# REPRESENTATIONS OF SOME LATTICES INTO THE GROUP OF ANALYTIC DIFFEOMORPHISMS OF THE SPHERE $\mathbb{S}^2$

by

Julie Déserti

#### November 19, 2018

**Abstract.** — In [10] it is proved that any morphism from a subgroup of finite index of  $SL(n,\mathbb{Z})$  to the group of analytic diffeomorphisms of  $\mathbb{S}^2$  has a finite image as soon as  $n \geq 5$ . The case n = 4 is also claimed to follow along the same arguments; in fact this is not straightforward and this case indeed needs a modification of the argument. In this paper we recall the strategy for  $n \geq 5$  and then focus on the case n = 4. 2010 Mathematics Subject Classification. — 58D05, 58B25

## 1. Introduction

After the works of Margulis ([14, 19]) on the linear representations of lattices of simple, real Lie groups with  $\mathbb{R}$ -rank larger than 1, some authors, like Zimmer, suggest to study the actions of lattices on compact manifolds ([20, 21, 22, 23]). One of the main conjectures of this program is the following: let us consider a connected, simple, real Lie group G and let  $\Gamma$  be a lattice of G of  $\mathbb{R}$ -rank larger than 1. If there exists a morphism of infinite image from  $\Gamma$  to the group of diffeomorphisms of a compact manifold M, then the  $\mathbb{R}$ -rank of G is bounded by the dimension of M. There are a lot of contributions in that direction ([3, 4, 5, 7, 8, 9, 10, 11, 16, 17]). In this article we will focus on the embeddings of subgroups of finite index of  $SL(n, \mathbb{Z})$  into the group  $Diff^{\omega}(\mathbb{S}^2)$  of real analytic diffeomorphisms of  $\mathbb{S}^2$  (see [10]).

The article is organized as follows. First of all we will recall the strategy of [10]: the study of the nilpotent subgroups of Diff $^{\omega}(\mathbb{S}^2)$  implies that such subgroups are metabelian. But subgroups of finite index of  $SL(n,\mathbb{Z})$ , for  $n \geq 5$ , contain nilpotent subgroups of length n-1 of finite index which are not metabelian; as a consequence Ghys gets the following statement.

**Theorem** A ([10]). — Let  $\Gamma$  be a subgroup of finite index of  $SL(n,\mathbb{Z})$ . As soon as  $n \ge 5$  there is no embedding of  $\Gamma$  into  $Diff^{\omega}(\mathbb{S}^2)$ .

To study nilpotent subgroups of  $\mathrm{Diff}^\omega(\mathbb{S}^2)$  one has to study nilpotent subgroups of  $\mathrm{Diff}^\omega_+(\mathbb{S}^1)$  (see §2) and then nilpotent subgroups of the group of formal diffeomorphisms of  $\mathbb{C}^2$  (see §3). The last section is devoted to establish the following result.

The author is supported by the Swiss National Science Foundation grant no PP00P2\_128422 /1 and the A.N.R. project "BirPol".

**Theorem B.** — Let  $\Gamma$  be a subgroup of finite index of  $SL(n,\mathbb{Z})$ . As soon as  $n \ge 4$  there is no embedding of  $\Gamma$  into  $Diff^{\omega}(\mathbb{S}^2)$ .

The proof relies on the characterization, up to isomorphism, of nilpotent subalgebras of length 3 of the algebra of formal vector fields of  $\mathbb{C}^2$  which vanish at the origin.

**Acknowledgements.** — The author would like to thank Dominique Cerveau and Étienne Ghys for interesting discussions and advices.

## 2. Nilpotent subgroups of the group of analytic diffeomorphisms of $\mathbb{S}^1$

Let G be a group; let us set

$$G^{(0)} = G$$
 &  $G^{(i)} = [G, G^{(i-1)}] \ \forall i \ge 1.$ 

The group G is *nilpotent* if there exists an integer n such that  $G^{(n)} = \{id\}$ ; the *length of nilpotence* of G is the smallest integer k such that  $G^{(k)} = \{id\}$ .

