

Generalized McKay quivers of rank three

Xiaoli Hu, Naihuan Jing*, and Wuxing Cai

ABSTRACT. For each finite subgroup G of $SL_n(\mathbb{C})$, we introduce the *generalized Cartan matrix* C_G in view of McKay correspondence from the fusion rule of its natural representation. Using group theory, we show that the *generalized Cartan matrices* have similar favorable properties such as positive semi-definiteness as in the classical case of affine Cartan matrices (the case of $SL_2(\mathbb{C})$). The complete McKay quivers for $SL_3(\mathbb{C})$ are explicitly described and classified based on representation theory.

1. Introduction

McKay correspondence reveals deep relations and connections among subgroups G of $SL_2(\mathbb{C})$, classical Lie groups of simply-laced types, and resolution of singularities of \mathbb{C}^2/G [18, 20]. It has long been expected that such a correspondence can be generalized to the special linear group $SL_n(\mathbb{C})$, and there are already several important works in this direction [15, 11, 10, 4]. However the complete picture is still not clear, and most results in this direction have focused on some special subgroups such as abelian subgroups. In this paper we give an algebraic description of the complete generalized McKay correspondence of rank three.

One formulation is from representation theoretic viewpoint. We take the original elementary approach of McKay [14] to study the fusion rule of subgroups of $SL_n(\mathbb{C})$, and in particular we focus on the case of $n = 3$. We find that to certain degree some of the beautiful phenomena in two dimensional case are still visible in n dimensional case. The diagrams we constructed are in general some digraphs, and the associated undirected graphs, when looking from a distance, are similar to ADE cases.

Let G be a finite nontrivial subgroup of $SL_n(\mathbb{C})$. We denote the embedding of G into $SL_n(\mathbb{C})$ as π , and let ρ_0, \dots, ρ_s be the complete list of inequivalent irreducible representations of G over \mathbb{C} . We then construct a

π_G -digraph with the irreducible representations of G as nodes and $m_{i,j}$ directed edges from ρ_i to ρ_j , where $\pi \otimes \rho_i = \bigoplus_j m_{ij} \rho_j$. We make a convention that an undirected edge between ρ_i and ρ_j represents the pair of arrows between ρ_i and ρ_j . This digraph is called the *generalized McKay quiver* associated with π . We prove in general that all the corresponding matrices are positive semi-definite and also a non-trivial eigenvector is the dimension vector, which defines the specialty of affine Cartan matrices in rank two case.

Our method can produce the generalized McKay correspondence in any dimension. In the second part of the paper we determine the complete list of generalized McKay quivers in rank three, including all the exceptional graphs in this case. Of course this list also includes the usual extended affine Dynkin diagrams as special cases, and if one blurs some of the nodes and edges in the quivers they also look much like the rank two cases.

We remark that a different approach to McKay correspondence in rank 3 was recently given in [5] where a partial list of McKay graphs is produced. Our approach is completely different and we have obtained the complete list of McKay quivers in rank three, and we also indicate how to produce similar McKay graphs in higher dimensions.

One profound problem for McKay correspondence in dimension three is to bridge the geometric approach [3, 4] and the algebraic method in this paper. We only discuss the algebraic picture of the so-called McKay correspondence in rank 3 in this paper. Nevertheless, there seems to be some partial progress between algebra representation theory [1] and the generalized McKay quivers, most results so far are about some subcases (such as abelian subgroups of $SL_3(\mathbb{C})$), it would be extremely important to understand the intrinsic connection between our digraphs and quiver theory of representation theory.

2. The generalized McKay-Cartan matrices

Let G be a finite nontrivial subgroup of $SL_n(\mathbb{C})$, and let γ_i be its irreducible characters afforded by ρ_i on the space V_i ($i = 0, \dots, |G^*| = s$). The space $R(G)$ of complex class functions on G has $\{\gamma_i\}$ as a canonical basis. For $f, g \in R(G)$, the inner product is defined by

$$(2.1) \quad \langle f, g \rangle = \frac{1}{|G|} \sum_{x \in G} f(x)g(x^{-1}) = \sum_{C \in G_*} \xi_C^{-1} f(C)g(C^{-1}),$$

where as a convention we denote by $\xi_C = |Z_G(C)|$, and $Z_G(C)$ is the centralizer of one of the elements in C .

As usual we denote by G_* the set of conjugacy classes: $\{C_0, C_1, \dots, C_s\}$, where $C_0 = \{1\}$. The orthogonality relation of irreducible characters now

reads

$$(2.2) \quad \begin{aligned} \sum_C \xi_C^{-1} \gamma_i(C) \gamma_j(C^{-1}) &= \delta_{ij}, \\ \sum_j \gamma_j(C') \gamma_j(C^{-1}) &= \delta_{CC'} \xi_C. \end{aligned}$$

Let π be the natural representation of G on \mathbb{C}^n . The tensor product $\pi \otimes \rho_i$ decomposes itself into irreducible representations

$$(2.3) \quad \pi \otimes \rho_i \cong \bigoplus_j m_{ij} \rho_j.$$

Then,

$$(2.4) \quad (nId - \pi) \otimes \rho_i \cong \bigoplus_j b_{ij} \rho_j,$$

where $b_{ij} = n\delta_{ij} - m_{ij}$. The matrix $M = (m_{ij})$ is called the adjacency matrix, and $B = (b_{ij})$ the *pre-Cartan matrix* for the finite group G associated to π .

DEFINITION 2.1. The matrix $A = B + B^t$ is called the *generalized Cartan matrix* for the finite group G associated with π .

We remark that A is twice of the extended Cartan matrix in the case of $n = 2$.

