The State-Dependent Semideterministic Broadcast Channel

Amos Lapidoth, *Fellow, IEEE* and Ligong Wang, *Member, IEEE*

Abstract—We derive the capacity region of the state-dependent semideterministic broadcast channel with noncausal state-information at the transmitter. One of the two outputs of this channel is a deterministic function of the channel input and the channel state, and the state is assumed to be known noncausally to the transmitter but not to the receivers. We show that appending the state to the deterministic output does not increase capacity.

We also derive an outer bound on the capacity of general (not necessarily semideterministic) state-dependent broadcast channels.

Index Terms—Broadcast channel, capacity region, channel-state information, Gel'fand-Pinsker problem, semideterministic.

I. INTRODUCTION

WE characterize the capacity region of the discrete, memoryless, state-dependent, semideterministic broadcast channel. This channel has a single transmitting node, two receiving nodes, and an internal state, all of which are assumed to take value in finite sets. One of the receiving nodes—the "deterministic receiver"—observes a symbol Y that is a deterministic function of the transmitted symbol x and the (random) state S

$$Y = f(x, S) \quad \text{with probability one,} \tag{1a}$$

and the other receiving node—the "nondeterministic receiver"—observes a symbol Z, which is random: conditional on the input being x and the state being s, the probability that it equals z is $W(z|x,s)$:

$$\Pr[Z = z | X = x, S = s] = W(z|x,s). \tag{1b}$$

The state sequence $\mathbf{S}$ is assumed to be independent and identically distributed (IID) according to some law $P_S(\cdot)$

$$\Pr[S = s] = P_S(s) \tag{1c}$$

and to be revealed to the encoder in a noncausal way: all future values of the state are revealed to the transmitter before transmission begins.

We consider a scenario where the encoder wishes to convey *two private messages*: $M_y \in \{1, \ldots, 2^{nR_y}\}$ to the deterministic receiver, and $M_z \in \{1, \ldots, 2^{nR_z}\}$ to the nondeterministic

receiver, where R_y and R_z denote the *rates* (in bits per channel use) of data transmission to the deterministic and nondeterministic receivers.[1] The messages M_y and M_z are assumed to be independent and uniformly distributed. As for the broadcast channel without a state [1], [2], we define the *capacity region* of this channel as the closure of all rate-pairs that are achievable in the sense that the probability that at least one of the receivers decodes its message incorrectly can be made arbitrarily close to zero.

The main result of this paper is a single-letter characterization of the capacity region:

Theorem 1: The capacity region of the channel (1) when the states are known noncausally to the transmitter is the convex closure of the union of rate-pairs (R_y, R_z) satisfying

$$R_y < H(Y|S) \tag{2a}$$
$$R_z < I(U;Z) - I(U;S) \tag{2b}$$
$$R_y + R_z < H(Y|S) + I(U;Z) - I(U;S,Y) \tag{2c}$$

over all joint distribution on (X, Y, Z, S, U) whose marginal on S is the given state distribution P_S and under which, conditional on X and S, the channel outputs Y and Z are drawn according to the channel law (1) independently of U:

$$P_{XYZSU}(x, y, z, s, u)$$
$$= P_S(s) \, P_{XU|S}(x, u|s) \, \mathbf{1}\{y = f(x, s)\} \, W(z|x, s). \tag{3}$$

Here $\mathbf{1}\{\cdot\}$ denotes the indicator function.[2] Moreover, this is also the capacity region when the state sequence is also revealed to the deterministic receiver, i.e., when the mapping $f(\cdot, \cdot)$ is replaced by the mapping $(x, s) \mapsto \big(f(x, s), s\big)$.

Proof: See Sections II and III. ∎

As to the cardinality of the auxiliary random variable U:

Proposition 1: To exhaust the capacity region of the channel (1), we may restrict the auxiliary random variable U in (2) to take value in a set $\mathcal{U}$ whose cardinality $|\mathcal{U}|$ is bounded by

$$|\mathcal{U}| \leq |\mathcal{X}| \cdot |\mathcal{S}| + 1, \tag{4}$$

where $\mathcal{X}$ and $\mathcal{S}$ denote the input and state alphabets.

Proof: See Appendix A. ∎

Broadcast channels *without states* have been studied extensively [3]. Our work can be considered as an extension to broadcast channels with states of prior work by Gel'fand, Marton, and Pinsker on deterministic and semideterministic broadcast channels without states [2], [4]–[8]. State-dependent

[1]To be precise, we should replace 2^{nR_y} and 2^{nR_z} with their integer parts, but, for typographical reasons, we shall not.

[2]The value of $\mathbf{1}\{\text{statement}\}$ is 1 if the statement is true and is 0 otherwise.

broadcast channels were also considered before [9]–[11], but capacity regions of most such channels are still unknown.

Steinberg [9] studied the *degraded* state-dependent broadcast channel with causal and with noncausal state-information at the transmitter. He derived the capacity region for the causal case, but for the noncausal case his outer and inner bounds do not coincide. Steinberg and Shamai [10] then derived an inner bound for general (not necessarily degraded) state-dependent broadcast channels with noncausal state-information. This inner bound is based on Marton's inner bound for broadcast channels without states [7] and on Gel'fand-Pinsker coding [12]. In fact, the direct part of our Theorem 1 can be deduced from [10] with a proper choice of the auxiliary random variables (see Section II-A).

Our proof of the converse part of Theorem 1 borrows from the Gel'fand-Pinsker converse for single-user channels with states [12] as well as from the Körner-Marton [7] and the Nair-El Gamal [13] approaches to outer-bounding the capacity region of broadcast channels without states. But it also has a new element: *the choice/definition of the auxiliary random variable depends on the codebook.* As we demonstrate in Section V, our proof can be extended to general (not necessarily semideterministic) state-dependent broadcast channels.

Some special cases of Theorem 1 were solved by Khosravi-Farsani and Marvasti [11]: the *fully* deterministic case, the case where the states are known to the nondeterministic receiver, and the case where the channel is degraded so $(X,S)\!-\!\!\circ\!\!-\!Y\!-\!\!\circ\!\!-\!Z$ forms a Markov chain.

The rest of this paper is organized as follows. We prove the direct and converse parts of Theorem 1 in Sections II and III. In Section IV we apply Theorem 1 to a specific channel whose nondeterministic output is unaffected by the state. Even so, noncausal state-information is strictly better than causal. We finally derive a new outer bound on general state-dependent broadcast channels in Section V.

II. DIRECT PART

In this section we prove the direct part of Theorem 1. One way to do this is to use [10, Theorem 1] with the choice of the auxiliary random variables that we propose in Section II-A. For completeness and simplicity, we also provide a self-contained proof in Section II-B.

