qquad (A.1)$$

$$\varepsilon_{\alpha\beta} = q_1^{\zeta} M_{11}^{\alpha} M_{11}^{\beta} + (1 - q_1^{\zeta}) M_{01}^{\alpha} M_{01}^{\beta}, \tag{A.2}$$

$$\varepsilon_{\alpha\gamma} = q_1^{\zeta} M_{11}^{\alpha} M_{11}^{\gamma} + (1 - q_1^{\zeta}) M_{01}^{\alpha} M_{01}^{\gamma}, \tag{A.3}$$

$$\varepsilon_{\beta\gamma} = q_1^{\zeta} M_{11}^{\beta} M_{11}^{\gamma} + (1 - q_1^{\zeta}) M_{01}^{\beta} M_{01}^{\gamma}, \tag{A.4}$$

$$\varepsilon_{\alpha} = q_1^{\zeta} M_{11}^{\alpha} + (1 - q_1^{\zeta}) M_{01}^{\alpha}, \tag{A.5}$$

$$\varepsilon_{\beta} = q_1^{\zeta} M_{11}^{\beta} + (1 - q_1^{\zeta}) M_{01}^{\beta}, \tag{A.6}$$

$$\varepsilon_{\gamma} = q_1^{\zeta} M_{11}^{\gamma} + (1 - q_1^{\zeta}) M_{01}^{\gamma}. \tag{A.7}$$

613 Equations (A.5)-(A.7) yield

$$(1-q_1^{\zeta})M_{01}^{\alpha} = \varepsilon_{\alpha} - q_1^{\zeta}M_{11}^{\alpha}, \quad (1-q_1^{\zeta})M_{01}^{\beta} = \varepsilon_{\beta} - q_1^{\zeta}M_{11}^{\beta}, \quad (1-q_1^{\zeta})M_{01}^{\gamma} = \varepsilon_{\gamma} - q_1^{\zeta}M_{11}^{\gamma}.$$
(A.8)

614 Inserting (A.8) into (A.2) returns

$$(1 - q_1^{\zeta})\varepsilon_{\alpha\beta} = q_1^{\zeta}(1 - q_1^{\zeta})M_{11}^{\alpha}M_{11}^{\beta} + (\varepsilon_{\alpha} - q_1^{\zeta}M_{11}^{\alpha})(\varepsilon_{\beta} - q_1^{\zeta}M_{11}^{\beta})$$
$$= q_1^{\zeta}M_{11}^{\alpha}M_{11}^{\beta} + \varepsilon_{\alpha}\varepsilon_{\beta} - q_1^{\zeta}(\varepsilon_{\alpha}M_{11}^{\beta} + \varepsilon_{\beta}M_{11}^{\alpha}),$$

615 and in consequence

$$q_1^{\zeta} M_{11}^{\beta} (M_{11}^{\alpha} - \varepsilon_{\alpha}) = \tau_{\alpha\beta} + q_1^{\zeta} (\varepsilon_{\beta} M_{11}^{\alpha} - \varepsilon_{\alpha\beta}), \qquad (A.9)$$

$$q_1^{\zeta} M_{11}^{\gamma} (M_{11}^{\alpha} - \varepsilon_{\alpha}) = \tau_{\alpha\gamma} + q_1^{\zeta} (\varepsilon_{\gamma} M_{11}^{\alpha} - \varepsilon_{\alpha\gamma}).$$
(A.10)

 $_{616}$  We insert (A.9)-(A.10) back into (A.8)

$$(1 - q_1^{\zeta})M_{01}^{\beta}(M_{11}^{\alpha} - \varepsilon_{\alpha}) = \varepsilon_{\beta}(M_{11}^{\alpha} - \varepsilon_{\alpha}) - \tau_{\alpha\beta} - q_1^{\zeta}(\varepsilon_{\beta}M_{11}^{\alpha} - \varepsilon_{\alpha\beta})$$
$$= (1 - q_1^{\zeta})(\varepsilon_{\beta}M_{11}^{\alpha} - \varepsilon_{\alpha\beta}).$$

