

# VIRTUAL AMALGAMATION OF RELATIVELY QUASICONVEX SUBGROUPS

EDUARDO MARTÍNEZ-PEDROZA AND ALESSANDRO SISTO

ABSTRACT. For relatively hyperbolic groups, we investigate conditions guaranteeing that the subgroup generated by two relatively quasiconvex subgroups  $Q_1$  and  $Q_2$  is relatively quasiconvex and isomorphic to  $Q_1 *_{Q_1 \cap Q_2} Q_2$ . The main theorem extends results for quasiconvex subgroups of word-hyperbolic groups, and results for discrete subgroups of isometries of hyperbolic spaces.

## 1. INTRODUCTION

This paper continues the work that started in [6] motivated by the following question:

*Problem 1.* Suppose  $G$  is a relatively hyperbolic group,  $Q_1$  and  $Q_2$  are relatively quasiconvex subgroups of  $G$ . Investigate conditions guaranteeing that the natural homomorphism

$$Q_1 *_{Q_1 \cap Q_2} Q_2 \longrightarrow G$$

is injective and that its image  $\langle Q_1 \cup Q_2 \rangle$  is relatively quasiconvex.

Let  $G$  be a group hyperbolic relative to a finite collection of subgroups  $\mathbb{P}$ , and let  $\text{dist}$  be a proper left invariant metric on  $G$ .

**Definition 1.** Two subgroups  $Q$  and  $R$  of  $G$  have *compatible parabolic subgroups* if for any maximal parabolic subgroup  $P$  of  $G$  either  $Q \cap P < R \cap P$  or  $R \cap P < Q \cap P$ .

**Theorem 2.** *For any pair of relatively quasiconvex subgroups  $Q$  and  $R$  of  $G$ , there is a constant  $M = M(Q, R, \text{dist}) \geq 0$  with the following property. Suppose that  $Q' < Q$  and  $R' < R$  are subgroups such that*

- (1)  $Q' \cap R'$  has finite index in  $Q \cap R$ ,
- (2)  $Q'$  and  $R'$  have compatible parabolic subgroups, and
- (3)  $\text{dist}(1, g) \geq M$  for any  $g$  in  $Q' \setminus Q' \cap R'$  or  $R' \setminus Q' \cap R'$ .

*Then the subgroup  $\langle Q' \cup R' \rangle$  of  $G$  satisfies:*

---

*Date:* November 23, 2018.

*Key words and phrases.* Relatively hyperbolic groups, quasiconvex subgroups, combination theorem, amalgamation.

(1) *The natural homomorphism*

$$Q' *_{Q' \cap R'} R' \longrightarrow \langle Q' \cup R' \rangle$$

*is an isomorphism.*

(2) *If  $Q'$  and  $R'$  are relatively quasiconvex, then so is  $\langle Q' \cup R' \rangle$ .*

Theorem 2 extends results by Gitik [4, Theorem 1] for word-hyperbolic groups and by the the first author [6, Theorem 1.1] for relatively hyperbolic groups, as well as the case of [1, Theorem 5.3] when  $\Gamma$  is geometrically finite.

**Definition 3.** Two subgroups  $Q$  and  $R$  of a group  $G$  can be *virtually amalgamated* if there are finite index subgroups  $Q' < Q$  and  $R' < R$  such that the natural map  $Q' *_{Q' \cap R'} R' \longrightarrow G$  is injective.

Let  $Q$  and  $R$  be relatively quasiconvex subgroups of  $G$ , and let  $M$  be the constant provided by Theorem 2. If either  $G$  is residually finite or  $Q \cap R$  is a separable subgroup of  $G$ , then there is a finite index subgroup  $G'$  of  $G$  such that  $\text{dist}(1, g) > M$  for every  $g \in G$  with  $g \notin Q \cap R$ . In the case that there is such subgroup  $G'$ , then the subgroups  $Q' = G' \cap Q$  and  $R' = G' \cap R$  are relatively quasiconvex and satisfy the hypothesis of Theorem 2; hence they have a quasiconvex virtual amalgam.

**Corollary 4** (First Virtual Quasiconvex Amalgam Theorem). *Let  $Q$  and  $R$  quasiconvex subgroups of  $G$  with compatible parabolic subgroups, and suppose that  $Q \cap R$  is separable. Then  $Q$  and  $R$  can be virtually amalgamated in  $G$ .*

**Corollary 5** (Second Virtual Quasiconvex Amalgam Theorem). *Suppose that  $G$  is residually finite. Then any pair of relatively quasiconvex subgroups with compatible parabolic subgroups has a quasiconvex virtual amalgam.*

An immediate corollary of the Virtual Quasiconvex Amalgam Theorem for residually finite relatively hyperbolic groups provides the following result by Baker-Cooper [1, Theorem 5.3].