A. *Proof based on [10]*

It was shown in [10, Theorem 1] that the capacity region of a general (not necessarily semideterministic) state-dependent broadcast channel with noncausal state-information at the transmitter contains the convex closure of the union of rate-pairs (R_y, R_z) satisfying

$$R_y \leq I(U_0, U_y; Y) - I(U_0, U_y; S) \tag{5a}$$

$$R_z \leq I(U_0, U_z; Z) - I(U_0, U_z; S) \tag{5b}$$

$$\begin{aligned} R_y + R_z \leq &-\big[\max\{I(U_0; Y), I(U_0; Z)\} - I(U_0; S)\big]^+ \\ &+ I(U_0, U_y; Y) - I(U_0, U_y; S) + I(U_0, U_z; Z) \\ &- I(U_0, U_z; S) - I(U_y; U_z | U_0, S), \end{aligned} \tag{5c}$$

where the union is over all joint distribution on $(X, Y, Z, S, U_0, U_y, U_z)$ whose marginal is P_S; that satisfies the Markov condition

$$(U_0, U_y, U_z)\!-\!\!\circ\!\!-\!(X,S)\!-\!\!\circ\!\!-\!(Y,Z); \tag{6}$$

and under which the conditional law of (Y, Z) given (X, S) is that of the given channel.

For the semideterministic channel, we choose the auxiliary random variables in (5) as follows:

$$U_0 = 0 \quad \text{(deterministic)} \tag{7a}$$

$$U_y = Y \tag{7b}$$

$$U_z = U. \tag{7c}$$

Note that the Markov condition (6) is satisfied because Y is a deterministic function of (X, S) and because in Theorem 1 we restrict U to be such that $U\!-\!\!\circ\!\!-\!(X,S)\!-\!\!\circ\!\!-\!(Y,Z)$. With this choice of U_0, U_y, and U_z, (5) reduces to (2).

B. *Self-contained proof*

We next provide a self-contained proof of the direct part of Theorem 1. As in [10, Theorem 1], our proof is based on Marton's inner bound for general broadcast channels [7], [14] and on Gel'fand-Pinsker coding [12].

First note that the joint distribution (3) can also be written as

$$\begin{aligned} P_{XYZSU}&(x,y,z,s,u) \\ &= P_S(s)\, P_{YU|S}(y,u|s)\, P_{X|YSU}(x|y,s,u)\, W(z|x,s) \end{aligned} \tag{8}$$

with the additional requirement that

$$y = f(x, s). \tag{9}$$

Further note that, when P_{YSU} is fixed, all the terms on the right-hand side (RHS) of (2) are fixed except for $I(U; Z)$, which is convex in $P_{X|YUS}$. Since $I(U; Z)$ only appears with a positive sign on the RHS of (2), it follows that the union over all joint distributions of the form (2) can be replaced by a union only over those where x is a deterministic function of (y, u, s), i.e., of the form

$$\begin{aligned} P_{XYZSU}&(x,y,z,s,u) \\ &= P_S(s)\, P_{YU|S}(y,u|s)\, \mathbf{1}\big\{x = g(y,u,s)\big\}\, W(z|x,s) \end{aligned} \tag{10}$$

for some $g\colon (y,u,s) \mapsto x$ (and subject to (9)). We shall thus only establish the achievability of rate pairs that satisfy (2) for some distribution of the form (10).

Choose a stochastic kernel $P_{YU|S}$ and a mapping $g\colon (y,u,s) \mapsto x$ which, combined with P_S and the channel law, determines the joint distribution (10) for which (9) is satisfied. For a given block-length n, we construct a random code as follows:

Codebook: Generate 2^{nR_y} y-bins, each containing $2^{n\tilde{R}_y}$ y-tuples where the l_y-th y-tuple in the m_y-th bin

$$\mathbf{y}(m_y, l_y), \quad m_y \in \{1, \ldots, 2^{nR_y}\},\, l_y \in \{1, \ldots, 2^{n\tilde{R}_y}\}$$

is generated IID according to P_Y (the Y-marginal of (10)) independently of the other y-tuples. Additionally, generate

2^{nR_z} u-bins, each containing $2^{n\tilde{R}_z}$ u-tuples, where the l_z-th u-tuple in the m_z-th u-bin

$$\mathbf{u}(m_z, l_z), \quad m_z \in \{1, \ldots, 2^{nR_z}\}, \, l_z \in \{1, \ldots, 2^{n\tilde{R}_z}\}$$

is drawn IID according to P_U (the U-marginal of (10)) independently of the other u-tuples and of the y-tuples.

Encoder: To send Message $m_y \in \{1, \ldots, 2^{nR_y}\}$ to the deterministic receiver and Message $m_z \in \{1, \ldots, 2^{nR_z}\}$ to the nondeterministic receiver, look for a y-tuple $\mathbf{y}(m_y, l_y)$ in y-bin m_y and a u-tuple $\mathbf{u}(m_z, l_z)$ in u-bin m_z such that $(\mathbf{y}(m_y, l_y), \mathbf{u}(m_z, l_z))$ is jointly typical with the state sequence $\mathbf{s}$:

$$\big(\mathbf{y}(m_y, l_y), \mathbf{u}(m_z, l_z), \mathbf{s}\big) \in \mathcal{T}_\epsilon^{(n)}(P_{YUS}), \qquad (11)$$

where $\mathcal{T}_\epsilon^{(n)}(\cdot)$ denotes the ϵ-*strongly typical set* with respect to a certain distribution. If such a pair can be found, send

$$\mathbf{x} = g\big(\mathbf{y}(m_y, l_y), \mathbf{u}(m_z, l_z), \mathbf{s}\big), \qquad (12)$$

where in the above $g(\mathbf{y}, \mathbf{u}, \mathbf{s})$ denotes the application of the function $g(y, u, s)$ componentwise. (Note that in this case the sequence received by the deterministic receiver will be $\mathbf{y}(m_y, l_y)$.) Otherwise send an arbitrary codeword.

Deterministic decoder: Try to find the *unique* y-bin, say m'_y, that contains the received sequence $\mathbf{y}$ and output its number m'_y. If there is more than one such bin, declare an error.

Nondeterministic decoder: Try to find the *unique* u-bin m'_z which contains a $\mathbf{u}(m'_z, l'_z)$ that is jointly typical with the received sequence $\mathbf{z}$:

$$\big(\mathbf{u}(m'_z, l'_z), \mathbf{z}\big) \in \mathcal{T}_{2\epsilon}^{(n)}(P_{UZ}), \qquad (13)$$

and output m'_z. If more than one or no such bin can be found, declare an error.