Set

$$G_{(0)} = G$$
 &  $G_{(i)} = [G_{(i-1)}, G_{(i-1)}] \quad \forall i \ge 1.$ 

The group G is *solvable* if  $G_{(n)} = \{id\}$  for a certain n; the *length of solvability* of G is the smallest integer k such that  $G_{(k)} = \{id\}$ .

We say that the group G (resp. algebra  $\mathfrak{g}$ ) is metabelian if [G,G] (resp.  $[\mathfrak{g},\mathfrak{g}]$ ) is abelian.

**Proposition 2.1** ([10]). — Any nilpotent subgroup of  $\mathrm{Diff}^{\omega}_{+}(\mathbb{S}^{1})$  is abelian.

*Proof.* — Let G be a nilpotent subgroup of  $\mathrm{Diff}^{\omega}_{+}(\mathbb{S}^{1})$ . Assume that G is not abelian; it thus contains a Heisenberg group

$$\langle f, g, h | [f, g] = h, [f, h] = [g, h] = id \rangle.$$

The application "rotation number"

$$\operatorname{Diff}^{\omega}_{+}(\mathbb{S}^{1}) \to \mathbb{R}/\mathbb{Z}, \qquad \qquad \psi \mapsto \lim_{n \to +\infty} \frac{\psi^{n}(x) - x}{n}$$

is not a morphism but its restriction to a solvable subgroup is ([1]). Thus the rotation number of h is zero and the set Fix(h) of fixed points of h is non-empty and finite. Considering some iterates of f and g instead of f and g one can assume that f and g fix any point of Fix(h). The set of fixed points of a non trivial element of  $\langle f, g \rangle$  is finite and invariant by h so the action of  $\langle f, g \rangle$  is free (1) on each component of  $\mathbb{S}^1 \setminus Fix(h)$ . But the action of a free group on  $\mathbb{R}$  is abelian: contradiction.

<sup>1.</sup> The stabilizer of every point is trivial, *i.e.* the action of a non trivial element of  $\langle f, g \rangle$  has no fixed point.

## 3. Nilpotent subgroups of the group of formal diffeomorphisms of $\mathbb{C}^2$

Let us denote  $\widehat{\mathrm{Diff}}(\mathbb{C}^2,0)$  the group of formal diffeomorphisms of  $\mathbb{C}^2$ , *i.e.* the formal completion of the group of germs of holomorphic diffeomorphisms at 0. For any i let  $\widehat{\mathrm{Diff}}_i$  be the quotient of  $\widehat{\mathrm{Diff}}(\mathbb{C}^2,0)$  by the normal subgroups of formal diffeomorphisms tangent to the identity with multiplicity i; it can be viewed as the set of jets of diffeomorphisms at order i with the law of composition with truncation at order i. Note that  $\widehat{\mathrm{Diff}}_i$  is a complex linear algebraic group. One can see  $\widehat{\mathrm{Diff}}(\mathbb{C}^2,0)$  as the projective limit of the  $\widehat{\mathrm{Diff}}_i$ 's:  $\widehat{\mathrm{Diff}}(\mathbb{C}^2,0) = \lim_{\leftarrow} \widehat{\mathrm{Diff}}_i$ . Let us denote by  $\widehat{\chi}(\mathbb{C}^2,0)$  the algebra of formal vector fields in  $\mathbb{C}^2$  vanishing at 0. One can define the set  $\chi_i$  of the i-th jets of vector fields; one has  $\lim \chi_i = \widehat{\chi}(\mathbb{C}^2,0)$ .

Let  $\widehat{O}(\mathbb{C}^2)$  be the ring of formal series in two variables and let  $\widehat{K}(\mathbb{C}^2)$  be its fraction field;  $O_i$  is the set of elements of  $\widehat{O}(\mathbb{C}^2)$  truncated at order i.

