An Enhanced DMT-optimality Criterion for STBC-schemes for Asymmetric MIMO Systems

K. Pavan Srinath and B. Sundar Rajan, *Senior Member, IEEE*

Abstract—For any n_t transmit, n_r receive antenna $(n_t \times n_r)$ MIMO system in a quasi-static Rayleigh fading environment, it was shown by Elia et al. that linear space-time block code-schemes (LSTBC-schemes) which have the non-vanishing determinant (NVD) property are diversity-multiplexing gain tradeoff (DMT)-optimal for arbitrary values of n_r if they have a code-rate of n_t complex dimensions per channel use. However, for asymmetric MIMO systems (where $n_r < n_t$), with the exception of a few LSTBC-schemes, it is unknown whether general LSTBC-schemes with NVD and a code-rate of n_r complex dimensions per channel use are DMT-optimal. In this paper, an enhanced sufficient criterion for any STBC-scheme to be DMT-optimal is obtained, and using this criterion, it is established that any LSTBC-scheme with NVD and a code-rate of $\min\{n_t, n_r\}$ complex dimensions per channel use is DMT-optimal. This result settles the DMT-optimality of several well-known, low-ML-decoding-complexity LSTBC-schemes for certain asymmetric MIMO systems.

Index Terms—Asymmetric MIMO system, diversity-multiplexing gain tradeoff, linear space-time block codes, low ML-decoding complexity, non-vanishing determinant, outage-probability, STBC-schemes.

I. Introduction and Background

Space-time coding (STC) [1] for multiple-input, multiple-output (MIMO) antenna systems has extensively been studied as a tool to exploit the diversity provided by the MIMO fading channel. MIMO systems have the capability of permitting reliable data transmission at higher rates compared to that provided by the single-input, single-output (SISO) antenna system. In particular, when the delay requirement of the system is less than the coherence time (the time frame during which the channel gains are constant and independent of the channel gains of other time frames) of the channel, Zheng and Tse showed in their seminal paper [2] that for the Rayleigh fading channel with STC, there exists a fundamental tradeoff between diversity gain and multiplexing gain (see Definition 3 and Definition 4, Section II), referred to as "diversity-multiplexing gain tradeoff" (DMT). The optimal DMT was also characterized with the assumption that the block length of the space-time block codes (STBC) of the scheme (see Definition 2, Section

II, for a definition of "STBC-scheme") is at least $n_t + n_r - 1$, where n_t and n_r are the number of transmit and receive antennas, respectively. The first explicit DMT-optimal STBC-scheme was presented in [3] for 2 transmit antennas, and subsequently, in another landmark paper [4], explicit DMT-optimal STBC-schemes consisting of both square (minimal-delay) and rectangular STBCs from cyclic division algebras were presented for arbitrary values of n_t and n_r. In the same paper, a sufficient criterion for achieving DMT-optimality was proposed for general STBC-schemes. For a class of STBC-schemes based on linear STBCs[1] (LSTBCs) which have a code-rate (see Definition 6, Section IV, for a formal definition of "code-rate", and Definition 7 for a definition of "LSTBC-scheme". Henceforth in this paper, an LSTBC-scheme with code-rate equal to k complex dimensions per channel use is referred to as "rate-k LSTBC-scheme") of n_t complex dimensions per channel use, this criterion translates to the *non-vanishing determinant* property (see Definition 8, Section IV), a term first coined in [6], being sufficient for DMT-optimality. It was later shown in [7] that the DMT-optimal LSTBC-schemes constructed in [4] are also approximately universal for arbitrary number of receive antennas. In the literature, there exist several other rate-n_t LSTBC-schemes with NVD - for example, see [8], [9], [10], and references therein. It is to be noted that the sufficient criterion presented in [4] for DMT-optimality holds only for LSTBC-schemes whose code-rate equals n_t complex dimensions per channel use.

A few LSTBC-schemes with code-rate less than n_t complex dimensions per channel use have been shown to be DMT-optimal for certain asymmetric MIMO systems. The Alamouti code-scheme [11] for the 2×1 system is known to be DMT-optimal [2] while diagonal rate-1 STBC-schemes with NVD have been shown to be DMT-optimal for arbitrary $n_t \times 1$ systems [7]. In [12], the DMT-optimality of a few rate-1 LSTBC-schemes for certain multiple-input, single-output (MISO) systems has been established, including that of the full-diversity quasi-orthogonal STBC-scheme of Su and Xia [13] for the 4×1 system. For asymmetric MIMO systems with $n_r \geq 2$, the only known DMT-optimal, rate-n_r LSTBC-schemes are the rectangular LSTBC-schemes of [14], which exist for $n_r = 2$ and $n_r = n_t - 1$. Whether every rate-n_r LSTBC-scheme that is equipped with the non-vanishing determinant property is DMT-optimal for an asymmetric $n_t \times n_r$ MIMO system has been an open problem up to now.

---

[1]In the literature, linear STBCs are also popularly called linear dispersion codes [5].

A. Motivation for our results

It is natural to question the need for establishing the DMT-optimality of rate-n_r LSTBC-schemes for asymmetric MIMO systems when there already exist DMT-optimal, rate-n_t LSTBC-schemes for arbitrary values of n_t and n_r. However, it is important to note that all the known results on DMT-optimality of explicit LSTBC-schemes are with regards to maximum-likelihood (ML)-decoding, and in the literature, barring a few notable exceptions (for example, [14]), the issue of ML-decoding complexity is generally excluded from the discussion on DMT-optimal LSTBC-schemes. There exist several low-ML-decoding complexity LSTBC-schemes that have a code-rate less than n_t complex dimensions per channel use and are equipped with the NVD property. Examples of these for asymmetric MIMO systems are rate-n_r LSTBC-schemes that are based on fast-decodable LSTBCs [15] from cyclic division algebras, LSTBC-schemes from co-ordinate interleaved orthogonal designs [16], and four-group decodable LSTBC-schemes [17]-[20]. For these LSTBC-schemes, the sufficient criterion provided in [4] for DMT-optimality, which requires that LSTBCs have a code-rate of n_t complex dimensions per channel use *irrespective* of the number of receive antennas, is not applicable. Hence, there is a clear need for obtaining a new DMT-criterion that can take into account LSTBC-schemes (with NVD) whose code-rate is less than n_t complex dimensions per channel use.

Further, for asymmetric MIMO systems, the standard sphere decoder [21] or its variations (see, for example, [22], [23], and references therein) cannot be used in entirety to decode-rate-n_t LSTBCs. For an $n_t \times n_r$ MIMO system, the standard sphere decoder can be used to decode LSTBCs whose code-rate is at most[2] $n_{min} = \min\{n_t, n_r\}$ complex dimensions per channel use. Recent results on fixed-complexity sphere decoders [25], [26] are extremely promising from the point of view of low complexity decoding. In particular, it has been shown analytically in [26] that the fixed-complexity sphere decoder, although provides quasi-ML performance, helps achieve the *same* diversity order of ML-decoding with a worst-case complexity of the order of $M^{\sqrt{K}}$, where M is the number of possibilities for each complex symbol (or the size of the signal constellation employed when each symbol is encoded independently), and K is the dimension of the search. On the other hand, an exhaustive ML-search would incur a complexity of the order of M^K. In the same paper, it has also been shown that the gap between quasi-ML performance and the actual ML performance approaches zero at high signal-to-noise ratio, independent of the constellation employed. In any case, it has been established in [27] that the exact ML-decoding complexity of the sphere decoder is lesser than that of other known ML-decoders at high SNR. This motivates one to seek DMT-optimal LSTBC-schemes whose LSTBCS are entirely sphere decodable, i.e., have a code-rate that is at most n_{min} complex dimensions per channel use.

[2] When a rate-n_t STBC is used in an asymmetric MIMO system, there exist techniques (see [24] and references therein) to make use of the sphere decoder. However, these are either sub-optimal decoding techniques with no guarantee on preserving the diversity order of ML-decoding, or demand a high computational complexity when ML-decoding is employed.

In this paper, we present a new criterion for DMT-optimality of general STBC-schemes using which we prove the DMT-optimality of many low-ML-decoding-complexity LSTBC-schemes [15]-[20] for asymmetric MIMO systems. Since the new criterion enables us to identify a larger class of DMT-optimal LSTBC-schemes which was not possible using the DMT-criterion in [4], we call our criterion an enhanced one.

B. Contributions and paper organization

The contributions of this paper are the following.

1) We present a new criterion for DMT-optimality of general STBC-schemes. This criterion enables us to encompass all rate-n_{min} LSTBC-schemes with NVD which was not possible using the DMT-criterion of [4].
2) In the context of LSTBCs, we show that a code-rate of n_{min} complex dimensions per channel use is necessary for LSTBC-schemes to be DMT-optimal, and for asymmetric MIMO systems, we show that rate-n_r LSTBC-schemes are DMT-optimal if they have the NVD property.
3) We show that some well-known low-ML-decoding-complexity LSTBC-schemes (STBC-schemes based on LSTBCs with low ML-decoding complexity) are DMT-optimal for certain asymmetric MIMO systems (see Table I).

The rest of the paper is organized as follows. Section II deals with the system model and relevant definitions while Section III presents the main result of the paper - an enhanced sufficient criterion for DMT-optimality of general STBC-schemes. Section IV gives a brief introduction to linear STBCs along with a few relevant definitions, and provides a new criterion for DMT-optimality of LSTBCs for asymmetric MIMO systems. A discussion on the DMT-optimality of some well-known low-ML-decoding-complexity LSTBC-schemes is presented in Section V. Concluding remarks constitute Section VI.

Notation: Throughout the paper, bold, lowercase letters are used to denote vectors, and bold, uppercase letters are used to denote matrices. For a complex matrix $\mathbf{X}$, its Hermitian transpose, transpose, trace, determinant, rank, and Frobenius norm are denoted by $\mathbf{X}^H$, $\mathbf{X}^T$, $tr(\mathbf{X})$, $det(\mathbf{X})$, $Rank(\mathbf{X})$, and $\|\mathbf{X}\|$, respectively. The set of all real numbers, complex numbers, and integers are denoted by $\mathbb{R}$, $\mathbb{C}$, and $\mathbb{Z}$, respectively. The real and the imaginary parts of a complex-valued vector $\mathbf{x}$ are denoted by $\mathbf{x}_I$ and $\mathbf{x}_Q$, respectively. The cardinality of a set $\mathcal{S}$ is denoted by $|\mathcal{S}|$, while $\mathcal{S} \times \mathcal{T}$ denotes the Cartesian product of sets $\mathcal{S}$ and $\mathcal{T}$, meaning which $\mathcal{S} \times \mathcal{T} = \{(s, t) \mid s \in \mathcal{S}, t \in \mathcal{T}\}$. The notation $\mathcal{S} \subset \mathcal{T}$ implies that $\mathcal{S}$ is a proper subset of $\mathcal{T}$. The $T \times T$ sized identity matrix is denoted by $\mathbf{I}_T$, and $\mathbf{O}$ denotes the null matrix of appropriate dimension.