We next analyze the error probability of the above coding scheme. There are three types of errors:

Encoder errs. This happens only if there is no pair $(l_y, l_z) \in \{1, \ldots, 2^{n\tilde{R}_y}\} \times \{1, \ldots, 2^{n\tilde{R}_z}\}$ that satisfies (11). To bound this probability, we use the Multivariate Covering Lemma [2, Lemma 8.2], which we restate as follows:

Lemma 1: Fix some joint distribution $P_{A_{(0)} \cdots A_{(k)}}$ on $(A_{(0)}, \ldots, A_{(k)})$, and fix positive $\tilde{\epsilon}$ and ϵ with $\tilde{\epsilon} < \epsilon$. Let $A_{(0)}^n$ be a random sequence satisfying

$$\lim_{n \to \infty} \Pr\left[A_{(0)}^n \in \mathcal{T}_{\tilde{\epsilon}}^{(n)}(P_{A_{(0)}})\right] = 1. \qquad (14)$$

For each $j \in \{1, \ldots, k\}$, let $A_{(j)}^n(m_j)$, $m_j \in \{1, \ldots, 2^{nr_j}\}$, be pairwise independent conditional on $A_{(0)}^n$, each distributed according to $\prod_{i=1}^n P_{A_{(j)}|A_{(0)}=a_{(0),i}}$. Assume that

$$\left\{A_{(j)}^n(m_j) \colon m_j \in \{1, \ldots, 2^{nr_j}\}\right\}, \quad j \in \{1, \ldots, k\}$$

are mutually independent conditional on $A_{(0)}^n$. Then there exists $\delta(\epsilon)$ which tends to zero as ϵ tends to zero such that

$$\lim_{n \to \infty} \Pr\left[\begin{array}{c}(A_{(0)}^n, A_{(1)}^n(m_1), \ldots, A_{(k)}^n(m_k)) \notin \mathcal{T}_\epsilon^{(n)} \\ \text{for all } (m_1, \ldots, m_k)\end{array}\right] = 0 \qquad (15)$$

provided that, for all $\mathcal{J} \subseteq \{1, \ldots, k\}$ with $|\mathcal{J}| \geq 2$,

$$\sum_{j \in \mathcal{J}} r_j > \sum_{j \in \mathcal{J}} H(A_{(j)}|A_{(0)}) - H(\{A_{(j)} \colon j \in \mathcal{J}\}|A_{(0)}) + \delta(\epsilon), \qquad (16)$$

where the conditional entropies are computed with respect to $P_{A_{(0)} \cdots A_{(k)}}$.

We apply Lemma 1 by choosing $k = 3$, $A_{(0)} = 0$ (deterministic) so $\tilde{\epsilon} = 0$, and

$$A_{(1)} = Y, \quad r_1 = \tilde{R}_y, \qquad (17a)$$
$$A_{(2)} = U, \quad r_2 = \tilde{R}_z, \qquad (17b)$$
$$A_{(3)} = S, \quad r_3 = 0. \qquad (17c)$$

The joint distribution is chosen to be P_{YUS}. We then obtain that the probability that the encoder errs tends to zero as n tends to infinity provided that

$$\tilde{R}_y > I(Y; S) + \delta(\epsilon) \qquad (18a)$$
$$\tilde{R}_z > I(U; S) + \delta(\epsilon) \qquad (18b)$$
$$\tilde{R}_y + \tilde{R}_z > H(Y) + H(U) + H(S)$$
$$\qquad - H(Y, U, S) + \delta(\epsilon). \qquad (18c)$$

Deterministic decoder errs. This happens only if there is more than one bin that contains the received $\mathbf{y}$. We may now assume that the encoding was successful so (11) is satisfied. Then $\mathbf{y}$ is in $\mathcal{T}_\epsilon^{(n)}(P_Y)$, and

$$P_Y(\mathbf{y}) \leq 2^{-n(H(Y)-\delta(\epsilon))} \qquad (19)$$

where $\delta(\epsilon)$ tends to zero when ϵ tends to zero. Hence the probability that a specific y-tuple in a bin that was not chosen by the encoder, which, by our code construction, was independently chosen from the received $\mathbf{y}$, happens to be the same as $\mathbf{y}$, is upper-bounded by the RHS of (19). Further note that the total number of y-tuples outside the bin chosen by the encoder is $2^{n\tilde{R}_y}(2^{nR_y} - 1)$. Using the union bound, we obtain that the probability that the deterministic decoder errs is at most

$$2^{n\tilde{R}_y}(2^{nR_y} - 1) 2^{-n(H(Y)-\delta(\epsilon))}, \qquad (20)$$

which tends to zero as n tends to infinity provided that

$$R_y + \tilde{R}_y < H(Y) - \delta(\epsilon). \qquad (21)$$

Nondeterministic decoder errs. This happens if either the u-tuple $\mathbf{u}(m_z, l_z)$ is not jointly typical with the received z-tuple, or if a u-tuple in a different bin happens to be jointly typical with the received z-tuple. Assuming that the encoding was successful, the probability of the former case tends to zero as n tends to infinity by (11) and by the Markov Lemma [2, Lemma 12.1]. To upper-bound the probability of the latter case, note that any $\mathbf{u}(m'_z, l'_z)$, where $m'_z \neq m_z$, is chosen independently of $\mathbf{u}(m_z, l_z)$ and $\mathbf{y}(m_y, l_y)$, and is hence also independent of the received $\mathbf{z}$. By the Joint Typicality Lemma [2, p.29] we have

$$\Pr\left[(\mathbf{U}(m'_z, l'_z), \mathbf{Z}) \in \mathcal{T}_{2\epsilon}^{(n)}(P_{UZ})\right] \leq 2^{-n(I(U;Z)-\delta(\epsilon))} \qquad (22)$$

where the probability is computed with respect to the randomly chosen codebook. Next note that the total number of such

u-tuples is $2^{n\tilde{R}_z}\left(2^{nR_z}-1\right)$. Applying the union bound, we obtain that the probability that there exists at least one u-tuple that is not in the chosen bin but that is jointly typical with $\mathbf{z}$ is at most

$$2^{n\tilde{R}_z}\left(2^{nR_z}-1\right)2^{-n(I(U;Z)-\delta(\epsilon))}, \tag{23}$$

which tends to zero as n tends to infinity provided that

$$R_z + \tilde{R}_z < I(U;Z) - \delta(\epsilon). \tag{24}$$

Summarizing (18), (21), and (24), and letting ϵ tend to zero, we conclude that the above coding scheme has vanishing error probability as n tends to infinity for all (R_y, R_z) satisfying (2). By time-sharing we further achieve the convex hull of all rate-pairs satisfying (2) for joint distributions of the form (10). This concludes the proof of the direct part of Theorem 1.

