Abstract

We present an NLO analysis of the massive vector current correlator at temperatures above a few hundred MeV. The physics of this correlator originates from a transport peak, related to heavy quark diffusion, and from the quark-antiquark threshold, related to quarkonium physics. In the bottom case both can be studied with separate effective theories, but for charm these may not be accurate, so a study within the full theory is needed. Working in imaginary time, the NLO correlator can be computed in unresummed perturbation theory; comparing with lattice data, we find good agreement. Subsequently we inspect how non-perturbative modifications of the transport peak would affect the imaginary-time correlator. The massive NLO quark-number susceptibility is also contrasted with numerical measurement.

October 2012

1. Introduction

Heavy (charm and bottom) quarks are excellent probes for the properties of the hot QCD plasma generated in heavy ion collision experiments. On the theoretical side, the existence of a mass scale $M \gg \pi T \gg 200$ MeV renders the heavy quarks relatively tractable, permitting for an interpolation between the simple static dynamics of the infinite mass limit and the high mobility case manifested by lighter quarks. It is particularly fortunate that two heavy flavours are available, offering for a handle on the functional dependence on $M/\pi T$. On the experimental side, heavy quarks and quarkonia are readily tagged because of their distinctive leptonic decays. Indeed thermal modifications of the bottomonia spectra were among the first spectacular results produced by the LHC heavy ion program [1].

For the bottom quark case, recent years have seen significant progress in theoretical studies of the main phenomena involved, namely single quark “transport” (diffusion, kinetic equilibration) as well as physics near the quark-antiquark threshold (quarkonium dissociation, chemical equilibration) (cf. ref. [2] for a review and refs. [3]–[11] for recent contributions). Largely this progress has been achieved through the use of modern effective field theory methods (Heavy Quark Effective Theory, or HQET, for single quarks; Non-Relativistic QCD, or NRQCD, for quarkonium physics). Once properly formulated the effective field theory observables can be measured non-perturbatively with lattice Monte Carlo methods, and indeed first results suggest that these avenues may lead to substantial progress [12]–[16].

In the charm quark case, however, it is not guaranteed that the heavy quark expansion converges fast enough to yield quantitatively accurate results for all observables of interest. On the other hand, it no longer appears prohibitively expensive to treat charm quarks as “light” degrees of freedom in lattice QCD. Indeed, results have appeared concerning both thermodynamic quantities [17, 18, 19] and imaginary-time correlators relevant for determining dynamical properties of the system [20] (earlier works can be found in refs. [21]–[24] and references therein). Yet, a modest scale hierarchy between πT and M does exist, and consequently systematic errors, both from lattice artifacts and from the unavoidable analytic continuation [25], are likely to be harder to control than in the light quark case. In fact, given that systematic errors related to analytic continuation remain substantial even for light quarks [26], further crosschecks appear welcome.

The goal of the current study is to derive results within next-to-leading order (NLO) perturbation theory which may help in the analysis of lattice data such as those in ref. [20]. In order to allow for a direct appreciation of Euclidean measurements, we inspect how specific modifications of transport properties and threshold features manifest themselves in imaginary time. Ultimately, in accordance with the philosophy of ref. [27] and practical tests of refs. [26, 28], the goal would be to subtract “trivial” ultraviolet features from continuum-extrapolated lattice data, in order to allow for a model-independent extraction of real-time physics [29].

On the technical side, the current work represents a continuation of our earlier study [30], in which the massive vector current *spectral function* was computed at NLO in the domain $M \gg \pi T$ (keeping only those thermal effects which are not exponentially suppressed). Here we keep the full mass dependence, permitting for an extrapolation also to the regime $M \ll \pi T$, as well as contributions from the transport peak at $\omega \ll 2M$ which were omitted in ref. [30]. Moreover we work directly in *imaginary time*, which has the benefit that the usual problems of convergence at small ω are milder. In particular, at NLO infrared safe results can be obtained without resummations, similarly to what has previously been achieved for gluonic observables [31, 28].

The plan of this paper is the following. After specifying the observables considered and discussing the methods employed (sec. 2), we outline the qualitative structure of our findings in sec. 3. The detailed analytic and numerical results of the strict NLO analysis comprise sec. 4, whereas in secs. 5 and 6 the effects of non-perturbative modifications of the transport peak and quarkonium threshold, respectively, are inspected. Sec. 7 presents our conclusions; appendix A results for all the “master” sum-integrals considered; and appendix B details related to renormalization.