For a complex number x, its complex conjugate is denoted by x^*, and the $(\check{.})$ operator acting on x is defined as

$$\check{x} \triangleq \left[\begin{array}{cc} x_I & -x_Q \\ x_Q & x_I \end{array} \right].$$

The $(\check{.})$ operator can similarly be applied to any matrix $\mathbf{X} \in \mathbb{C}^{n \times m}$ by replacing each entry x_{ij} with $\check{x}_{ij}$, $i = 1, 2, \cdots, n, j = 1, 2, \cdots, m$, resulting in a matrix denoted by

	LSTBC	Number of transmit antennas n_t	Block length of the STBC T	Code-Rate (in complex dimensions per channel use)	No. of Rx antennas n_r for which STBC-scheme is DMT-optimal	Constellation used
Known DMT-optimal LSTBC-schemes	Alamouti Code [11]	2	2	1	1	QAM

	Punctured perfect STBCs£ for asymmetric MIMO	any n_t	n_t	$n_r < n_t$	$n_r < n_t$	QAM
	Punctured Lattice Codes [29]	$n_t = n_r m,$ $m \in \mathbb{Z}^+$	n_t	$n_r < n_t$	$n_r < n_t$	QAM
	Block-diagonal STBCs [29]	$n_t = n_r m,$ $m \in \mathbb{Z}^+$	n_t	$n_r < n_t$	$n_r < n_t$	QAM

£ Punctured perfect STBCs refer to rate-n_r STBCs obtained from rate-n_t perfect STBCs [10] (which transmit n_t^2 complex information symbols in n_t channel uses) by restricting the number of complex information symbols transmitted to be only $n_t n_r$.

TABLE I
A TABLE (BY NO MEANS EXHAUSTIVE) OF DMT-OPTIMAL LINEAR STBC-SCHEMES

$\check{\mathbf{X}} \in \mathbb{R}^{2n \times 2m}$. Given a complex vector $\mathbf{x} = [x_1, x_2, \cdots, x_n]^{\mathrm{T}}$, $\tilde{\mathbf{x}}$ is defined as $\tilde{\mathbf{x}} \triangleq [x_{1I}, x_{1Q}, \cdots, x_{nI}, x_{nQ}]^{\mathrm{T}}$. It follows that for matrices $\mathbf{A} \in \mathbb{C}^{m \times n}, \mathbf{B} \in \mathbb{C}^{n \times p},$ and $\mathbf{C} = \mathbf{AB}$, the equalities $\check{\mathbf{C}} = \check{\mathbf{A}}\check{\mathbf{B}}$, and $vec(\check{\mathbf{C}}) = (\mathbf{I}_p \otimes \check{\mathbf{A}})vec(\check{\mathbf{B}})$ hold.

For a complex random matrix $\mathbf{X}$, $\mathbb{E}_{\mathbf{X}}(f(\mathbf{X}))$ denotes the expectation of a real-valued function $f(\mathbf{X})$ over $\mathbf{X}$. For any real number x, $\lfloor x \rfloor$ denotes the largest integer not greater than x, and $x^+ = \max\{0, x\}$. The Q-function of x is denoted by $Q(x)$ and given as

$$Q(x) = \int_x^\infty \frac{1}{\sqrt{2\pi}} e^{-\frac{t^2}{2}} \, dt.$$

Throughout the paper, $\log x$ denotes the logarithm of x to base 2, and $\log_e x$ denotes the natural logarithm of x. For real-valued functions $f(x)$ and $g(x)$, we write $f(x) = o(g(x))$ as $x \to \infty$ if and only if

$$\lim_{x \to \infty} \frac{f(x)}{g(x)} = 0.$$

Further, $f(x) \doteq x^b$ implies that $\lim_{x \to \infty} \frac{\log f(x)}{\log x} = b$, and $\dot{\leq}, \dot{\geq}, \dot{>}, \dot{<}$ are similarly defined.

II. SYSTEM MODEL

We consider an n_t transmit antenna, n_r receive antenna MIMO system ($n_t \times n_r$ system) with perfect channel-state information available at the receiver (CSIR) alone. The channel is assumed to be quasi-static with Rayleigh fading. The system

model is

$$\mathbf{Y} = \mathbf{H}\mathbf{X} + \mathbf{N}, \tag{1}$$

where $\mathbf{Y} \in \mathbb{C}^{n_r \times T}$ is the received signal matrix, $\mathbf{X} \in \mathbb{C}^{n_t \times T}$ is the codeword matrix that is transmitted over a block of T channel uses, $\mathbf{H} \in \mathbb{C}^{n_r \times n_t}$ and $\mathbf{N} \in \mathbb{C}^{n_r \times T}$ are respectively the channel matrix and the noise matrix with entries independently and identically distributed (i.i.d.) circularly symmetric complex Gaussian random variables with zero mean and unit variance. The average signal-to-noise ratio at each receive antenna is denoted by SNR.

Definition 1: (*Space-time block code*) A space-time block code (STBC) of block-length T for an n_t transmit antenna MIMO system is a finite set of complex matrices of size $n_t \times T$.

Definition 2: (*STBC-scheme*) An STBC-scheme $\mathcal{X}$ is defined as a family of STBCs indexed by SNR, each STBC of block length T so that $\mathcal{X} = \{\mathcal{X}(SNR)\}$, where the STBC $\mathcal{X}(SNR)$ corresponds to a signal-to-noise ratio of SNR at each receive antenna.

At a signal-to-noise ratio of SNR, the codeword matrices of $\mathcal{X}(SNR)$ are transmitted over the channel. Assuming that all the codeword matrices of $\mathcal{X}(SNR) \triangleq \{\mathbf{X}_i(SNR), i = 1, \cdots, |\mathcal{X}(SNR)|\}$ are equally likely to be transmitted, we have

$$\frac{1}{|\mathcal{X}(SNR)|} \sum_{i=1}^{|\mathcal{X}(SNR)|} \|\mathbf{X}_i(SNR)\|^2 = T\ SNR. \tag{2}$$

It follows that for the STBC-scheme $\mathcal{X}$,

$$\|\mathbf{X}_i(SNR)\|^2 \ \dot{\leq}\ SNR, \ \ \forall\ i = 1, 2, \cdots, |\mathcal{X}(SNR)|. \tag{3}$$

The bit rate of transmission is $(1/T) \log |\mathcal{X}(SNR)|$ bits per channel use. Henceforth in this paper, a codeword $\mathbf{X}_i(SNR) \in \mathcal{X}(SNR)$ is simply referred to as $\mathbf{X}_i \in \mathcal{X}(SNR)$.

Definition 3: (*Multiplexing gain*) Let the bit rate of transmission of the STBC $\mathcal{X}(SNR)$ in bits per channel use be denoted by $R(SNR)$. Then, the multiplexing gain r of the STBC-scheme is defined [2] as

$$r = \lim_{SNR \to \infty} \frac{R(SNR)}{\log SNR}.$$

Equivalently, $R(SNR) = r \log SNR + o(\log SNR)$ where, for reliable communication, $r \in [0, n_{min}]$ [2].

Definition 4: (*Diversity gain*) Let the probability of codeword error of the STBC $\mathcal{X}(SNR)$ be denoted by $P_e(SNR)$. Then, the diversity gain $d(r)$ of the STBC-scheme corresponding to a multiplexing gain of r is given by

$$d(r) = -\lim_{SNR \to \infty} \frac{\log P_e(SNR)}{\log SNR}.$$

For an $n_t \times n_r$ MIMO system, the maximum achievable diversity gain is $n_t n_r$.

Definition 5: (*Optimal DMT curve [2]*) *The optimal DMT curve $d^*(r)$ that is achievable with STBC-schemes for an $n_t \times n_r$ MIMO system is a piecewise-linear function connecting the points $(k, d(k))$, $k = 0, 1, \cdots, n_{min}$, where*

$$d(k) = (n_t - k)(n_r - k). \tag{4}$$

Theorem 3 of [4], which provides a sufficient criterion for DMT-optimality of an STBC-scheme, is rephrased here with its statement consistent with the notation and terminology used in this paper.

Theorem 1: [4] For a quasi-static $n_t \times n_r$ MIMO channel with Rayleigh fading and perfect CSIR, an STBC-scheme $\mathcal{X}$ that satisfies (3) is DMT-optimal for any value of n_r if for all possible pairs of distinct codewords $(\mathbf{X}_1, \mathbf{X}_2)$ of $\mathcal{X}(SNR)$, the difference matrix $\mathbf{X}_1 - \mathbf{X}_2 = \Delta\mathbf{X} \neq \mathbf{O}$ is such that,

$$det\left(\Delta\mathbf{X}\Delta\mathbf{X}^H\right) \ \dot{\geq}\ SNR^{n_t\left(1 - \frac{r}{n_t}\right)}. \tag{5}$$

Relying on Theorem 1, an explicit construction scheme was presented to obtain DMT-optimal LSTBC-schemes whose LSTBCs are minimal-delay ($T = n_t$) and obtained from cyclic division algebras (CDA). All these STBCs have a code-rate of n_t complex dimensions per channel use irrespective of the value of n_r. However, Theorem 1 does not account for LSTBC-schemes whose LSTBCs have code-rate less than n_t complex dimensions per channel use. In the following section, we present an enhanced DMT-criterion that brings within its scope all rate-n_{min} LSTBC-schemes with NVD.

III. MAIN RESULT

We present below the main result of our paper - an enhanced sufficient criterion for DMT-optimality of general STBC-schemes.

Theorem 2: For a quasi-static $n_t \times n_r$ MIMO channel with Rayleigh fading and perfect CSIR, an STBC-scheme $\mathcal{X}$ that satisfies (3) is DMT-optimal for any value of n_r if for all possible pairs of distinct codewords $(\mathbf{X}_1, \mathbf{X}_2)$ of $\mathcal{X}(SNR)$, the difference matrix $\mathbf{X}_1 - \mathbf{X}_2 = \Delta\mathbf{X} \neq \mathbf{O}$ is such that,

$$det(\Delta\mathbf{X}\Delta\mathbf{X}^H) \ \dot{\geq}\ SNR^{n_t\left(1 - \frac{r}{n_{min}}\right)}. \tag{6}$$

Remark 1: Notice that compared to the criterion given by (5), our criterion given by (6) places less demand on the determinants of codeword difference matrices of the STBCs that the STBC-scheme comprises of. This enables one to widen the class of DMT-optimal LSTBC-schemes, and for this reason, we call our criterion an "enhanced criterion" compared to that given by (5).

Proof of Theorem 2: To prove the theorem, we first show that the STBC-scheme $\mathcal{X}$ is DMT-optimal when each codeword difference matrix $\Delta\mathbf{X} \neq \mathbf{O}$ of $\mathcal{X}(SNR)$ satisfies

$$det\left(\Delta\mathbf{X}\Delta\mathbf{X}^H\right) \ \dot{\geq}\ SNR^{n_t\left(1 - \frac{r}{n_r}\right)}, \tag{7}$$

and then conclude the proof taking aid of Theorem 1. Towards this end, we assume without loss of generality that the codeword $\mathbf{X}_1$ of $\mathcal{X}(SNR)$ is transmitted. It is also assumed that $T \geq n_t$, which is a prerequisite for achieving a diversity gain of $n_t n_r$ when the bit rate of the STBC-scheme is constant with SNR (a special case of the $r = 0$ condition). Let $\Delta\mathbf{X}_l = \mathbf{X}_1 - \mathbf{X}_l$, where $\mathbf{X}_l$, $l = 2, \cdots, |\mathcal{X}(SNR)|$, are the remaining codewords of $\mathcal{X}(SNR)$. It is to be noted that the bit rate of transmission is $r \log SNR + o(\log SNR)$ bits per channels use, and so, $|\mathcal{X}(SNR)| \doteq SNR^{rT}$, with $r \in [0, n_{min}]$. Considering the channel model given by (1) with ML-decoding employed at the receiver, the probability

$$\mathcal{O} \triangleq \left\{ \mathbf{H} \;\middle|\; \log det \left(\mathbf{I}_{n_r} + \frac{SNR}{n_t} \mathbf{H}\mathbf{H}^H \right) \le r \log SNR + o(\log SNR) \right\}, \tag{8}$$

$$\bar{\mathcal{O}} \triangleq \left\{ \mathbf{H} \;\middle|\; \sum_{i=1}^{n_r} \log \left(1 + \frac{SNR}{n_t} \|\mathbf{h}_i\|^2 \right) > r \log SNR + o(\log SNR) \right\}. \tag{9}$$

that $\mathbf{X}_1$ is wrongly decoded to $\mathbf{X}_2$ for a particular channel matrix $\mathbf{H}$ is given by

$$P_e(\mathbf{X}_1 \to \mathbf{X}_2 | \mathbf{H}) = Q\left(\frac{\|\mathbf{H}\Delta\mathbf{X}_2\|}{\sqrt{2}} \right).$$