Suppose π is afforded by the representation V , the dual representation π^* is the G -module afforded by $V^* = \text{Hom}_{\mathbb{C}}(V, \mathbb{C})$ and the action is given by

$$(2.5) \quad x.f(v) = f(x^{-1}v), x \in G, v \in V.$$

Let χ_π be the character of π , it is well-known that

$$(2.6) \quad \chi_\pi(x) = \chi_{\pi^*}(x^{-1}).$$

We also recall a well-known fact: if U, V, W are G -modules, then

$$(2.7) \quad \text{Hom}(U^* \otimes V, W) \cong \text{Hom}(V, U \otimes W)$$

as G -modules. Hence $\langle U^* \otimes V, W \rangle = \langle V, U \otimes W \rangle$.

LEMMA 2.2. $\pi^* \otimes \rho_i \cong \bigoplus_j m_{ji} \rho_j$.

Proof: Suppose $\pi^* \otimes \rho_i \cong \bigoplus_j m'_{ij} \rho_j$, then

$$m'_{ij} = \langle \pi^* \otimes \rho_i, \rho_j \rangle = \langle \rho_i, \pi \otimes \rho_j \rangle = m_{ji}.$$

PROPOSITION 2.3. Let ρ be a representation of G , and suppose $\rho \otimes \rho_i \cong \bigoplus_j b_{ij} \rho_j$. Let $p_i = (\gamma_0(C_i), \dots, \gamma_s(C_i))^t \in \mathbb{C}^s$, then p_i is an eigenvector of $B = (b_{ij})$ with eigenvalue $\chi_\rho(C_i)$.

Proof: By the orthogonality of γ_i one has that

$$(2.8) \quad b_{ij} = \langle \rho \otimes \rho_i, \rho_j \rangle = \sum_C \xi_C^{-1} \chi_\rho(C) \gamma_i(C) \gamma_j(C^{-1}).$$

We compute that

$$(2.9) \quad \begin{aligned} \sum_j b_{ij} \gamma_j(C_k) &= \sum_{j,C} \xi_C^{-1} \chi_\rho(C) \gamma_i(C) \gamma_j(C^{-1}) \gamma_j(C_k) \\ &= \sum_C \chi_\rho(C) \gamma_i(C) \delta_{C, C_k} \\ &= \chi_\rho(C_k) \gamma_i(C_k), \end{aligned}$$

which means that $Bp_k = \chi_\rho(C_k)p_k$.

As a special case, the dimension vector $\delta = (\dim \gamma_0, \dots, \dim \gamma_s)^t$ is an eigenvector with eigenvalue $\dim \rho$.

THEOREM 2.4. *The generalized Cartan matrix $A = B + B^t$ is positive semi-definite, and the dimension vector δ is an eigenvector with eigenvalue zero.*

Proof: Since A is the matrix of $\rho \otimes \gamma_i = \sum a_{ij} \gamma_j$, where $\rho = (nId - \pi) \oplus (nId - \pi^*)$, we claim that A is positive semi-definite if and only if $\langle \rho \otimes \gamma, \gamma \rangle \geq 0$ for any $\gamma \in R(G)$. In fact, let $\gamma = \sum x_i \gamma_i$, $X^T = (x_0, \dots, x_s)$, then

$$(2.10) \quad \langle \chi_\rho \otimes \gamma, \gamma \rangle = \sum_{i,j} x_i \langle \chi_\rho \otimes \gamma_i, \gamma_j \rangle \bar{x}_j = \sum_{i,j} x_i a_{ij} \bar{x}_j = X^T A \bar{X}.$$

On the other hand, let χ be the any real character of degree n , then

$$(2.11) \quad \langle \chi \otimes \gamma, \gamma \rangle = \frac{1}{|G|} \sum_{g \in G} \chi(g) \gamma(g) \gamma(g^{-1}) \leq n \langle \gamma, \gamma \rangle.$$

Hence $\langle \chi_\rho \otimes \gamma, \gamma \rangle = 2n \langle \gamma, \gamma \rangle - \langle (\chi_\pi + \chi_{\pi^*}) \otimes \gamma, \gamma \rangle \geq 0$.

3. The $SL_3(\mathbb{C})$ McKay digraphs

The classification of finite subgroups of $SL_3(\mathbb{C})$ (up to isomorphism) was given by Blichfeldt [2] in 1917 and completed in [21] (see also [13]). There are 12 types of nontrivial subgroups of $SL_3(\mathbb{C})$, and each type consists of several non-isomorphic subgroups that bear similar properties. We will construct the π_G -graphs as defined in Section 1 for all types. For each group we first find its irreducible representations and then decompose their tensor products with the natural representation to construct the corresponding *generalized Cartan matrix* and the π_G -graph. Except for the type of subgroups that are essentially the same as the $SL_2(\mathbb{C})$ case, we show each π_G -graph together with the corresponding matrix. Some types may have more than one graphs.

The following result will be useful in construction of irreducible representations of semidirect products.

LEMMA 3.1. (*Wigner-Mackey's Little Group method*) [17] Suppose G is the semi-direct product of a subgroup T by a normal abelian subgroup H .

Let $X = \text{Hom}(H, \mathbb{C}^*)$. Then G acts on X by $(s\chi)(h) = \chi(s^{-1}hs)$ for $s \in G, \chi \in X, h \in H$. Let $(\chi_i)_{i \in X/T}$ be a system of representatives for the orbits of T . For each $i \in X/T$, let $T_i = \{t \mid t\chi_i = \chi_i\}$ and $G_i = HT_i$ be the corresponding subgroups of G . Extend the function χ_i to G_i by setting $\chi_i(at) = \chi_i(a)$ for $a \in H, t \in T_i$. Let ρ be an irreducible representation of T_i and $\tilde{\rho}$ be the composition of ρ with the canonical projection $G_i \rightarrow T_i$. Finally, let $\theta_{i,\rho} = (\chi_i \otimes \tilde{\rho}) \uparrow_{G_i}^G$. Then

- (a) $\theta_{i,\rho}$ is irreducible;
- (b) If $\theta_{i,\rho}$ and $\theta_{i',\rho'}$ are isomorphic, then $i = i'$, and $\rho \simeq \rho'$;
- (c) Every irreducible representation of G is isomorphic to one of the $\theta_{i,\rho}$.

