ASYMPTOTIC CONDITIONAL DISTRIBUTION OF EXCEEDANCE COUNTS: FRAGILITY INDEX WITH DIFFERENT MARGINS

MICHAEL FALK AND DIANA TICHY

ABSTRACT. Let $\mathbf{X} = (X_1, \ldots, X_d)$ be a random vector, whose components are not necessarily independent nor are they required to have identical distribution functions F_1, \ldots, F_d . Denote by N_s the number of exceedances among X_1, \ldots, X_d above a high threshold s. The fragility index, defined by $FI = \lim_{s \nearrow} E(N_s | N_s > 0)$ if this limit exists, measures the asymptotic stability of the stochastic system X as the threshold increases. The system is called stable if $FI = 1$ and fragile otherwise. In this paper we show that the asymptotic conditional distribution of exceedance counts (ACDEC) $p_k = \lim_{s \to \infty} P(N_s = k \mid N_s > 0), 1 \leq k \leq d$, exists, if the copula of X is in the domain of attraction of a multivariate extreme value distribution, and if $\lim_{s \to (1 - F_i(s))/(1 - F_\kappa(s)) = \gamma_i \in [0, \infty)$ exists for $1 \leq i \leq d$ and some $\kappa \in \{1, \ldots, d\}$. This enables the computation of the FI corresponding to X and of the extended FI as well as of the asymptotic distribution of the exceedance cluster length also in that case, where the components of X are not identically distributed.

1. INTRODUCTION

Let $\mathbf{X} = (X_1, \ldots, X_d)$ be a random vector (rv), whose components are identically distributed but not necessarily independent. The number of exceedances among X_1, \ldots, X_d above the threshold s is denoted by $N_s := \sum_{i=1}^d 1_{(s,\infty)}(X_i)$. The fragility index (FI) corresponding to X is the asymptotic conditional expected number of exceedances, given that there is at least one exceedance, i.e., $FI = \lim_{s \nearrow} E(N_s \mid N_s > 0)$. The FI was introduced in [Geluk et al. \(2007\)](#page-10-0) to measure the stability of the stochastic system $\{X_1, \ldots, X_d\}$. The system is called *stable* if $FI = 1$, otherwise it is called *fragile*.

In the 2-dimensional case, the FI is directly linked to the upper tail dependence coefficient $\lambda^{up} := \lim_{t \downarrow 0} P(X_2 > F_2^{-1}(1-t) | X_1 > F_1^{-1}(1-t)),$ which goes back to [Geffroy \(1958,](#page-10-1) [1959\)](#page-10-2) and [Sibuya \(1960](#page-11-0)). We have $FI = 2/(2 - \lambda^{up})$, provided the df F_1 , F_2 of X_1 , X_2 are continuous and λ^{up} exists. In contrast to the upper tail dependence coefficient, the FI presents a measure for tail dependence in an arbitrary dimensions.

In [Falk and Tichy \(2010](#page-10-3)) the asymptotic conditional distribution $p_k := \lim_{s \nearrow k}$ $P(N_s = k \mid N_s > 0)$ of the number of exceedances was investigated, given that there is at least one exceedance, $1 \leq k \leq d$.

It turned out that this *asymptotic conditional distribution of exceedance counts* (ACDEC) exists, if the copula C corresponding to X is in the domain of attraction of a (multivariate) extreme value distribution (EVD) G, denoted by $C \in D(G)$, i.e. $C^n\left(\left(1+\frac{x_1}{n},\ldots,1+\frac{x_d}{n}\right)\right)\to_{n\to\infty}G(\boldsymbol{x}),\,\boldsymbol{x}\leq\boldsymbol{0}\in\mathbb{R}^d.$

Key words and phrases. Exceedance over high threshold and Fragility index and Extended fragility index and Multivariate extreme value theory and Peaks-over-threshold approach and Copula and Exceedance cluster length.

In this paper we investigate the ACDEC, dropping the assumption that the margins X_i , $1 \leq i \leq d$, are identically distributed. This will be done in Section [2.](#page-1-0) If the ACDEC exists then the FI exists and we have in particular $FI = \sum_{k=1}^{d} kp_k$. In Section [3](#page-3-0) we will compute the FI under quite general conditions on \overline{X} .

The extended fragility index $FI(m)$ is the extension of the $FI = FI(1)$ through the condition that there are at least $m \geq 1$ exceedances, i.e.,

$$
FI(m) = \lim_{s \nearrow} E(N_s \mid N_s \ge m) = \frac{\sum_{k=m}^d k p_k}{\sum_{k=m}^d p_k},
$$

if the ACDEC exists. But now we encounter the problem that the denominator in the definition of $FI(m)$ may vanish: $\sum_{k=m}^{d} p_k = 0$. In Section [4](#page-5-0) we will establish a characterization of $\sum_{k=m}^{d} p_k = 0$ in terms of tools from multivariate extreme value theory.

The total number of sequential time points at which a stochastic process exceeds a high threshold is an *exceedance cluster length*. The asymptotic distribution as the threshold increases of the remaining exceedance cluster length, conditional on the assumption that there is an exceedance at index $\kappa \in \{1, \ldots, d\}$, will be computed for $\mathbf{X} = (X_1, \ldots, X_d)$ in Section [5.](#page-7-0) It turns out that this can be expressed in terms of the minimum of a *generator* of the D-norm, cf equation [\(4.2\)](#page-6-0).

2. ACDEC

By Sklar's Theorem (see, for example, [\(Nelsen, 2006](#page-11-1), Theorem 2.10.9)) we can assume the representation $(X_1, \ldots, X_d) = (F_1^{-1}(U_1), \ldots, F_d^{-1}(U_d))$, where F_i is the (univariate) distribution function (df) of X_i , $1 \leq i \leq d$, and the rv $\boldsymbol{U} = (U_1, \ldots, U_d)$ follows a copula on \mathbb{R}^d , i.e., each U_i is uniformly on $(0, 1)$ distributed, $1 \leq i \leq d$. By $F^{-1}(q) := \inf \{ t \in \mathbb{R} : F(t) \geq q \}, q \in (0,1)$, we denote the generalized inverse of a df F.