**Corollary 6** (GF subgroups have virtual amalgams.). *Suppose that  $G$  is a geometrically finite subgroup of  $\text{Isom}(\mathbb{H}^n)$ . If  $Q$  and  $R$  are subgroups of  $G$  with compatible parabolic subgroups, then  $Q$  and  $R$  have a virtual amalgam. The resulting subgroup is geometrically finite if  $Q$  and  $R$  are geometrically finite.*

## 2. PRELIMINARIES

**2.1. Gromov-hyperbolic Spaces.** Let  $(X, \text{dist})$  be a proper and geodesic  $\delta$ -hyperbolic space. Recall that a  $(\lambda, \mu)$ -quasi-geodesic is a curve

$\gamma: [a, b] \rightarrow X$  parametrize by arc-length such that

$$|x - y|/\lambda - \mu \leq \text{dist}(\gamma(x), \gamma(y)) \leq \lambda|x - y| + \mu$$

for all  $x, y \in [a, b]$ . The curve  $\gamma$  is a  $k$ -local  $(\lambda, \mu)$ -quasi-geodesic if the above condition is required only for  $x, y \in [a, b]$  such that  $|x - y| \leq k$ .

**Lemma 7.** [3, Chapter 3, Theorem 1.2] (*Morse Lemma*) *For each  $\lambda, \mu, \delta$  there exists  $k > 0$  with the following property. In an  $\delta$ -hyperbolic geodesic space, any  $(\lambda, \mu)$ -quasi-geodesic at  $k$ -Hausdorff-distance from the geodesic between its endpoints.*

**Lemma 8.** [3, Chapter 3, Theorem 1.4] *For each  $\lambda, \mu, \delta$  there exist  $k, \lambda', \mu'$  so that any  $k$ -local  $(\lambda, \mu)$ -quasi-geodesic in a  $\delta$ -hyperbolic geodesic space is a  $(\lambda', \mu')$ -quasi-geodesic.*

Fix a basepoint  $x_0 \in X$ . If  $G$  is a subgroup of  $\text{Isom}(X)$ , we identify each element  $g$  of  $G$  with the point  $gx_0$  of  $X$ . For  $g_1, g_2 \in G$  denote by  $\text{dist}(g_1, g_2)$  the distance  $\text{dist}(g_1x_0, g_2x_0)$ . Observe that if  $G$  is a discrete subgroup, this is a proper and left invariant pseudo-metric on  $G$ .

**Lemma 9** (Bounded Intersection). [6, Lemma 4.2] *Let  $G$  be a discrete subgroup of  $\text{Isom}(X)$ , let  $Q$  and  $R$  be subgroups of  $G$ , and let  $\mu > 0$  be a real number. Then there is a constant  $M = M(Q, R, \mu) \geq 0$  so that*

$$Q \cap \mathcal{N}_\mu(R) \subset \mathcal{N}_M(Q \cap R).$$

**2.2. Relatively Quasiconvex Subgroups.** We follow the approach to relatively hyperbolic groups as developed by Hruska [5].

**Definition 10** (Relative Hyperbolicity). A group  $G$  is *relatively hyperbolic with respect to a finite collection of subgroups  $\mathbb{P}$*  if  $G$  acts properly discontinuously and by isometries on a proper and geodesic  $\delta$ -hyperbolic space  $X$  with the following property:  $X$  has a  $G$ -equivariant collection of pairwise disjoint horoballs whose union is an open set  $U$ ,  $G$  acts cocompactly on  $X - U$ , and  $\mathbb{P}$  is a set of representatives of the conjugacy classes of parabolic subgroups of  $G$ .

Throughout the rest of the paper,  $G$  is a relatively hyperbolic group acting on a proper and geodesic  $\delta$ -hyperbolic space  $X$  with a  $G$ -equivariant collection of horoballs satisfying all conditions of Definition 10. As before, we fix a basepoint  $x_0 \in X - U$ , identify each element  $g$  of  $G$  with  $gx_0 \in X$  and let  $\text{dist}(g_1, g_2)$  denote  $\text{dist}(g_1x_0, g_2x_0)$  for  $g_1, g_2 \in G$ .

