# SPECTRUM OF PERMANENT'S VALUES AND ITS EXTREMAL MAGNITUDES IN $\Lambda_{n}^{3}$ AND $\Lambda_{n}(\alpha, \beta, \gamma)$ 

VLADIMIR SHEVELEV

#### Abstract

Let $\Lambda_{n}^{k}$ denote the class of $(0,1)$ square matrices containing in each row and in each column exactly $k$ 1's. The minimal value of $k$, for which the behavior of the permanent in $\Lambda_{n}^{k}$ is not quite studied, is $k=3$. We give a simple algorithm for calculation upper magnitudes of permanent in $\Lambda_{n}^{3}$ and consider some extremal problems in a generalized class $\Lambda_{n}(\alpha, \beta, \gamma)$, the matrices of which contain in each row and in each column nonzero elements $\alpha, \beta, \gamma$ and $n-3$ zeros.

## 1. Introduction

Let $\Lambda_{n}^{k}$ denote the class of $(0,1)$ square matrices containing in each row and in each column exactly $k$ 's. If $A \in \Lambda_{n}^{3}$, then matrix $k^{-1} A$ is doubly stochastic. Therefore, $\Lambda_{n}^{k}$-matrices are also called doubly stochastic ( 0,1 )matrices (cf. [11]). Furthermore, for a given real or complex numbers $\alpha, \beta, \ldots \gamma$, denote $\Lambda_{n}(\alpha, \beta, \ldots \gamma)$ the class of square matrices containing every number from $\{\alpha, \beta, \ldots \gamma\}$ exactly one time in each row and in each column, such that the other elements are 0's.

Definition 1. We call p-spectrum in $\Lambda_{n}^{k}$ (denoting it $p s\left[\Lambda_{n}^{k}\right]$ ) the set of all the values which are taken by the permanent in $\Lambda_{n}^{k}$.

Note that $p$-spectrum in $\Lambda_{n}^{1}$ trivially is $\{1\}$. It is known (cf. Tarakanov [25]) that

$$
p s\left[\Lambda_{n}^{2}\right]=\left\{2,2^{2}, 2^{3}, \ldots, 2^{\left\lfloor\frac{n}{2}\right\rfloor}\right\} .
$$

But, for $k \geq 3, p$-spectrum of $\Lambda_{n}^{k}$, generally speaking, is unknown. Greenstein (cf. [11], point 8.4, Problem 3) put the problem of describing the p-spectrum in $\Lambda_{n}^{3}$. In this paper we find $p$-spectrum on symmetric matrices in $\Lambda_{n}^{3}$ with ones on the main diagonal and give an algorithm for calculation upper values of $p$-spectrum in $\Lambda_{n}^{3}$. We also obtain several results for a generalized class $\Lambda_{n}(\alpha, \beta, \gamma)$ with real nonzero numbers $\alpha, \beta, \gamma$. Some results of the present paper were announced by the author in [21].

## 2. What is known about $\Lambda_{n}^{3}$ ?

1) Explicit formula for $\left|\Lambda_{n}^{3}\right|$ (cf. Stanley [24], Ch.1)

$$
\begin{equation*}
\left|\Lambda_{n}^{3}\right|=6^{-n} \sum_{k_{1}+k_{2}+k_{3}=n, k_{i} \geq 0} \frac{(-1)^{k_{2}} n!^{2}\left(k_{2}+3 k_{3}\right)!2^{k_{1}} 3^{k_{2}}}{k_{1}!k_{2}!k_{3}!6^{k_{3}}} \tag{2.1}
\end{equation*}
$$

2) Asymptotic formula for $\left|\Lambda_{n}^{3}\right|$ (cf. O'Neil [12])

$$
\begin{equation*}
\left|\Lambda_{n}^{3}\right|=\frac{(3 n)!}{(36)^{n}} e^{-2}\left(1+O\left(n^{-1+\varepsilon}\right)\right) \tag{2.2}
\end{equation*}
$$

where $\varepsilon>0$ is arbitrary small for sufficiently large $n$.
In addition, note that $\left|\Lambda_{n}(\alpha, \beta, \gamma)\right|$ with different $\alpha, \beta, \gamma$ is, evidently, the number of 3 -rowed Latin rectangles of length $n$ such that

$$
\begin{equation*}
\left|\Lambda_{n}(\alpha, \beta, \gamma)\right|=n!K_{n} \tag{2.3}
\end{equation*}
$$

where $K_{n}$ is the number of reduced 3-rowed Latin rectangles with the first row $\{1,2, \ldots, n\}$. It is known (Riordan [13], pp. 204-210) that

$$
\begin{equation*}
K_{n}=\sum_{k=0}^{\left\lfloor\frac{n}{2}\right\rfloor}\binom{n}{k} D_{n-k} D_{k} U_{n-2 k} \tag{2.4}
\end{equation*}
$$

where $D_{n}$ is subfactorial.

$$
\begin{equation*}
D_{0}=1, \quad D_{n}=n D_{n-1}+(-1)^{n}, \quad n \geq 1 \tag{2.5}
\end{equation*}
$$

$\left\{U_{n}\right\}$ is sequence of Lucas numbers of the Ménage problem which is defined by Cayley recursion (cf. [13], p. 201)

$$
\begin{gather*}
U_{0}=1, \quad U_{1}=-1, \quad U_{2}=0 \\
U_{n}=n U_{n-1}+\frac{n}{n-2} U_{n-2}+4 \frac{(-1)^{n}}{n-2}, \quad n \geq 3 \tag{2.6}
\end{gather*}
$$

(see [23], sequences A102761, A000186).
Denote, furthermore, $\bar{\Lambda}_{n}^{3}$ the set of matrices in $\Lambda_{n}^{3}$ with 1's on the main diagonal. Note that

$$
\begin{equation*}
p s\left[\Lambda_{n}^{3}\right]=p s\left[\bar{\Lambda}_{n}^{3}\right] . \tag{2.7}
\end{equation*}
$$

Indeed, it is well known that every $\Lambda_{n}^{3}$-matrix $A$ has a diagonal of ones (i.e., a set of 1's no two in the same row or column). Let $l$ be such a diagonal. There exists a permutation of rows and columns $\pi$ such that $\pi(l)$ will be the main diagonal of $\pi(A)$. Nevertheless, $\operatorname{per}(\pi(A))=\operatorname{per} A$ and (2.7) follows.
3) A known explicit formula for $\left|\bar{\Lambda}_{n}^{3}\right|$ (Shevelev [19]) has a close structure to (2.4):

$$
\begin{equation*}
\left|\bar{\Lambda}_{n}^{3}\right|=\sum_{k=0}^{\left\lfloor\frac{n}{2}\right\rfloor}\binom{n}{k} S_{n-k} S_{k} U_{n-2 k} \tag{2.8}
\end{equation*}
$$

where sequence $\left\{S_{n}\right\}$ is defined by recursion

$$
\begin{equation*}
S_{0}=1, \quad S_{1}=0, \quad S_{n}=(n-1)\left(S_{n-1}+\frac{1}{2} S_{n-2}\right), \quad n \geq 2 \tag{2.9}
\end{equation*}
$$

4) Asymptotic formula for $\left|\bar{\Lambda}_{n}^{3}\right|$ (Shevelev [19])

$$
\begin{equation*}
\left|\bar{\Lambda}_{n}^{3}\right|=C \sqrt{n}\left(\frac{n}{e}\right)^{2 n}\left(1+O\left(n^{-1+\varepsilon}\right)\right. \tag{2.10}
\end{equation*}
$$

where

$$
C=2 \sqrt{\pi e^{-5}}=0.29098 \ldots
$$

and $\varepsilon>0$ is arbitrary small for sufficiently large $n$.
5) Denote $\widehat{\Lambda}_{n}^{3}$ the set of symmetric matrices in $\bar{\Lambda}_{n}^{3}$. P-spectrum on $\widehat{\Lambda}_{n}^{3}$ is given by the following theorem (Shevelev [16])

Theorem 1. Let $R(n ; 3)$ denote the set of all partitions of $n$ with parts more than or equal to 3 . To every partition $r \in R(n ; 3): n=n_{1}+n_{2}+\ldots+$ $n_{m}, m=m(r)$, put in a correspondence the number

$$
\begin{equation*}
H(r)=\prod_{i=1}^{m} a\left(n_{i}\right) \tag{2.11}
\end{equation*}
$$

where sequence $\{a(n)\}$ is defined by the recursion

$$
\begin{equation*}
a(3)=6, \quad a(4)=9, \quad a(n)=a(n-1)+a(n-2)-2, \quad n \geq 5 \tag{2.12}
\end{equation*}
$$

Then we have

$$
\begin{equation*}
p s\left[\widehat{\Lambda}_{n}^{3}\right]=\{H(r): r \in R(n ; 3)\} . \tag{2.13}
\end{equation*}
$$

6) The maximal value $M(n)$ of permanent in $\Lambda_{n}^{3}$ was found by Merriell 9].