The following condition is crucial for the present paper. It substitutes the condition of equal margins $F_1 = \cdots = F_d$ in [Falk and Tichy \(2010\)](#page-10-3). By $\omega(F) :=$ $\sup\{F^{-1}(q): q \in (0,1)\} = \sup\{t \in \mathbb{R}: F(t) < 1\}$ we denote the upper endpoint of a df F .

We require throughout the existence of an index $\kappa \in \{1, \ldots, d\}$ with $\omega(F_{\kappa}) =: \omega^*$, such that

(C)
$$
\lim_{s \uparrow \omega^*} \frac{1 - F_i(s)}{1 - F_{\kappa}(s)} = \gamma_i \in [0, \infty), \qquad 1 \le i \le d.
$$

Note that condition [\(C\)](#page-1-1) implies $\omega(F_i) \leq \omega^*$ for each *i*, since otherwise we would get $\gamma_i = \infty$, which is excluded. We, thus, have $\omega^* = \max_{i \leq d} \omega(F_i)$.

The following result is taken from [Aulbach et al. \(2011\)](#page-10-4). By e_i we denote the *i*-th unit vector in \mathbb{R}^d , $1 \le i \le d$; all operations on vectors such as $x \le 0 \in \mathbb{R}^d$ are meant componentwise.

Proposition 2.1. An arbitrary copula C on \mathbb{R}^d is in the domain of attraction of *an EVD G if and only if there exists a norm* $\|\cdot\|_D$ *on* \mathbb{R}^d *with* $\|e_i\|_D = 1$, $1 \leq i \leq d$, *such that*

$$
C(\boldsymbol{y}) = 1 - \|\boldsymbol{y} - \boldsymbol{1}\|_D + o\left(\|\boldsymbol{y} - \boldsymbol{1}\|_D\right),\,
$$

uniformly for $y \in [0,1]^d$. In this case $G(x) = \exp(-\Vert x \Vert_D)$, $x \le 0 \in \mathbb{R}^d$.

The following result is an immediate consequence of Proposition [2.1](#page-1-2) and the equivalence $F^{-1}(q) \leq t \iff q \leq F(t)$, $q \in (0,1)$, $t \in \mathbb{R}$, which holds for an arbitrary df F.

Corollary 2.2. *Suppose that the copula* C *corresponding to the rv* X *is in the domain of attraction of an EVD* G *and that condition* [\(C\)](#page-1-1) *is satisfied. Then there exists a norm* $\left\| \cdot \right\|_D$ *on* \mathbb{R}^d *with* $\left\| e_i \right\|_D = 1, 1 \leq i \leq d$ *, such that for any nonempty index set* $K \subset \{1, \ldots, d\}$

$$
P(X_k \le s, k \in K) = 1 - (1 - F_{\kappa}(s)) \left\| \sum_{k \in K} \gamma_k \mathbf{e}_k \right\|_D + o(1 - F_{\kappa}(s))
$$

 $as\;s\uparrow\omega^*$.

The following result provides the asymptotic unconditional distribution of exceedance counts.

Lemma 2.3. *Under the conditions of Corollary* [2.2](#page-2-0) *we obtain with* $c := 1 - F_{\kappa}(s)$

$$
a_k := \lim_{s \uparrow \omega^*} \frac{P(N_s = k)}{c}
$$

=
$$
\sum_{0 \le j \le k} (-1)^{k-j+1} {d-j \choose k-j} \sum_{\substack{\emptyset \ne T \subseteq \{1, \dots, d\} \\ |T| = d-j}} \left\| \sum_{i \in T} \gamma_i e_i \right\|_D
$$

for $1 \leq k \leq d$ *, and*

$$
a_0 := \lim_{s \uparrow \omega^*} \frac{1 - P(N_s = 0)}{c} = \left\| \sum_{j=1}^d \gamma_j e_j \right\|_D.
$$

Proof. Corollary [2.2](#page-2-0) implies

$$
P(N_s = 0) = 1 - c \left\| \sum_{j=1}^d \gamma_j e_j \right\|_D + o(c),
$$

for $s \uparrow \omega^*$.

From the additivity formula, Corollary [2.2](#page-2-0) and the equality $\sum_{\emptyset \neq T \subset S} (-1)^{|T|+1}$ 1 for any nonempty subset $S \subset \{1, \ldots, d\}$, we obtain for $1 \leq k \leq d$ as $s \uparrow \omega^*$

$$
P(N_s = k)
$$
\n
$$
= \sum_{\substack{S \subset \{1, ..., d\} \\ |S| = k}} P(X_i > s, i \in S, X_j \le s, j \in S^{\complement})
$$
\n
$$
= \sum_{\substack{S \subset \{1, ..., d\} \\ |S| = k}} P(X_i > s, i \in S | X_j \le s, j \in S^{\complement}) P(X_j \le s, j \in S^{\complement})
$$
\n
$$
= \sum_{\substack{S \subset \{1, ..., d\} \\ |S| = k}} \left(1 - \sum_{\emptyset \neq T \subset S} (-1)^{|T|+1} P(X_i \le s, i \in T | X_j \le s, j \in S^{\complement})\right) \times P(X_j \le s, j \in S^{\complement})
$$
\n
$$
= \sum_{\substack{S \subset \{1, ..., d\} \\ |S| = k}} \left(P(X_j \le s, j \in S^{\complement}) - \sum_{\emptyset \neq T \subset S} (-1)^{|T|+1} P(X_i \le s, i \in T \cup S^{\complement}) \right)
$$
\n
$$
= \sum_{\substack{S \subset \{1, ..., d\} \\ |S| = k}} \left(1 - c \left\| \sum_{j \in S^{\complement}} \gamma_j e_j \right\|_D - \sum_{\emptyset \neq T \subset S} (-1)^{|T|+1} \left(1 - c \left\| \sum_{j \in T \cup S^{\complement}} \gamma_j e_j \right\|_D \right) \right)
$$
\n
$$
+ o(c)
$$