In the case of  $q_1^{\zeta} = 1$  we get from (A.5) and (A.2) that  $M_{11}^{\alpha} = \varepsilon_{\alpha}$  and  $\varepsilon_{\alpha\beta} = \varepsilon_{\alpha}\varepsilon_{\beta}$ . Hence, we remove  $1 - q_1^{\zeta}$  from the above equation without destroying equality. Thus, we get

$$M_{01}^{\beta}(M_{11}^{\alpha} - \varepsilon_{\alpha}) = \varepsilon_{\beta}M_{11}^{\alpha} - \varepsilon_{\alpha\beta}, \qquad (A.11)$$

$$M_{01}^{\gamma}(M_{11}^{\alpha} - \varepsilon_{\alpha}) = \varepsilon_{\gamma} M_{11}^{\alpha} - \varepsilon_{\alpha\gamma}.$$
 (A.12)

 $_{619}$  We insert (A.8) in (A.1) to get

$$M_{11}^{\alpha}\varepsilon_{\beta\gamma} - \varepsilon_{\alpha\beta\gamma} = M_{01}^{\beta}M_{01}^{\gamma}(M_{11}^{\alpha} - \varepsilon_{\alpha}).$$

 $_{620}$  Applying (A.11) and (A.12) to this gives us

$$0 = (M_{11}^{\alpha}\varepsilon_{\beta\gamma} - \varepsilon_{\alpha\beta\gamma})(M_{11}^{\alpha} - \varepsilon_{\alpha}) - (\varepsilon_{\beta}M_{11}^{\alpha} - \varepsilon_{\alpha\beta})(\varepsilon_{\gamma}M_{11}^{\alpha} - \varepsilon_{\alpha\gamma}) = (M_{11}^{\alpha})^{2}\tau_{\beta\gamma} - M_{11}^{\alpha}(\tau_{\alpha\beta\gamma} + 2\varepsilon_{\alpha}\tau_{\beta\gamma}) + \varepsilon_{\alpha\beta\gamma}\varepsilon_{\alpha} - \varepsilon_{\alpha\beta}\varepsilon_{\alpha\gamma}.$$

We can apply the solution formula for quadratic equations provided  $\tau_{\beta\gamma} \neq 0$ , i.e. our condition (5) is satisfied. In that case we get

$$(M_{11}^{\alpha})_{\pm} = \frac{\tau_{\alpha\beta\gamma} + 2\varepsilon_{\alpha}\tau_{\beta\gamma}}{2\tau_{\beta\gamma}} \pm \frac{\sqrt{(\tau_{\alpha\beta\gamma} + 2\varepsilon_{\alpha}\tau_{\beta\gamma})^2 - 4(\varepsilon_{\alpha\beta\gamma}\varepsilon_{\alpha} - \varepsilon_{\alpha\beta}\varepsilon_{\alpha\gamma})\tau_{\beta\gamma}}}{2\tau_{\beta\gamma}}$$
$$= \varepsilon_{\alpha} + \frac{\tau_{\alpha\beta\gamma} \pm \sqrt{\tau_{\alpha\beta\gamma}^2 + 4\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma}}}{2\tau_{\beta\gamma}}.$$
(A.13)

<sup>623</sup> Thus we have established the term for  $M_{11}^{\alpha}$ . The next step is to derive  $q_1^{\zeta}$ . We insert <sup>624</sup> (A.9)-(A.12) into (A.4) and get