Theorem 2. If $n \equiv h(\bmod 3), \quad h=0,1,2$, then

$$
\begin{equation*}
M(n)=6^{\frac{n-h}{3}}\left\lfloor\left(\frac{3}{2}\right)^{h}\right\rfloor \tag{2.14}
\end{equation*}
$$

Note that, the case $h=0$ of (2.14) easily follows from a general MincBregman inequality for permanent of $(0,1)$-matrices (see [11], point 6.2 , and [4]).
7) Put $\left.M(n)=M^{(1)}\right)(n)$. In case of $n \equiv 0(\bmod 3)$, Bolshakov [3] showed that the second maximal $\left.M^{(2)}<M^{(1}\right)(n)$ of permanent in $\Lambda_{n}^{3}$ (such that interval $\left(M^{(2)}, M^{(1)}\right)$ is free from values of permanent in $\left.\Lambda_{n}^{3}\right)$ equals to

$$
M^{(2)}(n)= \begin{cases}20, & \text { if } n=6  \tag{2.15}\\ 120, & \text { if } n=9 \\ \frac{9}{16} 6^{\frac{n}{3}}, & \text { if } n \geq 12\end{cases}
$$

Note that both $M^{(1)}(n)$ and $M^{(2)}(n)$ are attained in $\widehat{\Lambda}_{n}^{3}$ (Shevelev [16]).
8) Denote $m(n)$ the minimal value of permanent in $\Lambda_{n}^{3}$. In 1979, Voorhoeve [26] obtain a beautiful lower estimate for $m(n)$ :

$$
\begin{equation*}
m(n) \geq 6\left(\frac{4}{3}\right)^{n-3} \tag{2.16}
\end{equation*}
$$

This estimate remains the best even after proof by Egorychev [7] and Falikman [8] the famous Van der Waerden conjectural lower estimate per $A \geq \frac{n!}{n^{n}}$ for every $n \times n$ doubly stochastic matrix $A$. Indeed, this estimate yields only $m(n) \geq 3^{n} \frac{n!}{n^{n}}$, such that (2.16) is stronger for $n \geq 4$.
9) Bolshakov [2] found $p$-spectrum in $\Lambda_{n}^{3}$ in cases $n \leq 8$. Namely, he added to the evident $p$-spectrums $p s\left[\Lambda_{3}^{3}\right]=\{6\}$ and $p s\left[\Lambda_{4}^{3}\right]=\{9\}$ also the following p-spectrums

$$
p s\left[\Lambda_{5}^{3}\right]=\{12,13\}, \quad p s\left[\Lambda_{6}^{3}\right]=\left\{\begin{array}{ll}
17, & 18,
\end{array} 20,36\right\}
$$

$$
\begin{equation*}
p s\left[\Lambda_{8}^{3}\right]=\{33,34,35,36,37,38,39,40,41,42,44,45,48,49,52,72,78,81\} \tag{2.17}
\end{equation*}
$$

## 3. A generalization of Theorem 1 on matrices of class

$\Lambda_{n}(\alpha, \beta, \gamma)$ WITh Symmetric positions of elements
Denote $\bar{\Lambda}_{n}(\alpha, \beta, \gamma)$ the set of matrices in $\Lambda_{n}(\alpha, \beta, \gamma)$ with $\beta$ 's on the main diagonal. It is clear that, together with (2.3),

$$
\begin{equation*}
\left|\bar{\Lambda}_{n}(\alpha, \beta, \gamma)\right|=K_{n} \tag{3.1}
\end{equation*}
$$

Note that, as for sets $\Lambda_{n}^{3}, \bar{\Lambda}_{n}^{3}$, we have

$$
\begin{equation*}
p s\left[\Lambda_{n}(\alpha, \beta, \gamma)\right]=p s\left[\bar{\Lambda}_{n}(\alpha, \beta, \gamma)\right] . \tag{3.2}
\end{equation*}
$$

Denote, furthermore, $\widehat{\Lambda}_{n}(\alpha, \beta, \gamma)$ the set of matrices $M=\left\{m_{i, j}\right\}$ in $\bar{\Lambda}_{n}(\alpha, \beta, \gamma)$ with symmetric positions of elements: $m_{i, j}=\alpha$ if and only if $m_{j, i}=\gamma$.
$P$-spectrum on $\widehat{\Lambda}_{n}(\alpha, \beta, \gamma)$ is given by the following theorem.
Theorem 3. If to every partition $r \in R(n ; 3): n=n_{1}+n_{2}+\ldots+n_{m}, \quad m=$ $m(r)$, corresponds the number

$$
\begin{equation*}
H_{\alpha, \beta, \gamma}(r)=\prod_{i=1}^{m} a\left(n_{i}\right), \tag{3.3}
\end{equation*}
$$

where sequence $\{a(n)=a(\alpha, \beta, \gamma ; n\}$ is defined by the recursion

$$
\begin{gather*}
a(3)=\alpha^{3}+\beta^{3}+\gamma^{3}+3 \alpha \beta \gamma, \\
a(4)=\alpha^{4}+\beta^{4}+\gamma^{4}+4 \alpha \beta^{2} \gamma+2(\alpha \gamma)^{2}, \\
a(n)=\beta a(n-1)+\alpha \gamma a(n-2)+ \\
\alpha^{n-1}(\alpha-\beta-\gamma)+\gamma^{n-1}(\gamma-\beta-\alpha), \quad n \geq 5, \tag{3.4}
\end{gather*}
$$

then we have

$$
\begin{equation*}
\operatorname{ps}\left[\widehat{\Lambda}_{n}(\alpha, \beta, \gamma)\right]=\left\{H_{\alpha, \beta, \gamma}(r): r \in R(n ; 3)\right\} \tag{3.5}
\end{equation*}
$$

Proof. Let $S_{n}$ be the symmetric permutation group of elements $1, \ldots, n$. Two positions $\left(i_{1}, j_{1}\right),\left(i_{2}, j_{2}\right)$ are called independent if $i_{k} \neq j_{k}, \mathrm{k}=1,2$. We shall say that in the $n \times n$ matrix $M=\left\{m_{i j}\right\}$ a weight $m_{i j}$ is appropriated to the position $(i, j)$. Let $s \in S_{n}$ has not any cycle of length less than $n$. Consider a map

$$
\sigma:(i, j) \mapsto\left(s^{i}(1), \quad s^{j}(1)\right)
$$

appropriating to the position $\left(s^{i}(1), s^{j}(1)\right.$ the weight $m_{i j}$.
Lemma 1. 1) the map $\sigma$ is bijective; 2) if $E$ is a set of pairwise independent positions, then $\sigma(E)$ is also a set of pairwise independent positions.

Proof. a) Consider two distinct positions

$$
\begin{equation*}
\left(i_{1}, j_{1}\right), \quad\left(i_{2}, j_{2}\right) \tag{3.6}
\end{equation*}
$$

such that, at least, one of two inequalities holds

$$
\begin{equation*}
i_{1} \neq i_{2}, \quad j_{1} \neq j_{2} \tag{3.7}
\end{equation*}
$$

Let $i_{1} \neq i_{2}$ such that, say, $i_{1}>i_{2}$. Show that $s^{i_{1}}(1) \neq s^{i_{2}}(1)$. Indeed, if to suppose that $s^{i_{1}}(1)=s^{i_{2}}(1)$, then $s^{i_{1}-i_{2}}=1$, i.e., $s$ has a cycle of length $i_{1}-i_{2}<n$ in spite of the condition. Conversely, if $s^{i_{1}}(1) \neq s^{i_{2}}(1)$, then $i_{1} \neq i_{2}$, since $s^{-1}$ has not any cycle of length less than $n$ as well.
b) Let positions (3.6) be independent. The both of inequalities (3.7) hold and, as in a), we have $s^{i_{1}}(1) \neq s^{i_{2}}(1), s^{j_{1}}(1) \neq s^{j_{2}}(1)$, i.e. the positions $\sigma\left(\left(i_{1}, j_{1}\right)\right), \sigma\left(\left(i_{1}, j_{1}\right)\right)$ are independent as well.

Lemma 2. Let $s \in S_{n}$ have not any cycle of length less than $n$. Then (0,1)-matrix $S$ having 1's on only positions

$$
\left(s^{1}(1), s^{2}(1)\right),\left(s^{2}(1), s^{3}(1)\right), \ldots,\left(s^{n-1}(1), s^{n}(1)\right),\left(s^{n}(1), s^{1}(1)\right)
$$

is a incidence matrix of $s$.
Proof. Since $s$ has not cycles of length less than $n$, then $\left\{s^{1}(1), \ldots, s^{n}(1)\right\}$ is a permutation of numbers $\{1, \ldots, n\}$. Thus the set of positions of 1 's of matrix $S$ coincides with the set of 1's of the incidence matrix of $s$ : $(1, s(1)), \ldots,(n, s(n))$.

Let $P=P_{n}$ be ( 0,1 )-matrix with 1's on positions $(1,2),(2,3), \ldots,(n-$ $1, n),(n, 1)$ only.

Lemma 3. Let $s \in S_{n}$ have not any cycle of length less than $n$. If $S$ and $S^{-1}$ are the incidence matrices of $s$ and $s^{-1}$, then we have

$$
\begin{equation*}
\sigma^{-1}(S)=P, \quad \sigma^{-1}\left(S^{-1}\right)=P^{-1} \tag{3.8}
\end{equation*}
$$

Proof. Both of formulas follows from Lemma 2.

Noting that $\sigma(I)=I$, where $I$ is the identity matrix, we conclude that

$$
\begin{equation*}
S^{-1}+I+S=\sigma\left(P^{-1}+I+P\right) \tag{3.9}
\end{equation*}
$$

Moreover, since, by the bijection $\sigma$, to every diagonal (i.e., to every set of $n$ pairwise independent positions) of the matrix $\alpha S^{-1}+\beta I+\gamma S$ corresponds one and only one diagonal of the matrix $\alpha P^{-1}+\beta I+\gamma P$ with the same products of weights, then we have

$$
\begin{equation*}
\operatorname{per}\left(\alpha S^{-1}+\beta I+\gamma S\right)=\operatorname{per}\left(\alpha P^{-1}+\beta I+\gamma P\right) \tag{3.10}
\end{equation*}
$$

Note that from the definition it follows that, for every matrix $M \in \widehat{\Lambda}_{n}(\alpha, \beta, \gamma)$, we have a representation

$$
\begin{equation*}
M=\alpha S^{-1}+\beta I_{n}+\gamma S \tag{3.11}
\end{equation*}
$$

where $S$ is the incidence matrix of a substitution $s$. In case when $s$ has not any cycle of length less than $n$, the matrix $M$ is completely indecomposable matrix in $\widehat{\Lambda}_{n}(\alpha, \beta, \gamma)$. Thus, by (3.10), all completely indecomposable matrices of $\widehat{\Lambda}_{n}(\alpha, \beta, \gamma)$ have the same permanent, equals to $\operatorname{per}\left(\alpha P^{-1}+\beta I_{n}+\gamma P\right)$.