III. Converse Part

In this section we show that, even if the state sequence $\mathbf{S}$ is revealed to the deterministic receiver (which observes $\mathbf{Y}$), any achievable rate-pair must be in the convex closure of the union of rate-pairs satisfying (2).

Given any code of block-length n, we first derive a bound on R_y:

$$nR_y = H(M_y) \tag{25}$$
$$\leq I(M_y; Y^n, S^n) + n\epsilon_n \tag{26}$$
$$= I(M_y; Y^n | S^n) + n\epsilon_n \tag{27}$$
$$= \sum_{i=1}^{n} I(M_y; Y_i | Y^{i-1}, S^n) + n\epsilon_n \tag{28}$$
$$\leq \sum_{i=1}^{n} H(Y_i | Y^{i-1}, S^n) + n\epsilon_n \tag{29}$$
$$\leq \sum_{i=1}^{n} H(Y_i | S_i) + n\epsilon_n, \tag{30}$$

where ϵ_n tends to zero as n tends to infinity. Here, (26) follows from Fano's Inequality; (27) because M_y and S^n are independent; (28) from the chain rule; (29) by dropping negative terms; and (30) because conditioning cannot increase entropy.

We next bound R_z as in [12]:

$$nR_z = H(M_z) \tag{31}$$
$$\leq I(M_z; Z^n) + n\epsilon_n \tag{32}$$
$$= \sum_{i=1}^{n} I(M_z; Z_i | Z^{i-1}) + n\epsilon_n \tag{33}$$
$$= \sum_{i=1}^{n} I\left(M_z, S_{i+1}^n; Z_i \big| Z^{i-1}\right)$$
$$\quad - \sum_{i=1}^{n} I\left(S_{i+1}^n; Z_i \big| M_z, Z^{i-1}\right) + n\epsilon_n \tag{34}$$
$$= \sum_{i=1}^{n} I\left(M_z, S_{i+1}^n; Z_i \big| Z^{i-1}\right)$$
$$\quad - \sum_{i=1}^{n} I\left(Z^{i-1}; S_i \big| M_z, S_{i+1}^n\right) + n\epsilon_n \tag{35}$$

$$= \sum_{i=1}^{n} I\left(M_z, S_{i+1}^n; Z_i \big| Z^{i-1}\right)$$
$$\quad - \sum_{i=1}^{n} I\left(M_z, Z^{i-1}, S_{i+1}^n; S_i\right) + n\epsilon_n \tag{36}$$
$$\leq \sum_{i=1}^{n} I\left(M_z, Z^{i-1}, S_{i+1}^n; Z_i\right)$$
$$\quad - \sum_{i=1}^{n} I\left(M_z, Z^{i-1}, S_{i+1}^n; S_i\right) + n\epsilon_n \tag{37}$$
$$= \sum_{i=1}^{n} I(V_i; Z_i) - I(V_i; S_i) + n\epsilon_n. \tag{38}$$

Here, (32) follows from Fano's Inequality; (33) and (34) from the chain rule; (35) from Csiszár's Identity [15]

$$\sum_{i=1}^{n} I\left(C_{i+1}^n; D_i \big| D^{i-1}\right) = \sum_{i=1}^{n} I\left(D^{i-1}; C_i \big| C_{i+1}^n\right); \tag{39}$$

(36) because S_i and (M_z, S_{i+1}^n) are independent; (37) from the chain rule and by dropping negative terms; and (38) by defining the auxiliary random variables

$$V_i \triangleq (M_z, Z^{i-1}, S_{i+1}^n), \quad i \in \{1, \ldots, n\}. \tag{40}$$

We next bound the sum rate $R_y + R_z$:

$$n(R_y + R_z) = H(M_y, M_z) \tag{41}$$
$$= H(M_z) + H(M_y | M_z) \tag{42}$$
$$\leq I(M_z; Z^n) + I(M_y; Y^n, S^n | M_z) + n\epsilon_n, \tag{43}$$

where the last step follows from Fano's Inequality. Of the two mutual informations on the RHS of (43) we first bound $I(M_z; Z^n)$:

$$I(M_z; Z^n) = \sum_{i=1}^{n} I(M_z; Z_i | Z^{i-1}) \tag{44}$$
$$\leq \sum_{i=1}^{n} I(M_z, Z^{i-1}; Z_i) \tag{45}$$
$$= \sum_{i=1}^{n} I\left(M_z, Z^{i-1}, S_{i+1}^n, Y_{i+1}^n; Z_i\right)$$
$$\quad - \sum_{i=1}^{n} I\left(S_{i+1}^n, Y_{i+1}^n; Z_i \big| M_z, Z^{i-1}\right) \tag{46}$$
$$= \sum_{i=1}^{n} I\left(M_z, Z^{i-1}, S_{i+1}^n, Y_{i+1}^n; Z_i\right)$$
$$\quad - \sum_{i=1}^{n} I\left(Z^{i-1}; S_i, Y_i \big| M_z, S_{i+1}^n, Y_{i+1}^n\right) \tag{47}$$
$$= \sum_{i=1}^{n} I\left(M_z, Z^{i-1}, S_{i+1}^n, Y_{i+1}^n; Z_i\right)$$
$$\quad - \sum_{i=1}^{n} I\left(M_z, Z^{i-1}, S_{i+1}^n, Y_{i+1}^n; S_i, Y_i\right)$$
$$\quad + \sum_{i=1}^{n} I\left(M_z, S_{i+1}^n, Y_{i+1}^n; S_i, Y_i\right). \tag{48}$$

Here, (44), (45), and (46) follow from the chain rule; (47) by applying Csiszár's Identity (39) between (S^n, Y^n) and Z^n; and (48) again from the chain rule.