2. Observables and methods

2.1. Basic definitions

The main quantity considered is the vector current correlator related to a massive flavour. Like in lattice QCD we work in Euclidean signature, with the usual thermal boundary conditions imposed across the time direction. Then the correlator is defined as

$$G_{\mathbf{v}}(\tau) \equiv \sum_{\mu=0}^d \int_{\mathbf{x}} \left\langle (\bar{\psi} \gamma_{\mu} \psi)(\tau, \mathbf{x}) (\bar{\psi} \gamma^{\mu} \psi)(0, \mathbf{0}) \right\rangle_T \quad (2.1)$$

$$\equiv G_{00}(\tau) - G_{ii}(\tau), \quad 0 < \tau < \frac{1}{T}, \quad (2.2)$$

where the Dirac matrices are Minkowskian, and a sum over spatial indices is implied. Because of current conservation the temporal component is independent of τ , and we denote the corresponding “susceptibility” by

$$\chi \equiv \int_0^{\beta} d\tau G_{00}(\tau) = \beta G_{00}(0), \quad \beta \equiv \frac{1}{T}. \quad (2.3)$$

For future reference let us also record the *free massless* results for these correlators [32]:

$$G_{ii}^{\text{free}}(\tau) \equiv 2N_c T^3 \left[\pi (1 - 2\tau T) \frac{1 + \cos^2(2\pi\tau T)}{\sin^3(2\pi\tau T)} + \frac{2 \cos(2\pi\tau T)}{\sin^2(2\pi\tau T)} + \frac{1}{6} \right], \quad (2.4)$$

$$\chi^{\text{free}} \equiv \frac{N_c T^2}{3}. \quad (2.5)$$

Here $C_A \equiv N_c = 3$ refers to the number of colours. Later on the group theory factor $C_F \equiv (N_c^2 - 1)/(2N_c)$ will also appear. Spacetime dimension is denoted by $D = d + 1 = 4 - 2\epsilon$.

At NLO, we find it convenient to compute the correlators G_V and G_{00} . The spatial part G_{ii} is then obtained from eq. (2.2). Verifying explicitly the τ -independence of G_{00} provides for a nice crosscheck of the computation.

2.2. Wick contractions for the vector current correlator

The Wick contractions for G_V are as given in ref. [30]. Denoting

$$Q \equiv (\omega_n, \mathbf{0}), \quad \Delta_P \equiv P^2 + M^2, \quad (2.6)$$

the leading-order (LO) vector correlator reads, in momentum space,

$$\text{Diagram} = 2C_A \mathfrak{F}_{\{P\}} \left\{ \frac{(D-2)Q^2 - 4M^2}{\Delta_P \Delta_{P-Q}} - \frac{2(D-2)}{\Delta_P} \right\}. \quad (2.7)$$

Here $\{P\}$ denotes fermionic Matsubara momenta, and $\mathfrak{F}_{\{P\}} \equiv T \sum_{\{p_n\}} \int_{\mathbf{p}}$.

At NLO, we have to decide on a meaning of the renormalized mass. Although conceptually subtle, it is technically convenient to employ a pole mass; then the bare mass parameter, M_B^2 , can be expressed as $M_B^2 = M^2 + \delta M^2$ where at NLO

$$\delta M^2 = -g^2 C_F \int_K \left\{ (D-2) \left[\frac{1}{K^2} - \frac{1}{\Delta_{\bar{P}-K}} \right] + \frac{4M^2}{K^2 \Delta_{\bar{P}-K}} \right\}_{\bar{P}^2 = -M^2} \quad (2.8)$$

$$= -g^2 C_F \int_{\mathbf{k}} \frac{1}{2\epsilon_k E_{pk}} \left[(D-2)(E_{pk} - \epsilon_k) + \frac{4M^2(\epsilon_k + E_{pk})}{(\epsilon_k + E_{pk})^2 - E_p^2} \right] \quad (2.9)$$

$$= -\frac{6g^2 C_F M^2}{(4\pi)^2} \left(\frac{1}{\epsilon} + \ln \frac{\bar{\mu}^2}{M^2} + \frac{4}{3} \right). \quad (2.10)$$

Here $\bar{\mu}$ is the scale parameter of the $\overline{\text{MS}}$ scheme, terms of $\mathcal{O}(\epsilon)$ were omitted, and

$$\epsilon_k \equiv |\mathbf{k}|, \quad E_p \equiv \sqrt{p^2 + M^2}, \quad E_{pk} \equiv \sqrt{(\mathbf{p} - \mathbf{k})^2 + M^2}. \quad (2.11)$$

Because of Lorentz invariance the vector \bar{P} in eq. (2.8) can be chosen at will, as long as we set $p_0 = \pm iE_p$ after carrying out the K -integral; this means that the vector \mathbf{p} in eq. (2.9) is arbitrary. The corresponding counterterm contribution reads

$$\text{Diagram} = 4C_A \delta M^2 \mathfrak{F}_{\{P\}} \left\{ \frac{D-2}{\Delta_P^2} - \frac{2}{\Delta_P \Delta_{P-Q}} + \frac{4M^2 - (D-2)Q^2}{\Delta_P^2 \Delta_{P-Q}} \right\}, \quad (2.12)$$

and it is often convenient to identify \mathbf{p} of eq. (2.9) as the integration variable of eq. (2.12).