In general, a substitution $s$ with the incidence matrix $S$ in (3.11) cannot have cycles of length less than 3. Indeed, if for some $i$, we have either $s(i)=i$ or $s(s(i))=i$, then in both cases $s(i)=s^{-1}(i)$ which means coincidence of positions 1's of the matrices $S$ and $S^{-1}$ in the $i$-th row.

Let $s \in S_{n}$ be an arbitrary substitution with cycles of length more than 2. Let

$$
\begin{equation*}
s=\prod_{j=1}^{r} s_{j} \tag{3.12}
\end{equation*}
$$

where $s_{j} \in S_{l_{j}}, \quad l_{j} \geq 3, \sum_{j=1}^{r} l_{j}=n$, be the decomposition of $s$ in a product of cycles. Then the matrix $M=\alpha S^{-1}+\beta I_{n}+\gamma S$ is a direct sum of the matrices $M_{j}=\alpha S_{l_{j}}^{-1}+\beta I+\gamma S_{l_{j}}$ such that, by (3.10), $\operatorname{per} M_{j}=\operatorname{per}\left(\alpha P^{-1}+\right.$ $\left.\beta I_{l_{j}}+\gamma P\right)$ and we have

$$
\begin{equation*}
\operatorname{per} M=\prod_{j=1}^{r} \operatorname{per} M_{j}=\prod_{j=1}^{r} \operatorname{per}\left(\alpha P^{-1}+\beta I_{l_{j}}+\gamma P\right) \tag{3.13}
\end{equation*}
$$

It is left to notice that Minc [10] found a recursion (3.4) for $\operatorname{per}\left(\alpha I_{n}+\beta P+\right.$ $\gamma P^{2}$ ) and, as well known, the multiplication an $n \times n$ matrix by $P^{-1}$ does not change its permanent.

Therefore, $\operatorname{per}\left(\alpha P^{-1}+\beta I_{l_{j}}+\gamma P\right)=\operatorname{per}\left(\alpha I_{n}+\beta P+\gamma P^{2}\right)$.

Example 1. Let us find $p s\left[\widehat{\Lambda}_{11}(-1,3,2)\right]$.
We have the following partitions of 11 with the parts not less than 3:

$$
11=8+3=7+4=6+5=3+4+4=3+3+5 .
$$

According to (3.4), for $a(n)=a(-1,3,2 ; n)$, we have $a(3)=16, a(4)=34$ and for $n \geq 5$,

$$
a(n)=3 a(n-1)-2 a(n-2)+6(-1)^{n} .
$$

Using induction, we find

$$
a(n)= \begin{cases}2^{n+1}, & \text { if } n \text { is odd } \\ 2^{n+1}+2, & \text { if } n \text { is even }\end{cases}
$$

Therefore,

$$
\begin{gathered}
p s\left[\widehat{\Lambda}_{11}(-1,3,2)\right]= \\
\left\{a(11), a(3) a(8), a(5) a(6), a^{2}(3) a(5), a(3) a^{2}(4)\right\}= \\
\{4096,8224,8320,8704,16384,18496\} .
\end{gathered}
$$

In the following examples we calculate $p$-spectrum for arbitrary $n$.
Example 2. Let us find $p s\left[\widehat{\Lambda}_{n}(-1,2,1)\right]$.
By induction, for $a(n)=a(-1,2,1 ; n)$, we have

$$
a(n)= \begin{cases}2, & \text { if } n \text { is odd } \\ 4, & \text { if } n \text { is even }\end{cases}
$$

Further, again using induction, one can find that, if $n$ is even, then

$$
p s\left[\widehat{\Lambda}_{n}(-1,2,1)\right]=\left\{4,4^{2}, \ldots, 4^{\left.\left\lfloor\frac{n}{4}\right)\right\rfloor}\right\}
$$

and, if $n$ is odd, then

$$
\operatorname{ps}\left[\widehat{\Lambda}_{n}(-1,2,1)\right]=\left\{2,2 \cdot 4,2 \cdot 4^{2}, \ldots, 2 \cdot 4^{\left\lfloor\left(\frac{n-3}{4}\right)\right\rfloor}\right\} .
$$

Example 3. Analogously, in case of $\widehat{\Lambda}_{n}(-1,1,1)$, for $a(n)=a(-1,1,1 ; n)$, we have

$$
a(n)=\left\{\begin{array}{l}
4, \text { if } n \equiv 0 \quad(\bmod 6) \\
-2, \text { if } n \equiv 3 \quad(\bmod 6), \\
1, \text { otherwise }
\end{array}\right.
$$

and

$$
\begin{aligned}
& \operatorname{ps}\left[\widehat{\Lambda}_{n}(-1,1,1)\right]= \\
& \left\{\begin{array}{lll}
\{1, & -2, & \left.4, \ldots,(-2)^{\left\lfloor\left(\frac{n-3}{3}\right)\right\rfloor}\right\}, \\
\{1, & -2, & 4, \ldots,(-2)^{\left\lfloor\left\lfloor\frac{n-6}{3}\right)\right\rfloor}, \\
\left.(-2)^{\left\lfloor\left(\frac{n}{3}\right)\right\rfloor}\right\}, & \text { if } n \equiv 0 & (\bmod 3),
\end{array}\right.
\end{aligned}
$$

It is interesting that, in case of $n$ multiple of 3 , the permanent omits the value $(-2)^{\left\lfloor\left(\frac{n-3}{3}\right)\right\rfloor}$.

## 4. Merriell type theorems in a subclasses of $\widehat{\Lambda}_{n}(\alpha, \beta, \gamma)$

Note that in class $\Lambda_{n}(\alpha, \beta, \gamma)$ the Minc-Bregman inequality and the Merriell theorem, generally speaking, do not hold even for positive $\alpha, \beta, \gamma$. Nevertheles, some restrictions on $\alpha, \beta, \gamma$ allow to prove some analogs of the Merriell theorem. Recall that $M(n)(2.14)$ is attained in $\widehat{\Lambda}_{n}^{3}$. Denote $M_{n}(\alpha, \beta, \gamma)$ the maximal value of permanent in $\widehat{\Lambda}_{n}(\alpha, \beta, \gamma)$.

Theorem 4. Consider a class $\widehat{\Lambda}_{n}(\alpha, \beta, \gamma)$ with the numbers $\alpha, \beta, \gamma$ satisfying "triangle inequlities"

$$
\begin{equation*}
0 \leq \alpha \leq \beta+\gamma, \quad 0 \leq \gamma \leq \alpha+\beta \tag{4.1}
\end{equation*}
$$

and the following additional conditions

$$
\begin{equation*}
a^{3}(4) \leq a^{4}(3), \quad \alpha \gamma+\beta(a(3))^{\frac{1}{3}} \leq(a(3))^{\frac{2}{3}} \tag{4.2}
\end{equation*}
$$

where sequence $\{a(n)\}$ is defined by recursion (3.4). Then, for $n$ multiple of 3, we have

$$
\begin{equation*}
M_{n}(\alpha, \beta, \gamma)=(a(3))^{\frac{n}{3}} \tag{4.3}
\end{equation*}
$$

Proof. Note that conditions (4.1)-(4.2) are satisfied, e.g., in case $\alpha=$ $\beta=\gamma=1$. Using induction, let us prove that

$$
\begin{equation*}
a(n) \leq(a(3))^{\frac{n}{3}} . \tag{4.4}
\end{equation*}
$$

Indeed, for $n=3$, this inequality is trivial, while, for $n=4$, it follows from the first condition (4.2). Let it hold for $n \leq m-1$. Then, according to (3.4), we have

$$
\begin{gathered}
a(m)=\beta a(m-1)+\alpha \gamma a(m-2)+\alpha^{m-1}(\alpha-\beta-\gamma)+\gamma^{m-1}(\gamma-\alpha-\beta) \leq \\
\beta(a(3))^{\frac{m-1}{3}}+\alpha \gamma(a(3))^{\frac{m-2}{3}}= \\
(a(3))^{\frac{m-2}{3}}\left(\beta(a(3))^{\frac{1}{3}}+\alpha \gamma\right) \leq(a(3))^{\frac{m-2}{3}}(a(3))^{\frac{2}{3}}=(a(3))^{\frac{m}{3}} .
\end{gathered}
$$

Note that, according Theorem 3, the equality in (4.4) holds in a direct sum of $(3 \times 3)$-matrices of $\widehat{\Lambda}_{3}(\alpha, \beta, \gamma)$ which corresponds to the partition $n=3+3+\ldots+3$. Let now $A \in \widehat{\Lambda}_{n}(\alpha, \beta, \gamma)$. By Theorem 3, there exists a partition of $n$ with the parts not less than $3, n=n_{1}+\ldots+n_{m}$, such that

$$
\operatorname{per} A=\prod_{i=3}^{m} a\left(n_{i}\right)
$$

and, in view of (4.4), we have

$$
\operatorname{per} A \leq \prod_{i=3}^{m} a(3)^{\frac{n_{i}}{3}}=(a(3))^{\frac{n}{3}}
$$

This proves (4.3).