So, the probability that $\mathbf{X}_1$ is wrongly decoded conditioned on $\mathbf{H}$ is upper bounded as

$$P_e(\mathbf{X}_1 | \mathbf{H}) \le \sum_{l=2}^{|\mathcal{X}(SNR)|} Q\left(\frac{\|\mathbf{H}\Delta\mathbf{X}_l\|}{\sqrt{2}} \right). \tag{10}$$

The probability of codeword error averaged over all channel realizations is given by

$$\begin{aligned} P_e &= \mathbb{E}_{\mathbf{H}} \left(P_e(\mathbf{X}_1 | \mathbf{H}) \right) \\ &= \int p(\mathbf{H}) P_e(\mathbf{X}_1 | \mathbf{H}) d\mathbf{H}, \end{aligned}$$

where throughout the paper, $p(.)$ denotes the probability density function (pdf). Let

$$\mathcal{E} := \text{event that there is a codeword error},$$

and consider the set of channel realizations $\mathcal{O}$ defined in (8) at the top of the page. Now,

$$\begin{aligned} P_e &= \int_{\mathcal{O}} p(\mathbf{H}) P_e(\mathbf{X}_1 | \mathbf{H}) d\mathbf{H} + \int_{\mathcal{O}^c} p(\mathbf{H}) P_e(\mathbf{X}_1 | \mathbf{H}) d\mathbf{H} \\ &= \mathrm{P}(\mathcal{O}, \mathcal{E}) + \mathrm{P}(\mathcal{O}^c, \mathcal{E}) \\ &= \mathrm{P}(\mathcal{O})\mathrm{P}(\mathcal{E}|\mathcal{O}) + \mathrm{P}(\mathcal{O}^c, \mathcal{E}), \end{aligned} \tag{11}$$

where $\mathrm{P}(.)$ denotes "probability of", and $\mathcal{O}^c = \{\mathbf{H} \mid \mathbf{H} \notin \mathcal{O}\}$. $\mathrm{P}(\mathcal{O})$ is the well-known probability of outage[3] [2], and $\mathrm{P}(\mathcal{E}|\mathcal{O})$ is the probability of codeword error given that the channel is in outage. $P(\mathcal{O})$ and $\mathrm{P}(\mathcal{E}|\mathcal{O})$ have been derived [2] to be

$$\mathrm{P}(\mathcal{O}) \doteq SNR^{-d^*(r)}, \tag{12}$$
$$\mathrm{P}(\mathcal{E}|\mathcal{O}) \doteq SNR^0, \tag{13}$$

where $d^*(r)$ is given in Definition 5. So, the DMT curve of an STBC-scheme is determined completely by $\mathrm{P}(\mathcal{O}^c, \mathcal{E})$, which is the probability that there is a codeword error and the channel is not in outage. To obtain an upper bound on $\mathrm{P}(\mathcal{O}^c, \mathcal{E})$, we proceed as follows. Note that $\mathbf{I}_{n_r} + (SNR/n_t)\mathbf{H}\mathbf{H}^H$ is a positive definite matrix. Denoting the rows of $\mathbf{H}$ by $\mathbf{h}_i$, $i = 1, \cdots, n_r$, we have

$$\log det \left(\mathbf{I}_{n_r} + \frac{SNR}{n_t} \mathbf{H}\mathbf{H}^H \right) \le \sum_{i=1}^{n_r} \log \left(1 + \frac{SNR}{n_t} \|\mathbf{h}_i\|^2 \right),$$

which is due to Hadamard's inequality which states that the determinant of a positive definite matrix is less than or equal

[3]In the literature, '$<$' is often used instead of '$\le$' in (8) to define the outage probability. However, for either definition, (12) holds true.

to the product of its diagonal entries. We define the set of channel realizations $\bar{\mathcal{O}}$ as shown in (9) at the top of the page. Clearly, $\mathcal{O}^c \subseteq \bar{\mathcal{O}}$, and hence,

$$\mathrm{P}(\mathcal{O}^c, \mathcal{E}) \le \mathrm{P}(\bar{\mathcal{O}}, \mathcal{E}). \tag{14}$$

Hence, using (14) in (11), we have

$$P_e \le \mathrm{P}(\mathcal{O})\mathrm{P}(\mathcal{E}|\mathcal{O}) + \mathrm{P}(\bar{\mathcal{O}}, \mathcal{E}). \tag{15}$$

We now need to evaluate $\mathrm{P}(\bar{\mathcal{O}}, \mathcal{E})$. Denoting the entries of $\mathbf{H}$ by h_{ij}, $i = 1, \cdots, n_r$, $j = 1, \cdots, n_t$, we observe that $\sum_{i=1}^{n_r} \log \left(1 + \frac{SNR}{n_t} \|\mathbf{h}_i\|^2 \right)$

$$\begin{aligned} &= \sum_{i=1}^{n_r} \log \left(\frac{1}{n_t} \sum_{j=1}^{n_t} \left(1 + SNR|h_{ij}|^2 \right) \right) \\ &\ge \frac{1}{n_t} \sum_{i=1}^{n_r} \sum_{j=1}^{n_t} \log(1 + SNR|h_{ij}|^2), \end{aligned} \tag{16}$$

with (16) following from the concavity of $\log(.)$ and Jensen's inequality.

We now define two disjoint sets of channel realizations $\widetilde{\mathcal{O}}$ and $\ddot{\mathcal{O}}$ as shown in (21) and (22) at the top of the next page. Clearly, $\bar{\mathcal{O}}$ is the disjoint union of $\widetilde{\mathcal{O}}$ and $\ddot{\mathcal{O}}$. Therefore,

$$\begin{aligned} \mathrm{P}(\bar{\mathcal{O}}, \mathcal{E}) &= \mathrm{P}\left(\widetilde{\mathcal{O}}, \mathcal{E}\right) + \mathrm{P}\left(\ddot{\mathcal{O}}, \mathcal{E}\right) \\ &= \mathrm{P}(\widetilde{\mathcal{O}})\mathrm{P}\left(\mathcal{E}|\widetilde{\mathcal{O}}\right) + \mathrm{P}\left(\ddot{\mathcal{O}}, \mathcal{E}\right) \\ &\le \mathrm{P}(\widetilde{\mathcal{O}}) + \mathrm{P}\left(\ddot{\mathcal{O}}, \mathcal{E}\right). \end{aligned} \tag{17}$$

In Appendix A, it is shown that

$$\mathrm{P}(\widetilde{\mathcal{O}}) \doteq SNR^{-n_t(n_r-r)}. \tag{18}$$

So, we are now left with the evaluation of $\mathrm{P}\left(\ddot{\mathcal{O}}, \mathcal{E}\right)$, which is done as follows.

$$\begin{aligned} \mathrm{P}\left(\ddot{\mathcal{O}}, \mathcal{E}\right) &= \int_{\ddot{\mathcal{O}}} p(\mathbf{H}) P_e(\mathbf{X}_1 | \mathbf{H}) d\mathbf{H} \\ &\le \sum_{l=2}^{|\mathcal{X}(SNR)|} \int_{\ddot{\mathcal{O}}} p(\mathbf{H}) Q\left(\frac{\|\mathbf{H}\Delta\mathbf{X}_l\|}{\sqrt{2}} \right) d\mathbf{H} \quad (19) \\ &= \sum_{l=2}^{|\mathcal{X}(SNR)|} \int_{\ddot{\mathcal{O}}} p(\mathbf{H}) Q\left(\frac{\|\mathbf{H}\mathbf{U}_l\mathbf{D}_l\mathbf{V}_l^H\|}{\sqrt{2}} \right) d\mathbf{H} \\ &= \sum_{l=2}^{|\mathcal{X}(SNR)|} \int_{\ddot{\mathcal{O}}} p(\mathbf{H}) Q\left(\frac{\|\mathbf{H}\mathbf{U}_l\mathbf{D}_l\|}{\sqrt{2}} \right) d\mathbf{H} \\ &= \sum_{l=2}^{|\mathcal{X}(SNR)|} \int_{\mathcal{O}_l} p(\mathbf{H}_l) Q\left(\frac{\|\mathbf{H}_l\mathbf{D}_l\|}{\sqrt{2}} \right) d\mathbf{H}_l, \tag{20} \end{aligned}$$

where (19) is obtained using (10), and $\Delta \mathbf{X}_l = \mathbf{U}_l \mathbf{D}_l \mathbf{V}_l^H$, obtained upon singular value decomposition (SVD), with $\mathbf{U}_l \in \mathbb{C}^{n_t \times n_t}$, $\mathbf{D}_l \in \mathbb{R}^{n_t \times T}$, $\mathbf{V}_l \in \mathbb{C}^{T \times T}$. In (20), $\mathbf{H}_l = \mathbf{H}\mathbf{U}_l$, and $\mathcal{O}_l$ is as defined in (23) at the top of the next page. Denoting the entries of $\mathbf{H}_l = \mathbf{H}\mathbf{U}_l$ by $h_{ij}(l)$, we define the set $\mathcal{O}'_l$ as shown in (24) at the top of the page. In Appendix B, it is shown that $\mathcal{O}_l = \mathcal{O}'_l$ almost surely as $SNR \to \infty$. As a result, in the high SNR scenario, (20) becomes

$$P\left(\ddot{\mathcal{O}}, \mathcal{E}\right) \leq \sum_{l=2}^{|\mathcal{X}(SNR)|} \int_{\mathcal{O}'_l} p(\mathbf{H}_l) Q\left(\frac{\|\mathbf{H}_l \mathbf{D}_l\|}{\sqrt{2}}\right) d\mathbf{H}_l. \quad (26)$$

Now, we evaluate each of the summands of (26). Let

$$P_{\mathcal{O}'_l} \triangleq \int_{\mathcal{O}'_l} p(\mathbf{H}_l) Q\left(\frac{\|\mathbf{H}_l \mathbf{D}_l\|}{\sqrt{2}}\right) d\mathbf{H}_l.$$

Now, we define $P_{\mathcal{O}'_l}(\delta)$ as

$$P_{\mathcal{O}'_l}(\delta) \triangleq \int_{\mathcal{O}'_l(\delta)} p(\mathbf{H}_l) Q\left(\frac{\|\mathbf{H}_l \mathbf{D}_l\|}{\sqrt{2}}\right) d\mathbf{H}_l,$$

where $\mathcal{O}'_l(\delta)$ is as defined in (25) at the top of the page with $\delta > 0$. It is clear that as $SNR \to \infty$,

$$P_{\mathcal{O}'_l} \geq P_{\mathcal{O}'_l}(\delta_1) \geq P_{\mathcal{O}'_l}(\delta_2) \geq P_{\mathcal{O}'_l}(\delta_3) \geq \cdots$$

for $0 < \delta_1 < \delta_2 < \delta_3 < \cdots$. To be precise,

$$\lim_{SNR \to \infty} P_{\mathcal{O}'_l} \geq \lim_{SNR \to \infty} P_{\mathcal{O}'_l}(\delta_1) \geq \lim_{SNR \to \infty} P_{\mathcal{O}'_l}(\delta_2) \geq \cdots$$

and hence

$$\lim_{SNR \to \infty} \frac{\log P_{\mathcal{O}'_l}}{\log SNR} \geq \lim_{SNR \to \infty} \frac{\log P_{\mathcal{O}'_l}(\delta_1)}{\log SNR}$$
$$\geq \lim_{SNR \to \infty} \frac{\log P_{\mathcal{O}'_l}(\delta_2)}{\log SNR} \geq \cdots$$

for $0 < \delta_1 < \delta_2 < \cdots$. Also, from the definitions of $P_{\mathcal{O}'_l}$ and $P_{\mathcal{O}'_l}(\delta)$, it is evident that

$$\lim_{\delta \to 0^+} \left(\lim_{SNR \to \infty} P_{\mathcal{O}'_l}(\delta)\right) = \lim_{SNR \to \infty} P_{\mathcal{O}'_l},$$

where "$\delta \to 0^+$" means that δ tends to 0 through positive values. Therefore,

$$\lim_{\delta \to 0^+} \left(\lim_{SNR \to \infty} \frac{\log P_{\mathcal{O}'_l}(\delta)}{\log SNR}\right) = \lim_{SNR \to \infty} \frac{\log P_{\mathcal{O}'_l}}{\log SNR} \quad (27)$$