$$q_{1}^{\zeta}(M_{11}^{\alpha} - \varepsilon_{\alpha})^{2}\varepsilon_{\beta\gamma} = (\tau_{\alpha\beta} + q_{1}^{\zeta}(\varepsilon_{\beta}M_{11}^{\alpha} - \varepsilon_{\alpha\beta}))(\tau_{\alpha\gamma} + q_{1}^{\zeta}(\varepsilon_{\gamma}M_{11}^{\alpha} - \varepsilon_{\alpha\gamma})) + q_{1}^{\zeta}(1 - q_{1}^{\zeta})(\varepsilon_{\beta}M_{11}^{\alpha} - \varepsilon_{\alpha\beta})(\varepsilon_{\gamma}M_{11}^{\alpha} - \varepsilon_{\alpha\gamma}) = (1 - q_{1}^{\zeta})\tau_{\alpha\beta}\tau_{\alpha\gamma} + q_{1}^{\zeta}\varepsilon_{\beta}\varepsilon_{\gamma}(M_{11}^{\alpha} - \varepsilon_{\alpha})^{2}$$

and hence we get the quadratic relation

$$0 = (1 - q_1^{\zeta})\tau_{\alpha\beta}\tau_{\alpha\gamma} - q_1^{\zeta}\tau_{\beta\gamma}(M_{11}^{\alpha} - \varepsilon_{\alpha})^2$$
(A.14)

 $_{626}$  We insert (A.13) and get

$$\tau_{\alpha\beta}\tau_{\alpha\gamma} = q_1^{\zeta} \left( \tau_{\alpha\beta}\tau_{\alpha\gamma} + \tau_{\beta\gamma} (M_{11}^{\alpha} - \varepsilon_{\alpha})^2 \right), 4\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma} = q_1^{\zeta} \left( 4\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma} + \left(\tau_{\alpha\beta\gamma} + \sqrt{\chi}\right)^2 \right), 4\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma} = 2q_1^{\zeta}\sqrt{\chi} \left(\sqrt{\chi} + \tau_{\alpha\beta\gamma}\right).$$

627 We use the equality

$$4\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma} = \chi - \tau_{\alpha\beta\gamma}^2 = (\sqrt{\chi} + \tau_{\alpha\beta\gamma})(\sqrt{\chi} - \tau_{\alpha\beta\gamma})$$

and the observation that  $\sqrt{\chi}(\sqrt{\chi} - \tau_{\alpha\beta\gamma}) = 0$  if and only if the conditions in (5) are violated to get

$$q_1^{\zeta} = \frac{\sqrt{\chi} - \tau_{\alpha\beta\gamma}}{2\sqrt{\chi}} = \frac{1}{2} - \frac{\tau_{\alpha\beta\gamma}}{2\sqrt{\chi}},\tag{A.15}$$

thus inferring the proposed term for  $q_1^{\zeta}$ . Next we infer the term for  $M_{01}^{\alpha}$ . To this end we insert (A.13) and (A.15) into (A.8):

$$-q_{1}^{\zeta}(M_{11}^{\alpha}-\varepsilon_{\alpha}) = (1-q_{1}^{\zeta})(M_{01}^{\alpha}-\varepsilon_{\alpha}),$$
  
$$(\tau_{\alpha\beta\gamma}-\sqrt{\chi})(\tau_{\alpha\beta\gamma}+\sqrt{\chi}) = 2\tau_{\beta\gamma}(\tau_{\alpha\beta\gamma}+\sqrt{\chi})(M_{01}^{\alpha}-\varepsilon_{\alpha}),$$
  
$$M_{01}^{\alpha} = \varepsilon_{\alpha} + \frac{\tau_{\alpha\beta\gamma}-\sqrt{\chi}}{2\tau_{\beta\gamma}},$$

thus inferring the proposed term. The remaining terms are inferred analogously. This completes the proof.  $\hfill \Box$ 

634 Proof of Theorem 7. We bound the parameters from (6) between 0 and 1:

$$0 \leq \frac{1}{2} - \frac{\tau_{\alpha\beta\gamma}}{2\sqrt{\chi}} \leq 1,$$
$$-\sqrt{\chi} \leq \tau_{\alpha\beta\gamma} \leq \sqrt{\chi},$$
$$0 \leq \tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma}.$$