Example 4. Consider case $\beta=\gamma-\alpha$.
Let us find the values of $\alpha$, depending on the magnitude of $\gamma$, for which the conditions of Theorem 4 are satisfied. According to (3.4), we have

$$
\begin{gather*}
a(3)=\alpha^{3}+(\gamma-\alpha)^{3}+\gamma^{3}+3 \alpha(\gamma-\alpha) \gamma=2 \gamma^{3}  \tag{4.5}\\
a(4)=\alpha^{4}+(\gamma-\alpha)^{4}+\gamma^{4}+4 \alpha(\gamma-\alpha)^{2} \gamma+2(\alpha \gamma)^{2}=2\left(\alpha^{4}+\gamma^{4}\right) . \tag{4.6}
\end{gather*}
$$

Thus the condition $a^{3}(4) \leq a^{4}(3)$ means that $\alpha^{4}+\gamma^{4} \leq 2^{\frac{1}{3}} \gamma^{4}$, or

$$
\begin{equation*}
0 \leq \alpha \leq\left(2^{\frac{1}{3}}-1\right)^{\frac{1}{4}} \gamma=0.7140199 \ldots \gamma \tag{4.7}
\end{equation*}
$$

and it is easy to verify that the second condition in (4.2) is satisfied as well. As a collorary, we obtain the following result.

Theorem 5. If (4.7) holds, then, for $n$ multiple of 3 , we have

$$
\begin{equation*}
M_{n}(\alpha, \gamma-\alpha, \gamma)=2^{\frac{n}{3}} \gamma^{n} \tag{4.8}
\end{equation*}
$$

Simple forms of sequence $\{a(n)\}$ in Examples $1+2$ allow to suppose that in case $\beta=\gamma-\alpha$ (or symmetrical case $\beta=\alpha-\gamma$ ) sequence $\{a(n)\}$ keeps a sufficiently simple form. We find this form in the following lemma.

Lemma 4. If $\beta=\gamma-\alpha$, then sequence $\{a(n)\}$ which is defined by recursion (3.4) has the form

$$
a(n)= \begin{cases}2 \gamma^{n}, & \text { if } n \text { is odd }  \tag{4.9}\\ 2\left(\alpha^{n}+\gamma^{n}\right), & \text { if } n \text { is even }\end{cases}
$$

Proof. Using induction with the base (4.5) -(4.6), suppose that (4.9) holds for $m \leq n$. Then, by (3.4), for even $n$, we have

$$
a(n+1)=(\gamma-\alpha) a(n)+\alpha \gamma a(n-1)+2 \alpha^{n}(\alpha-\gamma)=
$$

$$
2(\gamma-\alpha)\left(\alpha^{n}+\gamma^{n}\right)+2 \alpha \gamma^{n}+2 \alpha^{n}(\alpha-\gamma)=2 \gamma^{n+1}
$$

while, if $n$ is odd, then we have

$$
\begin{gathered}
a(n+1)=2(\gamma-\alpha) \gamma^{n}+ \\
2 \alpha \gamma\left(\alpha^{n-1}+\gamma^{n-1}\right)+2 \alpha^{n}(\alpha-\gamma)=2\left(\alpha^{n+1}+\gamma^{n+1}\right) .
\end{gathered}
$$

Let now

$$
\begin{equation*}
\alpha \geq\left(2^{\frac{1}{3}}-1\right)^{\frac{1}{4}} \gamma=0.7140199 \ldots \gamma \tag{4.10}
\end{equation*}
$$

Theorem 6. If (4.10) holds, then, for $n$ multiple of 4 , we have

$$
\begin{equation*}
M_{n}(\alpha, \gamma-\alpha, \gamma)=\left(2\left(\alpha^{4}+\gamma^{4}\right)\right)^{\frac{n}{4}} \tag{4.11}
\end{equation*}
$$

Proof. From (4.5), (4.6) and (4.10) we conclude that

$$
\begin{equation*}
a(3) \leq(a(4))^{\frac{3}{4}} \tag{4.12}
\end{equation*}
$$

Let us show that, for $n \geq 3$,

$$
\begin{equation*}
a(n) \leq(a(4))^{\frac{n}{4}} . \tag{4.13}
\end{equation*}
$$

For $n=4$, inequality (4.13) is trivial. For $n \geq 5$, we have

$$
\alpha^{n}+\gamma^{n}=\alpha^{n}\left(1+\left(\frac{\gamma}{\alpha}\right)^{n}\right) \leq \alpha^{n}\left(1+\left(\frac{\gamma}{\alpha}\right)^{4}\right)^{\frac{n}{4}} \leq\left(\alpha^{4}+\gamma^{4}\right)^{\frac{n}{4}}
$$

and thus, using Lemma 4, we have

$$
a(n) \leq 2\left(\alpha^{n}+\gamma^{n}\right)<2^{\frac{n}{4}}\left(\alpha^{4}+\gamma^{4}\right)^{\frac{n}{4}}=(a(4))^{\frac{n}{4}}, \quad n \geq 3
$$

Let now $A \in \widehat{\Lambda}_{n}(\alpha, \beta, \gamma)$. By Theorem 3, there exists a partition of $n$ with the parts not less than $3, n=n_{1}+\ldots+n_{m}$, such that

$$
\operatorname{per} A=\prod_{i=3}^{m} a\left(n_{i}\right)
$$

and, in view of (4.13), we have

$$
\operatorname{per} A \leq \prod_{i=3}^{m} a(4)^{\frac{n_{i}}{4}}=(a(3))^{\frac{n}{4}}
$$

with the equality in a direct sum of $(4 \times 4)$-matrices of $\widehat{\Lambda}_{3}(\alpha, \beta, \gamma)$ which corresponds to the partition $n=4+4+\ldots+4$.

Note that, if $\alpha \neq\left(2^{\frac{1}{3}}-1\right)^{\frac{1}{4}} \gamma$, then in Theorem 5 we have only maximizing matrix (up to a permutation of the rows and columns) which corresponds to the partition $n=3+3+\ldots+3$; in Theorem 6 we also have only maximizing matrix (up to a permutation of the rows and columns) which corresponds to the partition $n=4+4+\ldots+4$. It is interesting that, only in case of the equality
$\alpha=\theta \gamma$, where $\theta=\left(2^{\frac{1}{3}}-1\right)^{\frac{1}{4}}$, the both of Theorems 5-6 are true for every $n$ multiple of 12 with the equality of the maximums: $\left(2\left(\alpha^{4}+\gamma^{4}\right)\right)^{\frac{n}{4}}=2^{\frac{n}{3}} \gamma^{n}$. Thus, up to a positive factor $\gamma$, the class

$$
\begin{equation*}
\widehat{\Lambda}_{n}(\theta, 1-\theta, 1), \quad \theta=\left(2^{\frac{1}{3}}-1\right)^{\frac{1}{4}} \tag{4.14}
\end{equation*}
$$

possesses an interesting extremal property: it contains $\frac{n}{12}+1$ maximizing matrices (up to a permutation of the rows and columns), instead of only maximizing matrix, if $\theta \neq\left(2^{\frac{1}{3}}-1\right)^{\frac{1}{4}}$.

Indeed, the number of the maximizing matrices (up to a permutation rows and columns), is defined by the number of the following partitions of $n \equiv(\bmod 12):$

$$
\begin{gathered}
n=3+3+\ldots+3, \quad n=(4+4+4)+(3+\ldots+3), \ldots \\
n=\underbrace{4+\ldots+4}_{3 i}+\underbrace{3+\ldots+3}_{n-12 i}, \quad i=0,1, \ldots, \frac{n}{12} .
\end{gathered}
$$

## 5. Estimate of cardinality of p-SPECTRUM on CIRCULANTS in $\Lambda_{n}^{3}$

$$
\operatorname{AND} \Lambda_{n}(\alpha, \beta, \gamma)
$$

Denote $\Delta_{n}^{3} \subset \Lambda_{n}^{3}$ the set of the circulants in $\Lambda_{n}^{3}$. Note that a circulant $A \in \Delta_{n}^{3}$ has a form $A=P^{i}+P^{j}+P^{k}, 0 \leq i<j<k \leq n$, where $P=P_{n}$ is ( 0,1 )-matrix with 1 's on positions $(1,2),(2,3), \ldots,(n-1, n),(n, 1)$ only. Multiplicating $A$ by $P^{-i}$ we obtain circulant $B$ of the form

$$
B=I_{n}+P^{r}+P^{s}
$$

with $\operatorname{per} B=\operatorname{per} A$. Since $B$ is defined by a choice of two different values $0<r<k \leq n$, then trivially

$$
p s\left[\Delta_{n}^{3}\right] \leq\binom{ n}{2}<\frac{n^{2}}{2}
$$

Now we prove essentially more exact and practically unimprovable estimate.
Theorem 7. We have

$$
\begin{equation*}
p s\left[\Delta_{n}^{3}\right] \leq\left\lfloor\frac{n^{2}+3}{12}\right\rfloor . \tag{5.1}
\end{equation*}
$$

Proof. Let us back to the general form

$$
A=P^{i}+P^{j}+P^{k}, \quad 0 \leq i<j<k \leq n .
$$

Note that, $A$ is defined by a choice of a vector $(i, j, k)$, but its rotation, i.e., a passage to a vector of the form $(i+l, j+l, k+l)(\bmod n)$, does not change the magnitude of $\operatorname{per} A$. Indeed it corresponds to the multiplication $A$ by $P^{l}$, and our statement follows from the equality $\operatorname{per}\left(P^{l} A\right)=\operatorname{per} A$. Besides,
its reflection relatively some diameter of the imaginary circumference of the rotation, by the symmetry, keeps magnitude of the permanent. Since geometrically three points on the imaginary circumference define a triangle, then our problem reduces to a triangle case of the following general problem, posed by Professor Richard H. Reis (South-East University of Massachusetts, USA) in a private communication to Hansraj Gupta in 1978):
" Let a circumference is split by the same n parts. It is required to find the number $R(n, k)$ of the incongruent convex $k$-gons, which could be obtaind by connection of some $k$ from $n$ dividing points. Two $k$-gons are considered congruent if they are coincided at the rotation of one relatively other along the circumference and (or) by reflection of one of the $k$-gons relatively some diameter."