We next study the sum of the last term on the RHS of (48) and the second mutual information on the RHS of (43):

$$\sum_{i=1}^{n} I\left(M_z, S_{i+1}^n, Y_{i+1}^n; S_i, Y_i\right) + I(M_y; Y^n, S^n | M_z)$$

$$= \sum_{i=1}^{n} I\left(M_z, S_{i+1}^n, Y_{i+1}^n; S_i, Y_i\right)$$
$$+ \sum_{i=1}^{n} I\left(M_y; S_i, Y_i \,\middle|\, M_z, S_{i+1}^n, Y_{i+1}^n\right) \quad (49)$$

$$= \sum_{i=1}^{n} I\left(M_y, M_z, S_{i+1}^n, Y_{i+1}^n; S_i, Y_i\right) \quad (50)$$

$$= \sum_{i=1}^{n} I\left(M_y, M_z, S_{i+1}^n, Y_{i+1}^n; S_i, Y_i\right)$$
$$+ \sum_{i=1}^{n} I\left(S^{i-1}; S_i, Y_i \,\middle|\, M_y, M_z, S_{i+1}^n, Y_{i+1}^n\right)$$
$$- \sum_{i=1}^{n} I\left(S_{i+1}^n, Y_{i+1}^n; S_i \,\middle|\, M_y, M_z, S^{i-1}\right) \quad (51)$$

$$= \sum_{i=1}^{n} I\left(M_y, M_z, S^{i-1}, S_{i+1}^n, Y_{i+1}^n; S_i, Y_i\right)$$
$$- \sum_{i=1}^{n} I\left(S_{i+1}^n, Y_{i+1}^n; S_i \,\middle|\, M_y, M_z, S^{i-1}\right) \quad (52)$$

$$= \sum_{i=1}^{n} I\left(M_y, M_z, S^{i-1}, S_{i+1}^n, Y_{i+1}^n; S_i, Y_i\right)$$
$$- \sum_{i=1}^{n} I\left(M_y, M_z, S^{i-1}, S_{i+1}^n, Y_{i+1}^n; S_i\right) \quad (53)$$

$$= \sum_{i=1}^{n} I\left(M_y, M_z, S^{i-1}, S_{i+1}^n, Y_{i+1}^n; Y_i \,\middle|\, S_i\right) \quad (54)$$

$$= \sum_{i=1}^{n} H(Y_i | S_i). \quad (55)$$

Here, (49) and (50) follow from the chain rule; (51) by applying Csiszár's Identity between (S^n, Y^n) and S^n; (52) from the chain rule; (53) because S_i and (M_y, M_z, S^{i-1}) are independent; (54) again from the chain rule; and (55) because, given (M_y, M_z, S^n), the channel inputs X^n are determined by the encoder, and hence Y^n are also determined, so

$$H\left(Y_i \,\middle|\, M_y, M_z, S^n, Y_{i+1}^n\right) = 0. \quad (56)$$

Combining (43), (48), and (55), using the definitions (40), and further defining

$$T_i \triangleq Y_{i+1}^n, \quad i \in \{1, \ldots, n\}, \quad (57)$$

we obtain

$$n(R_y + R_z) \leq \sum_{i=1}^{n} I(V_i, T_i; Z_i) - \sum_{i=1}^{n} I(V_i, T_i; S_i, Y_i)$$
$$+ \sum_{i=1}^{n} H(Y_i | S_i) + n\epsilon_n. \quad (58)$$

Summarizing (30), (38), and (58) and letting n tend to infinity, we obtain that any achievable rate-pair (R_y, R_z) must be contained in the convex closure of the union of rate-pairs satisfying

$$R_y < H(Y|S) \quad (59a)$$
$$R_z < I(V; Z) - I(V; S) \quad (59b)$$
$$R_y + R_z < H(Y|S) + I(V, T; Z) - I(V, T; S, Y) \quad (59c)$$

where, given (X, S), the outputs (Y, Z) are drawn according to the channel law (1) independently of the auxiliary random variables (V, T).

To prove the converse part of Theorem 1, it remains to replace V and T with a single auxiliary random variable. I.e., it remains to find an auxiliary random variable U such that

$$I(V; Z) - I(V; S) \leq I(U; Z) - I(U; S) \quad (60a)$$

and

$$H(Y|S) + I(V, T; Z) - I(V, T; S, Y) \leq$$
$$H(Y|S) + I(U; Z) - I(U; S, Y). \quad (60b)$$

In fact, as we shall see, either choosing U to be V will satisfy (60) or else choosing it to be (V, T) will satisfy (60). If we choose $U = V$, then (60a) is satisfied with equality, and the requirement (60b) becomes

$$I(T; Z|V) - I(T; S, Y|V) \leq 0. \quad (61)$$

On the other hand, if we choose $U = (V, T)$, then (60b) is satisfied with equality, and the requirement (60a) becomes

$$I(T; Z|V) - I(T; S|V) \geq 0. \quad (62)$$

It remains to show that *at least one* of the two requirements (61) and (62) must be satisfied: if it is (61), then we shall choose U as V, and if it is (62), then we shall choose U as (V, T). To this end we note that for all random variables T, Z, V, S, Y

$$I(T; Z|V) - I(T; S, Y|V) \leq I(T; Z|V) - I(T; S|V), \quad (63)$$

because the RHS minus the left-hand side is $I(T; Y|S, V)$, which is nonnegative. This implies that at least one of (61) and (62) must hold. We have thus shown that there must exist a U which satisfies both inequalities in (60), hence the bounds (59) can be relaxed to (2). This concludes the proof of the converse part of Theorem 1.

IV. AN EXAMPLE

Consider a broadcast channel whose input, output, and state alphabets are all binary and whose law is

$$P_S(1) = 1 - P_S(0) = \sigma \quad (64a)$$
$$Y = x \oplus S \quad (64b)$$
$$W(Z = x | x, s) = 1 - W(Z = x \oplus 1 | x, s) = 1 - p \quad (64c)$$

for some constants $0 \leq p, \sigma \leq 1$. The deterministic output Y of this channel is the modulo-two sum of the input x and the state S, and the channel from x to the nondeterministic

output Z is unaffected by the state and is a binary symmetric channel with crossover probability p.

To cancel the state's effect, the encoder could flip the input x whenever $S = 1$, but this would hurt the nondeterministic receiver. In fact, if the state is unbiased ($\sigma = 0.5$), and if *only causal* state-information is available at the encoder,[3] then one cannot do better than time-sharing:

Proposition 2: The capacity region of the channel (64) with $\sigma = 0.5$ when the states are known *causally* to the transmitter but not to the receivers, is the union over $\lambda \in [0, 1]$ of rate-pairs (R_y, R_z) satisfying

$$R_y \leq \lambda \tag{65a}$$
$$R_z \leq (1 - \lambda)\big(1 - H_{\mathrm{b}}(p)\big) \tag{65b}$$

I.e., it is the collection of rate pairs satisfying

$$R_y + \frac{R_z}{1 - H_{\mathrm{b}}(p)} \leq 1. \tag{66}$$

Proof: See Appendix B. ∎

However, with *noncausal* state-information the transmitter can cancel the effect of the state without hurting the nondeterministic receiver:

Proposition 3: The capacity region of the channel (64) when the states are known noncausally to the transmitter but not to the receivers, is the union over $\alpha \in [0, 1]$ of rate-pairs (R_y, R_z) satisfying

$$R_y \leq H_{\mathrm{b}}(\alpha) \tag{67a}$$
$$R_z \leq 1 - H_{\mathrm{b}}(\beta) \tag{67b}$$

where

$$\beta \triangleq \alpha(1 - p) + (1 - \alpha)p. \tag{67c}$$

The capacity regions of the channel (64) when $\sigma = 0.5$ and $p = 0.2$ with noncausal and with causal state-information are depicted in Figure 1.