In Appendix C, it is shown that for every $\delta > 0$, as $SNR \to \infty$,

$$P_{\mathcal{O}'_l}(\delta) \leq \frac{1}{2} e^{-\left(a SNR^{\frac{\delta}{n_r}} + o\left(SNR^{\frac{\delta}{n_r}}\right)\right)} \quad (28)$$

where $a \doteq SNR^0$. Using (28) in (27), we obtain

$$\lim_{SNR \to \infty} \frac{\log P_{\mathcal{O}'_l}}{\log SNR} = -\infty$$

so that

$$P_{\mathcal{O}'_l} \doteq SNR^{-\infty}. \quad (29)$$

The interpretation of (29) is that $P_{\mathcal{O}'_l}$ experiences an *exponential fall* with increasing SNR, and the dependency with SNR is not polynomial (unlike, for example, $P(\widetilde{\mathcal{O}})$ given by (18)).

Using (29) in (26), we have as $SNR \to \infty$,

$$P\left(\ddot{\mathcal{O}}, \mathcal{E}\right) \leq \sum_{l=2}^{|\mathcal{X}(SNR)|} P_{\mathcal{O}'_l} \doteq SNR^{-\infty}, \quad (30)$$

which is because $|\mathcal{X}(SNR)|$ has a polynomial dependency with SNR (since $|\mathcal{X}(SNR)| \doteq SNR^{rT}$) but all the $P_{\mathcal{O}'_l}$ experience an exponential fall with increasing SNR (so that they are exponentially equal to $SNR^{-\infty}$). Using (18) and (30) in (17), we obtain

$$P(\bar{\mathcal{O}}, \mathcal{E}) \leq SNR^{\max\{-n_t(n_r - r), -\infty\}}$$
$$= SNR^{-n_t(n_r - r)}. \quad (31)$$

Using (12), (13), and (31) in (15), we arrive at

$$P_e \doteq SNR^{\max\{-d^*(r), -n_t(n_r - r)\}} = SNR^{-d^*(r)},$$

where $d^*(r)$ is given in Definition 5. This proves the DMT-optimality of the STBC-scheme when (7) is satisfied.

Now, combining this obtained result with that of Theorem 1, we see that an STBC-scheme is DMT-optimal if for each codeword difference matrix $\Delta \mathbf{X} \neq \mathbf{O}$,

$$det\left(\Delta \mathbf{X} \Delta \mathbf{X}^H\right) \doteq SNR^{\left(\min\left\{n_t\left(1 - \frac{r}{n_r}\right), n_t\left(1 - \frac{r}{n_t}\right)\right\}\right)}$$
$$= SNR^{n_t\left(1 - \frac{r}{n_{min}}\right)}.$$

This completes the proof of the theorem. ∎

Note 1: Theorem 1 can also be proved using the steps of the proof of Theorem 2. To do so, we need to redefine $\mathcal{O}$ given by (8) as being equal to

$$\left\{ \mathbf{H} \quad \middle| \quad \begin{aligned} \log det\left(\mathbf{I}_{n_t} + \frac{SNR}{n_t}\mathbf{H}^H\mathbf{H}\right) &\leq r \log SNR \\ &+ o(\log SNR) \end{aligned} \right\}.$$

Redefining $\mathcal{O}$ this way is justified because $det(\mathbf{I} + \mathbf{AB}) = det(\mathbf{I} + \mathbf{BA})$, with $\mathbf{I}$ begin the identity matrix of compatible dimensions. With $\mathcal{O}$ thus redefined, proceeding as in the proof of Theorem 2 from (8) onwards helps us arrive at the proof of Theorem 1.

The implication of Theorem 2 is that for asymmetric MIMO systems, the requirement demanded by Theorem 1 on the minimum of the determinants of the codeword difference matrices of STBCs that the STBC-scheme consists of is relaxed. In the following section, we show the usefulness of Theorem 2 in the context of LSTBCs for asymmetric MIMO systems.

IV. DMT-OPTIMALITY CRITERION FOR LSTBC-SCHEMES

In its most general form, an LSTBC $\mathcal{X}_L$ is given by

$$\mathcal{X}_L = \left\{ \sum_{i=1}^{k} (s_{iI}\mathbf{A}_{iI} + s_{iQ}\mathbf{A}_{iQ}) \right\}, \quad (32)$$

where $[s_{1I}, s_{1Q}, \cdots, s_{kI}, s_{kQ}]^{\mathrm{T}} \in \mathcal{A} \subset \mathbb{R}^{2k \times 1}$, and $\mathbf{A}_{iI}$, $\mathbf{A}_{iQ} \in \mathbb{C}^{n_t \times T}$ are called *weight matrices* [16] associated with the real information symbols s_{iI} and s_{iQ}, respectively. In the case of most known LSTBCs, either all the real symbols s_{iI}, s_{iQ}, respectively take values independently from the same

$$\widetilde{\mathcal{O}} \triangleq \left\{ \mathbf{H} \;\middle|\; \sum_{i=1}^{n_r} \log\left(1 + \frac{SNR}{n_t}\|\mathbf{h}_i\|^2\right) > r\log SNR + o(\log SNR) \geq \frac{1}{n_t}\sum_{i=1}^{n_r}\sum_{j=1}^{n_t}\log(1 + SNR|h_{ij}|^2) \right\}, \quad (21)$$

$$\ddot{\mathcal{O}} \triangleq \left\{ \mathbf{H} \;\middle|\; \frac{1}{n_t}\sum_{i=1}^{n_r}\sum_{j=1}^{n_t}\log(1 + SNR|h_{ij}|^2) > r\log SNR + o(\log SNR) \right\}, \quad (22)$$

$$\mathcal{O}_l \triangleq \left\{ \mathbf{H}_l \;\middle|\; \sum_{i=1}^{n_r}\sum_{j=1}^{n_t}\log\left(1 + SNR|h_{ij}|^2\right) > n_t r\log SNR + o(\log SNR) \right\}, \quad (23)$$

$$\mathcal{O}'_l \triangleq \left\{ \mathbf{H}_l \;\middle|\; \sum_{i=1}^{n_r}\sum_{j=1}^{n_t}\log\left(1 + SNR|h_{ij}(l)|^2\right) > n_t r\log SNR + o(\log SNR) \right\}, \quad (24)$$

$$\mathcal{O}'_l(\delta) \triangleq \left\{ \mathbf{H}_l \;\middle|\; \sum_{i=1}^{n_r}\sum_{j=1}^{n_t}\log\left(1 + SNR|h_{ij}(l)|^2\right) \geq n_t(r+\delta)\log SNR \right\}. \quad (25)$$

---

signal set $\mathcal{A}'$, in which case

$$\mathcal{A} = \underbrace{\mathcal{A}' \times \mathcal{A}' \times \cdots \times \mathcal{A}'}_{2k \text{ times}},$$

or each symbol pair (s_{iI}, s_{iQ}) jointly takes values from a real constellation $\mathcal{A}'' \subset \mathbb{R}^{2\times1}$ (the same can be viewed as each complex symbol $s_i = s_{iI} + js_{iQ}$, $j = \sqrt{-1}$, taking values from a complex constellation that is subset of $\mathbb{C}$), independent of other symbol pairs, in which case

$$\mathcal{A} = \underbrace{\mathcal{A}'' \times \mathcal{A}'' \times \cdots \times \mathcal{A}''}_{k \text{ times}}.$$

For the LSTBC given by (32), the system model given by (1) can be rewritten as

$$\widetilde{vec(\mathbf{Y})} = \left(\mathbf{I}_T \otimes \check{\mathbf{H}}\right)\mathbf{Gs} + \widetilde{vec(\mathbf{N})}, \quad (33)$$

where $\mathbf{G} \in \mathbb{R}^{2Tn_t \times 2k}$ is called the *Generator matrix* of the STBC, and $\mathbf{s} \in \mathbb{R}^{2k\times1}$, both defined as

$$\mathbf{G} \triangleq \left[\widetilde{vec(\mathbf{A}_{1I})}\; \widetilde{vec(\mathbf{A}_{1Q})}, \cdots, \widetilde{vec(\mathbf{A}_{kQ})}\right], \quad (34)$$

$$\mathbf{s} \triangleq [s_{1I}, s_{1Q}, \cdots, s_{kI}, s_{kQ}]^{\mathrm{T}}, \quad (35)$$

with $\mathbb{E}_\mathbf{s}\left(tr\left(\mathbf{Gss}^{\mathrm{T}}\mathbf{G}^{\mathrm{T}}\right)\right) \leq T\, SNR$.

Definition 6: (*Code-rate of an LSTBC*) The code-rate[4] of the LSTBC $\mathcal{X}_L$ defined in (32) is

$$\begin{aligned}
\text{Code-Rate}(\mathcal{X}_L) &= \frac{Rank(\mathbf{G})}{T} \text{ real dpcu} \\
&= \frac{Rank(\mathbf{G})}{2T} \text{ complex dpcu}
\end{aligned}$$

where "dpcu" stands for "dimensions per channel use", and $\mathbf{G}$ is the generator matrix of $\mathcal{X}_L$. If $Rank(\mathbf{G}) = 2k$, $\mathcal{X}_L$ is called a rate-k/T STBC, meaning which it has a code-rate of k/T complex dpcu.

A necessary condition for an LSTBC given by (32) to be sphere-decodable [21] is that the constellation $\mathcal{A}$ should be

[4]In the literature, "code-rate" is referred to simply as 'rate'. In this paper, to avoid confusion with the bit rate which is $\frac{\log|\mathcal{A}|}{T}$ bits per channel use, we have opted to use the term "code-rate".

a finite subset of a $2k$-dimensional real lattice with each of the real symbols independently taking $|\mathcal{A}|^{\frac{1}{2k}}$ possible values. Further, if $k/T \leq n_{min}$, all the symbols of the STBC can be entirely decoded using the standard sphere-decoder [21] or its variations [22], [23]. However, when $k/T > n_{min}$, for each of the $|\mathcal{A}|^{\left(1 - \frac{n_{min}T}{k}\right)}$ possibilities for any $2(k - n_{min}T)$ real symbols, the remaining $2n_{min}T$ real symbols can be evaluated using the sphere decoder. Hence, the ML-complexity of the rate-$\frac{k}{T}$ STBC in such a scenario is approximately $|\mathcal{A}|^{\left(1 - \frac{n_{min}T}{k}\right)}$ times the sphere-decoding complexity of a rate-n_{min} STBC.

Definition 7: (*LSTBC-scheme*) A rate-k/T LSTBC-scheme $\mathcal{X}$ is defined as a family of rate-k/T LSTBCs (indexed by SNR) of block length T so that $\mathcal{X} \triangleq \{\mathcal{X}_L(SNR)\}$, where the STBC $\mathcal{X}_L(SNR)$ corresponds to a signal-to-noise ratio of SNR at each receive antenna.