The family  $(\exp_i : \chi_i \to \operatorname{Diff}_i)_i$  is filtered, *i.e.* compatible with the truncation. We then define the exponential application as follows:  $\exp = \limsup_i : \widehat{\chi}(\mathbb{C}^2, 0) \to \widehat{\operatorname{Diff}}(\mathbb{C}^2, 0)$ .

As in the classical case, if X belongs to  $\widehat{\chi}(\mathbb{C}^2,0)$ , then  $\exp(X)$  can be seen as the "flow at time 1" of X. Indeed an element  $X_i$  of  $\chi_i$  can be seen as a derivation of  $O_i$ ; so it can be written  $S_i + N_i$  where  $S_i$  and  $N_i$  are two semi-simple, resp. nilpotent derivations which commute. Taking the limit, one gets X = S + N where S is a semi-simple vector field and N a nilpotent one and  $[S,N] = \operatorname{id}(see\ [15])$ . A semi-simple vector field is a formal vector field conjugate to a diagonal linear vector field which is complete. A vector field is nilpotent if and only if its linear part is; let us remark that the usual flow  $\varphi_t$  of a nilpotent vector field is polynomial in t

$$\varphi_t(x) = \sum_{I} P_I(t) x^I, \qquad P_I \in (\mathbb{C}[t])^2$$

so  $\varphi_1(x)$  is well defined. As a consequence  $\exp(tX) = \exp(tS)\exp(tN)$  is well defined for t = 1. Note that the Jordan decomposition is purely formal: if X is holomorphic, S and N are not necessary holomorphic.

**Proposition 3.1** ([10]). — Any nilpotent subalgebra of  $\widehat{\chi}(\mathbb{C}^2,0)$  is metabelian.

*Proof.* — Let  $\mathfrak{l}$  be a nilpotent subalgebra of  $\widehat{\chi}(\mathbb{C}^2,0)$  and let  $Z(\mathfrak{l})$  be its center. Since  $\widehat{\chi}(\mathbb{C}^2,0)\otimes\widehat{K}(\mathbb{C}^2)$  is a vector space of dimension 2 over  $\widehat{K}(\mathbb{C}^2)$  one has the following alternative:

- the dimension of the subspace generated by  $Z(\mathfrak{l})$  in  $\widehat{\chi}(\mathbb{C}^2,0)\otimes\widehat{K}(\mathbb{C}^2)$  is 1;
- the dimension of the subspace generated by  $Z(\mathfrak{l})$  in  $\widehat{\chi}(\mathbb{C}^2,0)\otimes\widehat{K}(\mathbb{C}^2)$  is 2.

Let us study these different cases.

Under the first assumption there exists an element X of  $Z(\mathfrak{l})$  having the following property: any vector field of  $Z(\mathfrak{l})$  can be written uX with u in  $\widehat{K}(\mathbb{C}^2)$ . Let us consider the subalgebra  $\mathfrak{g}$  of  $\mathfrak{l}$  given by

$$\mathfrak{g} = \big\{ \widetilde{X} \in \mathfrak{l} \, | \, \exists \, u \in \widehat{K}(\mathbb{C}^2), \, \widetilde{X} = uX \big\}.$$

Since X belongs to  $Z(\mathfrak{l})$ , the algebra  $\mathfrak{g}$  is abelian; it is also an ideal of  $\mathfrak{l}$ . Let us assume that  $\mathfrak{l}$  is not abelian: let Y be an element of  $\mathfrak{l}$  whose projection on  $\mathfrak{l}/\mathfrak{g}$  is non trivial and central. Any vector field of  $\mathfrak{l}$  can be written as uX + vY with u, v in  $\widehat{K}(\mathbb{C}^2)$ . As X belongs to  $Z(\mathfrak{l})$  and Y is central modulo  $\mathfrak{g}$  one has

$$X(u) = X(v) = Y(v) = 0.$$

The vector fields  $\frac{\partial}{\partial x}$  and  $\frac{\partial}{\partial y}$  being some linear combinations of X and Y with coefficients in  $\widehat{K}(\mathbb{C}^2,0)$ , the partial derivatives of v are zero so v is a constant. Therefore  $[\mathfrak{l},\mathfrak{l}] \subset \mathfrak{g}$ ; but  $\mathfrak{g}$  is abelian so  $\mathfrak{l}$  is metabelian.