In 1979, Gupta [6] gave a solution of the Reis problem in the form (for a short solution, see author's paper [22]):

$$
\begin{equation*}
R(n, k)=\frac{1}{2}\left(\binom{\left\lfloor\left(\frac{n-h_{k}}{2}\right)\right\rfloor}{\left\lfloor\left(\frac{k}{2}\right)\right\rfloor}+\frac{1}{k} \sum_{d \mid \operatorname{gcd}(k, n)} \varphi(d)\binom{\frac{n}{d}-1}{\frac{k}{d}-1}\right) . \tag{5.2}
\end{equation*}
$$

If to denote $\Delta_{n}^{k} \subset \Lambda_{n}^{k}$ the set of the circulants in $\Lambda_{n}^{k}$, then from our arguments it follows that

$$
\begin{equation*}
p s\left[\Delta_{n}^{k}\right] \leq R(n, k) \tag{5.3}
\end{equation*}
$$

In case $k=3$, from (5.2)-(5.3) we find

$$
p s\left[\Delta_{n}^{3}\right] \leq\left\{\begin{array}{l}
\frac{n^{2}}{12}, \text { if } n \equiv 0 \quad(\bmod 6), \\
\frac{n^{2}-1}{12}, \text { if } n \equiv 1,5(\bmod 6), \\
\frac{n^{2}-4}{12}, \text { if } n \equiv 2,4(\bmod 6), \\
\frac{n^{2}+3}{12}, \\
\text { if } n \equiv 3(\bmod 6),
\end{array}\right.
$$

and (5.1) follows.

Example 5. In case $n=5$ we have only two incongruent triangles corresponding to circulants $I_{5}+P+P^{2}$ and $I_{5}+P+P^{3}$.

Nevertheless, the calculations give $\operatorname{per}\left(I_{5}+P+P^{2}\right)=\operatorname{per}\left(I_{5}+P+P^{3}\right)=$ 13. Thus $p s\left[\Delta_{5}^{3}\right]=\{13\}$, and $\left|p s\left[\Delta_{5}^{3}\right]\right|=1$.

Example 6. In case $n=6$ we have three incongruent triangles corresponding to circulants $I_{6}+P+P^{2}, I_{6}+P+P^{3}$ and $I_{6}+P^{2}+P^{4}$.

The calculations give $\operatorname{per}\left(I_{6}+P+P^{2}\right)=20, \operatorname{per}\left(I_{6}+P+P^{3}\right)=17$, while $\operatorname{per}\left(I_{6}+P^{2}+P^{4}\right)=36$. Thus $p s\left[\Delta_{6}^{3}\right]=\{17,20,36\}$, and $\left|p s\left[\Delta_{6}^{3}\right]\right|=3$.

Note that a respectively large magnitude of $\operatorname{per}\left(I_{6}+P^{2}+P^{4}\right)$ is explained
by its decomposability in a direct product of circulants $\left(I_{3}+P+P^{2}\right) \otimes$ $\left(I_{3}+P+P^{2}\right)$, such that $\operatorname{per}\left(I_{6}+P^{2}+P^{4}\right)=\left(\operatorname{per}\left(I_{3}+P+P^{2}\right)\right)^{2}=6^{2}=36$.

It is clear that, in case of circulants in $\Lambda_{n}(\alpha, \beta, \gamma)$, the upper estimate (5.1) yields either the same estimate, if $\alpha=\beta=\gamma$, or $\left\lfloor\frac{n^{2}+3}{4}\right\rfloor$, if $\alpha=\beta \neq \gamma$ (and in the symmetric cases), or $\left\lfloor\frac{n^{2}+3}{2}\right\rfloor$, if $\alpha, \beta, \gamma$ are distinct numbers.

Add that a bijection indicated in [22] allows to apply formula (5.2) to enumerating the two-color bracelets of $n$ beads, $k$ of which are black and $n-$ $k$ are white (see, e.g., the author's explicit formulas for sequences A032279A032282, A005513-A005516 in [23]).

## 6. Algorithm of calculations of upper magnitudes of The PERMANENT IN $\widehat{\Lambda}_{n}^{3}$

Theorem 1 allows, using some additional arguments, to give an algorithm of calculations of upper magnitudes of the permanent in $\widehat{\Lambda}_{n}^{3}$. In connection with this, we need an important lemma for numbers (2.12).

Lemma 5. For $n_{1}, n_{2} \geq 3$, we have

$$
\begin{equation*}
a\left(n_{1}+n_{2}\right) \leq a\left(n_{1}\right) a\left(n_{2}\right), n_{1}, n_{2} \geq 3 \tag{6.1}
\end{equation*}
$$

Proof. By usual way, from (2.12) we find

$$
\begin{equation*}
a(n)=\varphi^{n}+2+(-1)^{n} \varphi^{-n} \tag{6.2}
\end{equation*}
$$

where $\varphi=\frac{\sqrt{5}+1}{2}$ is the golden ratio.
Denote $\varepsilon(n)=(-1)^{n} \varphi^{-n}$. Since $n \geq 3$, then $|\varepsilon(n)|<0.24$, and, consequently, if $n=n_{1}+n_{2}$, then $\left(2+\varepsilon\left(n_{1}\right)\right)\left(2+\varepsilon\left(n_{2}\right)>1.76^{2}>3\right.$. Therefore, we have

$$
\begin{align*}
& a\left(n_{1}\right) a\left(n_{2}\right)=\left(\varphi^{n_{1}}+2+\varepsilon\left(n_{1}\right)\right)\left(\varphi^{n_{2}}+2+\varepsilon\left(n_{2}\right)\right)> \\
& \varphi^{n_{1}+n_{2}}+3>\varphi^{n_{1}+n_{2}}+2+\varepsilon\left(n_{1}+n_{2}\right)=a\left(n_{1}+n_{2}\right) \tag{6.3}
\end{align*}
$$

Note that, actually, the difference between the hand sides of (6.3) more than $1.76\left(\varphi^{n_{1}}+\varphi^{n_{2}}\right)$.

Let now $n \equiv j(\bmod 3), j=0,1,2$, and $t \in \mathbf{N}$. Let $R(m ; \nu)$ denote the set of all partitions of $n$ with parts more than or equal to $\nu$. For us an important role play cases $\nu=3,4$. To $r \in R(m ; 3), \rho \in R(m ; 4)$ put in a correspondence the sets

$$
\begin{equation*}
H_{m ; 3}(r)=\left\{\Pi_{r_{i} \in r} a_{r_{i}}\right\} ; H_{m ; 4}(\rho)=\left\{\Pi_{\rho_{i} \in \rho} a_{\rho_{i}}\right\} . \tag{6.4}
\end{equation*}
$$

In case $m=3$, when $\rho=\varnothing$, let us agree that $H_{3 ; 4}$ is a singleton $\{6\}$.
Consider now the set $L_{t}^{(j)}=L_{t}^{(j)}(n)$ :

$$
\begin{equation*}
L_{t}^{(j)}=\bigcup_{i=1}^{4 t+j}\left\{6^{\frac{n-j-3 i}{3}} y: y \in H_{3 i+j ; 4}(\rho), y \geq 9^{3 t+j} 6^{i-4 t-j}\right\} \tag{6.5}
\end{equation*}
$$

Theorem 8. (algorithm of calculation of upper magnitudes of the permanent in $\left.\widehat{\Lambda}_{n}^{3}\right)$. If $n \geq 4(3 t+j)$, then the ordered over decrease set $L_{t}^{(j)}$ gives the $\left|L_{t}^{(j)}\right|$ upper magnitudes of the permanent in $\widehat{\Lambda}_{n}^{3}$.

Proof. Note that the proof is the same for every value of $j$. Therefore, let us consider, say, $j=0$. From (6.1) it follows that, if $r \in R(n ; 3)$ contains $\lambda_{3}$ parts 3 and $\lambda_{3} \leq \frac{n}{3}-4 t$, then, for $y \in H_{n-3 \lambda_{3} ; 4}(\rho)$, we have

$$
6^{\lambda_{3}} y \leq 6^{\frac{n}{3}-4 t} 9^{3 t}
$$

This means that for the formation the list of all upper magnitudes of the permanent in $\widehat{\Lambda}_{n}^{3}$ in the condition $n \geq 12 t$, which are bounded from below by $6^{\frac{n}{3}-4 t} 9^{3 t}$, it is sufficient to consider only a part of the spectrum containing numbers $\left\{6^{\lambda_{3}} y\right\}$, where $y \in H_{n-3 \lambda_{3} ; 4}(\rho)$ with the opposite condition $\lambda_{3} \geq$ $\frac{n}{3}-4 t$. From the equality $3 \lambda_{3}+\ldots+n \lambda_{n}=n$ with the condition $\lambda_{3} \geq \frac{n}{3}-4 t$, we have

$$
4 \lambda_{4}+\ldots+n \lambda_{n} \leq n-3\left(\frac{n}{3}-4 t\right)=12 t
$$

Since $12 t$ does not depend on $n$, there is only a finite assembly of such partition for arbitrary $n$. This ensures a possibility of the realization of the algorithm.