We present two different proofs for Proposition 3: the first is based on the achievability part of Theorem 1; the second is based on the fact that revealing the states to the deterministic receiver does not increase the capacity region.

First proof of Proposition 3: We let U be a uniform binary random variable that is independent of S, and let X be the outcome of feeding U into a binary symmetric channel of crossover probability α (independently of S). Note that now the channel from U to Z is a binary symmetric channel with crossover probability β as defined in (67c). Using Theorem 1 we obtain that the capacity region contains all rate-pairs (R_y, R_z) satisfying

$$R_y < H(Y|S) = 1 \tag{68}$$
$$R_z < I(U; Z) - I(U; S) \tag{69}$$
$$= \big(1 - H_{\mathrm{b}}(\beta)\big) - 0 \tag{70}$$
$$= 1 - H_{\mathrm{b}}(\beta) \tag{71}$$
$$R_y + R_z < H(Y|S) + I(U; Z) - I(U; S, Y) \tag{72}$$
$$= 1 + \big(1 - H_{\mathrm{b}}(\beta)\big) - I(U; X) \tag{73}$$

---

[3]By "causal" we mean that the transmitter, when transmitting X_i, knows the past and present states S^i but not the future states S_{i+1}^n.

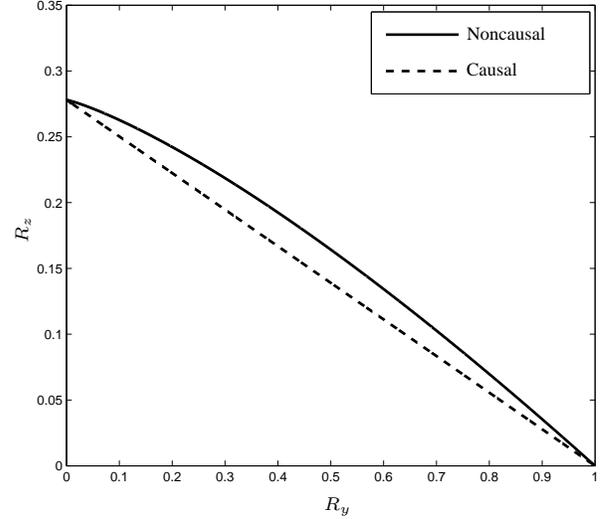

Fig. 1. The capacity regions of the channel (64) when $\sigma = 0.5$ and $p = 0.2$ with noncausal (solid line) and with causal (dashed line) state-information at the transmitter.

$$= 1 + \big(1 - H_{\mathrm{b}}(\beta)\big) - \big(1 - H_{\mathrm{b}}(\alpha)\big) \tag{74}$$
$$= 1 - H_{\mathrm{b}}(\beta) + H_{\mathrm{b}}(\alpha) \tag{75}$$

where (73) follows because X can be computed from S and Y, and because, given X, U is independent of (S, Y). Taking the convex closure of (68), (71), and (75) over $\alpha \in [0, 1]$, we obtain the region characterized by (67).

To see that one cannot do better than (67), we observe that the capacity region of the channel (64) with states known noncausally to the transmitter must be contained in the capacity region when the states are also known to both receivers. The latter case, however, is equivalent to the following broadcast channel without states:

$$y = x \tag{76a}$$
$$W(Z = x|x) = 1 - W(Z = x \oplus 1|x) = 1 - p. \tag{76b}$$

The capacity region of (76) can be found in [1, Example 15.6.5] and is the same as the region characterized by (67). ∎

Second proof of Proposition 3: By Theorem 1, the capacity region of the channel (64) with states known noncausally to the transmitter is unchanged if the states are also revealed to the deterministic receiver. When S is revealed to the deterministic receiver, it can form $Y \oplus S$ and thus recover x. This reduces the channel to the one without states (76). Hence the capacity region of interest is the same as the capacity region of (76), which is given by the union over $\alpha \in [0, 1]$ of rate-pairs satisfying (67) [1, Example 15.6.5]. ∎

V. A GENERAL OUTER BOUND

We next generalize our converse of Section III to a broadcast channel that is not necessarily semideterministic. Such a channel is described by the transition law and the state law

$$\Pr[Y = y, Z = z|X = x, S = s] = W(y, z|x, s) \tag{77a}$$
$$\Pr[S = s] = P_S(s). \tag{77b}$$

We let the state sequence $\mathbf{S}$ be known noncausally to the transmitter and also known to the receiver which observes Y. The capacity region is defined in the same way as for the semideterministic broadcast channel. In particular, we consider only two private messages.

Applying the techniques of Section III, we obtain the following outer bound on the capacity region of the channel (77). (The bound is tight for semideterministic channels.)

Proposition 4: The capacity region of the channel (77), with the state sequence being revealed noncausally to the transmitter and also revealed to the receiver which observes Y, is contained in the convex closure of rate-pairs satisfying

$$R_y < I(X;Y|S) \tag{78a}$$
$$R_z < I(U;Z) - I(U;S) \tag{78b}$$
$$R_y + R_z < I(X;Y|S) + I(U;Z) - I(U;S,Y) \tag{78c}$$

for joint distributions of the form

$$P_{XYZSU}(x,y,z,s,u) = P_S(s)\,P_{XU|S}(x,u|s)\,W(y,z|x,s). \tag{79}$$

Proof: To bound R_y, we note that (28) holds also for the general broadcast channel (77), and we continue (28) as follows:

$$nR_y \leq \sum_{i=1}^{n} I(M_y;Y_i|Y^{i-1},S^n) + n\epsilon_n \tag{80}$$

$$\leq \sum_{i=1}^{n} I(M_y,X_i;Y_i|Y^{i-1},S^n) + n\epsilon_n \tag{81}$$

$$= \sum_{i=1}^{n} H(Y_i|Y^{i-1},S^n) - H(Y_i|X_i,S_i) + n\epsilon_n \tag{82}$$

$$\leq \sum_{i=1}^{n} I(X_i;Y_i|S_i) + n\epsilon_n. \tag{83}$$

Here (82) follows because, given (X_i,S_i), the channel output Y_i is independent of $(M_y,Y^{i-1},S^{i-1},S_{i+1}^n)$.

We bound R_z exactly as (38) with V_i, $i \in \{1,\ldots,n\}$, defined as in (40).