The ‘‘genuine’’ 2-loop graphs amount to

$$\begin{aligned}
\text{Diagram 1} + \text{Diagram 2} &= 4g^2 C_A C_F \not\int_{K\{P\}} \left\{ \right. \\
&\frac{(D-2)^2}{K^2 \Delta_P^2} - \frac{(D-2)^2}{\Delta_P^2 \Delta_{P-K}} - \frac{2(D-2)}{K^2 \Delta_P \Delta_{P-K}} + \frac{4(D-2)M^2}{K^2 \Delta_P^2 \Delta_{P-K}} \\
&- \frac{2(D-2)}{K^2 \Delta_P \Delta_{P-Q}} + \frac{4(D-2)M^2 - (D-2)^2 Q^2}{K^2 \Delta_P^2 \Delta_{P-Q}} + \frac{2(D-2)}{K^2 \Delta_{P-K} \Delta_{P-Q}} \\
&+ \frac{4(D-2)}{\Delta_P \Delta_{P-K} \Delta_{P-Q}} - \frac{4(D-2)M^2 - (D-2)^2 Q^2}{\Delta_P^2 \Delta_{P-K} \Delta_{P-Q}} \\
&- \frac{16M^2 + 2(D-2)^2 K \cdot Q - 4(D-2)Q^2}{K^2 \Delta_P \Delta_{P-K} \Delta_{P-Q}} + \frac{16M^4 - 4(D-2)Q^2 M^2}{K^2 \Delta_P^2 \Delta_{P-K} \Delta_{P-Q}} \\
&- \frac{2(D-4)M^2 + \frac{1}{2}(D-2)(8-D)Q^2 + (D-2)K^2}{\Delta_P \Delta_{P-K} \Delta_{P-Q} \Delta_{P-K-Q}} \\
&\left. + \frac{8M^4 - 2(D-4)M^2 Q^2 - (D-2)Q^4}{K^2 \Delta_P \Delta_{P-K} \Delta_{P-Q} \Delta_{P-K-Q}} \right\}. \tag{2.13}
\end{aligned}$$

2.3. Wick contractions for the susceptibility

In the case of the zero components, *viz.* G_{00} , the LO correlator reads, in momentum space,

$$\text{Diagram 3} = 2C_A \not\int_{\{P\}} \left\{ \frac{2}{\Delta_P} - \frac{Q^2 + 4E_p^2}{\Delta_P \Delta_{P-Q}} \right\}, \tag{2.14}$$

whereas the counterterm graph can be expressed as

$$\text{Diagram 4} = 4C_A \delta M^2 \not\int_{\{P\}} \left\{ \frac{Q^2 + 4E_p^2}{\Delta_P^2 \Delta_{P-Q}} - \frac{2}{\Delta_P \Delta_{P-Q}} - \frac{1}{\Delta_P^2} \right\}. \tag{2.15}$$

The genuine 2-loop graphs amount to¹

$$\begin{aligned}
\text{Diagram 5} + \text{Diagram 6} &= 4g^2 C_A C_F \not\int_{K\{P\}} \left\{ \right. \\
&- \frac{D-2}{K^2 \Delta_P^2} + \frac{D-2}{\Delta_P^2 \Delta_{P-K}} + \frac{2}{K^2 \Delta_P \Delta_{P-K}} - \frac{4M^2}{K^2 \Delta_P^2 \Delta_{P-K}}
\end{aligned}$$

¹The appearance of the ‘‘energy variables’’ in the numerators implies that there is a certain redundancy in the basis:

$$0 = \not\int_{K\{P\}} \left\{ \frac{2K \cdot Q}{K^2 \Delta_P \Delta_{P-K} \Delta_{P-Q}} - \frac{Q^2}{\Delta_P \Delta_{P-K} \Delta_{P-Q} \Delta_{P-K-Q}} + \frac{Q^2 \epsilon_k^2}{K^2 \Delta_P \Delta_{P-K} \Delta_{P-Q} \Delta_{P-K-Q}} \right\}. \tag{2.16}$$

We have used this to eliminate terms containing $Q^2 \epsilon_k^2$ in the numerator.

$$\begin{aligned}
& -\frac{2(D-2)}{K^2\Delta_P\Delta_{P-Q}} + \frac{(D-2)(4E_p^2 + Q^2)}{K^2\Delta_P^2\Delta_{P-Q}} - \frac{2}{K^2\Delta_{P-K}\Delta_{P-Q}} \\
& + \frac{4(D-2)}{\Delta_P\Delta_{P-K}\Delta_{P-Q}} - \frac{(D-2)(4E_p^2 + Q^2)}{\Delta_P^2\Delta_{P-K}\Delta_{P-Q}} \\
& - \frac{16M^2 - 4K \cdot Q + 4Q^2}{K^2\Delta_P\Delta_{P-K}\Delta_{P-Q}} + \frac{4M^2(4E_p^2 + Q^2)}{K^2\Delta_P^2\Delta_{P-K}\Delta_{P-Q}} \\
& - \frac{(D-2)(E_p^2 + E_{pk}^2 - \epsilon_k^2 + K^2 + \frac{1}{2}Q^2) - 4M^2}{\Delta_P\Delta_{P-K}\Delta_{P-Q}\Delta_{P-K-Q}} \\
& + \left. \frac{4M^2(E_p^2 + E_{pk}^2 - \epsilon_k^2) + 2Q^2(E_p^2 + E_{pk}^2 + M^2) + Q^4}{K^2\Delta_P\Delta_{P-K}\Delta_{P-Q}\Delta_{P-K-Q}} \right\}. \tag{2.17}
\end{aligned}$$

2.4. Matsubara sums and spatial integrals

The next step is to convert the momentum-space expressions to configuration space. If we denote the above result (eqs. (2.7), (2.12), (2.13)) by $\tilde{G}_V(\omega_n)$, then the conversion is obtained as

$$G_V(\tau) = T \sum_{\omega_n} e^{-i\omega_n\tau} \tilde{G}_V(\omega_n), \tag{2.18}$$

and similarly for G_{00} . At NLO we are thereby faced with a three-fold Matsubara sum. Making use of standard techniques, reviewed in some detail in ref. [30], these sums can be carried out in a closed form, whereby we are left with integrals over at most two spatial momenta (i.e. two radial directions and one angle). Intermediate results at this stage are displayed for all individual master sum-integrals in appendix A, and for their sums in appendix B, in the latter case with the cancellation of $1/\epsilon$ -divergences verified as well.