For the considered $r \in R(n ; 3)$, for $\lambda_{3} \geq \frac{n}{3}-4 t$, we have $H_{n ; 3}(r)=6^{\frac{n-m}{3}}$, where $y \in H_{m ; 4}(\rho)$, and $m$ has the form $m=3 i, 1 \leq i \leq 4 t$. Thus we should choose only $H_{n ; 3}(r) \geq 6^{\frac{n}{3}-4 t} 9^{3 t}$, and this yields

$$
y \geq 9^{3 t} 6^{\frac{n}{3}-4 t}=9^{3 t} 6^{i-4 t}, \quad i=1,2, \ldots, 4 t
$$

In order to use Theorem 8 for calculation the upper magnitudes $M^{(1)}(n)>$ $\left.M^{(2}\right)(n)>\ldots$ of the permanent in $\widehat{\Lambda}_{n}^{3}$, in case, say, $n \equiv 0(\bmod 3)$,

1) we write a list of partition of numbers $3 i, i=2,3, \ldots, 4 t$ with the parts not less than 4.
2) The corresponding values of $y$ we compare with $9^{3 t} 6^{i-4 t}$ and keep only $y \geq 9^{3 t} 6^{i-4 t}$.
3) After that we regulate over decrease numbers $\left\{y 6^{\frac{n}{3}-i}\right\}$.

Below we give the first 10 upper magnitudes $\widehat{M^{(1)}}>\widehat{M}^{(2)}>\ldots>\widehat{M}^{(10)}$, of the permanent in $\widehat{\Lambda}_{n}^{3}$ for $n \geq 24$, via numbers $\{a(n)\}$ (2.12).

$$
\widehat{M}^{(1)}=\left\{\begin{array}{l}
a(3)^{\frac{n}{3}}=6^{\frac{n}{3}}, \text { if } n \equiv 0 \quad(\bmod 3)  \tag{6.6}\\
a(4) a(3)^{\frac{n-4}{3}}=\frac{3}{2} 6^{\frac{n-1}{3}}, \text { if } n \equiv 1 \quad(\bmod 3) \\
a(4)^{2} a(3)^{\frac{n-8}{3}}=\frac{9}{4} 6^{\frac{n-2}{3}}, \quad \text { if } n \equiv 2 \quad(\bmod 3)
\end{array}\right.
$$

Formula (6.6) shows that $M^{(1)}(n)$ is attained in $\widehat{\Lambda}_{n}^{3}$.

$$
\widehat{M}^{(4)}=\left\{\begin{array}{l}
a(4) a(5) a(3)^{\frac{n-9}{3}}=\frac{13}{24} 6^{\frac{n}{3}}, \text { if } n \equiv 0 \quad(\bmod 3),  \tag{6.9}\\
a(4) a(6) a(3)^{\frac{n-10}{3}}=\frac{5}{6} 6^{\frac{n-1}{3}}, \text { if } n \equiv 1 \quad(\bmod 3), \\
a(4) a(7) a(3)^{\frac{n-11}{3}}=\frac{31}{24} 6^{\frac{n-2}{3}}, \text { if } n \equiv 2 \quad(\bmod 3)
\end{array}\right.
$$

$$
\widehat{M}^{(5)}=\left\{\begin{array}{l}
a(9) a(3)^{\frac{n-9}{3}}=\frac{13}{36} 6^{\frac{n}{3}}, \text { if } n \equiv 0 \quad(\bmod 3),  \tag{6.10}\\
a(4)^{2} a(5) a(3)^{\frac{n-13}{3}}=\frac{13}{13} 6^{\frac{n-1}{3}}, \text { if } n \equiv 1 \quad(\bmod 3), \\
a(4)^{5} a(3)^{\frac{n-20}{3}}=\frac{81}{64} 6^{\frac{n-2}{3}}, \text { if } n \equiv 2 \quad(\bmod 3)
\end{array}\right.
$$

$$
\begin{gather*}
\widehat{M}^{(2)}= \begin{cases}a(4)^{3} a(3)^{\frac{n-12}{3}}=\frac{9}{16} 6^{\frac{n}{3}}, & \text { if } n \equiv 0 \quad(\bmod 3), \\
a(7) a(3)^{\frac{n-7}{3}}=\frac{31}{36} \frac{n-1}{3}, & \text { if } n \equiv 1 \quad(\bmod 3), \\
a(5) a(3)^{\frac{n-5}{3}}=\frac{13}{6} 6^{\frac{n-2}{3}}, & \text { if } n \equiv 2 \quad(\bmod 3) ;\end{cases}  \tag{6.7}\\
\widehat{M}^{(3)}=\left\{\begin{array}{l}
a(6) a(3)^{\frac{n-6}{3}}=\frac{5}{9} 6^{\frac{n}{3}}, \text { if } n \equiv 0 \quad(\bmod 3), \\
a(4)^{4} a(3)^{\frac{n-16}{3}}=\frac{27}{32} 6^{\frac{n-1}{3}}, \text { if } n \equiv 1 \quad(\bmod 3), \\
a(8) a(3)^{\frac{n-8}{3}}=\frac{49}{36} 6^{\frac{n-2}{3}}, \quad \text { if } n \equiv 2 \quad(\bmod 3) ;
\end{array}\right. \tag{6.8}
\end{gather*}
$$

$$
\widehat{M}^{(6)}=\left\{\begin{array}{l}
a(4) a(8) a(3)^{\frac{n-12}{3}}=\frac{49}{144} 6^{\frac{n}{3}}, \text { if } n \equiv 0 \quad(\bmod 3),  \tag{6.11}\\
\left.a(5)^{2}\right) a(3)^{\frac{n-10}{3}}=\frac{169}{216} 6^{\frac{n-1}{3}}, \text { if } n \equiv 1 \quad(\bmod 3) \\
a(4)^{2} a(6) a(3)^{\frac{n-14}{3}}=\frac{5}{4} 6^{\frac{n-2}{3}}, \text { if } n \equiv 2 \quad(\bmod 3)
\end{array}\right.
$$

$$
\widehat{M}^{(7)}=\left\{\begin{array}{l}
a(4)^{2} a(7) a(3)^{\frac{n-15}{3}}=\frac{31}{96} 6^{\frac{n}{3}}, \text { if } n \equiv 0 \quad(\bmod 3),  \tag{6.12}\\
a(10) a(3)^{\frac{n-10}{3}}=\frac{125}{216} 6^{\frac{n-1}{3}}, \text { if } n \equiv 1 \quad(\bmod 3) \\
a(4)^{3} a(5) a(3)^{\frac{n-17}{3}}=\frac{39}{32} 6^{\frac{n-2}{3}}, \text { if } n \equiv 2 \quad(\bmod 3)
\end{array}\right.
$$

$$
\widehat{M}^{(8)}=\left\{\begin{array}{l}
a(4)^{6} a(3)^{\frac{n-24}{3}}=\frac{81}{256} 6^{\frac{n}{3}}, \text { if } n \equiv 0 \quad(\bmod 3),  \tag{6.13}\\
a(4) a(9) a(3)^{\frac{n-13}{3}}=\frac{13}{24} 6^{\frac{n-1}{3}}, \text { if } n \equiv 1 \quad(\bmod 3), \\
a(5) a(6) a(3)^{\frac{n-11}{3}}=\frac{65}{54} 6^{\frac{n-2}{3}}, \text { if } n \equiv 2 \quad(\bmod 3)
\end{array}\right.
$$

$$
\widehat{M}^{(9)}=\left\{\begin{array}{l}
a(4)^{3} a(6) a(3)^{\frac{n-18}{3}}=\frac{5}{16} 6^{\frac{n}{3}}, \text { if } n \equiv 0 \quad(\bmod 3),  \tag{6.14}\\
a(5) a(8) a(3)^{\frac{n-13}{3}}=\frac{637}{1296} 6^{\frac{n-1}{3}}, \text { if } n \equiv 1 \quad(\bmod 3), \\
a(5)^{2} a(4) a(3)^{\frac{n-14}{3}}=\frac{169}{144} 6^{\frac{n-2}{3}}, \text { if } n \equiv 2 \quad(\bmod 3)
\end{array}\right.
$$

$$
\widehat{M}^{(10)}=\left\{\begin{array}{l}
a(5) a(7) a(3)^{\frac{n-12}{3}}=\frac{403}{1296} 6^{\frac{n}{3}}, \text { if } n \equiv 0 \quad(\bmod 3),  \tag{6.15}\\
a(4)^{3} a(7) a(3)^{\frac{n-19}{3}}=\frac{31}{64} 1^{\frac{n-1}{3}}, \text { if } n \equiv 1 \quad(\bmod 3), \\
a(11) a(3)^{\frac{n-11}{3}}=\frac{67}{72} 6^{\frac{n-2}{3}}, \text { if } n \equiv 2 \quad(\bmod 3)
\end{array}\right.
$$

## 7. Main conjectural inequality for maximum of Permanent in

 COMPLETELY INDECOMPOSABLE $\Lambda_{n}^{3}$-MATRICESDenote $\Lambda_{n, 1}^{3}$ the set of completely indecomposable matrices in $\Lambda_{n}^{3}$, i. e., the set of $\Lambda_{n}^{3}$-matrices containing no $\Lambda_{m}^{3}$-submatrices. Let $\mu_{1}(n)$ denote the
maximum of permanent in $\Lambda_{n, 1}^{3}$. Our very plausible conjecture which we call "main conjectural inequality (MCI)" is the following.