For an LSTBC $\mathcal{X}_L(SNR)$ of the form given by (32) with the $2k$-dimensional real constellation denoted by $\mathcal{A}(SNR)$, from (3), we have that for each codeword matrix $\mathbf{X}_i \in \mathcal{X}_L(SNR)$, $i = 1, 2, \cdots, |\mathcal{X}_L(SNR)|$,

$$\|\mathbf{X}_i\|^2 = \|\mathbf{Gs}\|^2 \doteq SNR,$$

where $\mathbf{G}$ and $\mathbf{s}$ are as defined in (34) and (35), respectively. For convenience, we assume that

$$\max_{\mathbf{s}\in\mathcal{A}(SNR)}\{\|\mathbf{Gs}\|^2\} \doteq SNR$$

and hence,

$$\left.\begin{array}{l} \max\limits_{s_{iI}}|s_{iI}|^2 \doteq SNR, \\ \max\limits_{s_{iQ}}|s_{iQ}|^2 \doteq SNR \end{array}\right\} \forall\, i = 1, \cdots, k. \quad (36)$$

When the bit rate of $\mathcal{X}_L(SNR)$ is $r\log SNR + o(\log SNR)$ bits per channel use, we have $|\mathcal{A}(SNR)| \doteq SNR^{rT}$. Further, when each of the $2k$ real symbols takes values from the same real constellation $\mathcal{A}'(SNR)$, it follows that

$$|\mathcal{A}'(SNR)| \doteq SNR^{\frac{rT}{2k}}. \quad (37)$$

Let $\mathcal{A}'(SNR) = \mu\mathcal{A}_{M-\text{PAM}}$, where μ is a scalar normalizing constant designed to satisfy the constraints in (36), $\mathcal{A}_{M-\text{PAM}}$ is the regular M-PAM constellation given by

$$\mathcal{A}_{M-\text{PAM}} = \left\{ 2\left\lfloor -\frac{M}{2} \right\rfloor + l \ , \ l = 1, 3, \cdots, 2M - 1 \right\}, \quad (38)$$

and $\mu\mathcal{A}_{M-\text{PAM}} = \{\mu a \mid a \in \mathcal{A}_{M-\text{PAM}}\}$. Now, we have from (37) and (36),

$$\begin{aligned} M &\doteq SNR^{\frac{rT}{2k}}, \\ \mu M &\doteq SNR^{\frac{1}{2}}, \end{aligned}$$

and hence, $\mu^2 \doteq SNR^{\left(1 - \frac{rT}{k}\right)}$.

For an LSTBC-scheme $\mathcal{X}$ that satisfies (3) and has a bit rate of $r \log SNR + o(\log SNR)$ bits per channel use with the real symbols of its LSTBCs taking values from a scaled M-PAM, the LSTBCs $\mathcal{X}_L(SNR)$ can be expressed as

$$\mathcal{X}_L(SNR) = \{\mu\mathbf{X} \mid \mathbf{X} \in \mathcal{X}_U(SNR)\},$$

where $\mu^2 \doteq SNR^{\left(1 - \frac{rT}{k}\right)}$, and $\mathcal{X}_U(SNR)$ is the *unnormalized* (so that it does not satisfy the energy constraint given in (3)) LSTBC given by

$$\mathcal{X}_U(SNR) = \left\{ \sum_{i=1}^{k} (s_{iI}\mathbf{A}_{iI} + s_{iQ}\mathbf{A}_{iQ}) \right\} \quad (39)$$

with $s_{iI}, s_{iQ} \in \mathcal{A}_{M-\text{PAM}}$, $i = 1, 2, \cdots, k$, and $M \doteq SNR^{\frac{rT}{2k}}$. With $\mathcal{X}_L(SNR)$ and $\mathcal{X}_U(SNR)$ thus defined, we define the non-vanishing determinant property of an LSTBC-scheme as follows.

Definition 8: (*Non-vanishing determinant*) An LSTBC-scheme $\mathcal{X}$ is said to have the non-vanishing determinant property if the codeword difference matrices $\Delta\mathbf{X}$ of $\mathcal{X}_U(SNR)$ are such that

$$\min_{\Delta\mathbf{X} \neq \mathbf{O}} det\left(\Delta\mathbf{X}\Delta\mathbf{X}^H\right) \doteq SNR^0.$$

A necessary and sufficient condition for an LSTBC-scheme $\mathcal{X} = \{\mathcal{X}_L(SNR)\}$, where $\mathcal{X}_L(SNR)$ has weight matrices $\mathbf{A}_{iI}, \mathbf{A}_{iQ}, i = 1, \cdots, k$, and encodes its real symbols using PAM, to have the non-vanishing determinant property is that the design $\mathcal{X}_{\mathbb{Z}}$, defined as

$$\mathcal{X}_{\mathbb{Z}} = \left\{ \sum_{i=1}^{k} (s_{iI}\mathbf{A}_{iI} + s_{iQ}\mathbf{A}_{iQ}) \left| \begin{array}{l} s_{iI}, s_{iQ} \in \mathbb{Z}, \\ i = 1, 2, \cdots, k. \end{array} \right. \right\}, \quad (40)$$

is such that for any non-zero matrix $\mathbf{X}$ of $\mathcal{X}_{\mathbb{Z}}$,

$$det\left(\mathbf{XX}^H\right) \geq C,$$

where C is some strictly positive constant bounded away from zero.

Remark 2: Any LSTBC is completely specified by a set of weight matrices (equivalently, its generator matrix, defined in (34)) and a $2k$-dimensional real constellation $\mathcal{A}$ that its real symbol vector takes values from, as evident from (32). However, for an LSTBC, the set of weight matrices (equivalently, its generator matrix) and the $2k$-dimensional constellation need not be unique. As an example, consider the perfect code for 3 transmit antennas, which encodes 9 independent complex

symbols, and can be expressed as

$$\mathcal{X}_P = \left\{ \sum_{i=1}^{9} (x_{iI}\mathbf{A}_{iI} + x_{iQ}\mathbf{A}_{iQ}) \left| \begin{array}{l} x_i \in \mathcal{A}_{M^2-HEX}, \\ i = 1, 2, \cdots, 9 \end{array} \right. \right\},$$

where $\mathcal{A}_{M^2-HEX}$ is an M^2-HEX constellation given by

$$\mathcal{A}_{M^2-HEX} = \left\{ a + \omega b \left| \begin{array}{l} a, b \in \mathcal{A}_{M-PAM}, \\ \omega = e^{\frac{j2\pi}{3}} \end{array} \right. \right\}.$$

We can equivalently express $\mathcal{X}_P$ as

$$\mathcal{X}_P = \left\{ \sum_{i=1}^{9} (s_{iI}\mathbf{A}'_{iI} + s_{iQ}\mathbf{A}'_{iQ}) \left| \begin{array}{l} s_{iI}, s_{iQ} \in \mathcal{A}_{M-PAM}, \\ i = 1, 2, \cdots, 9 \end{array} \right. \right\},$$

where $\mathbf{A}'_{iI} = \mathbf{A}_{iI}$, $\mathbf{A}'_{iQ} = -\frac{1}{2}\mathbf{A}_{iI} + \frac{\sqrt{3}}{2}\mathbf{A}_{iQ}$, $i = 1, 2, \cdots, 9$.

In general, any LSTBC $\mathcal{X}_L$ with a generator matrix $\mathbf{G}$ and a $2k$-dimensional constellation $\mathcal{A}$ that is a subset of a $2k$-dimensional real lattice $\mathcal{L}$ can be alternatively viewed to have $\mathbf{GG}_{\mathcal{L}}$ as its generator matrix and a $2k$-dimensional constellation $\mathcal{A}'$ that is a subset of $\mathbb{Z}^{2k \times 1}$, where $\mathbf{G}_{\mathcal{L}} \in \mathbb{R}^{2k \times 2k}$ is the generator matrix of $\mathcal{L}$.

In the following lemma, we prove that for an LSTBC-scheme to be DMT-optimal, the code-rate of its LSTBCs has to be at least equal to n_{min} complex dpcu.

Lemma 1: A rate-p LSTBC-scheme with $p < \min\{n_t, n_r\}$ is not DMT-optimal.

Proof: With the system model given by (33), from (2), we have $\mathbb{E}_s\left(tr\left(\mathbf{Gss}^T\mathbf{G}^T\right)\right) \leq T \, SNR$. Hence, $tr\left(\mathbf{GQG}^T\right) \leq T \, SNR$, where $\mathbf{Q} = \mathbb{E}_s\left(\mathbf{ss}^T\right) \in \mathbb{R}^{2k \times 2k}$. Since $\mathbf{G}$ is fixed for an LSTBC, we assume that $tr(\mathbf{Q}) = \alpha \, SNR$ for some finite positive constant α with the overall constraint $tr\left(\mathbf{GQG}^T\right) \leq T \, SNR$ being satisfied. Now, the ergodic capacity [36] C of the equivalent channel is given by [5]

$$\begin{aligned} C &= \max_{tr\left(\mathbf{GQG}^T\right) \leq T \, SNR} C(\mathbf{Q}), \\ C(\mathbf{Q}) &= \frac{1}{2T}\mathbb{E}_{\mathbf{H}}\left[\log det\left(\mathbf{I}_{2Tn_r} + \bar{\mathbf{H}}\mathbf{GQG}^T\bar{\mathbf{H}}^T\right)\right] \end{aligned}$$

where $\bar{\mathbf{H}} = \mathbf{I}_T \otimes \check{\mathbf{H}}$, and capacity is achieved if $\mathbf{s}$ is jointly Gaussian with zero mean and a covariance matrix $\mathbf{Q}$ that satisfies $tr(\mathbf{Q}) = \alpha \, SNR$. Now, $(\alpha \, SNR)\mathbf{I}_{2k} - \mathbf{Q}$ is positive semidefinite[5] and so is $\bar{\mathbf{H}}\mathbf{G}\left((\alpha \, SNR)\mathbf{I}_{2k} - \mathbf{Q}\right)\mathbf{G}^T\bar{\mathbf{H}}^T$. Hence,

$$\mathbf{I}_{2Tn_r} + (\alpha \, SNR)\bar{\mathbf{H}}\mathbf{GG}^T\bar{\mathbf{H}}^T \succeq \mathbf{I}_{2Tn_r} + \bar{\mathbf{H}}\mathbf{GQG}^T\bar{\mathbf{H}}^T,$$

where $\mathbf{A} \succeq \mathbf{B}$ denotes that $\mathbf{A} - \mathbf{B}$ is positive semidefinite. Using the inequality $det(\mathbf{A}) \geq det(\mathbf{B})$ when $\mathbf{A} \succeq \mathbf{B}$ [37, Corollary 7.7.4], we have

$$\begin{aligned} C &\leq \frac{1}{2T}\mathbb{E}_{\mathbf{H}}\left(\log det\left(\mathbf{I}_{2Tn_r} + (\alpha \, SNR)\bar{\mathbf{H}}\mathbf{GG}^T\bar{\mathbf{H}}^T\right)\right) \\ &= \frac{1}{2T}\mathbb{E}_{\mathbf{H}}\left(\log det\left(\mathbf{I}_{2k} + (\alpha \, SNR)\mathbf{G}^T\bar{\mathbf{H}}^T\bar{\mathbf{H}}\mathbf{G}\right)\right) \end{aligned} \quad (41)$$

---

[5]Since $\mathbf{Q}$ is symmetric and positive semidefinite with $tr(\mathbf{Q}) = \alpha \, SNR$, each eigenvalue of $\mathbf{Q}$ is at most equal to $\alpha \, SNR$. With $\mathbf{Q} = \mathbf{UPU}^T$, where $\mathbf{U}$ is an orthonormal matrix and $\mathbf{P}$ is a diagonal matrix with the diagonal entries being the eigenvalues of $\mathbf{Q}$, it is clear that $(\alpha \, SNR)\mathbf{I}_{2k} - \mathbf{Q}$ is positive semidefinite.