Two interesting crosschecks are available. First of all, all τ -dependent terms disappear from G_{00} , cf. eq. (B.3). Second, individual parts of the expressions contain ‘‘contact terms’’ $\propto \delta_\beta(\tau)$, where δ_β denotes the periodic Dirac-delta. These arise from structures that are independent of ω_n , but also from sum-integrals in which Q^2 appears in the numerator. It can be verified, however, that all contact terms cancel, both at LO and at NLO.

It remains to carry out the spatial integrals. We write

$$\int_{\mathbf{p},\mathbf{k}} = \int_{p,k} \int_z, \tag{2.19}$$

where the normalization of the angular variable $z = \cos\theta_{\mathbf{p},\mathbf{k}}$ is chosen so that $\int_z 1 = 1$. Depending on the case, it is convenient to substitute variables as

$$\int_z = \frac{1}{2pk} \int_{E_{pk}^-}^{E_{pk}^+} dE_{pk} E_{pk} = \frac{1}{2pk} \int_{\epsilon_{pk}^-}^{\epsilon_{pk}^+} d\epsilon_{pk} \epsilon_{pk}, \tag{2.20}$$

where $E_{pk}^\pm \equiv \sqrt{(p \pm k)^2 + M^2}$, $\epsilon_{pk}^\pm \equiv |p \pm k|$. The angular integrals are doable in most cases. In addition, it is also possible to carry out partial integrations with respect to the radial directions, which helps to reduce the number of independent terms (for the massless case, see ref. [33] for a recent discussion). Closed *massless* loop integrals are typically solvable, but in general the integrations remain to be carried out numerically. Our final expressions are given in the next two sections, cf. eqs. (3.2)–(3.5), (4.1), (4.4), (4.5).

3. Leading order results and qualitative pattern

In order to illustrate the qualitative structure of the results, we recall in this section the LO expressions for the quantities considered. In general, two types of contributions appear: those that depend on τ , and those that are constant. To display the τ -dependence we introduce the periodic dimensionless function

$$D_{E_1 \dots E_k}^{E_{k+1} \dots E_n}(\tau) \equiv \frac{e^{(E_1 + \dots + E_k)(\beta - \tau) + (E_{k+1} + \dots + E_n)\tau} + e^{(E_1 + \dots + E_k)\tau + (E_{k+1} + \dots + E_n)(\beta - \tau)}}{[e^{\beta E_1} \pm 1] \dots [e^{\beta E_n} \pm 1]}. \quad (3.1)$$

In the denominator, the sign is chosen according to whether the particle is a boson or a fermion (at NLO, there is only one boson, with the on-shell energy denoted by ϵ_k , cf. eq. (2.11)). We also denote $D_{2E_p} \equiv D_{E_p E_p}$. With these conventions, the LO result for G_V reads

$$G_V^{\text{LO}}(\tau)|_{\tau\text{-dep.}} = -G_{ii}^{\text{LO}}(\tau)|_{\tau\text{-dep.}} = -2C_A \int_p \left(2 + \frac{M^2}{E_p^2}\right) D_{2E_p}(\tau), \quad (3.2)$$

$$G_V^{\text{LO}}(\tau)|_{\text{const.}} = -4C_A \int_p \frac{M^2 T n'_F(E_p)}{E_p^2}. \quad (3.3)$$

Here n_F denotes the Fermi distribution (n_B denotes the Bose distribution). The susceptibility only contains a τ -independent part:

$$T\chi^{\text{LO}} = G_{00}^{\text{LO}} = -4C_A \int_p T n'_F(E_p). \quad (3.4)$$

Finally, the constant part of the spatial correlator is obtained through the use of eq. (2.2):

$$G_{ii}^{\text{LO}}(\tau)|_{\text{const.}} = -4C_A \int_p \left(1 - \frac{M^2}{E_p^2}\right) T n'_F(E_p). \quad (3.5)$$

To our knowledge none of these leading-order expressions can be integrated in terms of standard elementary functions.

In terms of the spectral function, *viz.* $\rho_{ii}(\omega)$, the constant contribution in eq. (3.5) arises from (an infinitely narrow) transport peak around $\omega = 0$, whereas the “fast” τ -dependence in eq. (3.2) originates from the quark-antiquark continuum at $|\omega| \geq 2M$. Around the middle of

the Euclidean time interval, $D_{2E_p}(\beta/2) = -2Tn'_F(E_p)$. Therefore, both terms contribute in a comparable manner at large Euclidean time separations, even though they originate from completely different types of physics.