 $\ddot{}$

$$
= c \sum_{\substack{S \subset \{1,\ldots,d\} \\ |S|=k}} \sum_{T \subset S} (-1)^{|T|+1} \left\| \sum_{j \in T \cup S^{\mathbf{G}}} \gamma_j e_j \right\|_{D} + o(c).
$$

With a suitable index transformation we get

$$
P(N_s = k) = c \sum_{S \subset \{1, ..., d\} \atop |S| = k} \sum_{0 \le r \le |S|} (-1)^{r+1} \sum_{\substack{K \subset S \\ |K| = r}} \left\| \sum_{\substack{i \in K \cup S^{\mathbf{0}} := T \\ |T| = r + d - k}} \gamma_i e_i \right\|_D + o(c)
$$

=
$$
c \sum_{0 \le j \le k} (-1)^{k-j+1} {d-j \choose k-j} \sum_{\substack{r \subset \{1, ..., d\} \\ |T| = d - j}} \left\| \sum_{j \in T} \gamma_j e_j \right\|_D + o(c),
$$

which completes the proof of Lemma [2.3.](#page-2-1) \Box

Note that $a_0 > 0$ as $\gamma_k = 1$ and that $a_k \geq 0, 1 \leq k \leq d$, in Lemma [2.3.](#page-2-1) The following main result of this section is, therefore, an immediate consequence of Lemma [2.3.](#page-2-1) It provides the ACDEC also in the case, where the components X_i of the rv $\mathbf{X} = (X_1, \ldots, X_d)$ are not identically distributed.

Theorem 2.4 (ACDEC). *Under the conditions of Corollary [2.2](#page-2-0) we have that the limits*

$$
p_k := \lim_{s \uparrow \omega^*} P(N_s = k \mid N_s > 0) = \frac{a_k}{a_0}, \qquad 1 \le k \le d,
$$

exist and that they define a probability distribution on $\{1, \ldots, d\}$ *.*

For the usual λ -norm $\|\boldsymbol{x}\|_{\lambda} = \left(\sum_{1 \leq i \leq d} |x_i|^{\lambda}\right)^{1/\lambda}, \boldsymbol{x} \in \mathbb{R}^d, \lambda \in [1, \infty)$, we obtain, for example, $a_0 = \left(\sum_{1 \leq i \leq d} \gamma_i^{\lambda}\right)^{1/\lambda}$ and

$$
a_k = \sum_{0 \le j \le k} (-1)^{k-j+1} {d-j \choose k-j} \sum_{\substack{\emptyset \ne T \subset \{1, \ldots, d\} \\ |T| = d-j}} \left(\sum_{i \in T} \gamma_i^{\lambda} \right)^{1/\lambda}, \qquad 2 \le k \le d.
$$

For $\lambda = 1$, which is the case of independent margins of G, we obtain in particular $a_0 = \sum_{1 \leq i \leq d} \gamma_i = a_1, a_k = 0, 2 \leq k \leq d$, and, thus, $p_1 = 1, p_k = 0, 2 \leq k \leq d$.

3. The Fragility Index

The following theorem is the main result of this section.

Theorem 3.1. *Under the conditions of Corollary [2.2](#page-2-0) we have*

$$
FI = \frac{\sum_{i=1}^{d} \gamma_i}{\left\| \sum_{i=1}^{d} \gamma_i \mathbf{e}_i \right\|_D} \in [1, d].
$$

Proof. We have

$$
E(N_s | N_s > 0) = \sum_{i=1}^d E\left(1_{(s,\infty)}(X_i) | N_s > 0\right)
$$

=
$$
\sum_{i=1}^d \frac{P(X_i > s)}{1 - P(N_s = 0)}
$$

=
$$
\sum_{i=1}^d \frac{1 - F_i(s)}{1 - F_\kappa(s)} \frac{1 - F_\kappa(s)}{1 - P(N_s = 0)}
$$

 \mathbf{H}

$$
\rightarrow_{s \rightarrow \infty} \frac{\sum_{i=1}^{d} \gamma_i}{\left\| \sum_{i=1}^{d} \gamma_i e_i \right\|_D}.
$$

by Lemma [2.3](#page-2-1) and condition (C) .

It is well known that an arbitrary D-norm satisfies the inequality $||x||_{\infty}$ ≤ $||x||_D \le ||x||_1, x \ge 0 \in \mathbb{R}^d$; see, for example [\(Falk et al.](#page-10-5), [2010,](#page-10-5) (4.37)). The range of the FI in Theorem [3.1](#page-3-1) is, consequently, $[1, d]$.

Suppose that $\gamma_i > 0$, $1 \leq i \leq d$. Then it follows from [Takahashi \(1988](#page-11-2)) that

$$
\left\| \sum_{i=1}^d \gamma_i e_i \right\|_D = \sum_{i=1}^d \gamma_i \iff \left\| \cdot \right\|_D = \left\| \cdot \right\|_1,
$$

where $\lVert \cdot \rVert_D = \lVert \cdot \rVert_1$ is the case of independence of the margins of G. We, thus, obtain in case $\gamma_i > 0, 1 \leq i \leq d$,

 $FI = 1 \iff ||\cdot||_D = ||\cdot||_1 \iff$ independence of the margins of G.