We start with some notations. For a natural number n we denote the primitive n th root of unity by $\xi_n = e^{2\pi i/n}$. Then a generator of the center of $SL_3(\mathbb{C})$ is given by

$$(3.1) \quad W = \text{diag}(\xi_3, \xi_3, \xi_3).$$

For positive integers m and n , the group

$$(3.2) \quad H_{m,n} = \{\text{diag}(\xi_m^k, \xi_n^l, \xi_m^{-k}\xi_n^{-l}) \mid k, l \in \mathbb{Z}\}$$

is an abelian group of order mn . Now we study the 12 types one by one.

(Type 1) Abelian Group $H_{m,n}$. It is well-known that $H_{m,n} \simeq \mathbb{Z}_m \otimes \mathbb{Z}_n$. Set $g_{k,l} = \text{diag}(\xi_m^k, \xi_n^l, \xi_m^{-k}\xi_n^{-l}) \in H_{m,n}$ and define

$$(3.3) \quad \rho_{i,j}(g_{k,l}) = \xi_m^{ik}\xi_n^{jl}, \text{ for } i = 1, \dots, m \text{ and } j = 1, \dots, n.$$

Then $\rho_{i,j}$ realize all mn (1-dimensional) irreducible representations of $H_{m,n}$.

Let $\pi = \rho_{1,0} \oplus \rho_{0,1} \oplus \rho_{-1,-1}$ be the embedding of $H_{m,n}$ into $SL_3(\mathbb{C})$. It follows that

$$(3.4) \quad \pi \otimes \rho_{i,j} = \rho_{i+1,j} \oplus \rho_{i,j+1} \oplus \rho_{i-1,j-1}.$$

So we get the following $\pi_{H_{m,n}}$ -graph.

Fig.1.

Here we label each node by the dimension of the corresponding representation. Note that the upper and lower parts of the graph are identified, similarly the left and right parts are identified, thus we can visualize the $\pi_{H_{m,n}}$ -graph as a torus.

Fig.1

We remark that in the special case of $m = 1$, the graph is the extended Dynkin diagram of $A_n^{(1)}$ if we erase all self directing loops, i.e., Fig. 1-2 degenerates into a cycle.

For the *generalized Cartan matrix* $C_{H_{m,n}} = (3I - M) + (3I - M)^T$, where M is the adjacency matrix of $\pi_{H_{m,n}}$ -graph, we have the following examples.

$$(3.5) \quad C_{H_{2,2}} = \begin{pmatrix} 3 & -1 & -1 & -1 \\ -1 & 3 & -1 & -1 \\ -1 & -1 & 3 & -1 \\ -1 & -1 & -1 & 3 \end{pmatrix}.$$

$$(3.6) \quad C_{H_{3,2}} = \begin{pmatrix} 6 & -2 & -1 & -1 & -1 & -1 \\ -2 & 6 & -1 & -1 & -1 & -1 \\ -1 & -1 & 6 & -2 & -1 & -1 \\ -1 & -1 & -2 & 6 & -1 & -1 \\ -1 & -1 & -1 & -1 & 6 & -2 \\ -1 & -1 & -1 & -1 & -2 & 6 \end{pmatrix},$$

$$(3.7) \quad C_{H_{3,3}} = \begin{pmatrix} 6 & -1 & -1 & -1 & 0 & -1 & 0 & 0 & -1 \\ -1 & 6 & -1 & 0 & -1 & -1 & -1 & -1 & 0 \\ -1 & -1 & 6 & -1 & 0 & -1 & 0 & -1 & -1 \\ -1 & 0 & -1 & 6 & -1 & -1 & -1 & -1 & 0 \\ 0 & -1 & 0 & -1 & 6 & -1 & 0 & -1 & -1 \\ -1 & -1 & -1 & -1 & -1 & 6 & -1 & 0 & -1 \\ 0 & -1 & 0 & -1 & 0 & -1 & 6 & -1 & -1 \\ 0 & -1 & -1 & -1 & -1 & 0 & -1 & 6 & -1 \\ -1 & 0 & -1 & 0 & -1 & -1 & -1 & -1 & 6 \end{pmatrix},$$

$$(3.8) \quad C_{H_{3,4}} = \begin{pmatrix} 6 & -1 & 0 & -1 & -1 & -1 & 0 & 0 & -1 & 0 & 0 & -1 \\ -1 & 6 & -1 & 0 & 0 & -1 & -1 & 0 & -1 & -1 & 0 & 0 \\ 0 & -1 & 6 & -1 & 0 & 0 & -1 & -1 & 0 & -1 & -1 & 0 \\ -1 & 0 & -1 & 6 & -1 & 0 & 0 & -1 & 0 & 0 & -1 & -1 \\ -1 & 0 & 0 & -1 & 6 & -1 & 0 & -1 & -1 & -1 & 0 & 0 \\ -1 & -1 & 0 & 0 & -1 & 6 & -1 & 0 & 0 & -1 & -1 & 0 \\ 0 & -1 & -1 & 0 & 0 & -1 & 6 & -1 & 0 & 0 & -1 & -1 \\ 0 & 0 & -1 & -1 & -1 & 0 & -1 & 6 & -1 & 0 & 0 & -1 \\ -1 & -1 & 0 & 0 & -1 & 0 & 0 & -1 & 6 & -1 & 0 & -1 \\ 0 & -1 & -1 & 0 & -1 & -1 & 0 & 0 & -1 & 6 & -1 & 0 \\ 0 & 0 & -1 & -1 & 0 & -1 & -1 & 0 & 0 & -1 & 6 & -1 \\ -1 & 0 & 0 & -1 & 0 & 0 & -1 & -1 & -1 & 0 & -1 & 6 \end{pmatrix}.$$