$$\leq \quad \frac{1}{2T} \log \det \left(\mathbb{E}_{\mathbf{H}} \left(\mathbf{I}_{2k} + (\alpha \ SNR) \mathbf{G}^{\mathrm{T}} \bar{\mathbf{H}}^{\mathrm{T}} \bar{\mathbf{H}} \mathbf{G} \right) \right) \quad (42)$$

$$= \quad \frac{1}{2T} \log \det \left(\mathbf{I}_{2k} + (\alpha n_r \ SNR) \mathbf{G}^{\mathrm{T}} \mathbf{G} \right)$$

$$= \quad \frac{1}{2T} \log \det \left(\mathbf{I}_{2k} + (\alpha n_r \ SNR) \mathbf{D} \right), \quad (43)$$

where (41) is due to the identity $\det(\mathbf{I} + \mathbf{AB}) = \det(\mathbf{I} + \mathbf{BA})$, (42) is due to Jensen's inequality and the fact that $\log \det(.)$ is concave [37, Theorem 7.6.7] on the convex set of positive definite matrices, and (43) is obtained upon the singular value decomposition of $\mathbf{G}^{\mathrm{T}} \mathbf{G}$, resulting in $\mathbf{G}^{\mathrm{T}} \mathbf{G} = \mathbf{U} \mathbf{D} \mathbf{U}^{\mathrm{T}}$. Let $Rank(\mathbf{G}) = 2pT$ (since the code-rate of the LSTBC is p complex dpcu), and denoting the non-zero diagonal entries of $\mathbf{D}$ by d_i, $i = 1, 2, \cdots, 2pT$, we have

$$C \quad \leq \quad \frac{1}{2T} \sum_{i=1}^{2pT} \log \left(1 + (\alpha n_r d_i) \ SNR \right). \quad (44)$$

Equation (44) reveals that as $SNR \to \infty$, $C \leq p \log SNR + o(\log SNR)$. Since the ergodic capacity itself is at most $p \log SNR + o(\log SNR)$, if $p < n_{min}$, the error probability of the LSTBC-scheme is bounded away from 0 when $r > p$. Hence, the diversity gain $d(r)$ of the LSTBC-scheme is not given by (4), making the LSTBC-scheme strictly sub-optimal with respect to DMT. ∎

So, for DMT-optimality, the LSTBCs of the LSTBC-scheme should have a code-rate of at least n_{min} complex dpcu. Now, we give a sufficiency criterion for an LSTBC-scheme to be DMT-optimal.

Corollary 1: Let the LSTBCs of an LSTBC-scheme $\mathcal{X}$ be given by $\mathcal{X}_L(SNR) = \{\mu \mathbf{X} \mid \mathbf{X} \in \mathcal{X}_U(SNR)\}$, with $\mu^2 \doteq SNR^{\left(1 - \frac{r}{n_{min}}\right)}$, and

$$\mathcal{X}_U(SNR) = \left\{ \sum_{i=1}^{n_{min}T} (s_{iI} \mathbf{A}_{iI} + s_{iQ} \mathbf{A}_{iQ}) \right\}$$

where $s_{iI}, s_{iQ} \in \mathcal{A}_{M-\mathrm{PAM}}$, $i = 1, 2, \cdots, n_{min}T$, $M \doteq SNR^{\frac{r}{2n_{min}}}$. Then, $\mathcal{X}$ is DMT optimal for the quasi-static Rayleigh faded $n_t \times n_r$ MIMO channel with CSIR if it has the non-vanishing determinant property.

The proof follows from the application of Theorem 2. Notice the difference between the result of Corollary 1 and that of Theorem 3 of [4]. The latter result relies on STBC-schemes that are based on rate-n_t LSTBCs, irrespective of the value of n_r, while our result only requires that the code-rate of the LSTBC be $\min\{n_t, n_r\}$ complex dpcu which, together with NVD, guarantees DMT-optimality of the LSTBC-scheme. The usefulness of our result for asymmetric MIMO systems is discussed in the following section.

V. DMT-OPTIMAL LSTBC-SCHEMES FOR ASYMMETRIC MIMO SYSTEMS

Rate-n_t LSTBC-schemes having the NVD property are known to be DMT-optimal for arbitrary number of receive antennas. The methods to construct LSTBCs of such schemes for arbitrary values of n_t with minimal-delay ($T = n_t$) have been proposed in [4], [10], and such constructions with additional properties have also been proposed for specific

number of transmit antennas - the perfect codes for 2, 3, 4, and 6 transmit antennas [9]. For the case $n_r < n_t$, Corollary 1 establishes that a rate-n_r LSTBC-scheme with the NVD property achieves the optimal DMT and such LSTBC-schemes can make use of the sphere decoder efficiently. For asymmetric MIMO systems, rate-n_r LSTBC-schemes with the NVD property can be obtained directly from rate-n_t LSTBC-schemes with the NVD property, as shown in the following corollary.

Corollary 2: Consider a rate-n_t, minimum delay LSTBC-scheme $\mathcal{X} = \{\mathcal{X}(SNR)\}$ equipped with the NVD property, where $\mathcal{X}(SNR) = \{\mu \mathbf{X} \mid \mathbf{X} \in \mathcal{X}_U(SNR)\}$, with $\mu^2 \doteq SNR^{\left(1 - \frac{r}{n_t}\right)}$ and

$$\mathcal{X}_U(SNR) = \left\{ \sum_{i=1}^{n_t^2} (s_{iI} \mathbf{A}_{iI} + s_{iQ} \mathbf{A}_{iQ}) \right\}$$

where $s_{iI}, s_{iQ} \in \mathcal{A}_{M-\mathrm{PAM}}$, $i = 1, 2, \cdots, n_t^2$, $M \doteq SNR^{\frac{r}{2n_t}}$. Let $\mathcal{I} \subset \{1, 2, \cdots, n_t^2\}$, with $|\mathcal{I}| = n_t n_r$, where $n_r < n_t$. Then, the rate-n_r LSTBC-scheme $\mathcal{X}'$ consisting of LST-BCs $\mathcal{X}'(SNR) = \{\mu \mathbf{X} \mid \mathbf{X} \in \mathcal{X}'_U(SNR)\}$, with $\mu^2 \doteq SNR^{\left(1 - \frac{r}{n_r}\right)}$ and

$$\mathcal{X}'_U(SNR) = \left\{ \sum_{i \in \mathcal{I}} (s_{iI} \mathbf{A}_{iI} + s_{iQ} \mathbf{A}_{iQ}) \right\}$$

where $s_{iI}, s_{iQ} \in \mathcal{A}_{M-\mathrm{PAM}}$, $i \in \mathcal{I}$, $M \doteq SNR^{\frac{r}{2n_r}}$, is DMT-optimal for the asymmetric $n_t \times n_r$ quasi-static MIMO channel with Rayleigh fading and CSIR.

The proof is a trivial application of Corollary 1 and the fact that $\mathcal{X}'$ also has the NVD property. As an example, consider the Golden code-scheme [6] $\mathcal{X}_G = \{\mathcal{X}_G(SNR)\}$, where

$$\mathcal{X}_G(SNR) = \left\{ \mu \left[\begin{array}{cc} \alpha(s_1 + s_2\theta) & \alpha(s_3 + s_4\theta) \\ j\bar{\alpha}(s_3 + s_4\bar{\theta}) & \bar{\alpha}(s_1 + s_2\bar{\theta}) \end{array} \right] \right\},$$

$s_{iI}, s_{iQ} \in \mathcal{A}_{M-\mathrm{PAM}}$, $i = 1, 2, 3, 4$, $M \doteq SNR^{\frac{r}{4}}$, $\mu^2 \doteq SNR^{\left(1 - \frac{r}{2}\right)}$, $\theta = (1 + \sqrt{5})/2$, $\bar{\theta} = (1 - \sqrt{5})/2$, $j = \sqrt{-1}$, $\bar{\alpha} = 1 + j\theta$, and $\alpha = 1 + j\bar{\theta}$. It is known that $\mathcal{X}_G$ is DMT-optimal for arbitrary values of n_r. So, from Corollary 2, the LSTBC-scheme $\mathcal{X}'_G = \{\mathcal{X}'_G(SNR)\}$, where

$$\mathcal{X}'_G(SNR) = \left\{ \mu \left[\begin{array}{cc} \alpha(s_1 + s_2\theta) & 0 \\ 0 & \bar{\alpha}(s_1 + s_2\bar{\theta}) \end{array} \right] \right\}$$

with $s_{iI}, s_{iQ} \in \mathcal{A}_{M-\mathrm{PAM}}$, $i = 1, 2$, $M \doteq SNR^{\frac{r}{2}}$, $\mu^2 \doteq SNR^{1-r}$, is DMT-optimal for the 2×1 MIMO system.

Note 2: The described method of obtaining a rate-n_r LSTBC from a rate-n_t LSTBC ($n_r < n_t$) is called *puncturing* [20].

A. Schemes based on CIOD for the 2×1 and 4×1 MIMO systems

The STBC from CIOD [16] for 4 transmit antennas, denoted by $\mathcal{X}_C$ and given by (45) at the top of the next page, is a rate-1 LSTBC with symbol-by-symbol ML-decodability. $\mathcal{X}_C$ has a minimum determinant of 10.24 when its symbols x_i, $i = 1, 2, 3, 4$ take values from a $\tan^{-1}(2)/2$ radian rotated M^2-QAM constellation, irrespective of the value of M. Expressing (45) as

$$\mathcal{X}_C = \left\{ \left[\begin{array}{cccc} x_{1I} + jx_{3Q} & x_{2I} + jx_{4Q} & 0 & 0 \\ -x_{2I} + jx_{4Q} & x_{1I} - jx_{3Q} & 0 & 0 \\ 0 & 0 & x_{3I} + jx_{1Q} & x_{4I} + jx_{2Q} \\ 0 & 0 & -x_{4I} + jx_{2Q} & x_{3I} - jx_{1Q} \end{array} \right] \middle| \begin{array}{l} x_i \in e^{j\theta} \mathcal{A}_{M^2 - QAM}, \\ i = 1, 2, 3, 4, \\ \theta = \frac{1}{2} \tan^{-1}(2) \end{array} \right\}. \tag{45}$$

$$\mathcal{X}_C = \left\{ \sum_{i=1}^{4} (x_{iI} \mathbf{A}_{iI} + x_{iQ} \mathbf{A}_{iQ}) \right\} \tag{46}$$

where $x_i \in e^{j\theta} \mathcal{A}_{M^2 - QAM}$, $i = 1, 2, 3, 4$, $\theta = \frac{1}{2} \tan^{-1}(2)$. we note that (46) can be alternatively written as

$$\mathcal{X}_C = \left\{ \sum_{i=1}^{4} (s_{iI} \mathbf{A}'_{iI} + s_{iQ} \mathbf{A}'_{iQ}) \right\}$$

where $s_{iI}, s_{iQ} \in \mathcal{A}_{M-PAM}$, $i = 1, \cdots, 4$, and

$$\begin{array}{rl} \mathbf{A}'_{iI} = & \cos\theta \mathbf{A}_{iI} + \sin\theta \mathbf{A}_{iQ}, \\ \mathbf{A}'_{iQ} = & -\sin\theta \mathbf{A}_{iI} + \cos\theta \mathbf{A}_{iQ}. \end{array} \left. \begin{array}{l} \\ \end{array} \right\} \begin{array}{l} i = 1, 2, 3, 4, \\ \theta = \frac{1}{2} \tan^{-1}(2). \end{array}$$

Since $\mathcal{X}_C$ has a minimum determinant of 10.24 independent of the value of M, any non-zero matrix $\mathbf{X}$ of

$$\mathcal{X}_{\mathbb{Z}} = \left\{ \sum_{i=1}^{4} (s_{iI} \mathbf{A}'_{iI} + s_{iQ} \mathbf{A}'_{iQ}) \middle| \ s_{iI}, s_{iQ} \in \mathbb{Z} \right\}$$

is such that

$$det \left(\mathbf{X}\mathbf{X}^H \right) \geq 0.04.$$

Hence, the CIOD based STBC-scheme has the NVD property and is DMT-optimal for the 4×1 MIMO system. Using the same analysis, one can show that the STBC-scheme based on the CIOD for 2 transmit antennas is DMT-optimal for the 2×1 MIMO system.