At NLO, the same three structures appear as at LO: a constant G_{00} , as well as a spatial correlator G_{ii} which has both a constant and a τ -dependent part. It is generally believed that the perturbative series for the constant part of G_{ii} breaks down at some point and that in the full theory, G_{ii} has no projection to the Matsubara zero mode; the reason is that the spatial components of the vector current do not couple to conserved charges. The corresponding “slow” τ -dependence then reflects the physics of a “smeared” transport peak. Yet it remains true that single quark physics from the transport peak and quark-antiquark physics from the threshold region are expected to contribute in a comparable manner to the Euclidean correlator around $\tau = \beta/2$. (This is demonstrated explicitly in figs. 3, 4 below.)

4. NLO results

4.1. Susceptibility

Proceeding to NLO, the result for the susceptibility is obtained from eq. (B.3) after partial integrations:

$$T\chi^{\text{NLO}} = G_{00}^{\text{NLO}} = 4g^2 C_A C_F \int_p \frac{Tn'_F(E_p)}{p^2} \int_k \left[\frac{n_B(\epsilon_k)}{\epsilon_k} + \frac{n_F(E_k)}{E_k} \left(1 - \frac{M^2}{k^2} \right) \right]. \quad (4.1)$$

This can be shown to agree with what can be extracted from ref. [34] as $T\partial_\mu^2 p(T, \mu)|_{\mu=0}$. (The substance of the information is already there in ref. [35].) The massless loop evaluates to $\int_k n_B(\epsilon_k)/\epsilon_k = T^2/12$, and in the limit $M \gg \pi T$ its effect can be interpreted as an effective mass correction to the LO result of eq. (3.4), $M^2 \rightarrow M^2 + g^2 T^2 C_F/6$ [36]. On the other hand, in the massless limit $M \ll \pi T$ eq. (4.1) reduces to the well-known correction (cf. [37] and references therein)

$$G_{00}^{\text{NLO}} \stackrel{M \ll \pi T}{\simeq} -\frac{g^2 N_c C_F T^3}{8\pi^2} + \mathcal{O}(g^3). \quad (4.2)$$

A numerical evaluation of eqs. (3.4), (4.1) is shown in fig. 1. For the gauge coupling we have inserted the 2-loop value for the thermal coupling g_E^2/T from ref. [38], and for comparison with quenched lattice data from refs. [39, 20] we assume that $T_c/\Lambda_{\overline{\text{MS}}} \simeq 1.25$, $T/T_c \simeq 1.45$. In the massive case, where no continuum extrapolation is available in ref. [20], we choose to compare with results obtained on a lattice $128^3 \times 48$. The quark mass cited, $m_{\overline{\text{MS}}}(m_c) = 1.094(1)$ GeV is phenomenologically on the low side [40]; based on eq. (2.10), *viz.*

$$M \simeq m_{\overline{\text{MS}}}(m_c) \left\{ 1 + \frac{4g_{\overline{\text{MS}}}^2(m_c)C_F}{(4\pi)^2} + \mathcal{O}(g^4) \right\}, \quad (4.3)$$

Figure 1: The quark-number susceptibility, eqs. (3.4), (4.1), normalized to the free result from eq. (2.5). The lattice result at $M = 0$ comes from ref. [39], that at $M > 0$ from ref. [20]; both are quenched ($N_f = 0$) and only the former represents the continuum limit. The uncertainty of M/T is our estimate (cf. the text). Lattice results for charm by other groups can be found in refs. [18, 19].

we get $M \simeq 1.3$ GeV but assign a large error to this number. Ref. [20] also cites $T_c/\sqrt{\sigma} = 0.630(5)$, $\sqrt{\sigma} = 428$ MeV, so we estimate $M/T \simeq 3.3 \pm 0.5$, but with substantial systematic uncertainties, from lattice artifacts, string tension measurement [41], quenching, as well as perturbative input. With this in mind, the excellent agreement seen in fig. 1 is remarkable, and supports the long-held belief that all quarks, and heavy quarks in particular, are well described by the weak-coupling expansion at surprisingly low temperatures.

4.2. Vector current correlator

The vector current correlator is obtained from eqs. (B.1), (B.2) after partial integrations. Its τ -dependent part reads

$$\begin{aligned}
\frac{G_V^{\text{NLO}}|_{\tau\text{-dep.}}}{4g^2 C_A C_F} &= \int_p \frac{D_{2E_p}(\tau)}{4\pi^2} \left[\left(3 + \frac{M^2}{E_p^2} \right) \left(1 - \frac{p}{2E_p} \ln \frac{E_p + p}{E_p - p} \right) - 1 - \left(2 + \frac{M^2}{E_p^2} \right) \int_0^\infty dk \frac{\theta(k)}{k} \right] \\
&+ \int_{p,k} \mathbb{P} \left\{ \int_z \frac{D_{\epsilon_k E_p E_{pk}}(\tau)}{\epsilon_k E_p E_{pk} \Delta_{+-} \Delta_{-+}} \left[-2E_p^2 + M^2 \left(\frac{\Delta_{--}}{\Delta_{++}} + \frac{2\epsilon_k^2}{\Delta_{+-} \Delta_{-+}} \right) + \frac{4\epsilon_k^2 M^4}{\Delta_{++}^2 \Delta_{+-} \Delta_{-+}} \right] \right. \\
&\quad \left. + \int_z \frac{D_{E_p \epsilon_k E_{pk}}(\tau)}{\epsilon_k E_p E_{pk} \Delta_{+-} \Delta_{-+}} \left[-2E_p^2 + M^2 \left(\frac{\Delta_{++}}{\Delta_{--}} + \frac{2\epsilon_k^2}{\Delta_{+-} \Delta_{-+}} \right) + \frac{4\epsilon_k^2 M^4}{\Delta_{--}^2 \Delta_{+-} \Delta_{-+}} \right] \right\}
\end{aligned}$$