In case of complete dependence of G, i.e., if $||x||_D = ||x||_{\infty} = \max_{1 \leq i \leq d} |x_i|$, we obtain for general $\gamma_i \geq 0$ that $FI = \sum_{i=1}^d \gamma_i / \max_{1 \leq i \leq d} \gamma_i$.

Example 3.2 (Weighted Pareto). Let Y_1, \ldots, Y_m be independent and identically Pareto distributed rv with parameter $\alpha > 0$. Put $X_i := \sum_{j=1}^m \lambda_{ij} Y_j$, $1 \le i \le d$, where the weights λ_{ij} are nonnegative and satisfy $\sum_{j=1}^{m} \lambda_{ij}^{\alpha} = 1, 1 \leq i \leq d$.

The df of the rv $\mathbf{X} = (X_1, \ldots, X_d)$ is in the domain of attraction of the EVD

$$
G^*(s) = \exp\left(-\sum_{j=1}^m \max_{i\leq d} \left(\frac{\lambda_{ij}}{s_i}\right)^{\alpha}\right), \qquad s = (s_1,\ldots,s_d) > 0,
$$

with standard Fréchet margins $G_k(s) = \exp(-s^{-\alpha}), s > 0, 1 \le k \le d$. This can be seen by proving that for $s > 0 \in \mathbb{R}^d$

$$
P\left(\sum_{j=1}^m \lambda_{ij} Y_j \le n^{1/\alpha} s_i, 1 \le i \le d\right) = 1 - \frac{1}{n} \left(\sum_{j=1}^m \max_{i \le d} \left(\frac{\lambda_{ij}}{s_i}\right)^{\alpha} + o(1)\right),
$$

which follows from tedious but elementary computations, using conditioning on $Y_i = y_i, j = 2, \ldots, m$.

We, thus, obtain that the copula pertaining to X is in the domain of attraction of $G(\boldsymbol{x}) = \exp(-\|\boldsymbol{x}\|_D), \ \boldsymbol{x} \leq \boldsymbol{0} \in \mathbb{R}^d$, where $\|\boldsymbol{x}\|_D := \sum_{j=1}^m (\max_{i \leq d} (\lambda_{ij}^{\alpha} |x_i|)),$ $\boldsymbol{x} \in \mathbb{R}^d.$

From [\(Embrechts et al.](#page-10-6), [1997](#page-10-6), Lemma A 3.26) we obtain that the df F_i of X_i satisfies $1 - F_i(s) \sim s^{-\alpha} \sum_{j=1}^m \lambda_{ij}^{\alpha} = s^{-\alpha}, 1 \le i \le d$, as $s \to \infty$ and, thus,

$$
\gamma_i = \lim_{s \to \infty} \frac{1 - F_i(s)}{1 - F_\kappa(s)} = 1, \qquad 1 \le i \le d,
$$

where $\kappa \in \{1, \ldots, d\}$ can be chosen arbitrarily. As a consequence we obtain for the fragility index

$$
FI = \frac{\sum_{i=1}^{d} \gamma_i}{\left\| \sum_{i=1}^{d} \gamma_i \mathbf{e}_i \right\|_D} = \frac{d}{\sum_{j=1}^{m} \max_{i \leq d} \lambda_{ij}^{\alpha}}.
$$

Example 3.3 (GPD-Copula). Take an arbitrary rv Z that realizes in $[0, c]^d$ and which satisfies $E(Z_i) = 1, 1 \leq i \leq d$. Choose $\beta_1, \ldots, \beta_d > 0$ and let U be a rv, which is uniformly on $(0, 1)$ distributed and that is independent of Z . Put $\boldsymbol{X} := (\beta_1 Z_1, \ldots, \beta_d Z_d) / U$. Then $F_i(x) = P(X_i \leq x) = 1 - \frac{\beta_i}{x}, x \geq c\beta_i, 1 \leq i \leq d$,

and the copula of X is in the domain of attraction of the EVD $G(\mathbf{x}) = \exp(-||\mathbf{x}||_D)$, $\boldsymbol{x} \leq \boldsymbol{0} \in \mathbb{R}^d$, with $\|\boldsymbol{x}\|_D = E \left(\max_{1 \leq i \leq d} (|x_i| \, Z_i) \right), \, \boldsymbol{x} \in \mathbb{R}^d$. Let $\beta_{\kappa} = \max_{1 \leq i \leq d} \beta_i$. Then we have

$$
\frac{1-F_i(s)}{1-F_\kappa(s)}=\frac{\beta_i}{\beta_\kappa}=:\gamma_i,\qquad s\ge c\beta_\kappa,\ 1\le i\le d,
$$

and we obtain for the fragility index corresponding to X

$$
FI = \frac{\sum_{i=1}^{d} \gamma_i}{E(\max_{1 \le i \le d} \gamma_i Z_i)}.
$$

Note that the copula C of X is actually a *GPD copula* ((multivariate) generalized Pareto distribution), characterized by the equation $C(\boldsymbol{u}) = 1 - ||\boldsymbol{1} - \boldsymbol{u}||_D$ for $\boldsymbol{u} \in$ $[0,1]^d$ close to 1, see [Aulbach et al. \(2011\)](#page-10-4). If $Z_1 = \cdots = Z_d$ a.s., then we obtain the maximum-norm $||x||_D = \max_{1 \le i \le d} |x_i|$, and $FI = \sum_{i=1}^d \gamma_i / \max_{1 \le i \le d} \gamma_i$.