**Lemma 11.** [2, Lemma 6.4] (*Cocompact actions of parabolic subgroups on thick horospheres*) *Let  $B$  be a horoball of  $X$  with  $G$ -stabilizer  $P$ . For any  $M > 0$ ,  $P$  acts cocompactly on  $\mathcal{N}_M(B) \cap (X - U)$ .*

**Lemma 12** (Parabolic Approximation). *Let  $Q$  be a subgroup of  $G$  and let  $\mu > 0$  be a real number. There is a constant  $M = M(Q, \mu)$  with the following property. If  $P$  is a maximal parabolic subgroup of  $G$  stabilizing a horoball  $B$ , and  $\{1, q\} \subset Q \cap \mathcal{N}_\mu(B)$  then there is  $p \in Q \cap P$  such that  $\text{dist}(p, q) < M$ .*

*Proof.* By Lemma 11,  $\text{dist}(q, P) < M_1$  for some constant  $M_1 = M_1(Q, P)$ . Then Lemma 9 implies that  $\text{dist}(q, Q \cap P) < M_2$  where  $M_2 = N(Q, P, M_1)$ . Since  $B$  is a horoball at distance less than  $\mu$  from 1, there are only finitely many possibilities for  $B$  and hence for the subgroup  $P$ . Let  $M$  the maximum of all  $N(Q, P, \mu)$  among the possible  $P$ .  $\square$

**Definition 13** (Relatively Quasiconvex Subgroup). A subgroup  $Q$  of  $G$  is *relatively quasiconvex* if there is  $\mu \geq 0$  such that for any geodesic  $c$  in  $X$  with endpoints in  $Q$ ,  $c \cap (X - U) \subset N_\mu(Q)$ .

The choice of horoballs turns out not to make a difference:

**Proposition 14.** [5] *If  $Q$  is relatively quasiconvex in  $G$  then for any  $L \geq 0$  there is  $\mu \geq 0$  such that for any geodesic  $c$  in  $X$  with endpoints in  $Q$ ,  $c \cap \mathcal{N}_L(X - U) \subset N_\mu(Q)$ .*

### 3. PROOF OF THE MAIN THEOREM

For the convenience of the reader, we report below the statement of Theorem 2.

**Theorem 15.** *For any pair of relatively quasiconvex subgroups  $Q$  and  $R$  of  $G$ , there is a constant  $M = M(Q, R, \text{dist}) \geq 0$  with the following property. Suppose that  $Q' < Q$  and  $R' < R$  are subgroups such that*

- (1)  $Q' \cap R'$  has finite index in  $Q \cap R$ ,
- (2)  $Q'$  and  $R'$  have compatible parabolic subgroups, and
- (3)  $\text{dist}(1, g) \geq M$  for any  $g$  in  $Q' \setminus Q' \cap R'$  or  $R' \setminus Q' \cap R'$ .

*Then the subgroup  $\langle Q' \cup R' \rangle$  of  $G$  satisfies:*

- (1) *The natural homomorphism*

$$Q' *_{Q' \cap R'} R' \longrightarrow \langle Q' \cup R' \rangle$$

*is an isomorphism.*

- (2) *If  $Q'$  and  $R'$  are relatively quasiconvex, then so is  $\langle Q' \cup R' \rangle$ .*

Consider  $1 \neq g \in Q' *_{Q' \cap R'} R'$  and write it as  $g = g_1 \dots g_n$  where the  $g_i$ 's are alternatively elements of  $Q' \setminus Q' \cap R'$  and  $R' \setminus Q' \cap R'$ . Moreover, assume that this product is *minimal* in the sense that  $\sum \text{dist}(1, g_i)$  is minimal among all such products describing  $g$ .

**Claim.** (Lemma 18 below). *There is a constant  $K = K(Q, R, \delta)$  with the following property. For each  $i$ , let  $h_i = g_1 \dots g_i$ . Then the concatenation  $\alpha = \alpha_1 \dots \alpha_{n-1}$  of geodesics  $\alpha_i$  from  $h_i$  to  $h_{i+1}$  is an  $M'$ -local  $(1, K)$ -quasi-geodesic for  $M' = \min\{\text{dist}(1, g_i)\}$ .*

**Conclusion of the proof using the claim.** If we require  $M$  as in the statement of the theorem to be large enough, then we can assume  $M' > k, \lambda', \mu'$  where  $k, \lambda'$  and  $\mu'$  are as in Lemma 8 for  $\lambda = 1, \mu = K$ . It follows that  $\alpha$  is a quasi-geodesic with distinct endpoints, and hence  $g \neq 1$  in  $G$ . Therefore we have shown that the map  $Q' *_{Q' \cap R'} R' \rightarrow G$  is injective.