$$\begin{aligned}
& + \int_z \frac{2D_{\epsilon_k E_p E_{pk}}^{E_p}(\tau)}{\epsilon_k E_p E_{pk} \Delta_{++} \Delta_{--}} \left[E_p^2 + E_{pk}^2 - M^2 \left(\frac{\Delta_{+-}}{\Delta_{-+}} + \frac{2\epsilon_k^2}{\Delta_{++} \Delta_{--}} \right) - \frac{4\epsilon_k^2 M^4}{\Delta_{-+} \Delta_{++} \Delta_{--}} \right] \\
& + \frac{D_{2E_p}(\tau)}{2\epsilon_k^3} \left(2 + \frac{M^2}{E_p^2} \right) \left[-1 + \frac{E_p^2(E_{pk}^+ - E_{pk}^-) - p\epsilon_k(E_{pk}^+ + E_{pk}^-)}{2p(E_p^2 - \epsilon_k^2)} + \frac{\epsilon_k^2 M^2(E_{pk}^+ - E_{pk}^-)}{p(E_p^2 - \epsilon_k^2) E_{pk}^+ E_{pk}^-} \right. \\
& \quad \left. + \frac{2E_p^2 - M^2}{2pE_p} \left(\ln \left| \frac{(E_p + p)(2p - \epsilon_k)}{(E_p - p)(2p + \epsilon_k)} \right| + \ln \left| \frac{1 - \epsilon_k^2/(E_p + E_{pk}^-)^2}{1 - \epsilon_k^2/(E_p + E_{pk}^+)^2} \right| \right) + \theta(k) \right] \\
& + \frac{D_{2E_p}(\tau) n_B(\epsilon_k)}{\epsilon_k} \left[\frac{3M^2}{2p^2 E_p^2} + \frac{1}{pE_p} \ln \frac{E_p + p}{E_p - p} \right. \\
& \quad \left. + \frac{1}{\epsilon_k^2} \left(2 + \frac{M^2}{E_p^2} \right) \left(-1 + \frac{2E_p^2 - M^2}{2pE_p} \ln \frac{E_p + p}{E_p - p} \right) \right] \\
& + \frac{D_{2E_p}(\tau) n_F(E_k)}{E_k} \left[\frac{3M^2}{2p^2 E_p^2} + \frac{10p^4 + 16p^2 M^2 + 3M^4}{2(p^2 - k^2)p^2 E_p^2} + \frac{M^2}{pkE_p^2} \ln \left| \frac{p+k}{p-k} \right| \right. \\
& \quad \left. - \frac{2E_p^4 + 2E_k^2 E_p^2 - M^4}{2pk(E_p - E_k)E_p^3} \left(\ln \left| \frac{p+k}{p-k} \right| + \frac{E_k}{E_p + E_k} \ln \left| \frac{M^2 + E_p E_k + pk}{M^2 + E_p E_k - pk} \right| \right) \right] \Bigg\}, \quad (4.4)
\end{aligned}$$

where \mathbb{P} denotes a principal value, and Δ_{++} etc are defined in eq. (A.2). The constant contribution reads

$$\begin{aligned}
\frac{G_V^{\text{NLO}}|_{\text{const.}}}{4g^2 C_A C_F} &= \int_p T n'_F(E_p) \int_k \left\{ \frac{n_B(\epsilon_k)}{\epsilon_k} \left[\frac{1}{p^2} - \frac{3}{E_p^2} \right] \right. \\
& \quad \left. + \frac{n_F(E_k)}{E_k} \left[\frac{1}{p^2} - \frac{3}{E_p^2} - \frac{M^2}{p^2 k^2} - \frac{M^2}{E_p^2 E_k^2} + \frac{M^2(4E_k^2 - M^2)}{2pkE_p^2 E_k^2} \ln \left| \frac{p+k}{p-k} \right| \right] \right\}. \quad (4.5)
\end{aligned}$$

The spatial correlator subsequently follows from eq. (2.2), with the susceptibility inserted from eq. (4.1).

Although the expression in eq. (4.4) is finite, its numerical evaluation is non-trivial. There are at least three separate challenges: at small k various parts of the expression are divergent, and care must be taken in order to avoid significance loss in their cancellation; at $k = p$ there is a pole which is defined in the sense of a principal value; and at large k there is a vacuum part which decreases only slowly (although it is integrable). For the reader's benefit, let us briefly specify how we have dealt with these challenges.