(Type 2) Group G_m^3 . The group is generated by $H_m := H_{m,m}$ and T , where

$$(3.9) \quad T = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix}.$$

It is easy to see that $G_m^3 = H_m \rtimes \langle T \rangle$ and $G_m^3 = H_m \uplus TH_m \uplus T^2H_m$, so we can get its irreducible representations by Lemma 3.1. Firstly, the orbits of $X = \text{Hom}(H_m, \mathbb{C}^*)$ under the action of $\langle T \rangle$ are listed as follows:

$$(3.10) \quad \begin{aligned} \mathcal{O}(\rho_{i,j}) &= \{ \rho_{i,j}, \rho_{-j,i-j}, \rho_{j-i,-i} \mid (i,j) \neq (0,0), (\frac{m}{3}, \frac{2m}{3}), (\frac{2m}{3}, \frac{m}{3}) \}, \\ (*)\mathcal{O}(\rho_{\frac{m}{3}, \frac{2m}{3}}) &= \{ \rho_{\frac{m}{3}, \frac{2m}{3}} \}, \quad \mathcal{O}(\rho_{\frac{2m}{3}, \frac{m}{3}}) = \{ \rho_{\frac{2m}{3}, \frac{m}{3}} \}, \\ \mathcal{O}(\rho_{0,0}) &= \{ \rho_{0,0} \}, \end{aligned}$$

where $i, j \in \{1, 2, \dots, m\}$. Note: the rows labeled with (*) are excluded when m is not divisible by 3, and the same for (3.13), (3.15), (3.17) and (3.24) in the following. Hence there are $\frac{m^2-1}{3} + 1$ orbits when $3 \nmid m$ and $\frac{m^2-3}{3} + 3$ orbits when $3 \mid m$. Let

$$(3.11) \quad \begin{aligned} T_1 &= \left\{ s \in \langle T \rangle \mid s \cdot \rho_{\frac{m}{3}, \frac{2m}{3}} = \rho_{\frac{m}{3}, \frac{2m}{3}} \right\} = \langle T \rangle, \\ T_2 &= \left\{ s \in \langle T \rangle \mid s \cdot \rho_{\frac{2m}{3}, \frac{m}{3}} = \rho_{\frac{2m}{3}, \frac{m}{3}} \right\} = \langle T \rangle, \\ T_3 &= \{ s \in \langle T \rangle \mid s \cdot \rho_{0,0} = \rho_{0,0} \} = \langle T \rangle, \end{aligned}$$

and let $\rho^j : T \rightarrow \xi_3^j$ ($j = 1, 2, 3$) be the 1-dimensional irreducible representations of subgroup $\langle T \rangle$. Therefore the Little Group method gives that

$$(3.12) \quad \theta_{0,0,j} = \rho_{0,0} \otimes \rho^j,$$

$$(3.13) \quad (*)\theta_{\frac{m}{3}, \frac{2m}{3}, j} = \rho_{\frac{m}{3}, \frac{2m}{3}} \otimes \rho^j, \quad \theta_{\frac{2m}{3}, \frac{m}{3}, j} = \rho_{\frac{2m}{3}, \frac{m}{3}} \otimes \rho^j$$

are irreducible representations of G_m^3 of degree 1. We can check that

$$(3.14) \quad \left\{ s \in \langle T \rangle \mid s \cdot \rho_{i,j} = \rho_{i,j}, (i,j) \neq (0,0), \left(\frac{m}{3}, \frac{2m}{3}\right), \left(\frac{2m}{3}, \frac{m}{3}\right) \right\} = Id,$$

then $\theta_{i,j} = (\rho_{i,j} \otimes id) \uparrow_{H_m}^{G_m^3}$ are 3-dimensional irreducible representations of G_m^3 , where id is the trivial representation. Hence there are nine 1-dimensional and $\frac{m^2-3}{3}$ 3-dimensional irreducible representations in the case of $3 \mid m$, and three 1-dimensional and $\frac{m^2-1}{3}$ 3-dimensional irreducible representations if $3 \nmid m$. For $n = 1, 2, 3$ and the indexes $(i, j) \in \{1, 2, \dots, m\} \times \{1, 2, \dots, m\} \setminus \{(0, 0), (\frac{m}{3}, \frac{2m}{3}), (\frac{2m}{3}, \frac{m}{3})\}$, let

$$(3.15) \quad \begin{aligned} \theta_{0,0,n}(T) &= \xi_3^n, & \theta_{0,0,n}(g_{k,l}) &= 1, \\ * \theta_{\frac{m}{3}, \frac{2m}{3}, n}(T) &= \xi_3^n, & \theta_{\frac{m}{3}, \frac{2m}{3}, n}(g_{k,l}) &= \xi_3^{k+2l}, \\ * \theta_{\frac{2m}{3}, \frac{m}{3}, n}(T) &= \xi_3^n, & \theta_{\frac{2m}{3}, \frac{m}{3}, n}(g_{k,l}) &= \xi_3^{2k+l}, \\ \theta_{i,j}(T) &= T, & \theta_{i,j}(g_{k,l}) &= \text{diag}(\xi_m^{ik+jl}, \xi_m^{(j-i)k-il}, \xi_m^{-jk+(i-j)l}). \end{aligned}$$

This gives all the irreducible representations of G_m^3 . Recall that π , the natural representation from G_m^3 to $SL_3(\mathbb{C})$, can be given in this type by

$$(3.16) \quad \pi(g_{k,l}) = \text{diag}(\xi_m^k, \xi_m^l, \xi_m^{-k-l}), \quad \pi(T) = T.$$

By computing characters, we find the following decompositions of the tensor product of the natural representation and the irreducible representations of G_m^3 :

$$(3.17) \quad \begin{aligned} \pi \otimes \theta_{0,0,n} &= \theta_{0,1,n}, & \pi \otimes \theta_{i,j} &= \theta_{i-1,j-1} \oplus \theta_{i,j+1} \oplus \theta_{i+1,j}, \\ * \pi \otimes \theta_{\frac{m}{3}, \frac{2m}{3}, n} &= \theta_{\frac{m}{3}+1, \frac{2m}{3}, n}, & \pi \otimes \theta_{\frac{2m}{3}, \frac{m}{3}, n} &= \theta_{\frac{2m}{3}+1, \frac{m}{3}, n}. \end{aligned}$$

We remark that the decomposition can also be confirmed by computing the inner product $\langle \pi \otimes \rho_i, \rho_j \rangle$. In the following this can always be used in getting the fusion product.