<sup>635</sup> With (5) this yields positivity for the unconditional covariances. Next we look at  $M_{01}^{\alpha}$ <sup>636</sup> and  $M_{11}^{\alpha}$ :

$$0 \leq \varepsilon_{\alpha} + \frac{\tau_{\alpha\beta\gamma} - \sqrt{\chi}}{2\tau_{\beta\gamma}} \leq 1,$$
  
$$-2\varepsilon_{\alpha}\tau_{\beta\gamma} \leq \tau_{\alpha\beta\gamma} - \sqrt{\chi} \leq 2(1 - \varepsilon_{\alpha})\tau_{\beta\gamma},$$
  
$$\tau_{\alpha\beta\gamma} - 2(1 - \varepsilon_{\alpha})\tau_{\beta\gamma} \leq \sqrt{\chi} \leq \tau_{\alpha\beta\gamma} + 2\varepsilon_{\alpha}\tau_{\beta\gamma},$$

637 and

$$0 \leq \varepsilon_{\alpha} + \frac{\tau_{\alpha\beta\gamma} + \sqrt{\chi}}{2\tau_{\beta\gamma}} \leq 1,$$
  
$$-2\varepsilon_{\alpha}\tau_{\beta\gamma} \leq \tau_{\alpha\beta\gamma} + \sqrt{\chi} \leq 2(1 - \varepsilon_{\alpha})\tau_{\beta\gamma},$$
  
$$-(2\varepsilon_{\alpha}\tau_{\beta\gamma} + \tau_{\alpha\beta\gamma}) \leq \sqrt{\chi} \leq 2(1 - \varepsilon_{\alpha})\tau_{\beta\gamma} - \tau_{\alpha\beta\gamma}.$$

<sup>638</sup> Squaring both inequalities reduces the four inequalities to the following two:

$$\tau_{\alpha\beta\gamma}^{2} + 4\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma} \le (2\varepsilon_{\alpha}\tau_{\beta\gamma} + \tau_{\alpha\beta\gamma})^{2}, \qquad (A.16)$$

$$\tau_{\alpha\beta\gamma}^2 + 4\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma} \le (2(1-\varepsilon_{\alpha})\tau_{\beta\gamma} - \tau_{\alpha\beta\gamma})^2.$$
(A.17)

We look first at inequality (A.16) and get 639

> $\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma} \leq \varepsilon_{\alpha}^2 \tau_{\beta\gamma}^2 + \varepsilon_{\alpha}\tau_{\beta\gamma}\tau_{\alpha\beta\gamma},$  $0 < \varepsilon_{\alpha}(\varepsilon_{\alpha}\tau_{\beta\gamma} + \tau_{\alpha\beta\gamma}) - \tau_{\alpha\beta}\tau_{\alpha\gamma},$  $0 \leq \varepsilon_{\alpha} \varepsilon_{\alpha\beta\gamma} - \varepsilon_{\alpha\beta} \varepsilon_{\alpha\gamma} = \tau_{\beta\gamma|1}.$

Set  $\widehat{\varepsilon}_{\alpha} := (1 - \varepsilon_{\alpha}) = p_{0\Sigma\Sigma}$  and look at (A.17): 640

$$\begin{aligned} \tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma} &\leq \widehat{\varepsilon}_{\alpha}^{2}\tau_{\beta\gamma}^{2} - \widehat{\varepsilon}_{\alpha}\tau_{\beta\gamma}\tau_{\alpha\beta\gamma},\\ 0 &\leq \widehat{\varepsilon}_{\alpha}(\widehat{\varepsilon}_{\alpha}\tau_{\beta\gamma} - \tau_{\alpha\beta\gamma}) - \tau_{\alpha\beta}\tau_{\alpha\gamma},\\ 0 &\leq p_{000}p_{011} - p_{001}p_{010} = \tau_{\beta\gamma|0}. \end{aligned}$$

- Hence, we have derived the proposed inequalities. 641
- *Proof of Proposition 8.* The tripod equations (4) imply: 642

$$\chi = \tau_{\alpha\beta\gamma}^2 + 4\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma} = (M_{11}^{\alpha} - M_{01}^{\alpha})^2 (M_{11}^{\beta} - M_{01}^{\beta})^2 (M_{11}^{\gamma} - M_{01}^{\gamma})^2 (1 - q_1^{\zeta})^2 (q_1^{\zeta})^2$$