In the second case  $Z(\mathfrak{l})$  has two elements X and Y which are linearly independent on  $\widehat{K}(\mathbb{C}^2)$ . Any vector field of  $\mathfrak{l}$  can be written as uX + vY with u and v in  $\widehat{K}(\mathbb{C}^2)$ . Since X and Y belong to  $Z(\mathfrak{l})$  one has

$$X(u) = X(v) = Y(u) = Y(v) = 0.$$

As a consequence u and v are constant, i.e.  $l \subset \{uX + vY \mid u, v \in \mathbb{C}\}$ ; in particular l is abelian.

**Proposition 3.2** ([10]). — Any nilpotent subgroup of  $\widehat{\text{Diff}}(\mathbb{C}^2,0)$  is metabelian.

*Proof.* — Let G be a nilpotent subgroup of  $\widehat{\text{Diff}}(\mathbb{C}^2,0)$  of length k. Let us denote  $G_i$  the projection of G on  $\widehat{\text{Diff}}_i$ . The Zariski closure  $\overline{G_i}$  of  $G_i$  in  $\widehat{\text{Diff}}_i$  is an algebraic nilpotent subgroup of length k. It is sufficient to prove that  $\overline{G_i}$  is metabelian.

Since  $\overline{G_i}$  is a complex algebraic subgroup it is the direct product of the subgroup  $\overline{G_{i,u}}$  of its unipotent elements and the subgroup  $\overline{G_{i,s}}$  of its semi-simple elements (*see for example* [2]).

An element of Diff<sub>i</sub> is unipotent if and only if its linear part, which is in  $GL(2,\mathbb{C})$ , is; so  $\overline{G_{i,s}}$  projects injectively onto a nilpotent subgroup of  $GL(2,\mathbb{C})$ . Therefore  $\overline{G_{i,s}}$  is abelian.

Let us now consider  $\overline{G_{i,u}}$ ; this group is the exponential of a nilpotent Lie algebra  $\mathfrak{l}_i$  of  $\chi_i$  of length k. Taking the limit one thus obtains the existence of a nilpotent subalgebra  $\mathfrak{l}$  of  $\widehat{\chi}(\mathbb{C}^2,0)$  of length k such that  $\exp(\mathfrak{l})$  projects onto  $\overline{G_{i,u}}$  for any i. According to Proposition 3.1 the subalgebra  $\mathfrak{l}$  and thus  $\overline{G_{i,u}}$  are metabelian.  $\square$ 

# 4. Nilpotent subgroups of the group of analytic diffeomorphisms of $\mathbb{S}^2$

**Proposition 4.1** ([10]). — Any nilpotent subgroup of Diff $^{\omega}(\mathbb{S}^2)$  has a finite orbit.

*Proof.* — Let G be a nilpotent subgroup of  $Diff^{\omega}(\mathbb{S}^2)$ ; up to finite index one can assume that the elements of G preserve the orientation. Let  $\phi$  be a non trivial element of G which commutes with G. Let  $Fix(\phi)$  be the set of fixed points of  $\phi$ ; it is a non empty analytic subspace of  $\mathbb{S}^2$  invariant by G. If p is an isolated fixed point of  $\phi$ , then the orbit of p under the action of G is finite. So it is sufficient to study the case where  $Fix(\phi)$  only contains curves; there are thus two possibilities:

- Fix( $\phi$ ) is a singular analytic curve whose set of singular points is a finite orbit for G;
- Fix( $\phi$ ) is a smooth analytic curve, not necessary connected. One of the connected component of  $\mathbb{S}^2 \setminus \operatorname{Fix}(\phi)$  is a disk denoted  $\mathbb{D}$ . Any subgroup  $\Gamma$  of finite index of G which contains  $\phi$  fixes  $\mathbb{D}$ . Let us consider an element  $\gamma$  of  $\Gamma$  and a fixed point m of  $\gamma$  which is in  $\overline{\mathbb{D}}$ . By construction  $\phi$  has no fixed point in  $\mathbb{D}$  so according to the Brouwer Theorem  $(\phi^k(m))_k$  has a limit point on the boundary  $\partial \mathbb{D}$  of  $\overline{\mathbb{D}}$ . Therefore  $\gamma$  has at least one fixed point on  $\partial \mathbb{D}$ . The group  $\Gamma$  thus acts on the circle  $\partial \mathbb{D}$  and any of its elements has a fixed point on  $\mathbb{D}$ . Then  $\Gamma$  has a fixed point on  $\partial \mathbb{D}$  (Proposition 2.1).

**Theorem 4.2** ([10]). — Any nilpotent subgroup of Diff $^{\omega}(\mathbb{S}^2)$  is metabelian.

*Proof.* — Let G be a nilpotent subgroup of  $Diff^{\omega}(\mathbb{S}^2)$  and let  $\Gamma$  be a subgroup of finite index of G having a fixed point m (such a subgroup exists according to Proposition 4.1). One can embed  $\Gamma$  into  $\widehat{Diff}(\mathbb{R}^2,0)$ , and so into  $\widehat{Diff}(\mathbb{C}^2,0)$ , by considering the jets of infinite order of elements of  $\Gamma$  in m. According to Proposition 3.2 the group  $\Gamma$  is metabelian.

One can assume that G is a finitely generated group.

Let us first assume that G has no element of finite order. Then G is a cocompact lattice of the nilpotent, simply connected Lie group  $G \otimes \mathbb{R}$  (see [18]). The group G is metabelian if and only if  $G \otimes \mathbb{R}$  is; but  $\Gamma$  is metabelian so  $G \otimes \mathbb{R}$  also.

Finally let us consider the case where G has at least one element of finite order. The set of such elements is a normal subgroup of G which thus intersects non trivially the center Z(G) of G. Let us consider a non trivial element  $\phi$  of Z(G) which has finite order. Let us recall that a finite group of diffeomorphisms of the sphere is conjugate to a group of isometries. Denote by  $G^+$  the subgroup of elements of G which preserve the orientation. It is thus sufficient to prove that  $G^+$  is metabelian; indeed if  $\phi$  does not preserve the orientation,  $\phi$  has order 2 and  $G = \mathbb{Z}/2\mathbb{Z} \times G^+$ . So let us assume that  $\phi$  preserves the orientation;  $\phi$  is conjugate to a direct isometry of  $\mathbb{S}^2$  and has exactly two fixed points on the sphere. The group G has thus an invariant set of two elements. By considering germs in the neighborhood of these two points, one gets that G can be embedded into  $2 \cdot \text{Diff}(\mathbb{R}^2,0)$  and thus into  $2 \cdot \text{Diff}(\mathbb{C}^2,0)$ :

$$1 \longrightarrow Diff(\mathbb{C}^2, 0) \longrightarrow 2 \cdot Diff(\mathbb{C}^2, 0) \longrightarrow \mathbb{Z}/2\mathbb{Z} \longrightarrow 0.$$

Let us remark that  $2 \cdot \text{Diff}(\mathbb{C}^2, 0)$  is the projective limit of the algebraic groups  $2 \cdot \text{Diff}_i$ . The end of the proof is thus the same as the proof of Proposition 3.2 except that the subgroup of the semi-simple elements of  $2 \cdot \text{Diff}_i$  embeds now in  $2 \cdot \text{GL}(2, \mathbb{C})$ ; it is metabelian because it contains an abelian subgroup of index 2.