The $\pi_{G_m^3}$ -graphs are shown in Fig.2-1 for $m = 6$ and Fig.2-2 for $m = 7$, one can draw the $\pi_{G_m^3}$ -graphs for any m according to our recipe. Here we label each node corresponding to the representation $\theta_{i,j}$ (resp. $\theta_{i,j,k}$) by its subscript (ij) (resp. (ijk)). (For example: $\theta_{0,0,1}$ is labeled by (001) .)

Fig.2-1.

Fig.2-2.

(Type 3) Group G_m^6 . The group G_m^6 is generated by H_m , T and R , where T was defined in (3.9) and

$$(3.18) \quad R = \begin{pmatrix} a & 0 & 0 \\ 0 & 0 & b \\ 0 & c & 0 \end{pmatrix}, abc = -1.$$

For simplicity we only consider the case of $a = b = c = -1$, which is enough to show the main feature of this type. It is not difficult to see that $G_m^6 = H_m \rtimes S_3$, so its irreducible representations are obtained again by using Lemma 3.1. The orbits of $X = Hom(H_m, \mathbb{C}^*)$ under the action of S_3

are listed as follows:

$$\begin{aligned}
(3.19) \quad \mathcal{O}(\rho_{i,j}) &= \{\rho_{i,j}, \rho_{j,i}, \rho_{-j,i-j}, \rho_{i-j,-j}, \rho_{j-i,-i}, \rho_{-i,j-i} | i, j = 0, \dots, m-1 \\
&\text{and } (i, j) \notin \{(k, 0), (0, l), (h, h), (\frac{m}{3}, \frac{2m}{3}), (\frac{2m}{3}, \frac{m}{3})\}\}, \\
\mathcal{O}(\rho_{i,0}) &= \{\rho_{i,0}, \rho_{0,i}, \rho_{-i,-i} | i \in \{1, 2, \dots, m-1\}\}, \\
(*) \quad \mathcal{O}(\rho_{\frac{m}{3}, \frac{2m}{3}}) &= \{\rho_{\frac{m}{3}, \frac{2m}{3}}, \rho_{\frac{2m}{3}, \frac{m}{3}}\}, \\
\mathcal{O}(\rho_{0,0}) &= \{\rho_{0,0}\},
\end{aligned}$$

where $k, l, h = 1, \dots, m-1$. The irreducible representations of G_m^6 can be similarly constructed as in the case of G_m^3 , and we obtain that (a) If $3|m$, there are two 1-dimensional, four 2-dimensional, $2(m-1)$ 3-dimensional and $\frac{m^2-3m}{6}$ 6-dimensional irreducible representations. (b) If $3 \nmid m$, there are two 1-dimensional, one 2-dimensional, $2(m-1)$ 3-dimensional and $\frac{m^2-3m+2}{6}$ 6-dimensional irreducible representations.

The irreducible representations corresponding to the orbit $\mathcal{O}(\rho_{0,0})$:

$$\begin{aligned}
(3.20) \quad &\theta_{0,0,1}(g_{k,l}) = 1, \quad \theta_{0,0,1}((12)) = \theta_{0,0,1}((23)) = -1. \\
&\theta_{0,0,2}(g_{k,l}) = 1, \quad \theta_{0,0,2}((12)) = \theta_{0,0,2}((23)) = 1. \\
&\theta_{0,0,3}(g_{k,l}) = E_{2 \times 2}, \theta_{0,0,3}(12) = \begin{pmatrix} -1 & -1 \\ 0 & 1 \end{pmatrix}, \theta_{0,0,3}(23) = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.
\end{aligned}$$

The irreducible representations corresponding to the orbit $\mathcal{O}(\rho_{\frac{m}{3}, \frac{2m}{3}})$:

$$\begin{aligned}
(3.21) \quad &* \theta_{\frac{m}{3}, \frac{2m}{3}, n_1}(g_{k,l}) = \text{diag}(\xi_3^{(k+2l)}, \xi_3^{(2k+l)}) \quad (n_1 = 1, 2, 3), \\
&* \theta_{\frac{m}{3}, \frac{2m}{3}, n_1}(12) = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \theta_{\frac{m}{3}, \frac{2m}{3}, n_1}(23) = \begin{pmatrix} 0 & \xi_3^{n_1} \\ \xi_3^{2n_1} & 0 \end{pmatrix},
\end{aligned}$$

The irreducible representations corresponding to the orbit $\mathcal{O}(\rho_{i,0})$:

$$\begin{aligned}
(3.22) \quad &\theta_{i,0,n_2}(g_{k,l}) = \text{diag}(\xi_m^{ik}, \xi_m^{il}, \xi_m^{i(-k-l)}) \quad (n_2 = 1, 2), \\
&\theta_{i,0,n_2}((12)) = (-1)^{n_2} \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad \theta_{i,0,n_2}((23)) = (-1)^{n_2} \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}.
\end{aligned}$$

The irreducible representations corresponding to the orbit $\mathcal{O}(\rho_{i,j})$:

(3.23)

$$\theta_{i,j}(g_{k,l}) = \text{diag}(\xi_m^{ik+jl}, \xi_m^{jk+il}, \xi_m^{-ik+(j-i)l}, \xi_m^{(i-j)k-jl}, \xi_m^{(j-i)k-il}, \xi_m^{-jk+(i-j)l}),$$

$$\theta_{i,j}((12)) = \begin{pmatrix} 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \end{pmatrix}, \theta_{i,j}((23)) = \begin{pmatrix} 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \end{pmatrix}.$$