- Together with (18) and (16) we see that there is no set of real or complex parameters 643
- such that  $\chi = 0$  but  $\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma} \neq 0$ . 644
- Proof of Proposition 9. The cases are easily verified by looking at Equation (16) and 645 inserting the selected parameters back into (4).  $\square$ 646
- Proof of Proposition 10. The function  $\chi: \mathbb{C}^8 \to \mathbb{C}$  is a nonconstant polynomial 647 mapping. Thus the set  $\{ \boldsymbol{p} \in \mathbb{R}^8 : \chi(\boldsymbol{p}) = 0 \}$  is a Lebesgue zero set. The same holds for 648 the set 649

$$\{ \boldsymbol{p} \in \mathbb{R}^8 : \tau_{\alpha\beta}(\boldsymbol{p}) = 0 \text{ or } \tau_{\alpha\gamma}(\boldsymbol{p}) = 0 \text{ or } \tau_{\beta\gamma}(\boldsymbol{p}) = 0 \}.$$

This completes the proof. 650

Proof of Proposition 11. We recover  $M^{\psi}$  by inserting the parameters from (6) into 651 (11). To infer the invariants we first look at the equality conditions. We do this 652

representatively by looking at  $\overline{M}^{\alpha} = \widetilde{M}^{\alpha}$ . In particular we look at 653

$$\overline{M}_{11}^{\alpha} - \overline{M}_{01}^{\alpha} = \widetilde{M}_{11}^{\alpha} - \widetilde{M}_{01}^{\alpha}, \quad \overline{M}_{11}^{\alpha} + \overline{M}_{01}^{\alpha} = \widetilde{M}_{11}^{\alpha} + \widetilde{M}_{01}^{\alpha},$$

and thus 654

$$\frac{\sqrt{\chi_{\alpha\beta\gamma}}}{\tau_{\beta\gamma}} = \frac{\sqrt{\chi_{\alpha\beta\delta}}}{\tau_{\beta\delta}}, \quad \frac{\tau_{\alpha\beta\gamma}}{\tau_{\beta\gamma}} = \frac{\tau_{\alpha\gamma\delta}}{\tau_{\beta\delta}},$$
$$\frac{\tau_{\alpha\beta\gamma}^2 + 4\tau_{\alpha\beta}\tau_{\alpha\gamma}\tau_{\beta\gamma}}{\tau_{\beta\gamma}^2} = \frac{\tau_{\alpha\beta\delta}^2 + 4\tau_{\alpha\beta}\tau_{\alpha\delta}\tau_{\beta\delta}}{\tau_{\beta\delta}^2}, \quad \frac{\tau_{\alpha\beta\gamma}}{\tau_{\beta\gamma}} = \frac{\tau_{\alpha\gamma\delta}}{\tau_{\beta\delta}},$$
$$\frac{\tau_{\alpha\gamma}}{\tau_{\beta\gamma}} = \frac{\tau_{\alpha\delta}}{\tau_{\beta\delta}}, \quad \frac{\tau_{\alpha\beta\gamma}}{\tau_{\beta\gamma}} = \frac{\tau_{\alpha\gamma\delta}}{\tau_{\beta\delta}},$$
$$\frac{\tau_{\alpha\beta\gamma}}{\tau_{\alpha\beta\delta}} = \frac{\tau_{\beta\gamma}}{\tau_{\beta\delta}} = \frac{\tau_{\alpha\gamma}}{\tau_{\alpha\delta}}.$$

Looking at  $\overline{M}^{\beta} = \widetilde{M}^{\beta}$  yields the same equalities. Reproducing the calculations for  $\widehat{M}^{\gamma} = \check{M}^{\gamma}$  yields the invariants  $f_1$  to  $f_3$ .