- The small- k divergence originates from the terms integrated over z in eq. (4.4) and from terms where the integral had already been carried out. For the latter type the divergent part reads

$$\frac{D_{2E_p}(\tau)}{\epsilon_k^3} \left(2 + \frac{M^2}{E_p^2} \right) \left(-1 + \frac{2E_p^2 - M^2}{2pE_p} \ln \frac{E_p + p}{E_p - p} \right) \left(\frac{1}{2} + n_B(\epsilon_k) \right), \quad (4.6)$$

containing both vacuum and Bose-enhanced structures. The integral \int_z needs to be carried out precisely enough such that the cancellation takes duly place.

Figure 2: Left: The vector correlator, normalized to the free result from eq. (2.4), for $M/T = 1.0, 2.0, 3.0, 4.0, 5.0$ (top to bottom). Right: The vector correlator, normalized to the “reconstructed” result from eqs. (4.9), (4.11), for the same masses (left to right). The lattice results are from ref. [20]; they are quenched ($N_f = 0$) and do not contain a continuum extrapolation ($N_\tau = 48$, $N_s = 128$).

- The principal value integration can be handled for instance by reflecting the range $p > k$ into the range $p < k$:

$$\int_0^\infty dp p^2 \phi(p) = k^3 \int_0^1 dx \left[x^2 \phi(kx) + \frac{1}{x^4} \phi\left(\frac{k}{x}\right) \right]. \quad (4.7)$$

Here ϕ has to be evaluated precisely enough for cancellations at $x = 1$ to take place.

- A possible way to accelerate the convergence at large k is with the help of the function $\theta(k)$ in eq. (4.4). (Note that a power tail only appears in the vacuum part.) The simplest subtraction removes just the leading asymptotic behaviour $-3E_p^2/k^2$, e.g.

$$\theta(k) \equiv \frac{3E_p^2 \Theta(k - k_{\min})}{k^2 + \lambda^2}, \quad \int_0^\infty dk \frac{\theta(k)}{k} = \frac{3E_p^2}{2\lambda^2} \ln\left(1 + \frac{\lambda^2}{k_{\min}^2}\right), \quad (4.8)$$

but of course more refined choices can be envisaged. (By replacing λ by a “gluon mass” it would be possible to take $k_{\min} \rightarrow 0$ and still carry out $\int_0^\infty dk \theta(k)/k$ exactly, cf. eqs. (B.22), (B.23), but the price to pay is that then the small- k range has more structure than before, with a would-be divergence only cut off at $k \lesssim \lambda$.)

For a transparent representation of the numerical results, we consider two different normalizations. A simple and theoretically clean possibility is to normalize the results to the

free massless expression from eq. (2.4). Another reference point is to make use of the full NLO spectral function in vacuum [42]–[45]:

$$\begin{aligned} \rho_V^{\text{vac}}(\omega) = & -\theta(\omega - 2M) \frac{C_A(\omega^2 - 4M^2)^{\frac{1}{2}}(\omega^2 + 2M^2)}{4\pi\omega} + \theta(\omega - 2M) \frac{8g^2 C_A C_F}{(4\pi)^3 \omega^2} \left\{ \right. \\ & (4M^4 - \omega^4) L_2 \left(\frac{\omega - \sqrt{\omega^2 - 4M^2}}{\omega + \sqrt{\omega^2 - 4M^2}} \right) + (7M^4 + 2M^2\omega^2 - 3\omega^4) \text{acosh} \left(\frac{\omega}{2M} \right) \\ & \left. + \omega(\omega^2 - 4M^2)^{\frac{1}{2}} \left[(\omega^2 + 2M^2) \ln \frac{\omega(\omega^2 - 4M^2)}{M^3} - \frac{3}{8}(\omega^2 + 6M^2) \right] \right\} + \mathcal{O}(g^4), \end{aligned} \quad (4.9)$$

where the function L_2 is defined as

$$L_2(x) \equiv 4\text{Li}_2(x) + 2\text{Li}_2(-x) + [2\ln(1-x) + \ln(1+x)] \ln x. \quad (4.10)$$

There is no transport peak in the vacuum expression, and recalling eq. (2.2), the corresponding spatial correlator can be obtained through

$$G_{ii}^{\text{rec}}(\tau) \equiv \int_0^\infty \frac{d\omega}{\pi} (-\rho_V^{\text{vac}})(\omega) \frac{\cosh\left(\frac{\beta}{2} - \tau\right)\omega}{\sinh\frac{\beta\omega}{2}}. \quad (4.11)$$

A normalization with respect to a similar “reconstructed” correlator $G_{ii}^{\text{rec}}(\tau)$ has been used in ref. [20] (see also ref. [46]), and may be useful for phenomenological purposes, although from the theoretical perspective it induces new systematic uncertainties.

In fig. 2 we show our results in both normalizations, compared with lattice data from ref. [20]. (The gauge coupling has been fixed as explained in connection with fig. 1; at very small τ a different running would appear reasonable but in the absence of an NNLO computation and continuum-extrapolated lattice data, we stick to the simplest choice in the following.) Like in fig. 1, an excellent agreement is found at large time separations, if a value $M/T \simeq 3.5$ is assumed. (The discrepancy in fig. 2(left) at small τ is probably due to the missing continuum extrapolation.)