Let  $\Gamma$  be a subgroup of finite index of  $SL(n,\mathbb{Z})$  for  $n \geq 5$ . Since  $\Gamma$  contains nilpotent subgroups of finite index of length n-1 (for example the group of upper triangular unipotent matrices) which are not metabelian one gets the following statement.

Corollary 4.3 ([10]). — Let  $\Gamma$  be a subgroup of finite index of  $SL(n,\mathbb{Z})$ ; as soon as  $n \geq 5$  there is no embedding of  $\Gamma$  into  $Diff^{\omega}(\mathbb{S}^2)$ .

## 5. Nilpotent subgroups of length 3 of the group of analytic diffeomorphisms of $\mathbb{S}^2$

Let us precise Proposition 3.1 for nilpotent subalgebras of length 3 of  $\widehat{\chi}(\mathbb{C}^2,0)$ . Let  $\mathfrak{l}$  be such an algebra. The center  $Z(\mathfrak{l})$  of  $\mathfrak{l}$  generates a subspace of dimension at most 1 of  $\widehat{\chi}(\mathbb{C}^2,0)\otimes\widehat{K}(\mathbb{C}^2)$ , for else  $\mathfrak{l}$  would be abelian (Proposition 3.1) and this is impossible under our assumptions. So let us assume that the dimension of the subspace generated by  $Z(\mathfrak{l})$  in  $\widehat{\chi}(\mathbb{C}^2,0)\otimes\widehat{K}(\mathbb{C}^2)$  is 1. There exists an element X in  $Z(\mathfrak{l})$  with the following property: any element of  $Z(\mathfrak{l})$  can be written uX with u in  $\widehat{K}(\mathbb{C}^2)$ . Let  $\mathfrak{g}$  denote the abelian ideal of  $\mathfrak{l}$  defined by

$$\mathfrak{g} = \{\widetilde{X} \in \mathfrak{l} \mid \exists u \in \widehat{K}(\mathbb{C}^2), \widetilde{X} = uX\}.$$

By hypothesis  $\mathfrak{l}$  is not abelian. Let Y be in  $\mathfrak{l}$ ; assume that its projection onto  $\mathfrak{l}/\mathfrak{g}$  is a non trivial element of  $Z(\mathfrak{l}/\mathfrak{g})$ . Any vector field of  $\mathfrak{l}$  can be written

$$uX + vY$$
,  $u, v \in \widehat{K}(\mathbb{C}^2)$ .

Since X, resp. Y belongs to  $Z(\mathfrak{l})$ , resp.  $Z(\mathfrak{l}/\mathfrak{g})$  and since the length of  $\mathfrak{l}$  is 3, one has

$$X(u) = Y^{3}(u) = X(v) = Y(v) = 0.$$
(5.1)

If X and Y are non singular, one can choose formal coordinates x and y such that  $X = \frac{\partial}{\partial x}$  and  $Y = \frac{\partial}{\partial y}$ . The previous conditions can be thus translated as follows: v is a constant and u is a polynomial in y of degree 2. We will see that we have a similar property without assumption on X and Y.

<sup>2.</sup> Let G be a group and let q be a positive integer;  $q \cdot G$  denotes the semi-direct product of  $G^q$  by  $\mathbb{Z}/q\mathbb{Z}$  under the action of the cyclic permutation of the factors.

**Lemma 5.1.** — Let X and Y be two vector fields of  $\widehat{\chi}(\mathbb{C}^2,0)$  that commute and are not colinear. One can assume that  $(X,Y) = \left(\frac{\partial}{\partial \widehat{x}},\frac{\partial}{\partial \widehat{y}}\right)$  where  $\widetilde{x}$  and  $\widetilde{y}$  are two independent variables in a Liouvillian extension of  $\widehat{K}(\mathbb{C}^2,0)$ .