For the inference of  $f_0$  observe that the equation system (2) can be written in a marginalised form, i.e. one replaces the equations in  $(p_{abcd})_{a,b,c,d\in\{0,1\}}$  by the linear transforms  $\varepsilon_{\alpha\beta\gamma\delta}$ ,  $\varepsilon_{\alpha\beta\gamma}$ ,  $\varepsilon_{\alpha\beta\delta}$ ,  $\varepsilon_{\beta\gamma\delta}$ ,  $\varepsilon_{\alpha\beta}$ ,  $\varepsilon_{\alpha\gamma}$ ,  $\varepsilon_{\alpha\delta}$ ,  $\varepsilon_{\beta\gamma}$ ,  $\varepsilon_{\beta\delta}$ ,  $\varepsilon_{\gamma\delta}$ ,  $\varepsilon_{\alpha}$ ,  $\varepsilon_{\beta}$ ,  $\varepsilon_{\gamma}$  and  $\varepsilon_{\delta}$ . We immediately see that all terms but  $\varepsilon_{\alpha\beta\gamma\delta}$  are covered by our investigation of

the tripod case. We insert the parameters obtained in (6) and (12) into the equation for  $\varepsilon_{\alpha\beta\gamma\delta}$  to get:

$$\varepsilon_{\alpha\beta\gamma\delta} = (1 - q_1^{\zeta})\overline{M}_{01}^{\alpha}\overline{M}_{01}^{\beta}((1 - M_{01}^{\psi})\widehat{M}_{01}^{\gamma}\widehat{M}_{01}^{\delta} + M_{01}^{\psi}\widehat{M}_{11}^{\gamma}\widehat{M}_{11}^{\delta}) + q_1^{\zeta}\overline{M}_{11}^{\alpha}\overline{M}_{11}^{\beta}((1 - M_{11}^{\psi})\widehat{M}_{01}^{\gamma}\widehat{M}_{01}^{\delta} + M_{11}^{\psi}\widehat{M}_{11}^{\gamma}\widehat{M}_{11}^{\delta}).$$

Reordering and restructuring this equation eventually yields invariant  $f_0$ . This completes the proof.

<sup>665</sup> Proof of Proposition 12. Theorem 7 covers the first part of the Proposition. The

remaining inequalities are obtained by bounding (12) between 0 and 1 and use the fact that the covariances are always positive with Lemma 2(1):

$$-1 \leq \frac{\tau_{\alpha\delta}\tau_{\alpha\beta\gamma} - \tau_{\alpha\beta}\tau_{\alpha\gamma\delta} - \tau_{\alpha\delta}\sqrt{\chi_{\alpha\beta\gamma}}}{\tau_{\alpha\beta}\sqrt{\chi_{\alpha\gamma\delta}}} \leq 1,$$
  
$$\tau_{\alpha\beta}(\tau_{\alpha\gamma\delta} - \sqrt{\chi_{\alpha\gamma\delta}}) \leq \tau_{\alpha\delta}(\tau_{\alpha\beta\gamma} - \sqrt{\chi_{\alpha\beta\gamma}}) \leq \tau_{\alpha\beta}(\tau_{\alpha\gamma\delta} + \sqrt{\chi_{\alpha\gamma\delta}}),$$
  
$$-1 \leq \frac{\tau_{\alpha\delta}\tau_{\alpha\beta\gamma} - \tau_{\alpha\beta}\tau_{\alpha\gamma\delta} + \tau_{\alpha\delta}\sqrt{\chi_{\alpha\beta\gamma}}}{\tau_{\alpha\beta}\sqrt{\chi_{\alpha\gamma\delta}}} \leq 1,$$
  
$$\tau_{\alpha\beta}(\tau_{\alpha\gamma\delta} - \sqrt{\chi_{\alpha\gamma\delta}}) \leq \tau_{\alpha\delta}(\tau_{\alpha\beta\gamma} + \sqrt{\chi_{\alpha\beta\gamma}}) \leq \tau_{\alpha\beta}(\tau_{\alpha\gamma\delta} + \sqrt{\chi_{\alpha\gamma\delta}}),$$