To bound the sum-rate $R_y + R_z$, note that (43), (48), and (54) still hold, but (55) should be replaced by

$$\sum_{i=1}^{n} I\big(M_y,M_z,S^{i-1},S_{i+1}^n,Y_{i+1}^n;Y_i\big|S_i\big) = \sum_{i=1}^{n} I(X_i;Y_i|S_i), \tag{84}$$

which is true because (M_y,M_z,S^n) determines X_i, and because, without feedback, given (X_i,S_i), the output Y_i is independent of $(M_y,M_z,S^{i-1},S_{i+1}^n,Y_{i+1}^n)$. These together yield

$$n(R_y + R_z) \leq \sum_{i=1}^{n} I(V_i,T_i;Z_i) - \sum_{i=1}^{n} I(V_i,T_i;S_i,Y_i)$$
$$+ \sum_{i=1}^{n} I(X_i;Y_i|S_i) + n\epsilon_n, \tag{85}$$

where T_i, $i \in \{1,\ldots,n\}$, are defined in (57).

Summarizing (83), (38), and (85) we conclude that the desired capacity region is contained in the convex closure of rate-pairs (R_y, R_z) satisfying

$$R_y < I(X;Y|S) \tag{86a}$$
$$R_z < I(V;Z) - I(V;S) \tag{86b}$$
$$R_y + R_z < I(X;Y|S) + I(V,T;Z) - I(V,T;S,Y) \tag{86c}$$

where, given (X,S), the outputs (Y,Z) are drawn according to the channel law (77) independently of the auxiliary random variables (V,T). Now to prove Proposition 4 it remains to find a single auxiliary random variable U satisfying

$$I(V;Z) - I(V;S) \leq I(U;Z) - I(U;S) \tag{87a}$$

and

$$I(X;Y|S) + I(V,T;Z) - I(V,T;S,Y)$$
$$\leq I(X;Y|S) + I(U;Z) - I(U;S,Y) \tag{87b}$$

to replace both V and T. Now note that (87) is equivalent to (60). Hence, according to our arguments in Section III, such a U can always be found. ∎

APPENDIX A
PROOF OF PROPOSITION 1

It suffices to show that, given any joint distribution P_{XYZSU} of the form (3), there exists another distribution $\tilde{P}_{XYZSU}$ of the same form

$$\tilde{P}_{XYZSU}(x,y,z,s,u)$$
$$= P_S(s)\,\tilde{P}_{XU|S}(x,u|s)\,\mathbf{1}\{y = f(x,s)\}\,W(z|x,s) \tag{88}$$

satisfying

$$\left|\left\{u\colon \tilde{P}_U(u) > 0\right\}\right| \leq |\mathcal{X}| \cdot |\mathcal{S}| + 1, \tag{89}$$

where $\tilde{P}_U$ denotes the marginal of $\tilde{P}_{XYZSU}$ on U, and

$$H(Y|S)\big|_P = H(Y|S)\big|_{\tilde{P}} \tag{90a}$$
$$I(U;Z) - I(U;S)\big|_P = I(U;Z) - I(U;S)\big|_{\tilde{P}} \tag{90b}$$
$$H(Y|S) + I(U;Z) - I(U;S,Y)\big|_P$$
$$= H(Y|S) + I(U;Z) - I(U;S,Y)\big|_{\tilde{P}}. \tag{90c}$$

To this end, consider the following $|\mathcal{X}| \cdot |\mathcal{S}| + 1$ functions of u, all of which are determined by the conditional distribution $P_{XYZS|U}$ and are independent of the marginal P_U:

$$h_0(u) \triangleq H(S|U = u) - H(Z|U = u) \tag{91a}$$
$$h_1(u) \triangleq H(Y,S|U = u) - H(Z|U = u) \tag{91b}$$
$$h_{x,s}(u) \triangleq P_{XS|U}(x,s|u),$$
$$x \in \mathcal{X}, s \in \mathcal{S}, (x,s) \neq (1,1). \tag{91c}$$

We now look for a $\tilde{P}_U$ (which will replace P_U) such that

$$\sum_{u \in \mathcal{U}} \tilde{P}_U(u) h_0(u) = H(S|U) - H(Z|U)\big|_P \tag{92a}$$
$$\sum_{u \in \mathcal{U}} \tilde{P}_U(u) h_1(u) = H(Y,S|U) - H(Z|U)\big|_P \tag{92b}$$
$$\sum_{u \in \mathcal{U}} \tilde{P}_U(u) h_{x,s}(u) = P_{XS}(x,s),$$
$$x \in \mathcal{X}, s \in \mathcal{S}, (x,s) \neq (1,1). \tag{92c}$$

By the Support Lemma [2, p.631], such a $\tilde{P}_U$ can be found whose support-size is at most the total number of constraints, which equals $|\mathcal{X}| \cdot |\mathcal{S}| + 1$. Choosing

$$\tilde{P}_{XYZSU}(x,y,z,s,u) \triangleq \tilde{P}_U(u)\, P_{XYZS|U}(x,y,z,s|u) \quad (93)$$

for all (x,y,z,s,u) yields a joint distribution that satisfies (89). We next show that this choice also satisfies (88) and (90). First note that (92c) implies that $\tilde{P}_{XYZUS}$ has the same marginal on (X,S) as P_{XYZUS}. In particular,

$$\tilde{P}_S(s) = P_S(s), \quad s \in \mathcal{S}. \quad (94)$$

This combined with the fact that we used the conditional distribution $P_{XYZS|U}$ to generate $\tilde{P}_{XYZSU}$ shows that $\tilde{P}_{XYZSU}$ is indeed of the form (88). Furthermore, these imply that

$$\tilde{P}_{XYZS}(x,y,z,s) = P_{XYZS}(x,y,z,s) \quad (95)$$

for all (x,y,z,s). Hence we have

$$H(Y|S)\big|_{\tilde{P}} = H(Y|S)\big|_P \quad (96a)$$
$$H(Z) - H(S)\big|_{\tilde{P}} = H(Z) - H(S)\big|_P \quad (96b)$$
$$H(Z) - H(Y,S)\big|_{\tilde{P}} = H(Z) - H(Y,S)\big|_P. \quad (96c)$$

On the other hand, (92a) and (92b) imply

$$H(S|U) - H(Z|U)\big|_{\tilde{P}} = H(S|U) - H(Z|U)\big|_P \quad (97a)$$
$$H(Y,S|U) - H(Z|U)\big|_{\tilde{P}} = H(Y,S|U) - H(Z|U)\big|_P. \quad (97b)$$

Combining (96) and (97) yields (90) and concludes the proof.