It is left to prove that if  $Q'$  and  $R'$  are relatively quasiconvex, then  $\langle Q', R' \rangle$  is relatively quasiconvex. By Lemma 7 (Morse Lemma), any  $(\lambda', \mu')$ -quasi-geodesic is at Hausdorff distance at most  $L$  from any geodesic between its endpoints. In particular, if  $\gamma$  is a geodesic from 1 to  $g$ , then  $\gamma \cap (X - U) \subseteq \mathcal{N}_L(\alpha) \cap (X - U)$ . It is enough to show that  $\alpha \cap \mathcal{N}_L(X - U)$  is contained in  $\mathcal{N}_\mu(\langle Q' \cup R' \rangle)$ . Let  $p \in \alpha \cap \mathcal{N}_L(X - U)$  and let  $i$  be so that  $p \in [h_i, h_{i+1}] \cap (X - U)$ . Assume  $g_{i+1} \in Q'$ , the other case being symmetric. As  $Q'$  is relatively quasiconvex and in view of Proposition 14, there is a constant  $\mu$  so that  $p \in \mathcal{N}_\mu(h_i Q') \subseteq \mathcal{N}_\mu(\langle Q' \cup R' \rangle)$  (as  $h_i \in \langle Q' \cup R' \rangle$ ).

**Proof of the Claim.** The proof is a sequence of three lemmas.

**Lemma 16.** *Suppose  $a \in Q' \cap R'$ ,  $p$  is a point at distance at most  $\delta$  from the geodesic segment  $[1, g_i g_{i+1}]$  and  $\text{dist}(p, g_i a) \leq M$ . Then*

$$\text{dist}(1, g_i) + \text{dist}(1, g_{i+1}) \leq \text{dist}(1, g_i g_{i+1}) + 2M + 2\delta.$$

*Proof.* Let  $p' \in [1, g_i g_{i+1}]$  be such that  $\text{dist}(p, p') < \delta$ . Then

$$\begin{aligned} \text{dist}(1, g_i a) + \text{dist}(1, a^{-1} g_{i+1}) &\leq \\ &\leq \text{dist}(1, p') + \text{dist}(p', g_i a) + \text{dist}(g_i a, p') + \text{dist}(p', g_i g_{i+1}) \\ &\leq \text{dist}(1, g_i g_{i+1}) + 2M + 2\delta \end{aligned}$$

As  $g$  can be written as  $g_1 \dots (g_i a)(a^{-1} g_{i+1}) \dots g_n$ , the minimality assumption implies  $\text{dist}(1, g_i) + \text{dist}(1, g_{i+1}) \leq \text{dist}(1, g_i g_{i+1}) + 2M + 2\delta$ .  $\square$

**Lemma 17.** (Gromov's Inner Product is Bounded) *There exists a constant  $K = K(Q, R)$ , not depending on  $g$ , such that*

$$\text{dist}(1, g_i) + \text{dist}(1, g_{i+1}) \leq \text{dist}(1, g_i g_{i+1}) + K.$$

*Proof.* Constants which depend only on  $Q, R$  and  $\delta$  are denoted by  $M_i$ , the index counts positive increments of the constant during the proof. The constant  $K$  of the statement corresponds to  $M_{11}$ .

Suppose  $g_i \in Q'$ , the other case being symmetric, and consider a triangle  $\Delta$  with vertices  $1, g_i, g_i g_{i+1}$  and let  $p \in [1, g_i]$  be a center of  $\Delta$ , i.e., the  $\delta$ -neighborhood of  $p$  intersects all sides of  $\Delta$ .

Suppose that  $p \in X - U$ . Then  $\text{dist}(p, Q), \text{dist}(p, g_i R) \leq M_1$  by relative quasiconvexity of  $Q$  and  $R$ . By Lemma 9, there exists  $a \in Q \cap R$  so that  $\text{dist}(p, g_i a) \leq M_2$ . Since  $Q' \cap R'$  is a finite index subgroup of  $Q \cap R$ , there is  $b \in Q' \cap R'$  such that  $\text{dist}(p, g_i b) \leq M_3$ . By Lemma 16,  $\text{dist}(1, g_i) + \text{dist}(1, g_{i+1}) \leq \text{dist}(1, g_i g_{i+1}) + 2M_3 + 2\delta$ .