*Proof.* — Since *X* and *Y* are non colinear, there exist two 1-forms  $\alpha$ ,  $\beta$  with coefficients in  $\widehat{K}(\mathbb{C}^2)$  such that

$$\alpha(X) = 1,$$
  $\alpha(Y) = 0,$   $\beta(X) = 0,$   $\beta(X) = 1.$ 

The vector fields X and Y commute if and only if  $\alpha$  and  $\beta$  are closed (this statement of linear algebra is true for convergent meromorphic vector fields and is also true in the completion). The 1-form  $\alpha$  is closed so according to [6] one has

$$\alpha = \sum_{i=1}^{r} \lambda_{i} \frac{d\widehat{\phi}_{i}}{\widehat{\phi}_{i}} + d\left(\frac{\widehat{\psi}_{1}}{\widehat{\psi}_{2}}\right) = d\left(\sum_{i=1}^{r} \lambda_{i} \log \widehat{\phi}_{i} + \frac{\widehat{\psi}_{1}}{\widehat{\psi}_{2}}\right)$$

where  $\widehat{\psi}_1$ ,  $\widehat{\psi}_2$  and the  $\widehat{\phi}_i$  denote some formal series and the  $\lambda_i$  some complex numbers. One has a similar expression for  $\beta$ . So there exists a Liouvillian extension  $\kappa$  of  $\widehat{K}(\mathbb{C}^2)$  having two elements  $\widetilde{x}$  and  $\widetilde{y}$  with  $\alpha = d\widetilde{x}$  and  $\beta = d\widetilde{y}$ . One thus has

$$X(\widetilde{x}) = 1,$$
  $Y(\widetilde{y}) = 0,$   $Y(\widetilde{x}) = 0,$   $Y(\widetilde{y}) = 1.$ 

From (5.1) one gets: v is a constant and u is a polynomial in  $\widetilde{y}$  of degree 2; so one proves the following statement.

**Proposition 5.2**. — Let  $\mathfrak{l}$  be a nilpotent subalgebra of  $\widehat{\chi}(\mathbb{C}^2,0)$  of length 3. Then  $\mathfrak{l}$  is isomorphic to a subalgebra of

$$\mathfrak{n} = \Big\{ P(\widetilde{y}) \frac{\partial}{\partial \widetilde{x}} + \alpha \frac{\partial}{\partial \widetilde{y}} \; \Big| \; \alpha \in \mathbb{C}, P \in \mathbb{C}[\widetilde{y}], \deg P = 2 \Big\}.$$

**Remark 5.3.** — We use a real version of this statement whose proof is an adaptation of the previous one: a nilpotent subalgebra  $\mathfrak{l}$  of length 3 of  $\widehat{\chi}(\mathbb{R}^2,0)$  is isomorphic to a subalgebra of

$$\mathfrak{n} = \left\{ P(\widetilde{y}) \frac{\partial}{\partial \widetilde{x}} + \alpha \frac{\partial}{\partial \widetilde{y}} \, \middle| \, \alpha \in \mathbb{R}, P \in \mathbb{R}[\widetilde{y}], \deg P = 2 \right\}.$$

**Theorem 5.4.** — Let  $\Gamma$  be a subgroup of finite index of  $SL(n,\mathbb{Z})$ ; as soon as  $n \geq 4$  there is no embedding of  $\Gamma$  into  $Diff^{\omega}(\mathbb{S}^2)$ .

*Proof.* — Let  $U(4,\mathbb{Z})$  (resp.  $U(4,\mathbb{R})$ ) be the subgroup of unipotent upper triangular matrices of  $SL(4,\mathbb{Z})$  (resp.  $SL(4,\mathbb{R})$ ); it is a nilpotent subgroup of length 3. Assume that there exists an embedding from a subgroup  $\Gamma$  of finite index of  $SL(4,\mathbb{Z})$  into  $Diff^\omega(\mathbb{S}^2)$ . Up to finite index  $\Gamma$  contains  $U(4,\mathbb{Z})$ . Let us set  $H = \rho(U(4,\mathbb{Z}))$ . Up to finite index H has a fixed point (Proposition 4.1). One can thus see H as a subgroup of  $Diff(\mathbb{R}^2,0) \subset \widehat{Diff}(\mathbb{R}^2,0)$  up to finite index.

