**Abstract.** We improve the Winitzki's Approximation of the error function  $\text{erf}(x) \cong \sqrt{1 - e^{-x^2 \frac{\frac{4}{\pi} + 0.147x^2}{1+0.147x^2}}}$  which has error  $|\varepsilon(x)| < 1.25 \cdot 10^{-4} \forall x \geq 0$  till reaching 4 decimals of precision with  $|\varepsilon(x)| < 2.27 \cdot 10^{-5}$ ; also reducing slightly the relative error. Old formula and ours are both explicitly invertible, essentially solving a biquadratic equation, after obvious substitutions. Then we derive approximations to 4 decimals of normal cumulative distribution function  $\Phi(x)$ , of  $\text{erfc}(x)$  and of the  $Q$  function (or cPhi).

**2010 Mathematics Subject Classification:** 33B20 , 33F05 , 65D20 , 97N50.

**Keywords:** normal cdf, Phi, error function, erf, erfc, cPhi, Q-function, approximation.

In this note we improve the Winitzki's Approximation of the error function till reaching 4 decimals of precision both for erf and  $\Phi$ , reducing about 5.5 times the respective absolute errors (and reducing the relative errors too).

**Lemma (Winitzki's Approximation of erf).** (See [1])

$$\text{erf}(x) \cong \sqrt{1 - e^{-x^2 \frac{\frac{4}{\pi} + 0.147x^2}{1+0.147x^2}}} \quad |\varepsilon(x)| < 1.25 \cdot 10^{-4} \quad |\varepsilon_r(x)| < 1.28 \cdot 10^{-4} \quad \forall x \geq 0$$

**Theorem (Improving of Winitzki's Approximation of erf).**

$$\text{erf}(x) \cong \sqrt{1 - e^{\frac{-1.2735457x^2 - 0.1487936x^4}{1+0.1480931x^2 + 0.0005160x^4}}} \quad (1)$$

$$|\varepsilon(x)| < 2.27 \cdot 10^{-5} \quad \forall x \geq 0 \quad |\varepsilon_r(x)| < 1.21 \cdot 10^{-4} \quad \forall x \geq 0$$

*Proof (only for absolute error).* For  $0 \leq x \leq 4$ , see the figure above <sup>[1]</sup>.

For  $x > 4$  let's consider that it is  $\text{erf}(4) = 0.99999998458\dots$  and  $\text{erf}(x) \rightarrow 1$  and erf is increasing, then

$$(\forall x > 4) \quad |1 - \text{erf}(x)| < 10^{-7}. \quad (2)$$

---

<sup>1</sup>The figure represents the graph of  $2.27 \cdot 10^{-5} - \left| \text{erf}(x) - \sqrt{1 - e^{\frac{-1.2735457x^2 - 0.1487936x^4}{1+0.1480931x^2 + 0.0005160x^4}}} \right|$ , made by the software Mathematica, showing that the quantity is positive.

To verify that the graph do not intersect the  $x$  axis, you may make zooms in the subdomains  $[0.2, 0.3]$ ,  $[0.75, 0.85]$ ,  $[1.35, 1.45]$  and  $[2.1, 2.2]$ .

Let's  $\eta(x)$  our approximation of  $\text{erf}(x)$  as in (1):  $\text{erf}(x) \cong \eta(x) := \sqrt{1 - e^{E(x)}}$  being  $E(x) := \frac{-1.2735457x^2 - 0.1487936x^4}{1 + 0.1480931x^2 + 0.0005160x^4}$ . It is:

$$\begin{aligned}
(\forall x > 4) \quad 0 < 3 &= \left(\frac{1}{3}15 - 1\right)^2 - 1 - 12 < (\frac{1}{3} \cdot 4^2 - 0.795)^2 - 0.795^2 - 12 < \\
&= \left(\frac{1}{3}x^2 - \frac{3}{2}0.53\right)^2 - \left(\frac{3}{2}0.53\right)^2 - 12 = \frac{1}{9}x^4 - 0.53x^2 - 12 < \\
&< 0.14176x^4 - 0.53x^2 - 12 = (0.148x^4 - 0.00624)x^4 + (1.27x^2 - 1.8)x^2 - 12 \\
&\Rightarrow 1.27x^2 + 0.148x^4 > 12 + 1.8x^2 + 0.00624x^4 \\
&\Rightarrow \frac{1.27x^2 + 0.148x^4}{12} > 1 + 0.15x^2 + 0.00052x^4 \\
\Rightarrow E(x) &= \frac{-1.2735457x^2 - 0.1487936x^4}{1 + 0.1480931x^2 + 0.0005160x^4} < \frac{-1.27x^2 - 0.148x^4}{1 + 0.15x^2 + 0.00052x^4} < -12 \\
\Rightarrow e^{R(x)} &< e^{-12} < e^{-12} + (e^{-12} - e^{-24}) = 2e^{-12} - e^{-24} = 1 - (1 - e^{-12})^2 \\
\Rightarrow (1 - e^{-12})^2 &< 1 - e^{R(x)} \Rightarrow 1 - e^{-12} < \sqrt{1 - e^{R(x)}} \\
\Rightarrow 0 < 1 - \eta(x) &= 1 - \sqrt{1 - e^{R(x)}} < e^{-12} \Rightarrow \\
(\forall x > 4) \quad |1 - \eta(x)| &< e^{-12}. \tag{3}
\end{aligned}$$

By (2) and (3) it is

$$(\forall x > 4) \quad |\text{erf}(x) - \eta(x)| \leq |1 - \text{erf}(x)| + |1 - \eta(x)| < 10^{-7} + e^{-12} < 10^{-5}.$$

□

## TABLE ERF2.27E-5

**Simply explicitly invertible approximations to 4 decimals of the error function erf, of complementary error function erfc, of the normal cumulative distribution function  $\Phi$ , and of Q function, for  $x \geq 0$ .  
With majorizations of absolute and relative errors, and definitions.**

$$erf(x) := \int_0^x \frac{2}{\sqrt{\pi}} e^{-t^2} dt = 1 - erfc(x) \quad \Phi(x) := \int_{-\infty}^x \frac{1}{\sqrt{2\pi}} e^{-\frac{t^2}{2}} = 1 - Q(x)$$

---

$A. \quad erf(x) \cong$ $\cong \sqrt{1 - e^{\frac{-1.2735457x^2 - 0.1487936x^4}{1 + 0.1480931x^2 + 0.0005160x^4}}}$	$ \varepsilon(x)  < 2.27 \cdot 10^{-5} \quad \forall x \geq 0$ [2] $ \varepsilon_r(x)  < 1.21 \cdot 10^{-4} \quad \forall x \geq 0$