Computing the characters of the tensor product of each irreducible representation by the natural representation $\pi = \theta_{1,0,2}$, we find that

$$\begin{aligned} \pi \otimes \theta_{0,0,1} &= \theta_{1,0,1}, & \pi \otimes \theta_{0,0,2} &= \theta_{1,0,2}, & \pi \otimes \theta_{0,0,3} &= \theta_{1,0,1} + \theta_{1,0,2}, \\ \pi \otimes \theta_{i,0,n_2} &= \theta_{i+1,0,n_2} \oplus \theta_{-i,1-i} \text{ for } i \neq 0, & n_2 &= 1, 2, \\ * \pi \otimes \theta_{\frac{m}{3}, \frac{2m}{3}, 1} &= \theta_{\frac{m}{3}+1, \frac{2m}{3}}, & \pi \otimes \theta_{\frac{m}{3}, \frac{2m}{3}, 2} &= \theta_{\frac{m}{3}, \frac{2m}{3}+1}, \\ (3.24) \quad * \pi \otimes \theta_{\frac{m}{3}, \frac{2m}{3}, 3} &= \theta_{\frac{m}{3}-1, \frac{2m}{3}-1}, \\ \pi \otimes \theta_{i,j} &= \theta_{i-1,j-1} \oplus \theta_{i+1,j} \oplus \theta_{i,j+1}, \text{ for } i, j \notin \{0, \frac{m}{3}, \frac{2m}{3}\}. \end{aligned}$$

These fusion rules completely determine the $\pi_{G_m^6}$ -graph. We draw the $\pi_{G_6^6}$ -graph (Fig.3-1) and $\pi_{G_5^6}$ -graph (Fig.3-2) as follows.

Fig.3-1.

Fig.3-2.

From the graph we get the adjacency matrix M associated to $\pi_{G_m^6}$ -graph. Then $C(G_m^6) = (3I - M) + (3I - M)^T$ is the corresponding *generalized Cartan matrix*.

(Type 4) Group \overline{G}_α . For any fixed non-zero α and a finite subgroup G of $SL_2(\mathbb{C})$ let $\overline{G}_\alpha = \{\text{diag}(\alpha^{-2}, \alpha A) | A \in G\} \leq SL_3(\mathbb{C})$. It is obvious that \overline{G}_α and G are isomorphic. So we just need to study the finite subgroups of $SL_2(\mathbb{C})$. It is well known that in the case of $SL_2(\mathbb{C})$ there are five types of finite subgroups and the π_G -graphs are exactly the Coxeter graphs of affine (simply laced) types [14]. Correspondingly, we have five subtypes here and the five \overline{G}_α -graphs are also the Coxeter diagram of affine types but with an extra circle for every node.

(Type 5) Group G_5 . The group G_5 is of order 108 and generated by T, S, V , where T is defined in type 2 (cf. (3.9)),

$$(3.25) \quad S = \text{diag}(1, \xi_3, \xi_3^2),$$

and

$$(3.26) \quad V = \frac{1}{\sqrt{-3}} \begin{pmatrix} 1 & 1 & 1 \\ 1 & \xi_3 & \xi_3^2 \\ 1 & \xi_3^2 & \xi_3 \end{pmatrix}.$$

The group G_5 has 14 conjugate classes. A set of conjugacy representatives is given by $\{I, W, W^2, S, ST\} \cup \{V^i W^k \mid 1 \leq i, j \leq 3, 0 \leq k \leq 2\}$, where W is the generator of $Z(SL_3(\mathbb{C}))$ (see 3.1). The 14 inequivalent irreducible representations can be described as follows. Set $H_3 = \langle T, S, W \rangle \triangleleft G_5$, then $G_5 = H_3 \uplus V H_3 \uplus V^2 H_3 \uplus V^3 H_3$. Let $\rho_j (j = 1, 2, 3, 4)$ be the 1-dimensional irreducible representations of G_5 :

$$(3.27) \quad \rho_j : S \longrightarrow 1, \quad T \longrightarrow 1, \quad V \longrightarrow \xi_3^j,$$

We also need to use the canonical involution σ of $SL_3(\mathbb{C})$ defined by:

$$(3.28) \quad \sigma : A \longrightarrow (A^{-1})^T.$$

In terms of the natural representation π , we can construct the irreducible representations of G_5 as follows. For $j = 1, 2, 3, 4$ we define

$$(3.29) \quad \rho_{4+j} = \pi \otimes \rho_j, \quad \rho_{8+j} = \sigma \circ \rho_{4+j}, \quad \rho_{12+j} = \psi_j \uparrow_{H_3}^{G_5}.$$

Again by computing their characters we obtain the following fusion rules, and the π_{G_5} -graph is drawn in Fig. 5.

$$(3.30) \quad \begin{aligned} \pi \otimes \rho_1 &= \rho_5, & \pi \otimes \rho_2 &= \rho_7, & \pi \otimes \rho_3 &= \rho_9, & \pi \otimes \rho_4 &= \rho_{11}, \\ \pi \otimes \rho_5 &= \rho_6 \oplus \rho_8 \oplus \rho_{10}, & \pi \otimes \rho_6 &= \rho_1 \oplus \rho_{13} \oplus \rho_{14}, \\ \pi \otimes \rho_7 &= \rho_6 \oplus \rho_8 \oplus \rho_{12}, & \pi \otimes \rho_8 &= \rho_2 \oplus \rho_{13} \oplus \rho_{14}, \\ \pi \otimes \rho_9 &= \rho_6 \oplus \rho_{10} \oplus \rho_{12}, & \pi \otimes \rho_{10} &= \rho_3 \oplus \rho_{13} \oplus \rho_{14}, \\ \pi \otimes \rho_{11} &= \rho_8 \oplus \rho_{10} \oplus \rho_{12}, & \pi \otimes \rho_{12} &= \rho_4 \oplus \rho_{13} \oplus \rho_{14}, \\ \pi \otimes \rho_{13} &= \rho_5 \oplus \rho_7 \oplus \rho_9 \oplus \rho_{11}, \\ \pi \otimes \rho_{14} &= \rho_5 \oplus \rho_7 \oplus \rho_9 \oplus \rho_{11}. \end{aligned}$$

Similarly, we let M be the adjacency matrix associated with π_{G_5} -graph, and the *generalized Cartan matrix* $C(G) = (3I - M) + (3I - M)^T$.