Let us denote  $j^1$  the morphism from  $\widehat{\mathrm{Diff}}(\mathbb{R}^2,0)$  to  $\mathrm{Diff}_i$ . Up to conjugation  $j^1(\rho(\mathrm{U}(4,\mathbb{Z})))$  is a subgroup of

$$\left\{ \left[ \begin{array}{cc} \lambda & t \\ 0 & \lambda \end{array} \right] \middle| \lambda \in \mathbb{R}^*, t \in \mathbb{R} \right\}.$$

Up to index 2 one can thus assume that  $j^1 \circ \rho$  takes values in the connected, simply connected group T defined by

$$T = \left\{ \left[ \begin{array}{cc} \lambda & t \\ 0 & \lambda \end{array} \right] \ \middle| \ \lambda, t \in \mathbb{R}, \lambda > 0 \right\}.$$

Let us set

$$\operatorname{Diff}_{i}(T) = \{ f \in \operatorname{Diff}_{i} | j^{1}(f) \in T \};$$

the group  $Diff_i(T)$  is a connected, simply connected, nilpotent and algebraic group. The morphism

$$\rho_i \colon \mathrm{U}(4,\mathbb{Z}) \to \mathrm{Diff}_i$$

can be extended to a unique continuous morphism  $\widetilde{\rho_i} \colon U(4,\mathbb{R}) \to \mathrm{Diff}_i(T)$  (see [13, 12]) so to an algebraic morphism (3). Let us note that  $\widetilde{\rho_i}(U(4,\mathbb{Z}))$  is an algebraic subgroup of  $\mathrm{Diff}_i(T)$  which contains  $\rho_i(U(4,\mathbb{Z}))$ ; in particular  $\overline{H_i} = \overline{\rho_i(U(4,\mathbb{Z}))} \subset \widetilde{\rho_i}(U(4,\mathbb{R}))$ . By construction the family  $(H_i)_i$  is filtered; since the extension is unique, the family  $(\widetilde{\rho_i})_i$  is also filtered. Therefore  $K = \varinjlim_i \overline{H_i}$  is well defined. Since  $\rho$  is injective, H is a nilpotent subgroup of length 3; as  $H \subset K$  and as any  $\overline{H_i}$  is nilpotent of length at most 3 the group K is nilpotent of length at most 3. For i sufficiently large  $\widetilde{\rho_i}(U(4,\mathbb{R}))$  is nilpotent of length 3; this group is connected so its Lie algebra is also nilpotent of length 3. Therefore the image of

$$D\widetilde{\rho} := \lim_{\leftarrow} D\widetilde{\rho_i} \colon \mathfrak{u}(4,\mathbb{R}) \to \widehat{\chi}(\mathbb{R}^2,0)$$

is isomorphic to  $\mathfrak n$  (Proposition 5.2). So there exists a surjective map  $\psi$  from  $\mathfrak u(4,\mathbb R)$  onto  $\mathfrak n$ . The kernel of  $\psi$  is an ideal of  $\mathfrak u(4,\mathbb R)$  of dimension 2; hence  $\ker \psi = \langle \delta_{14}, a\delta_{13} + b\delta_{24} \rangle$  where the  $\delta_{ij}$  denote the Kronecker matrices. One concludes by remarking that  $\dim Z(\mathfrak u(4,\mathbb R)/\ker \psi) = 2$  whereas  $\dim Z(\mathfrak n) = 1$ .

**Corollary 5.5.** — The image of a morphism from a subgroup of  $SL(n,\mathbb{Z})$  of finite index to  $Diff^{\omega}(\mathbb{S}^2)$  is finite as soon as  $n \geq 4$ .