4. The Extended Fragility Index

The extended FI is the asymptotic expected number of exceedances above a high threshold, conditional on the assumption that there are at least $m \geq 1$ exceedances:

$$
FI(m) := \lim_{s \nearrow} E(N_s \mid N_s \ge m), \qquad 1 \le m \le d.
$$

If the ACDEC corresponding to $X_1, \ldots X_d$ exists, then, obviously,

(4.1)
$$
FI(m) = \frac{\sum_{k=m}^{d} kp_k}{\sum_{k=m}^{d} p_k}, \qquad 1 \leq m \leq d.
$$

But now we encounter the problem that we might divide by 0 in [\(4.1\)](#page-5-1), i.e., $\sum_{k=m}^{d} p_k$ can vanish if $m \geq 2$. This is, for example, true for the L_1 -norm. But there are other norms in dimension $d \geq 3$ such that $\sum_{k=m}^{d} p_k = 0$, see [Falk and Tichy \(2010\)](#page-10-3). In this section we establish a characterization of $\sum_{k=m}^{d} p_k = 0$ also in that case, where the initial X_1, \ldots, X_d follow different distributions.

Lemma 4.1. *Assume the conditions of Corollary [2.2](#page-2-0) and put* $I := \{i \in \{1, ..., d\} :$ $\gamma_i = 0$ }. Then we obtain $\sum_{k=m}^d p_k = 0$ for $m > m^* := |I^{\complement}| = d - |I|.$

Proof. Without loss of generality we can assume that $I \neq \emptyset$. Recall, moreover, that $\gamma_{\kappa} = 1$, i.e., $I \neq \{1, ..., d\}$ as well. We have

$$
a_k = \lim_{s \uparrow \omega^*} \frac{P(N_s = k)}{1 - F_{\kappa}(s)} = \lim_{s \uparrow \omega^*} \sum_{\substack{S \subset \{1, \ldots, d\} \\ |S| = k}} \frac{P\left(X_i > s, \ i \in S, \ X_j \le s, \ j \in S^{\complement}\right)}{1 - F_{\kappa}(s)}.
$$

If $|S| = k \ge m^* + 1$, then S must contain an index i_S , say, with $i_S \in I$. We, thus, obtain for $k \geq m^* + 1$

$$
a_k \le \limsup_{s \uparrow \omega^*} \sum_{\substack{S \subset \{1, \ldots, d\} \\ |S| = k}} \frac{P(X_{is} > s)}{1 - F_{\kappa}(s)} = \sum_{\substack{S \subset \{1, \ldots, d\} \\ |S| = k}} \lim_{s \uparrow \omega^*} \frac{1 - F_{is}(s)}{1 - F_{\kappa}(s)} = 0.
$$

 \Box

The following characterization is the main result of this section. It is formulated in terms of different representations of a multivariate EVD G on \mathbb{R}^d with standard negative exponential margins $G(xe_i) = \exp(x)$, $x \leq 0$, $1 \leq i \leq d$. We have for $\boldsymbol{x} \leq \boldsymbol{0} \in \mathbb{R}^d$

(Hofmann)
$$
G(\mathbf{x}) = \exp(-\|\mathbf{x}\|_D)
$$

(Pickands-de Haan-Resnick)

(Balkema-Resnick) ,

$$
= \exp(-\|\mathbf{x}\|_{D})
$$

=
$$
\exp(-\int_{S_d} \max(-u_i x_i) \mu(d\mathbf{u})
$$

=
$$
\exp(-\nu([-\infty, \mathbf{x}]^{\complement})),
$$

where $\lVert \cdot \rVert_D$ is some norm on \mathbb{R}^d with $\lVert e_i \rVert_D = 1, 1 \leq i \leq d$, μ is the *angular measure* on the unit simplex $S_d = \{ \mathbf{u} \in [0,1]^d : \sum_{i \leq d} u_i = 1 \}$, satisfying $\mu(S_d) = d$, $\int_{S_d} u_i \mu(d\mathbf{u}) = 1$, $1 \leq i \leq d$, and ν is the σ -finite *exponent measure* on $[-\infty, 0]^d \setminus {\infty}$; for details we refer to [Falk et al. \(2010\)](#page-10-5). We also include the fact that each D-norm can be generated by nonnegative and bounded rv Z_1, \ldots, Z_d with $E(Z_i) = 1, 1 \le i \le d$, as

(4.2)
$$
\|x\|_{D} = E\left(\max_{1 \leq i \leq d}(|x_{i}| Z_{i})\right), \qquad x = (x_{1},...,x_{d}) \in \mathbb{R}^{d}.
$$

This is a consequence of the Pickands-de Haan-Resnick representation. The rv $\mathbf{Z} = (Z_1, \ldots, Z_d)$ is called *generator* of $\lVert \cdot \rVert_D$. Note that each rv $\mathbf{Z} = (Z_1, \ldots, Z_d)$ of nonnegative and bounded rv Z_i with $E(Z_i) = 1$ generates a D-norm via equation [\(4.2\)](#page-6-0).

Proposition 4.2. *Assume the conditions of Corollary* [2.2](#page-2-0) *and put* $I = \{i \in I\}$ $\{1,\ldots,d\}$: $\gamma_i = 0\}$. Then we have $\sum_{k=m}^d p_k = 0$ for some $m \leq m^* = |I^{\complement}|$ if and only if we have for each subset $K \subset I^{\complement}$ with at least m elements

(4.3)
$$
\lim_{s \uparrow \omega^{+}} \frac{P(X_{k} > s, k \in K)}{1 - F_{\kappa}(s)} = 0
$$

$$
\iff \sum_{T \subset K} (-1)^{|T|-1} \left\| \sum_{i \in T} x_{i} e_{i} \right\|_{D} = 0 \quad \text{for all } x \ge 0 \in \mathbb{R}^{d}
$$

$$
\iff \sum_{T \subset K} (-1)^{|T|-1} \left\| \sum_{i \in T} e_{i} \right\|_{D} = 0
$$

$$
(4.4) \iff \min_{k \in K} Z_{k} = 0 \quad a.s.
$$

$$
\iff \mu \left(\left\{ u \in S_{d} : \min_{i \in K} u_{i} > 0 \right\} \right) = 0
$$

$$
\iff \nu \left(\times_{k \in K} (-\infty, 0] \times_{i \notin K} [-\infty, 0] \right) = 0,
$$

i.e., the projection $\nu_K := \nu * (\pi_i, i \in K)$ *of the exponent measure* ν *onto its components* $i \in K$ *is the null measure on* $(-\infty, 0]^{K}$.