Fig. 5

(Type 6) Group G_6 . The group of order 216 is generated by G_5 and K , where

$$(3.31) \quad K = \frac{1}{\sqrt{-3}} \begin{pmatrix} 1 & 1 & \xi_3^2 \\ 1 & \xi_3 & \xi_3 \\ \xi_3 & 1 & \xi_3 \end{pmatrix}.$$

It is known that there are 16 conjugacy classes in G_6 , hence G_6 has 16 irreducible representations. Since G_5 is a normal subgroup of G_6 , we can find some irreducible representations of G_6 by induction. In fact we find two 6-dimensional irreducible representations denoted as ρ^{14} and ρ^{15} , one 2-dimensional representation denoted as ρ^{13} and one 8-dimensional irreducible representations denoted as ρ^{16} . The other four 1-dimensional and eight 3-dimensional irreducible representations are given as follows: for $i, j = 0, 1$,

$$(3.32) \quad \begin{aligned} \rho^{(i,j)} : T &\longrightarrow 1, \quad S \longrightarrow 1, \quad V \longrightarrow \xi_2^i, \quad K \longrightarrow \xi_2^j, \\ \rho^{(2+i,2+j)} &= \pi \otimes \rho^{(i,j)}, \quad \rho^{(4+i,4+j)} = \sigma \circ \rho^{(2+i,2+j)}. \end{aligned}$$

The natural representation is seen to be $\pi = \rho^{(2,2)}$, and we have the following decompositions by comparing characters. The π_{G_6} -graph is drawn in Fig.6., and the corresponding *generalized Cartan matrix* is then determined accordingly.

$$(3.33) \quad \begin{aligned} \pi \otimes \rho^{(i,j)} &= \rho^{(2+i,2+j)}, \\ \pi \otimes \rho^{(2+i,2+j)} &= \rho^{(5-i,5-j)} \oplus \rho^{14}, \\ \pi \otimes \rho^{(4+i,4+j)} &= \rho^{(1-i,1-j)} \oplus \rho^{16}, \\ \pi \otimes \rho^{13} &= \rho^{15}, \quad \pi \otimes \rho^{14} = 2\rho^{16} \oplus \rho^{13}, \\ \pi \otimes \rho^{15} &= \rho^9 \oplus \rho^{10} \oplus \rho^{11} \oplus \rho^{12} \oplus \rho^{14}, \\ \pi \otimes \rho^{16} &= \rho^5 \oplus \rho^6 \oplus \rho^7 \oplus \rho^8 \oplus 2\rho^{15}. \end{aligned}$$

Fig.6.

(Type 7) Group G_7 . The group G_7 of order 60 is generated by T , E_2 , and E_3 , where T was defined as above (3.9) and

$$(3.34) \quad E_2 = \text{diag}(1, -1, -1), \quad E_3 = \frac{1}{2} \begin{pmatrix} -1 & \mu_- & \mu_+ \\ \mu_- & \mu_+ & -1 \\ \mu_+ & -1 & \mu_- \end{pmatrix}, \quad \mu_{\pm} = \frac{1}{2}(-1 \pm \sqrt{5}).$$

Class	1	2	3	5	5
χ_1	1	1	1	1	1
χ_2	3	-1	0	ν_+	ν_-
χ_3	3	-1	0	ν_-	ν_+
χ_4	4	0	1	-1	-1
χ_5	5	1	-1	0	0

TABLE 1. The characters of G_7

Class	1	2	4	3	7_1	7_2
χ_1	1	1	1	1	1	1
χ_2	6	2	0	0	-1	-1
χ_3	7	-1	-1	1	0	0
χ_4	8	0	0	-1	1	1
χ_5	3	-1	1	0	α_+	α_-
χ_6	3	-1	1	0	α_-	α_+

TABLE 2. The characters of G_8

The group G_7 is isomorphic to the simple group A_5 , whose irreducible characters are known. Table 1 lists its character table, where $\nu_{\pm} = \frac{-1 \pm \sqrt{5}}{2}$. For the natural character $\chi_{\pi} = \chi_3$ of the imbedding, we have the following decompositions, and the π_{G_7} -graph is shown in Fig.7.

$$(3.35) \quad \begin{aligned} \chi_{\pi} \otimes \chi_1 &= \chi_3, \\ \chi_{\pi} \otimes \chi_2 &= \chi_2 \oplus \chi_4 \oplus \chi_5, \\ \chi_{\pi} \otimes \chi_3 &= \chi_1 \oplus \chi_3 \oplus \chi_4, \\ \chi_{\pi} \otimes \chi_4 &= \chi_2 \oplus \chi_3 \oplus \chi_4 \oplus \chi_5, \\ \chi_{\pi} \otimes \chi_5 &= \chi_2 \oplus \chi_4, \end{aligned} \quad C_{G_7} = \begin{pmatrix} 3 & 0 & -1 & 0 & 0 \\ 0 & 2 & 0 & -1 & -1 \\ -1 & 0 & 2 & -1 & 0 \\ 0 & -1 & -1 & 2 & -1 \\ 0 & -1 & 0 & -1 & 3 \end{pmatrix}.$$

Fig.7.