Suppose instead that  $p$  is in a horoball  $B$ , whose stabilizer is  $P$ . We can assume  $\text{dist}(g_i, B) \leq M_8$ . Indeed, let  $p_1$  be the entrance point of the geodesic  $[g_i, 1]$  in  $B$ ; then  $\text{dist}(p_1, Q) < M_4$  by quasiconvexity of  $Q$ . Notice that  $\text{dist}(p_1, [g_i, g_i g_{i+1}])$  is at most  $\delta$  since  $p$  is a center of  $\Delta$  and  $p_1 \in [g_i, p]$ . Notice that  $\text{dist}(p_1, [g_i, g_i g_{i+1}])$  is at most  $2\delta$  (consider a triangle with vertices  $p, g_i, p'$  for  $p' \in [g_i, g_i g_{i+1}]$  so that  $d(p, p') \leq \delta$ ). By quasiconvexity of  $R$ , there is  $p_2 \in [g_i, g_i g_{i+1}]$  such that  $\text{dist}(p_1, p_2), \text{dist}(p_2, g_i R) < M_5$ . Lemma 9 implies there is  $a \in Q \cap R$  such that  $\text{dist}(g_i a, p_1), \text{dist}(g_i a, p_2) < M_6$ . Since  $Q' \cap R'$  is a finite index subgroup of  $Q \cap R$ , there is  $b \in Q' \cap R'$  such that  $\text{dist}(g_i b, p_1), \text{dist}(g_i b, p_2) < M_7$ . Since  $g$  can be written as  $g_1 \dots (g_i b)(b^{-1} g_{i+1}) \dots g_n$ ; by minimality

$$\begin{aligned} \text{dist}(1, p_1) + \text{dist}(p_1, g_i) + \text{dist}(g_i, p_2) + \text{dist}(p_2, g_i g_{i+1}) &= \\ &= \text{dist}(1, g_i) + \text{dist}(1, g_i g_{i+1}) \\ &\leq \text{dist}(1, g_i b) + \text{dist}(1, b^{-1} g_{i+1}) \\ &= \text{dist}(1, p_1) + \text{dist}(p_1, g_i b) + \text{dist}(g_i b, p_2) + \text{dist}(p_2, g_i g_{i+1}), \end{aligned}$$

and therefore

$$\begin{aligned} 2 \text{dist}(g_i, B) &= 2 \text{dist}(p_1, g_i) \\ &\leq \text{dist}(p_1, g_i) + \text{dist}(g_i, p_2) + \text{dist}(p_1, p_2) \\ &\leq \text{dist}(p_1, g_i b) + \text{dist}(g_i b, p_2) + \text{dist}(p_1, p_2) \\ &\leq 2M_8. \end{aligned}$$

Since  $Q'$  and  $R'$  have compatible parabolic subgroups, assume that  $Q' \cap g_i^{-1}Pg_i \leq R' \cap g_i^{-1}Pg_i$ ; the other case being symmetric. By quasiconvexity of  $Q$ , there is  $q_1 \in Q$  at distance  $M_9$  from the entrance point of  $[1, g_i]$  to  $B$ . By the parabolic approximation lemma applied to  $\{1, g_i^{-1}q_1\} \subset Q' \cap \mathcal{N}_{M_9}(g_i^{-1}B)$ , there is an element  $a \in Q' \cap g_i^{-1}Pg_i$  such that  $\text{dist}(g_ia, q_1) \leq M_{10}$ . Observe that  $a \in Q' \cap R'$ . By Lemma 16,

$$\text{dist}(1, g_i) + \text{dist}(1, g_{i+1}) \leq \text{dist}(1, g_i g_{i+1}) + M_{11}. \quad \square$$

**Lemma 18.** *For each  $i$ , let  $h_i = g_1 \dots g_i$ . Then the concatenation  $\alpha = \alpha_1 \dots \alpha_{n-1}$  of geodesics  $\alpha_i$  from  $h_i$  to  $h_{i+1}$  is an  $M'$ -local  $(1, K)$ -quasigeodesic for  $M' = \min\{\text{dist}(1, g_i)\}$ .*

*Proof.* This holds in view of Lemma 17 and the following computation for  $x \in [h_{i-1}, h_i]$  and  $y \in [h_i, h_{i+1}]$ :

$$\begin{aligned} \text{dist}(h_{i-1}, x) + \text{dist}(x, y) + \text{dist}(y, h_{i+1}) &\geq \text{dist}(h_{i-1}, h_{i+1}) \geq \\ &\geq \text{dist}(h_{i-1}, h_i) + \text{dist}(h_i, h_{i+1}) - K = \\ &= \text{dist}(h_{i-1}, x) + \text{dist}(x, h_i) + \text{dist}(h_i, y) + \text{dist}(y, h_{i+1}) - K \end{aligned}$$

that yields  $\text{dist}(x, y) + K \geq \text{dist}(x, h_i) + \text{dist}(h_i, y)$ .  $\square$