While in the (bivariate) case $K = \{k_1, k_2\}$ the condition

$$
\sum_{T \subset K} (-1)^{|T|-1} \left\| \sum_{i \in T} e_i \right\|_{D} = 0
$$
\n
$$
\iff \|e_{k_1}\|_{D} + \|e_{k_2}\|_{D} - \|e_{k_1} + e_{k_2}\|_{D} = 0
$$
\n
$$
\iff \|e_{k_1} + e_{k_2}\|_{D} = 2 = \|e_{k_1} + e_{k_2}\|_{1}
$$

implies by Takahashi's Theorem [\(Takahashi \(1988](#page-11-2))) independence of the marginal distributions k_1, k_2 of the EVD $G(\mathbf{x}) = \exp(-||\mathbf{x}||_D^{\bullet}), \mathbf{x} \leq \mathbf{0} \in \mathbb{R}^d$, this is no longer true for $|K| \geq 3$. Take, for example, a rv ξ that attains only the values 1;2;3 with probability $1/6$; $1/3$; $1/2$ and put

$$
Z_1 := \begin{cases} 0 & \text{if } \xi = 1 \\ \frac{6}{5} & \text{elsewhere} \end{cases}, \quad Z_2 := \begin{cases} 0 & \text{if } \xi = 2 \\ \frac{3}{2} & \text{elsewhere} \end{cases}, \quad Z_3 := \begin{cases} 0 & \text{if } \xi = 3 \\ 2 & \text{elsewhere} \end{cases}.
$$

Then $E(Z_i) = 1$, $i = 1, 2, 3$, $\min_{1 \leq i \leq 3} Z_i = 0$, $E(\max_{1 \leq i \leq 3} Z_i) < 3$ as well as $E(\max(Z_i, Z_j)) < 2$ for all $1 \leq i \neq j \leq 3$, i.e., there is no marginal independence among Z_1, Z_2, Z_3 .

Proof. We have by Theorem [2.4](#page-3-2) and Lemma [2.3](#page-2-1)

$$
\sum_{k=m}^{d} p_k = 0
$$
\n
$$
\iff \lim_{s \uparrow \omega^*} \frac{P(N_s \ge m)}{1 - F_\kappa(s)} = 0
$$
\n
$$
\iff \lim_{s \uparrow \omega^*} \frac{P\left(\bigcup_{\substack{K \subset \{1, \ldots, d\} \\ |K| \ge m}} \{X_k > s, k \in K\}\right)}{1 - F_\kappa(s)} = 0
$$
\n
$$
\iff \lim_{s \uparrow \omega^*} \frac{P(X_k > s, k \in K)}{1 - F_\kappa(s)} = 0 \text{ for any } K \subset \{1, \ldots, d\} \text{ with } |K| \ge m
$$
\n
$$
\iff \lim_{s \uparrow \omega^*} \frac{P(X_k > s, k \in K)}{1 - F_\kappa(s)} = 0 \text{ for any } K \subset I^c \text{ with } |K| \ge m,
$$

which is equivalence [\(4.3\)](#page-6-1). Note that $\sum_{T \subset K} (-1)^{|T|-1} \max_{i \in T} a_i = \min_{k \in K} a_k$ for any set $\{a_k : k \in K\}$ of real numbers, which can be seen by induction. We, consequently, have

$$
\sum_{T \subset K} (-1)^{|T|-1} \left\| \sum_{i \in T} e_i \right\|_D = \sum_{T \subset K} (-1)^{|T|-1} E\left(\max_{i \in T} Z_i\right) = E\left(\min_{i \in T} Z_i\right)
$$

and, thus,

$$
\sum_{T \subset K} (-1)^{|T|-1} \left\| \sum_{i \in T} \mathbf{e}_i \right\|_D = 0 \iff E\left(\min_{i \in T} Z_i\right) = 0 \iff \min_{k \in K} Z_k = 0 \text{ a.s.}
$$

The other equivalences follow from Proposition 5.2 in [Falk and Tichy \(2010](#page-10-3)). \Box

5. Exceedance Cluster Lengths

The total number of sequential time points at which a stochastic process exceeds a high threshold is an exceedance cluster length. The mathematical tools developed in the preceding sections enable the computation of its distribution as well. Precisely, denote by $L_{\kappa}(s)$ the number of sequential exceedances above the threshold s, if we have an exceedance at $\kappa \in \{1, \ldots, d\}$, i.e.

$$
L_{\kappa}(s) := \sum_{k=0}^{d-\kappa} k \mathbb{1}(X_{\kappa} > s, \dots, X_{\kappa+k} > s, X_{\kappa+k+1} \leq s).
$$

We have, in particular, $L_d(s) = 0 = L_{\kappa}(s)$, if $X_{\kappa+1} \leq s$. We suppose throughout this section that condition [\(C\)](#page-1-1) holds for the index $\kappa \in \{1, \ldots, d\}$. The following auxiliary result will be crucial.