(Type 8) Group G_8 . The group G_8 is the Klein simple group of order 168 generated by T (defined in 3.9), X_7 and U defined below:

$$(3.36) \quad X_7 = \text{diag}(\beta, \beta^2, \beta^4), \quad U = \frac{1}{\sqrt{-7}} \begin{pmatrix} a & b & c \\ b & c & a \\ c & a & b \end{pmatrix},$$

where for $\beta = \xi_7$, $a = \beta^4 - \beta^3$, $b = \beta^2 - \beta^5$, and $c = \beta - \beta^6$. It is known that G_8 has 6 irreducible characters, whose character table is given in Table 2, where $\alpha_{\pm} = \frac{-1 \pm \sqrt{-7}}{2}$. The natural character $\chi_{\pi} = \chi_5$, then we have the

following decompositions of $\chi_\pi \otimes \chi_i (i = 1, 2, \dots, 6)$. The π_{G_8} -graph is drawn in Fig.8 and the *generalized Cartan matrix* is C_{G_8} .

(3.37)

$$\begin{aligned} \chi_\pi \otimes \chi_1 &= \chi_5, \\ \chi_\pi \otimes \chi_2 &= \chi_3 \oplus \chi_4 \oplus \chi_6, \\ \chi_\pi \otimes \chi_3 &= \chi_2 \oplus \chi_3 \oplus \chi_4, \\ \chi_\pi \otimes \chi_4 &= \chi_2 \oplus \chi_3 \oplus \chi_4 \oplus \chi_5, \\ \chi_\pi \otimes \chi_5 &= \chi_2 \oplus \chi_6, \\ \chi_\pi \otimes \chi_6 &= \chi_1 \oplus \chi_4, \end{aligned} \quad C_{G_8} = \begin{pmatrix} 6 & 0 & 0 & 0 & -1 & -1 \\ 0 & 6 & -2 & -2 & -1 & -1 \\ 0 & -2 & 4 & -2 & 0 & 0 \\ 0 & -2 & -2 & 4 & -1 & -1 \\ -1 & -1 & 0 & -1 & 6 & -1 \\ -1 & -1 & 0 & -1 & -1 & 6 \end{pmatrix}.$$

In this case we can obtain the fusion rule easily by observing the character table. For example, the product of the characters $\chi_5 = \chi_\pi$ and χ_2 is the sum of the character (row) vectors χ_3, χ_4 and χ_6 in Table 2.

(Type 9) Group G_9 . The group G_9 of order 180 is generated by group G_7 and matrix W (cf 3.1). We have $G_9 \simeq A_5 \times \langle W \rangle$, so it is easy to get all the irreducible representations of G_9 from those of A_5 and group $\langle W \rangle$. Then the π_{G_9} -graph is Fig.9. and the *generalized Cartan matrix* is C_{G_9} .

$$(3.38) \quad C_{G_9} = \begin{pmatrix} 6E & -B & -B \\ -B^t & 6E & -B \\ -B & -B^t & 6E \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 \\ 1 & 0 & 1 & 0 & 1 \\ 0 & 1 & 0 & 1 & 1 \\ 0 & 1 & 1 & 1 & 1 \end{pmatrix}.$$

Fig.9.

(Type 10) Group G_{10} . The group G_{10} of order 504 is generated by G_8 and matrix W . It is easy to see that $G_{10} \simeq G_8 \times \langle W \rangle$. The $\pi_{G_{10}}$ -graph is

drawn in Fig.10 and the *generalized Cartan matrix* is $C_{G_{10}}$.

$$(3.39) \quad C_{G_{10}} = \begin{pmatrix} 6E & -B & -B^t \\ -B^t & 6E & -B \\ -B & -B^t & 6E \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 1 & 1 & 0 \\ 0 & 1 & 1 & 1 & 0 & 0 \\ 0 & 1 & 1 & 1 & 0 & 1 \\ 1 & 0 & 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 0 & 1 & 0 \end{pmatrix}.$$

Fig.10.

(Type 11) Group G_{11} . The G_{11} of order 648 is generated by G_5 and the matrix M , where

$$(3.40) \quad M = \text{diag}(\varepsilon, \varepsilon, \varepsilon\xi_3), \quad \varepsilon^3 = \xi_3^2.$$

We first obtain three 1-dimensional representations ρ_i by the defining relations of G_{11} ($i = 0, 1, 2$). We then have three 3-dimensional irreducible representations $\rho_{2+i} = \pi \otimes \rho_i$, where π is the natural representation. Furthermore, we get three more non-isomorphic 3-dimensional irreducible representations $\rho_{5+i} = \sigma \cdot \rho_{2+i}$, where σ is the action of transpose inverse (3.28). Obviously, G_6 is a normal subgroup of G_{11} , so we can get eight 9-dimensional representations by inducing the 3-dimensional irreducible representations from G_6 to G_{11} . By Frobenius reciprocity we observe that among these induced representations, there are just two new irreducible representations which are 9-dimensional, and the rest can be decomposed into direct sums of one 3-dimensional and one new 6-dimensional representations. In short, there are three 1-dimensional, three 2-dimensional, seven 3-dimensional, six 6-dimensional, three 8-dimensional and two 9-dimensional irreducible representations. Finally, we decompose the tensor product of the natural representation π with the irreducible representations. The $\pi_{G_{11}}$ -graph is shown in Fig.11.

Fig.11.

(Type 12) Group G_{12} . The group of order 1080 is generated by G_7 and matrix E_4 , where

$$(3.41) \quad E_4 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & -w \\ 0 & -w^2 & 0 \end{pmatrix}.$$

The center of group G_{12} is $Z(G) = \langle W \rangle$ (cf. 3.1), and $G_{12}/Z(G) \simeq A_6$. Thus for an irreducible representation ρ of A_6 , we can lift it to an irreducible representation of G_{12} through the canonical map. In this way we can find two 5-dimensional, one 9-dimensional, one 10-dimensional and two 8-dimensional irreducible representations of G_{12} . Moreover, there are one 1-dimensional and four 3-dimensional irreducible representations. To sum up, G_{12} has one 1-dimensional, four 3-dimensional, two 5-dimensional, two 6-dimensional, two 8-dimensional, three 9-dimensional, one 10-dimensional and two 15-dimensional irreducible representations. Then we decompose the tensor product of the natural representation π with the irreducible representations, and the McKay quiver $\pi_{G_{12}}$ is drawn in Fig.12.