Conjecture 1. (Cf. [21], pp. 165-166) For $n_{1}, n_{2} \geq 3$, we have

$$
\begin{equation*}
\mu_{1}\left(n_{1}+n_{2}\right) \leq \mu_{1}\left(n_{1}\right) \mu_{1}\left(n_{2}\right) . \tag{7.1}
\end{equation*}
$$

In Lemma 5 we essentially proved that in subclass $\widehat{\Lambda}_{n}^{3}$ the MCI is valid.
Besides, in all known cases MCI holds. Moreover, as we shall see, our algorithm of calculation the consecutive upper magnitudes $\left(M=M_{1}>M_{2}>\right.$ ...) of permanent in $\Lambda_{n}^{3}$, which is based on MCI, reproduces all Merriell's and Bolshakov's results for $M_{1}$ and $M_{2}$. Note also that, for sufficiently large $n$, the number of consecutive upper magnitudes of permanent in $\Lambda_{n}^{3}$ grows very quickly with every step of extension of the list of known $p$-specrums for small $n$. E.g., using the found by Bolshakov $p s\left[\Lambda_{i}^{3}\right], i \leq 8$, we obtain, for sufficiently large $n, 4,7$ and 11 upper values of $p s\left[\Lambda_{n}^{3}\right]$ in cases $n=3 k, 2 k+1$ and $3 k+2$ correspondingly. After calculation $p s\left[\Lambda_{9}^{3}\right]$, the number of upper values of, e.g., $p s\left[\Lambda_{3 k}^{3}\right]$ increases more than thrice.

## 8. Algorithm of calculations of upper magnitudes of the PERMANENT IN $\Lambda_{n}^{3}$ BASED ON MCI

Let $n \equiv j(\bmod 3), j=0,1,2$, and $t \in \mathbf{N}$. Let $R(m ; \nu)$ denote the set of all partitions of $n$ with parts more than or equal to $\nu$. For us an important role play cases $\nu=3,4$. To $r \in R(m ; 3), \rho \in R(m ; 4)$ put in a correspondence sets

$$
\begin{equation*}
\pi_{m ; 3}(r)=\left\{\Pi_{r_{i} \in r} x_{r_{i}}\right\} ; \pi_{m ; 4}(\rho)=\left\{\Pi_{\rho_{i} \in \rho} x_{\rho_{i}}\right\} \tag{8.1}
\end{equation*}
$$

where $x_{s}$ runs through all values of permanent in set $\Lambda_{s, 1}^{3}$ of completely indecomposable matrices in $\Lambda_{s}^{3}$ ( in case $m=3$, when $\rho=\varnothing$, let us agree that $\pi_{3 ; 4}$ is a singleton $\{6\}$ ).

Consider now the set $E_{t}^{(j)}=E_{t}^{(j)}(n)$ :

$$
\begin{equation*}
E_{t}^{(j)}=\bigcup_{i=1}^{4 t+j}\left\{6^{\frac{n-j-3 i}{3}} y: y \in \pi_{3 i+j ; 4}(\rho), y \geq 9^{3 t+j} 6^{i-4 t-j}\right\} \tag{8.2}
\end{equation*}
$$

Theorem 9. (algorithm of calculation of upper magnitudes of the permanent in $\left.\Lambda_{n}^{3}\right)$. If $n \geq 4(3 t+j)$, then the ordered over decrease set $E_{t}^{(j)}$ gives the $\left|E_{t}^{(j)}\right|$ upper magnitudes of the permanent in $\Lambda_{n}^{3}$.

Proof. We need three lemmas.
Lemma 6. For $n \geq 4$, we have

$$
\begin{equation*}
\mu_{1}(n) \leq 3^{\frac{n}{2}} \tag{8.3}
\end{equation*}
$$

Proof. Let, firstly, $n \equiv 0(\bmod 4)$. Note that $\mu_{1}(4)=D_{4}=9$. Using (7.1), we find

$$
\mu_{1}(n) \leq \mu_{1}(4) \mu_{1}(n-4) \leq \ldots \leq\left(\mu_{1}(4)\right)^{\frac{n}{4}}=3^{\frac{n}{2}} .
$$

Let, furthermore, $n \equiv i(\bmod 4), \quad i=1,2,3$. Note that, by $(2.17), \mu_{1}(5) \leq$ $13<3^{2.5}$. Therefore, using (7.1), we have

$$
\mu_{1}(n) \leq\left(\mu_{1}(4)\right)^{\frac{n-5 i}{4}}\left(\mu_{1}(5)\right)^{i}<3^{\frac{n-5 i}{2}} 3^{2.5 i}=3^{\frac{n}{2}} .
$$

Lemma 7. Let $n=3 \lambda_{3}+4 \lambda_{4}+\ldots+n \lambda_{n}$ be a partition of $n$ with the parts not less than 3. If $\lambda_{3} \leq l$, and $n$ has the form $n=3 l+4 m$, then, for completely indecomposable matrices $A_{i} \in \Lambda_{i}^{3}, i=3,4, \ldots, n$, we have

$$
\begin{equation*}
\prod_{i=3}^{n}\left(\operatorname{per} A_{i}\right)^{\lambda_{i}} \leq 6^{l} 9^{m} \tag{8.4}
\end{equation*}
$$

Proof. Using Lemma 6, we have

$$
\prod_{i=3}^{n}\left(\operatorname{per} A_{i}\right)^{\lambda_{i}} \leq 6^{\lambda_{3}} \sqrt{3}^{4 \lambda_{4}+\ldots+n \lambda_{n}} \leq 6^{l} \sqrt{3}^{n-\lambda_{3}}=6 \sqrt{3}^{4 m}=6^{l} 9^{m}
$$

Lemma 8. Let $n=3 \lambda_{3}+4 \lambda_{4}+\ldots+n \lambda_{n}$ and

$$
\lambda_{3} \leq \frac{n-4 j}{3}-4 t, \quad n \geq 4(3 t+j)
$$

where $t$ is a nonnegative integer and $j$ is the residue of $n$ modulo $3, j=$ $0,1,2$, then, for completely indecomposable matrices $A_{i} \in \Lambda_{i}^{3}, i=3,4, \ldots, n$, we have

$$
\begin{equation*}
\prod_{i=3}^{n}\left(\operatorname{per} A_{i}\right)^{\lambda_{i}} \leq 6^{\frac{n-4 j}{3}-4 t} 9^{3 t+j} \tag{8.5}
\end{equation*}
$$

Proof. Put $l=\frac{n-4 j}{3}-4 t, m=\frac{n-3 l}{4}=3 t+j$. Now the lemma follows from Lemma 7.

It is left to note that, after these lemmas, the proof of Theorem 9 is the same as proof of Theorem 8,

Note that the using of this algorithm is based on the small elements of p-spectrum.

Consider, e.g., case $t=0, j=2$. According to (8.2), we have

$$
E_{0}^{(2)}=\bigcup_{i=1}^{2}\left\{6^{\frac{n-2-3 i}{3}} y: y \in \pi_{3 i+j ; 4}(\rho), y \geq 81 \cdot 6^{i-2}\right\}=
$$

$$
\begin{equation*}
\left\{6^{\frac{n-5}{3}} \operatorname{per} A, A \in \Lambda_{5}^{3}: 6 \operatorname{per} A \geq 81\right\} \cup\left\{81 \cdot 6^{\frac{n-8}{3}}\right\} \tag{8.6}
\end{equation*}
$$

Note that, the second set is a simpleton, since, by MCI, $\mu_{1}(8,3) \leq\left(\mu_{1}(4,3)\right)^{2}=$ 81. Since, by (2.17), $M(5)=13<\frac{81}{6}$, then the first set in (8.6) is empty. Thus $E_{0}^{(2)}=E_{0}^{(2)}(n)$ is simpleton:

$$
E_{0}^{(2)}=\left\{81 \cdot 6^{\frac{n-8}{3}}\right\}
$$

and we have

$$
M^{(1)}(n)=81 \cdot 6^{\frac{n-8}{3}}, \quad n \geq 8
$$

which corresponds to Merriell's result in case $n \equiv 2(\bmod 3)$.
Further research of the set (8.2), using (2.17), gives the following results:

1) $j=0, \quad n \geq 24$.

$$
\begin{gather*}
M^{(1)}(n)=6^{\frac{n}{3}}, \quad M^{(2)}(n)=\frac{9}{16} 6^{\frac{n}{3}}, \\
M^{(3)}(n)=\frac{5}{9} 6^{\frac{n}{3}}, \quad M^{(4)}(n)=\frac{13}{24} 6^{\frac{n}{3}} . \tag{8.7}
\end{gather*}
$$

The continuation of this list requires the knowing of $\operatorname{ps}\left[\Lambda_{9}^{3}\right]$. Note that a more detailed analysis shows that after calculation $p s\left[\Lambda_{9}^{3}\right]$ in this case one can obtain the first $12+|G|$ upper magnitudes of the permanent in $\Lambda_{n}^{3}$, where $G=p s\left[\Lambda_{9}^{3}\right] \cap([69,116] \backslash\{72,78,102,108\})$.
2) $j=1, \quad n \geq 28$.

$$
\begin{gather*}
M^{(1)}(n)=\frac{3}{2} 6^{\frac{n-1}{3}}, M^{(2)}(n)=\frac{8}{9} 6^{\frac{n-1}{3}}, \\
M^{(3)}(n)=\frac{31}{36} 6^{\frac{n-1}{3}}, M^{(4)}(n)=\frac{27}{32} 6^{\frac{n-1}{3}}, \\
M^{(5)}(n)=\frac{5}{6} 6^{\frac{n-1}{3}}, \quad M^{(6)}(n)=\frac{13}{15} 6^{\frac{n-1}{3}}, \quad M^{(7)}(n)=\frac{169}{216} 6^{\frac{n-1}{3}} . \tag{8.8}
\end{gather*}
$$

It is interesting that in this case $p s\left[\Lambda_{9}^{3}\right]$ is not used up to $M^{(7)}$, but the continuation of this list requires the knowing of $p s\left[\Lambda_{10}^{3}\right]$.
3) $j=2, \quad n \geq 32$.