B. Four-group decodable STBC-schemes for $n_t \times 1$ MIMO systems

For the special case of n_t being a power of 2, rate-1, 4-group decodable STBCS have been extensively studied in the literature [17]-[20]. For all these STBCs, the $2n_t$ real symbols taking values from PAM constellations can be separated into four equal groups such that the symbols of each group can be decoded independently of the symbols of all the other groups. For all these STBCs, the minimum determinant, irrespective of the size of the signal constellation, is given by [20]

$$\min_{\Delta \mathbf{X} \neq \mathbf{0}} (\Delta \mathbf{X} \Delta \mathbf{X}^H) = d_{P,\min}^4$$

where $d_{P,\min}$ is the minimum product distance in $n_t/2$ real dimensions, which has been shown to be a constant bounded away from 0 in [38]. Hence, from Corollary 1, LSTBC-schemes consisting of these 4-group decodable STBCs are DMT-optimal for $n_t \times 1$ MIMO systems with n_t being a power of 2.

C. Fast-decodable STBCs

In [20] a rate-2, LSTBC was constructed for the 4×2 MIMO system, and in [39], the LSTBC-scheme based on this code is shown to have the NVD property when QAM

is used. An interesting property of this LSTBC is that it allows fast-decoding, meaning which, for the ML-decoding of the 16 real symbols (or 8 complex symbols) of the STBC using a sphere decoder, it suffices to use a 9 real-dimensional sphere decoder instead of a 16 real-dimensional one. Since the LSTBC-scheme based on this fast-decodable STBC has the non-vanishing determinant property, it is DMT-optimal for the 4×2 MIMO system.

Several rate-n_r, fast-decodable STBCs have been constructed in [15] for various asymmetric MIMO configurations - for example, for 4×2, 6×2, 6×3, 8×2, 8×3, 8×4 MIMO systems. For an $n_t \times n_r$ asymmetric MIMO system, these STBCs transmit a total of $n_t n_r$ complex symbols in n_t channel uses, and with regards to ML-decoding, only an $n_t n_r - \frac{n_t}{2}$ complex-dimensional sphere decoder is required as against an $n_t n_r$ complex-dimensional sphere decoder required for decoding general rate-n_r LSTBCs. These STBCs are constructed from division algebra and the STBC-schemes based on these STBCs have the NVD property [15]. Hence, for an $n_t \times n_r$ asymmetric MIMO system, LSTBC-schemes consisting of these rate-n_r fast-decodable STBCs are DMT-optimal. Table I lists some known LSTBC-schemes that are now proven to be DMT-optimal using the sufficient criterion proposed in this paper.

The DMT curves for some well-known DMT-optimal LSTBC-schemes are shown in Fig. 1, Fig. 2, Fig. 3 and Fig. 4. In all the figures, the perfect code-scheme refers to the LSTBC-scheme that is based on rate-n_t perfect codes [9], [10], and this scheme is known to be DMT-optimal for arbitrary number of receive antennas [4]. The DMT-curves of the LSTBC-schemes that are based on rate-n_r LSTBCs coincide with that of the rate-n_t perfect code-scheme.

VI. CONCLUDING REMARKS

In this paper, we have presented an enhanced sufficient criterion for DMT-optimality of STBC-schemes using which we have established the DMT optimality of several low-ML-decoding-complexity LSTBC-schemes for certain asymmetric MIMO systems. However, obtaining a necessary and sufficient condition for DMT-optimality of STBC-schemes is still an open problem. Further, obtaining low-ML-decoding-complexity STBC-schemes with NVD for arbitrary number of transmit antennas is another possible direction of research.

APPENDIX A
EVALUATION OF $\mathrm{P}(\widetilde{\mathcal{O}})$

We have

$$
\begin{aligned}
\mathrm{P}(\widetilde{\mathcal{O}}) &= \int_{\widetilde{\mathcal{O}}} p(\mathbf{H}) d\mathbf{H} = \int_{\widetilde{\mathcal{O}}} \prod_{i=1}^{n_r} \prod_{j=1}^{n_t} p(h_{ij}) d(h_{ij}) \quad (48) \\
&= \int_{\breve{\mathcal{O}}} \prod_{i,j} p(|h_{ij}|^2) d(|h_{ij}|^2), \quad (49)
\end{aligned}
$$

where (48) is because of the independence of the entries of $\mathbf{H}$, and (49) is by change of variables with $\breve{\mathcal{O}}$ as defined in (47) at the bottom of the page. It is well known that $p(|h_{ij}|^2) = e^{-|h_{ij}|^2}$ for the case of Rayleigh fading. Let $|h_{ij}|^2 = SNR^{-\alpha_{ij}}$. Now, $p(\alpha_{ij}) = (\log_e SNR) e^{-SNR^{-\alpha_{ij}}} SNR^{-\alpha_{ij}}$. Defining the column vector $\boldsymbol{\alpha} \in \mathbb{R}^{n_t n_r \times 1}$ as $\boldsymbol{\alpha} =$

$[\alpha_{ij}]_{i=1,\cdots,n_r,\ j=1,\cdots,n_t}$, we have

$$
\mathrm{P}(\widetilde{\mathcal{O}}) = \kappa \int_{\vec{\mathcal{O}}} e^{-\sum_{i,j} SNR^{-\alpha_{ij}}} SNR^{-\sum_{i,j} \alpha_{ij}} d\boldsymbol{\alpha}, \quad (50)
$$

where $\kappa = (\log_e SNR)^{n_t n_r}$ and

$$
\vec{\mathcal{O}} = \left\{ \boldsymbol{\alpha} \left| \begin{array}{ll} \sum_i \log\left(1 + \sum_j \frac{SNR^{1-\alpha_{ij}}}{n_t}\right) > & r \log SNR \\ & + o(\log SNR), \\ \sum_{i,j} \log\left(1 + SNR^{1-\alpha_{ij}}\right) \le & n_t r \log SNR \\ & + o(\log SNR) \end{array} \right. \right\}
$$

$$
= \left\{ \boldsymbol{\alpha} \left| \begin{array}{ll} \sum_i \max\{(1-\alpha_{ij})^+, j = 1, \cdots, n_t\} & > r, \\ \sum_{i,j}(1-\alpha_{ij})^+ & \le n_t r \end{array} \right. \right\},
$$

where $\max\{.\}$ denotes "the largest element of". Note that in (50), the integrand is exponentially decaying with SNR when

$$
\breve{\mathcal{O}} \triangleq \left\{ |h_{ij}|^2 \left| \sum_{i=1}^{n_r} \log\left(1 + \frac{SNR}{n_t} \sum_{j=1}^{n_t} |h_{ij}|^2\right) > r \log SNR + o(\log SNR) \ge \frac{1}{n_t} \sum_{i=1}^{n_r} \sum_{j=1}^{n_t} \log(1 + SNR|h_{ij}|^2) \right. \right\} \quad (47)
$$

any one of the α_{ij} is negative, unlike a polynomial decay when all the α_{ij} are non-negative. Hence, using the concept developed in [2] (see [2, p. 1079] for details),

$$P(\widetilde{\mathcal{O}}) \doteq SNR^{-f(\boldsymbol{\alpha}^*)},$$

where

$$f(\boldsymbol{\alpha}^*) = \inf_{\vec{\mathcal{O}} \cap \mathbb{R}_+^{n_t n_r \times 1}} \left\{ \sum_{i=1}^{n_r} \sum_{j=1}^{n_t} \alpha_{ij} \right\},$$

with $\mathbb{R}_+$ representing the set of non-negative real numbers. It is easy to check that the infimum occurs when all but two of α_{ij} are $1 - \frac{r}{n_r}$, while the other two are $1 - \frac{r}{n_r} + \delta$ and $1 - \frac{r}{n_r} - \delta$ respectively, where $\delta \to 0^+$. Hence,

$$P(\widetilde{\mathcal{O}}) \doteq SNR^{-n_t(n_r - r)}.$$

APPENDIX B
PROOF THAT $\mathcal{O}_l = \mathcal{O}'_l$ ALMOST SURELY AS $SNR \to \infty$

As done earlier, the rows of the random matrix $\mathbf{H}$ are denoted by $\mathbf{h}_i$, $i = 1, 2, \cdots, n_r$. Let $|h_{ij}|^2 = SNR^{-\alpha_{ij}}$ with $\alpha_{ij} \in \mathbb{R}$, and $\mathbf{u} \triangleq [u_1, u_2, \cdots, u_{n_t}]^T$ be a complex column vector independent of $\mathbf{h}_i$, with either $|u_j|^2 \doteq SNR^0$ or $u_j = 0$, $j = 1, 2, \cdots, n_t$. Defining the indicators $I_1, I_2, \cdots, I_{n_t}$ as

$$I_j = \begin{cases} 1, & \text{if } |u_j|^2 \doteq SNR^0 \\ 0 & \text{otherwise}, \end{cases} \quad j = 1, \cdots, n_t,$$

we have, as $SNR \to \infty$,

$$\begin{aligned} |\mathbf{h}_i \mathbf{u}|^2 &= \sum_{j=1}^{n_t} h_{ij} u_j \sum_{k=1}^{n_t} h_{ik}^* u_k^* \\ &= \sum_{j=1}^{n_t} |h_{ij}|^2 |u_j|^2 + 2 \sum_{j=1}^{n_t-1} \sum_{k=j+1}^{n_t} \text{Re} \left(h_{ij} h_{ik}^* u_j u_k^* \right) \\ &\stackrel{.}{\geq} SNR^{-\beta} \quad \text{almost surely}, \end{aligned} \quad (51)$$

where $\text{Re}(.)$ denotes "the real part of", and

$$\beta = \min\{\alpha_{ij} \mid I_j \neq 0, \ j = 1, 2, \cdots, n_t\}.$$

We use the term "almost surely" in (51) because the 'h_{ij}'s are independent random variables. Now, denoting the ith row of $\mathbf{H}\mathbf{U}_l$ by $\mathbf{h}_i(l)$ (with entries $h_{ij}(l)$, $j = 1, \cdots, n_t$) and the $(i, j)^{th}$ entry of $\mathbf{U}_l$ by $u_{ij}(l)$, let $|h_{ij}(l)|^2 \doteq SNR^{-\beta_{ij}}$ with $\beta_{ij} \in \mathbb{R}$. It is to be noted that since $\mathbf{U}_l$ is unitary, each row and column of $\mathbf{U}_l$ has at least one non-zero entry. Since $\mathbf{U}_l$ is full-ranked, it is always possible to obtain $\eta_i \in \{1, \cdots, n_t\}$, $i = 1, 2, \cdots, n_t$, such that

$$\begin{aligned} [\eta_1, \cdots, \eta_{n_t}] &= [1, 2, \cdots, n_t]\mathbf{P}, & (52) \\ u_{\eta_j j}(l) &\neq 0, \quad \forall j = 1, \cdots, n_t, & (53) \end{aligned}$$

where $\mathbf{P}$ is some permutation matrix of size $n_t \times n_t$. In other words, for any unitary matrix, one can choose a non-zero element in each column such that in each column, the position of the chosen non-zero element is different from that of the chosen non-zero elements of all other columns. Using (51),