APPENDIX B
PROOF OF PROPOSITION 2

To prove Proposition 2, we need the following simple outer bound on the capacity region of any broadcast channel with causal state-information:

Lemma 2: The capacity region of any state-dependent two-receiver broadcast channel as in (77) with causal state-information at the transmitter is contained in the convex closure of the union of the rate pairs satisfying

$$R_y < I(T;Y) \quad (98a)$$
$$R_z < I(T;Z) \quad (98b)$$

where the union is over all joint distributions of the form

$$P_{XYZST}(x,y,z,s,t)$$
$$= P_S(s)\, P_T(t)\, \mathbf{1}\{x = g(t,s)\}\, W(y,z|x,s). \quad (99)$$

Proof: We bound R_y as for single-user channels with causal state-information [2], [16] as follows:

$$nR_y \leq I(M_y; Y^n) + n\epsilon_n \quad (100)$$
$$\leq I(M_y, M_z; Y^n) + n\epsilon_n \quad (101)$$
$$= \sum_{i=1}^n I(M_y, M_z; Y_i | Y^{i-1}) + n\epsilon_n \quad (102)$$
$$\leq \sum_{i=1}^n I(M_y, M_z, Y^{i-1}; Y_i) + n\epsilon_n \quad (103)$$
$$\leq \sum_{i=1}^n I(M_y, M_z, S^{i-1}, Y^{i-1}; Y_i) + n\epsilon_n \quad (104)$$

$$= \sum_{i=1}^n I(M_y, M_z, S^{i-1}, X^{i-1}, Y^{i-1}; Y_i) + n\epsilon_n \quad (105)$$
$$= \sum_{i=1}^n I(M_y, M_z, S^{i-1}, X^{i-1}; Y_i) + n\epsilon_n \quad (106)$$
$$= \sum_{i=1}^n I(M_y, M_z, S^{i-1}; Y_i) + n\epsilon_n. \quad (107)$$

Here, (105) and (107) follow because X^{i-1} is a function of (M_y, M_z, S^{i-1}); and (106) because, given $(M_y, M_z, S^{i-1}, X^{i-1})$, the output Y_i is independent of Y^{i-1}. In the same way we can obtain

$$nR_z \leq \sum_{i=1}^n I(M_y, M_z, S^{i-1}; Z_i). \quad (108)$$

We define

$$T_i \triangleq (M_y, M_z, S^{i-1}), \quad i \in \{1, \ldots, n\} \quad (109)$$

which clearly satisfy the conditions

$$T_i \perp\!\!\!\perp S_i, \quad T_i \multimap (X_i, S_i) \multimap (Y_i, Z_i), \quad i \in \{1, \ldots, n\}. \quad (110)$$

We now have

$$nR_y \leq \sum_{i=1}^n I(T_i; Y_i) + n\epsilon_n \quad (111a)$$
$$nR_z \leq \sum_{i=1}^n I(T_i; Z_i) + n\epsilon_n, \quad (111b)$$

which imply that the capacity region of interest is contained in the convex closure of (98) for distributions on (X,Y,Z,S,T) satisfying

$$T \perp\!\!\!\perp S, \quad T \multimap (X,S) \multimap (Y,Z). \quad (112)$$

It now only remains to show that, to exhaust this region, it suffices to consider joint distributions in which X is a function of (T,S). This is indeed the case because, given $P_{TS}(t,s)$ and the channel law, both terms on the RHS of (98) are convex in $P_{X|TS}$. ∎

We next proceed to prove Proposition 2. We begin with the achievability part, which is straightforward. If the transmitter only communicates to the receiver which observes Y, then it can cancel the interference of S by flipping the input symbol whenever $S = 1$. In this way the rate-pair

$$(R_y, R_z) = (1, 0) \quad (113)$$

can be achieved. On the other hand, if the transmitter only communicates to the receiver which observes Z, then it can ignore S and achieve the rate-pair

$$(R_y, R_z) = (0, 1 - H_{\mathrm{b}}(p)). \quad (114)$$

Time-sharing between (113) and (114) achieves the claimed capacity region.

To prove the converse part, we use Lemma 2. Note that the auxiliary random variable T in Lemma 2 can be restricted to take value in all "input strategies" [16]. Namely, its alphabet

is the set of all mappings from $\mathcal{S}$ to $\mathcal{X}$. There are four such mappings:

$$T = 0: \quad \text{maps 0 to 0 and 1 to 0} \tag{115a}$$
$$T = 1: \quad \text{maps 0 to 1 and 1 to 1} \tag{115b}$$
$$T = 2: \quad \text{maps 0 to 0 and 1 to 1} \tag{115c}$$
$$T = 3: \quad \text{maps 0 to 1 and 1 to 0.} \tag{115d}$$

Here, $T = 0$ or 1 means sending a fixed x independently of S, and $T = 2$ or 3 means flipping x whenever $S = 1$. Using the "fixed" strategies $T = 0$ or 1 one can transmit information to the receiver which observes Z but not to the receiver which observes Y:

$$H(Y|T = 0) = H(Y|T = 1) = 1 \tag{116}$$
$$H(Z|T = 0) = H(Z|T = 1) = 1 - H_{\mathrm{b}}(p); \tag{117}$$

while using the "flipped" strategies $T = 2$ or 3 one can transmit information to the receiver which observes Y but not to the receiver which observes Z:

$$H(Y|T = 2) = H(Y|T = 3) = 0 \tag{118}$$
$$H(Z|T = 2) = H(Z|T = 3) = 1. \tag{119}$$

We now have

$$R_y \le I(T;Y) \tag{120}$$
$$= H(Y) - H(Y|T) \tag{121}$$
$$= H(Y) - P_T(0)H(Y|T = 0)$$
$$\quad - P_T(1)H(Y|T = 1) \tag{122}$$
$$\le 1 - \Pr\big[T \in \{0,1\}\big] \cdot 1 \tag{123}$$
$$= \Pr\big[T \in \{2,3\}\big] \tag{124}$$
$$R_z \le I(T;Z) \tag{125}$$
$$= H(Z) - H(Z|T) \tag{126}$$
$$= H(Z) - P_T(0)H(Z|T = 0) - P_T(1)H(Z|T = 1)$$
$$\quad - P_T(2)H(Z|T = 2) - P_T(3)H(Z|T = 3) \tag{127}$$
$$\le 1 - \Pr\big[T \in \{0,1\}\big] \cdot (1 - H_{\mathrm{b}}(p))$$
$$\quad - \Pr\big[T \in \{2,3\}\big] \cdot 1 \tag{128}$$
$$= \big(1 - \Pr\big[T \in \{2,3\}\big]\big) \cdot (1 - H_{\mathrm{b}}(p)). \tag{129}$$

Denoting

$$\lambda \triangleq \Pr\big[T \in \{2,3\}\big] \tag{130}$$

we see that (R_y, R_z) indeed must satisfy (98). This ends our proof of Proposition 2.