Lemma 5.1. *Assume the conditions of Corollary [2.2.](#page-2-0) Then we obtain for* $\kappa \in$ $\{1,\ldots,d\}$ as $s \nearrow \omega^*$

$$
P(L_{\kappa}(s) \ge k \mid X_{\kappa} > s) = P(X_{\kappa} > s, \dots, X_{\kappa + k} > s \mid X_{\kappa} > s)
$$

=
$$
\sum_{\emptyset \ne T \subset \{\kappa, \dots, \kappa + k\}} (-1)^{|T|+1} \left\| \sum_{i \in T} \gamma_{i} e_{i} \right\|_{D} + o(1)
$$

=: $s_{\kappa}(k) + o(1), \qquad 0 \le k \le d - \kappa.$

Proof. From the additivity formula we obtain

$$
P(X_{\kappa} > s, ..., X_{\kappa+k} > s | X_{\kappa} > s)
$$

=
$$
\frac{1 - P\left(\bigcup_{0 \le i \le k} \{X_{\kappa+i} \le s\}\right)}{1 - F_{\kappa}(s)}
$$

=
$$
\frac{1 - \sum_{\emptyset \ne T \subset \{\kappa, ..., \kappa+k\}} (-1)^{|T|+1} P(X_i \le s, i \in T)}{1 - F_{\kappa}(s)}
$$

=
$$
\frac{1 - \sum_{\emptyset \ne T \subset \{\kappa, ..., \kappa+k\}} (-1)^{|T|+1} (1 - c ||\sum_{i \in T} \gamma_i e_i||_D) + o(1 - F_{\kappa}(s))}{1 - F_{\kappa}(s)}
$$

=
$$
\sum_{\emptyset \ne T \subset \{\kappa, ..., \kappa+k\}} (-1)^{|T|+1} ||\sum_{i \in T} \gamma_i e_i||_D + o(1).
$$

Corollary 5.2. *Suppose in addition to the assumptions in Corollary [2.2](#page-2-0) that* Z *is a generator of the D-norm* $\|\cdot\|_D$. Then we obtain for $\kappa \in \{1, ..., d\}$ as $s \nearrow \omega^*$

$$
P(X_{\kappa} > s, \ldots, X_{\kappa + k} > s \mid X_{\kappa} > s) = E\left(\min_{\kappa \leq i \leq \kappa + k} (\gamma_i Z_i)\right) + o(1),
$$

for $0 \leq k \leq d - \kappa$ *.*

Though the distribution of a generator of a D-norm is not uniquely determined, the preceding result entails that the numbers $E(\min_{\kappa \leq i \leq \kappa + k} (\gamma_i Z_i)), 0 \leq k \leq d - \kappa$, are uniquely determined by the D-norm.

The asymptotic distribution of the exceedance cluster length, conditional on the assumption that there is an exceedance at time point $\kappa \in \{1, \ldots, d\}$, is an immediate consequence of Lemma [5.1.](#page-8-0) It follows from the equation

$$
P(L_{\kappa}(s) = k | X_{\kappa} > s) = P(L_{\kappa}(s) \ge k | X_{\kappa} > s) - P(L_{\kappa}(s) \ge k + 1 | X_{\kappa} > s).
$$

Note, moreover, that $P(L_{\kappa}(s) = 0 \mid X_{\kappa} > s) = 1$ for $\kappa = d$.

Proposition 5.3. *Assume the conditions of Corollary [2.2.](#page-2-0) Then we have for* $\kappa < d$ $as \times \nearrow \omega^*$

$$
P(L_{\kappa}(s) = k | X_{\kappa} > s)
$$

=
$$
\begin{cases} \sum_{\emptyset \neq T \subset \{\kappa, ..., d\}} (-1)^{|T|+1} || \sum_{i \in T} \gamma_i e_i ||_D + o(1), \\ k = d - \kappa, \\ \sum_{T \subset \{\kappa, ..., \kappa + k\}} (-1)^{|T|+1} || \gamma_{\kappa + k + 1} e_{\kappa + k + 1} + \sum_{i \in T} \gamma_i e_i ||_D + o(1), \\ 0 \le k < d - \kappa. \end{cases}
$$

We obtain, for example, for $\kappa < d$

$$
P(L_{\kappa}(s) = 0 \mid X_{\kappa} > s) = ||e_{\kappa} + \gamma_{\kappa+1}e_{\kappa+1}||_{D} - 1 + o(1),
$$

which converges to $\gamma_{\kappa+1}$ if $\|\cdot\|_D = \|\cdot\|_1$. Recall that $\gamma_{\kappa} = 1$.

In terms of a generator Z of a D -norm, Proposition [5.3](#page-8-1) becomes the following result.

Corollary 5.4. *Assume in addition to the conditions of Corollary [2.2](#page-2-0) that* Z *is a generator of the D-norm* $\left\| \cdot \right\|_D$. Then we have for $\kappa < d$ as s $\nearrow \omega^*$ (i) $P(T(s) = k | Y)$

(i)
$$
P(L_{\kappa}(s) = k | X_{\kappa} > s)
$$

\n
$$
= \begin{cases} E(\min_{\kappa \le i \le d} (\gamma_{i} Z_{i})) + o(1), & k = d - \kappa \\ E(\min_{\kappa \le i \le \kappa + k} (\gamma_{i} Z_{i}) - \min_{\kappa \le i \le \kappa + k + 1} (\gamma_{i} Z_{i})) + o(1), & 0 \le k < d - \kappa. \end{cases}
$$

\n(ii) $P(L_{\kappa}(s) \le k | X_{\kappa} > s)$
\n
$$
= \begin{cases} 1, & k = d - \kappa \\ 1 - E(\min_{\kappa \le i \le \kappa + k + 1} (\gamma_{i} Z_{i})) + o(1), & 0 \le k < d - \kappa. \end{cases}
$$

We, thus, obtain the limit distribution of the exceedance cluster length:

$$
Q_{\kappa}([0,k]) := \lim_{s \nearrow \omega^*} P(L_{\kappa}(s) \le k \mid X_{\kappa} > s)
$$

=
$$
\begin{cases} 1, & k = d - \kappa \\ 1 - E(\min_{\kappa \le i \le \kappa + k + 1}(\gamma_i Z_i)), & 0 \le k < d - \kappa. \end{cases}
$$

Take, for example, the generator $\mathbf{Z} = 2(U_1, \ldots, U_d)$, where the U_i are independent and uniformly on $(0, 1)$ distributed rv. If, in addition, $\gamma_i = 1, \kappa \leq i \leq d$, then we obtain

$$
Q_{\kappa}([0,k]) = \begin{cases} 1, & k = d - \kappa \\ 1 - \frac{2}{k+3}, & 0 \le k < d - \kappa. \end{cases}
$$

Next we compute the asymptotic mean exceedance cluster length.