$$
\begin{aligned}
& M^{(1)}(n)=\frac{9}{4} 6^{\frac{n-2}{3}}, \quad M^{(2)}(n)=\frac{13}{6} 6^{\frac{n-2}{3}} \\
& M^{(3)}(n)=2 \cdot 6^{\frac{n-2}{3}}, \quad M^{(4)}(n)=\frac{13}{9} 6^{\frac{n-2}{3}} \\
& M^{(5)}(n)=\frac{49}{36} 6^{\frac{n-2}{3}}, \quad M^{(6)}(n)=\frac{4}{3} 6^{\frac{n-2}{3}} \\
& M^{(7)}(n)=\frac{31}{24} 6^{\frac{n-2}{3}}, \quad M^{(8)}(n)=\frac{81}{64} 6^{\frac{n-2}{3}}
\end{aligned}
$$

$$
\begin{equation*}
M^{(9)}(n)=\frac{5}{4} 6^{\frac{n-2}{3}}, \quad M^{(10)}(n)=\frac{11}{9} 6^{\frac{n-2}{3}}, \quad M^{(11)}(n)=\frac{39}{32} 6^{\frac{n-1}{3}} . \tag{8.9}
\end{equation*}
$$

Note that the method not only gives a possibility to calculate the upper magnitudes of the permanent in $\Lambda_{n}^{3}$, but also indicates those direct products on which they are attained. E.g., in (8.9) $M_{9}$ is attained on direct products of some matrices $A_{i} \in \Lambda_{i}^{3}$ :

Note also that the comparison of (8.7)-(8.9) with (6.6)-(6.15) shows that the following calculated $M^{(i)}$ are attained in $\widehat{\Lambda}_{n}^{3}, \quad n \geq 32$ :
in case $n \equiv 0 \bmod 3$,

$$
M^{(1)}, M^{(2)}, M^{(3)}, M^{(4)}
$$

in case $n \equiv 1 \bmod 3$,

$$
M^{(1)}, M^{(3)}, M^{(4)}, M^{(5)}, M^{(6)}, M^{(7)}
$$

(and is not attained $M^{(2)}$ );
in case $n \equiv 2 \bmod 3$,

$$
M^{(1)}, M^{(2)}, M^{(5)}, M^{(7)}, M^{(8)}, M^{(9)}, M^{(11)}
$$

(and are not attained $M^{(3)}, M^{(4)}, M^{(6)}, M^{(10)}$ ).

## 9. Algorithm of a testing the parity of values of the PERMANENT IN $\Lambda_{n}^{3}$

It seems that, among all known methods of calculation of the permanent, only Ryser's method (cf. [11], Ch.7) could be used for a creating an algorithm of a testing the parity of values of the permanent. Let $A$ be $n \times n$-matrix. Let $A_{r}$ be a matrix which is obtained by changing some $r$ columns of $A$ by zero columns. Denote $S\left(A_{r}\right)$ the product of row sums of $A_{r}$. Then, by Ryser's formula, we have

$$
\begin{gather*}
\operatorname{per} A=\sum S\left(A_{0}\right)-\sum S\left(A_{1}\right)+ \\
\sum S\left(A_{2}\right)-\ldots+(-1)^{n-1} \sum S\left(A_{n-1}\right) \tag{9.1}
\end{gather*}
$$

Let now $A$ have integer elements. Introduce the following matrix function

$$
\Upsilon(A)= \begin{cases}1, & \text { if all row sums of } A \text { are odd }  \tag{9.2}\\ 0, & \text { otherwise }\end{cases}
$$

From (9.1) we have

$$
\operatorname{per} A \equiv \sum \Upsilon\left(A_{0}\right)-\sum \Upsilon\left(A_{1}\right)+
$$

$$
\begin{equation*}
\sum \Upsilon\left(A_{2}\right)+\ldots+\sum \Upsilon\left(A_{n-1}\right) \quad(\bmod 2) \tag{9.3}
\end{equation*}
$$

Using (9.3), let us create an algorithm of a search of the odd values of the permanent in $\Lambda_{n}^{3}$. Since, evidently, $\operatorname{per} A \equiv \operatorname{det} A(\bmod 2)$, then $A$ should have pairwise distinct columns. Note that cases $n \equiv j(\bmod 3), \quad j=0,1,2$, are considered by the same way. Suppose, say, $n=3 t$. According to (9.3), we are interested in only cases when after removing $r \geq 1$ columns of $A$, all row sums will be odd. Suppose that after removing $r$ columns of $A$, we have that $p$ sums remain to equal to 3 and $n-p$ sums equal to 1 . This means that the total number of the removed 1's equals to $2(n-p)=6 t-2 p$. Since, removing a column, we remove three 1's, then the number of the removed columns equals to $r=2 t-\frac{2 p}{3}$. Thus $p=3 m$ and $r=2(t-m), m=0,1, \ldots, t-1$. However, if $m=t-1$, then $r=2$. By the condition, these two columns are distinct, therefore, we conclude that at least one row sum equals to 2 . The contradiction shows that the testing sequence is $r=4,6, \ldots, 2 t$. In cases $n \equiv 1,2(\bmod 3)$ we obtain the same testing sequence.

Example 7. Let us check the parities of values of the permanent of circulants in $\Delta_{7}^{3} \subset \Lambda_{7}^{3}$.

In this case $t=\left\lfloor\frac{7}{3}\right\rfloor=2$ and, therefore, the testing sequence contains only term $r=4$. Note that matrix $A_{r}$ has all odd rows if and only if one row sum equals to 3 and each of 6 other row sums equals to 1 . Indeed, let after the removing 4 columns of $A$, remain $p$ sums equal to 3 and $7-p$ sums equal to 1 . This means that the total number of the removed 1 's equals to $2(7-p)$ and the number of the removed columns equals to $r=4=\frac{14-2 p}{3}$, i.e., $p=1$. Moreover, since in a circulant all rows are congruent shifts of the first one, it is sufficient to consider the case when precisely the first row sum equals to 3 and others equal to 1 (the multiplication on 7 does not change the parity of the result). This opens a possibility of a momentary handy test on the parity every circulant of class $\Delta_{7}^{3}$. This test consists of the removing all four columns beginning with 0 . If now every rows $2, \ldots, 7$ has one 1 , then the permanent is even; otherwise, it is odd. We check now directly that from $\binom{7}{3}=35$ circulants exactly 21 ones have odd permanent.

Remark 1. In 1967, Ryser [14] did a conjecture that the number of the transversals of a latin square from elements $1, \ldots, n$ (i.e., the number of subsets of its $n$ pairwise distinct elements, none in the same row or column) has the same parity as $n$. If $n$ is even, then the conjecture has been proved
by Balasubramanian [1]. Besides, in [1] Balasubramanian did a conjecture for the parity of a sum of permanents, such that the truth of this conjecture yields Ryser's hypothesis for odd $n$. In the same year (1990), using the result of Example 7, the author disproved Balasubramanian's conjecture (private communication to Brualdi). It is interesting that soon Parker (see [5], p.258) indeed found several latin squares of order 7 with even number of transversals. Add that later ([18]) we found even an infinite set of counterexamples to the Balasubramanian conjecture.

## 10. Open problems

1. To prove the MCI (Section 7).
2. (Cf.[17], pp.171-172). Consider class $\Lambda_{n}(1,1+a, 1+b)$, where $0 \leq a \leq$ $b<\frac{4 e-9}{6}$. Since $\Lambda_{n}(1,1,1)=\Lambda_{n}^{3}$, then Voorhoeve's lower estimate for the permanent (2.16) trivially holds for matrices in $\Lambda_{n}(1,1+a, 1+b)$. It is clear that, for $a>0, b>0$, it should exist an essentially stronger lower estimate. However, using Van der Waerden-Egorychev-Falikman theorem to class $\Lambda_{n}\left(\frac{1}{3+a+b}, \frac{1+a}{3+a+b}, \frac{1+b}{3+a+b}\right)$ of doubly stochastic matrices, for the permanent of $\Lambda_{n}(1,1+a, 1+b)$-matrices we obtain even weaker lower estimate of the order $C_{1} \sqrt{n}\left(\frac{3+a+b}{e}\right)^{n} \ll C\left(\frac{4}{3}\right)^{n}$. The problem is to find a stronger lower estimate for the permanent in $\Lambda_{n}(1,1+a, 1+b)$.
3. (Cf.[17], pp.115-116). Let $M$ be a circulant of order n with integer elements. We conjecture that, for every integer $m$, we have per $M \equiv$ $(-1)^{n} \operatorname{per}\left(m J_{n}-M\right)(\bmod n)$, where $n \times n$-matrix $J_{n}$ consists of 1 's only. A special case of this conjecture, for $m=1, M=I_{n}+P+\ldots+P^{k-1}$ in the equivalent terms was formulated by Yamamoto [27] and proved for $k \leq 3$. The author [15] proved the truth of the conjecture in case $m=1$ for arbitrary circulant $M$ ( including Yamamoto's conjecture for every $k$ ). In [17] the conjecture was proved for every $m$ and prime $n$. The question is open in case of composite $n$ even in case $k=3$.
4. Two Latin rectangles let us call equivalent, if the sets of their elements in the corresponding columns are the same. Note that numbers $\left|\Lambda_{n}^{3}\right|$ one can treat as the numbers of equivalence classes of Latin triangles. Let $A=I_{n}+P+P^{2}$. In [20] the author proved that the cardinality of the corresponding equivalent class is $2^{n}+6+2(-1)^{n}$. To find the cardinality of the equivalent class which is defined by matrix $I_{n}+P+P^{3}$.