we have for all $i = 1, \cdots, n_r$, $j = 1, \cdots, n_t$,

$$\begin{aligned} |h_{ij}(l)|^2 &\stackrel{.}{\geq} SNR^{-\min\{\alpha_{ik} | u_{kj}(l) \neq 0, k=1, \cdots, n_t\}} \\ &\stackrel{.}{\geq} SNR^{-\alpha_{i\eta_j}} \end{aligned}$$

almost surely so that

$$\beta_{ij} \leq \alpha_{i\eta_j} \quad \text{almost surely}.$$

By assumption, $|h_{ij}(l)|^2 \doteq SNR^{-\beta_{ij}}$. So, let

$$|h_{ij}(l)|^2 = cSNR^{-\beta_{ij}} + o\left(SNR^{-\beta_{ij}}\right)$$

with $c \doteq SNR^0$. Hence, $\sum_{j=1}^{n_t} \log\left(1 + SNR|h_{ij}(l)|^2\right)$

$$\begin{aligned} &= \sum_{j=1}^{n_t} \log\left(1 + cSNR^{1-\beta_{ij}} + o\left(SNR^{1-\beta_{ij}}\right)\right) \\ &\geq \sum_{j=1}^{n_t} \log\left(1 + SNR^{1-\alpha_{i\eta_j}}\right), \quad SNR \to \infty, \\ &= \sum_{j=1}^{n_t} \log\left(1 + SNR^{1-\alpha_{ij}}\right), \quad (54) \\ &= \sum_{j=1}^{n_t} \log\left(1 + SNR|h_{ij}|^2\right) \quad \text{almost surely} \end{aligned}$$

and this is true for all $i = 1, 2, \cdots, n_r$. Note that (54) is due to (52). Hence, at a high SNR, almost surely

$$\sum_{i,j} \log\left(1 + SNR|h_{ij}(l)|^2\right) \geq \sum_{i,j} \log\left(1 + SNR|h_{ij}|^2\right).$$

So, if

$$\sum_{i,j} \log\left(1 + SNR|h_{ij}|^2\right) > n_t r \log SNR + o(\log SNR),$$

then

$$\sum_{i,j} \log\left(1 + SNR|h_{ij}(l)|^2\right) > n_t r \log SNR + o(\log SNR)$$

almost surely as $SNR \to \infty$. Since $\mathbf{U}_l$ is unitary, it can be similarly proven using the same steps taken in this appendix that if

$$\sum_{i,j} \log\left(1 + SNR|h_{ij}(l)|^2\right) > n_t r \log SNR + o(\log SNR),$$

then

$$\sum_{i,j} \log\left(1 + SNR|h_{ij}|^2\right) > n_t r \log SNR + o(\log SNR)$$

almost surely at a high SNR. Hence, as $SNR \to \infty$,

$$\sum_{i,j} \log\left(1 + SNR|h_{ij}|^2\right) > n_t r \log SNR + o(\log SNR)$$

is equivalent to

$$\sum_{i,j} \log\left(1 + SNR|h_{ij}(l)|^2\right) > n_t r \log SNR + o(\log SNR)$$

almost surely and so, $\mathcal{O}_l = \mathcal{O}'_l$ almost surely as $SNR \to \infty$.

APPENDIX C

PROOF THAT $P_{\mathcal{O}'_l}(\delta) \leq \frac{1}{2}e^{-\left(aSNR^{\frac{\delta}{n_r}}+o\left(SNR^{\frac{\delta}{n_r}}\right)\right)}, \delta > 0$

Recall that

$$P_{\mathcal{O}'_l}(\delta) = \int_{\mathcal{O}'_l(\delta)} p(\mathbf{H}_l) Q\left(\frac{\|\mathbf{H}_l\mathbf{D}_l\|}{\sqrt{2}}\right) d\mathbf{H}_l$$

where

$$\mathcal{O}'_l(\delta) \triangleq \left\{\mathbf{H}_l \left| \sum_{i,j} \log\left(1 + SNR|h_{ij}(l)|^2\right) \geq n_t(r+\delta)\log SNR\right.\right\}.$$

We define $\|\mathbf{H}_l\mathbf{D}_l\|_{min}(\delta)$ as

$$\|\mathbf{H}_l\mathbf{D}_l\|^2_{min}(\delta) = \min_{\mathcal{O}'_l(\delta)}\{\|\mathbf{H}_l\mathbf{D}_l\|^2\}. \quad (55)$$

We have

$$\begin{aligned}
P_{\mathcal{O}'_l}(\delta) &\leq \int_{\mathcal{O}'_l(\delta)} p(\mathbf{H}_l)Q\left(\frac{\|\mathbf{H}_l\mathbf{D}_l\|_{min}(\delta)}{\sqrt{2}}\right) d\mathbf{H}_l \\
&\leq Q\left(\frac{\|\mathbf{H}_l\mathbf{D}_l\|_{min}(\delta)}{\sqrt{2}}\right) \\
&\leq \frac{1}{2}e^{-\frac{\|\mathbf{H}_l\mathbf{D}_l\|^2_{min}(\delta)}{4}} \quad (56)
\end{aligned}$$

which is due to the bound $Q(x) \leq \frac{1}{2}e^{\frac{-x^2}{2}}$, $x \geq 0$. We now proceed to evaluate $\|\mathbf{H}_l\mathbf{D}_l\|^2_{min}(\delta)$ as follows. Denoting the non-zero entries of $\mathbf{D}_l$ by $d_j(l)$, $j = 1, 2, \cdots n_t$ (it is to be noted that these are the singular values of $\Delta\mathbf{X}_l$ and we assume that $\Delta\mathbf{X}_l$ is full-ranked, i.e. of rank n_t, which is necessary for the STBC to have a diversity gain of $n_t n_r$ when $r = 0$), and letting $a_{ij} \triangleq |h_{ij}(l)|^2$, the problem of evaluating $\|\mathbf{H}_l\mathbf{D}_l\|^2_{min}(\delta)$ can be interpreted as the following convex optimization problem:

$$\underset{a_{ij}}{\text{minimize}} \sum_{i=1}^{n_r}\sum_{j=1}^{n_t} a_{ij}d_j^2(l) \quad (57)$$

subject to

$$\begin{aligned}
-\frac{1}{n_t}\sum_{i=1}^{n_r}\sum_{j=1}^{n_t}\log(1 + a_{ij}SNR) & \\
+ (r+\delta)\log SNR &\leq 0, \\
-a_{ij} &\leq 0, \quad \left\{\begin{array}{l}\forall i = 1, \cdots, n_r, \\ \forall j = 1, \cdots, n_t.\end{array}\right.
\end{aligned}$$

The solution to this optimization problem is

$$a_{ij} = \frac{1}{SNR}\left[\frac{\lambda SNR}{n_t d_j^2(l)} - 1\right]^+, \quad (58)$$

where λ is the Karush-Kuhn-Tucker (KKT) multiplier satisfying

$$\sum_{i=1}^{n_r}\sum_{j=1}^{n_t}\log\left(1 + \left[\frac{\lambda SNR}{n_t d_j^2(l)} - 1\right]^+\right) = n_t(r+\delta)\log SNR,$$

and hence,

$$\sum_{i=1}^{n_r}\sum_{j=1}^{n_t}\left[\log\left(\frac{\lambda SNR}{n_t d_j^2(l)}\right)\right]^+ = n_t(r+\delta)\log SNR. \quad (59)$$

Noting that $d_j^2(l)$ are the eigenvalues of $\Delta\mathbf{X}_l\Delta\mathbf{X}_l^H$, we have $\|\Delta\mathbf{X}_l\|^2 \dot{\leq} SNR$ from (3). Therefore, $tr\left(\Delta\mathbf{X}_l\Delta\mathbf{X}_l^H\right) \dot{\leq} SNR$ which leads to $\sum_{j=1}^{n_t} d_j^2(l) \dot{\leq} SNR$. Therefore, we obtain

$$d_j^2(l) \dot{\leq} SNR, \quad \forall j = 1, 2, \cdots, n_t. \quad (60)$$

Without loss of generality, let a_{ij}, $i = 1, \cdots, n_r$, $j = 1, \cdots, k$, for some $k \leq n_t$, be positive. So, from (59), we have

$$\sum_{i=1}^{n_r}\sum_{j=1}^{k}\left[\log\left(\frac{\lambda SNR}{n_t d_j^2(l)}\right)\right] = n_t(r+\delta)\log SNR$$

so that

$$\begin{aligned}
\lambda &= n_t SNR^{-\left(1 - \frac{n_t(r+\delta)}{kn_r}\right)}\left(\prod_{j=1}^{k} d_j^2(l)\right)^{\frac{1}{k}} \\
&\dot{\geq} SNR^{-\left(1 - \frac{n_t(r+\delta)}{kn_r}\right)}\left(\frac{\prod_{j=1}^{n_t} d_j^2(l)}{SNR^{n_t - k}}\right)^{\frac{1}{k}} \quad (61) \\
&\dot{\geq} SNR^{-\left(1 - \frac{n_t(r+\delta)}{kn_r}\right)}\left(\frac{SNR^{n_t\left(1 - \frac{r}{n_r}\right)}}{SNR^{n_t - k}}\right)^{\frac{1}{k}} \quad (62) \\
&= SNR^{\frac{n_t\delta}{kn_r}},
\end{aligned}$$

where (61) is due to (60), and (62) is due to the assumption that $det(\Delta\mathbf{X}\Delta\mathbf{X}^H) = \prod_{j=1}^{n_t} d_j^2(l) \dot{\geq} SNR^{n_t\left(1 - \frac{r}{n_r}\right)}$. So, we have $\lambda \dot{\geq} SNR^{\frac{\delta n_t}{kn_r}}$, and using this in (58), we obtain, as $SNR \to \infty$,

$$a_{ij} = \left[\frac{\lambda}{n_t d_j^2(l)} - \frac{1}{SNR}\right], j = 1, \cdots, n_t.$$

It is now clear that all the a_{ij}, $i = 1, \cdots, n_r$, $j = 1, \cdots, n_t$, are positive (i.e., $k = n_t$) so that $\lambda \dot{\geq} SNR^{\frac{\delta}{n_r}}$. Using these obtained values of a_{ij} in (57), we have, as $SNR \to \infty$,

$$\begin{aligned}
\|\mathbf{H}_l\mathbf{D}_l\|^2_{min}(\delta) &= \sum_{i=1}^{n_r}\sum_{j=1}^{n_t}\left(\frac{\lambda}{n_t} - \frac{d_j^2(l)}{SNR}\right) \\
&\geq \sum_{i=1}^{n_r}\sum_{j=1}^{n_t}\left(\frac{\lambda}{n_t} - o(\log SNR)\right) \quad (63) \\
&= n_r\lambda - o(\log SNR) \\
&\dot{\geq} SNR^{\frac{\delta}{n_r}}, \quad (64)
\end{aligned}$$

where (63) is because $d_j^2(l) \dot{\leq} SNR$ so that $d_j^2(l)/SNR$ is $o(\log SNR)$, and (64) is due to the fact that $\lambda \dot{\geq} SNR^{\frac{\delta}{n_r}}$. So, $\|\mathbf{H}_l\mathbf{D}_l\|^2_{min}(\delta) \geq aSNR^{\frac{\delta}{n_r}} + o\left(SNR^{\frac{\delta}{n_r}}\right)$ with $a \doteq SNR^0$. Using this result in (56), we arrive at

$$P_{\mathcal{O}'_l}(\delta) \leq \frac{1}{2}e^{-\left(aSNR^{\frac{\delta}{n_r}}+o\left(SNR^{\frac{\delta}{n_r}}\right)\right)}.$$

This completes the proof.