Proposition 5.5. *Assume the conditions of Corollary [2.2](#page-2-0) and let* Z *be a generator of the D-norm* $\lVert \cdot \rVert_D$ *. Then we have for* $1 \leq \kappa \leq d$

$$
E(L_{\kappa}(s) | X_{\kappa} > s) = \begin{cases} 0, & \text{if } \kappa = d \\ \sum_{k=1}^{d-\kappa} s_{\kappa}(k) + o(1) & \text{else} \end{cases}
$$

$$
= \begin{cases} 0, & \text{if } \kappa = d \\ \sum_{k=1}^{d-\kappa} E(\min_{\kappa \le i \le \kappa + k} (\gamma_{i} Z_{i})) + o(1) & \text{else.} \end{cases}
$$

Proof. Since $L_{\kappa}(s)$ attains only nonnegative values, we have for $\kappa < d$

$$
E (L_{\kappa}(s) | X_{\kappa} > s) = \int_{0}^{\infty} P (L_{\kappa}(s) \ge t | X_{\kappa} > s) dt
$$

=
$$
\sum_{k=1}^{d-\kappa} P (L_{\kappa}(s) \ge k | X_{\kappa} > s)
$$

=
$$
\sum_{k=1}^{d-\kappa} P (X_{\kappa} > s, ..., X_{\kappa+k} > s | X_{\kappa} > s)
$$

=
$$
\sum_{k=1}^{d-\kappa} s_{\kappa}(k) + o(1).
$$

 \Box

Corollary 5.6. *Under the conditions of the preceding result we have for* $\kappa < d$, *if* $\gamma_k > 0, 1 \leq k \leq d,$

$$
\lim_{s \uparrow \omega^*} E(L_{\kappa}(s) \mid X_{\kappa} > s) = 0
$$

if and only if $||xe_{\kappa} + ye_{\kappa+1}||_D = ||xe_{\kappa} + ye_{\kappa+1}||_1 = x + y, x, y \ge 0.$

Proof. Note that $s_{\kappa}(1) \geq \cdots \geq s_{\kappa}(d - \kappa)$. We, thus, obtain from Proposition [5.5](#page-9-0) $\lim_{s \uparrow \omega^*} E(L_{\kappa}(s) \mid X_{\kappa} > s) = 0 \iff s_{\kappa}(1) = 0.$

The assertion is now a consequence of Proposition 6.1 in [Falk and Tichy](#page-10-3) [\(2010\)](#page-10-3). \Box

Suppose in addition to the assumptions of Corollary [2.2](#page-2-0) that the components X_1, \ldots, X_d of the rv **X** are exchangeable. Then we have $\gamma_1 = \cdots = \gamma_d = 1$, as well as $\left\|\sum_{i\in T} e_i\right\|_D = \left\|\right.$ $\sum_{i=1}^{|T|} e_i \Big\|_D$ for any nonempty subset $T \subset \{1, \ldots, d\}$. As a consequence we obtain

$$
s_{\kappa}(k) = \sum_{j=1}^{k+1} (-1)^{j+1} {k+1 \choose j} \left\| \sum_{i=1}^{j} e_i \right\|_D, \qquad 0 \le k \le d - \kappa,
$$

and, thus, by rearranging sums,

$$
\lim_{s \nearrow} E(L_{\kappa}(s) \mid X_{\kappa} > s) = \sum_{k=1}^{d-\kappa} s_{\kappa}(k)
$$
\n
$$
= \sum_{j=1}^{d-\kappa+1} (-1)^{j+1} \left\| \sum_{i=1}^{j} e_i \right\|_{D} \sum_{k=\max(1,j-1)}^{d-\kappa} {k+1 \choose j}
$$
\n(5.1)\n
$$
= -1 + \sum_{j=1}^{d-\kappa+1} (-1)^{j+1} {d-\kappa+2 \choose j+1} \left\| \sum_{i=1}^{j} e_i \right\|_{D},
$$

where the final equality follows from the general equation $\sum_{r=n}^{N} {r \choose n} = {N+1 \choose n+1}$.

Example 5.7 (Marshall-Olkin D-norm)*.* The Marshall-Olkin D-norm is the convex combination of the maximum-norm and the L_1 -norm:

$$
\|\boldsymbol{x}\|_{\mathrm{MO}} = \vartheta \, \|\boldsymbol{x}\|_1 + (1-\vartheta) \, \|\boldsymbol{x}\|_{\infty} \,, \qquad \boldsymbol{x} \in \mathbb{R}^d, \, \vartheta \in [0,1],
$$

see [\(Falk et al., 2010,](#page-10-5) Example 4.3.4). In this case we obtain from equation [\(5.1\)](#page-10-7)

$$
\lim_{s \nearrow} E\left(L_{\kappa}(s) \mid X_{\kappa} > s\right) = (1 - \vartheta)(d - \kappa),
$$

where we have used the general equation $\sum_{j=0}^{m}(-1)^{j}\binom{m}{j}=0$.

In the case $\vartheta = 0$ of complete tail dependence of the margins we, therefore, obtain $\lim_{s \nearrow} E(L_{\kappa}(s) | X_{\kappa} > s) = d - \kappa$, which is the full possible length, whereas in the tail independence case $\vartheta = 1$ we obtain the shortest length $\lim_{s \to \infty} E(L_{\kappa}(s) | X_{\kappa} > s)$ $= 0$, which is in complete accordance with Corollary [5.6.](#page-9-1)