5. Modification of the transport peak

As mentioned in sec. 3, the correlator G_{ii} has a constant (τ -independent) part at LO and at NLO, but within the full dynamics this is expected to turn into a slowly evolving function. The purpose of this section is to estimate how precisely Euclidean data should be measured in order to resolve the slow time dependence.

In order to reach this goal, we model the transport peak through a Lorentzian shape,

$$\rho_{ii}^{(L)}(\omega) \equiv 3D\chi \frac{\omega\eta^2}{\omega^2 + \eta^2} \frac{1}{\cosh\left(\frac{\omega}{2\pi T}\right)}. \quad (5.1)$$

Figure 3: Left: The effect of a modified transport peak, for $M/T = 3.5$ and $2\pi T D = 1.0, 2.0, 3.0, 4.0, 5.0$ (cf. eq. (5.1)). Right: A magnification of the large- τ region. It is clear that a high precision is needed for resolving the diffusion coefficient from the massive vector current correlator. (The curves could be put on top of lattice data through a minor change of M/T , but we have refrained from doing this in the absence of a continuum extrapolation of the reconstructed correlator.)

Here D corresponds to the heavy flavour diffusion coefficient. The Lorentzian shape can be correct only at small frequencies, $|\omega| \ll \pi T$, cf. e.g. ref. [47]; we have chosen to cut it off at large frequencies through the same recipe that has been used in the massless case [26]. The susceptibility χ is fixed according to ref. [20], $\chi/T^2 = 0.20894(1)$. We then vary D , in each case tuning the other parameter η so as to keep the area under the transport peak fixed at the value predicted by the NLO expression, eqs. (3.5), (4.1), (4.5), (2.2):

$$\frac{1}{\beta} \int_0^\beta d\tau G_{ii}^{(L)}(\tau) = \int_0^\infty \frac{d\omega}{\pi} \frac{2\rho_{ii}^{(L)}(\omega)}{\beta\omega} \equiv [G_{ii}^{\text{LO}} + G_{ii}^{\text{NLO}}]_{\text{const.}} \quad (5.2)$$

Subsequently the “correct” $G_{ii}(\tau)$ is obtained by replacing the part $[G_{ii}^{\text{LO}} + G_{ii}^{\text{NLO}}]_{\text{const.}}$ through a τ -dependent function, $G_{ii}^{(L)}(\tau)$, determined by $\rho_{ii}^{(L)}$ via eq. (4.11). As a guideline, we recall that $2\pi T D \simeq 3 - 5$ may be expected according to refs. [13, 14]; that ref. [20] found even $2\pi T D \sim 2$; and that in the massless case values down to $2\pi T D \sim 1$ appear possible [26].

Results are shown in fig. 3. We observe that if $2\pi T D \sim 1 - 2$, then there is hope of resolving it with high enough precision of the lattice data, but that in the case $2\pi T D \sim 3 - 5$ a reliable determination from the massive vector current correlator appears challenging.

Figure 4: Left: The effect of a modified amplitude of a resonance peak, for $M/T = 3.5$, $\Delta M/M = 0.1$, and $A = 0.1, 0.2, 0.3, 0.4, 0.5$ (cf. discussion below eq. (6.1)). Right: The effect of a modified shape of a resonance peak, for $A = 0.5$ and $\Delta M/M = 0.02, 0.04, 0.06, 0.08, 0.10$.

6. Modification of the threshold region

The second qualitative structure affecting the massive vector current correlator, the quarkonium threshold region inducing a “fast” time dependence from the energy scale $\sim 2M$, is also expected to undergo drastic changes in the interacting theory. At low temperatures, the spectral function is characterized by quarkonium resonances; at high temperatures, these are expected to move, broaden, and eventually dissolve into a mere threshold enhancement.

Based on our earlier investigations [48, 49], we expect that in the temperature range of interest there is at most one resonance peak in the vector channel spectral function, placed slightly to the left from the free quark-antiquark threshold. Akin to eq. (5.1), we model this by a skewed Breit-Wigner shape,²

$$\rho_{ii}^{(\text{BW})}(\omega) \equiv \frac{A \omega^2 \gamma^2}{(\omega')^2 + \gamma^2} \frac{1}{\cosh(\frac{\omega'}{2M})}, \quad \omega' \equiv \omega - 2M + \Delta M, \quad (6.1)$$

constructed so as not to contribute to the transport coefficient. To reduce the number of free parameters to two, we set $\Delta M \equiv 2\gamma$ in the following. The contribution from such a peak, determined through eq. (4.11), is added to the thermal NLO result as such, and to the vacuum result of eq. (4.9) with $A \rightarrow 5A$, $\gamma \rightarrow \gamma/5$, keeping the area under the peak roughly invariant. Obviously these choices are arbitrary, but they should nevertheless convey

²The approach in this section is schematic; for possible other model shapes see, e.g., ref. [50].

a qualitative impression on the importance of resonance contributions. Based on ref. [30], in which a resonance peak around a threshold was matched to the thermal NLO spectral function above the threshold, we expect that $A \lesssim 0.5$ and $\Delta M/M \lesssim 0.1$.

Results are shown in fig. 4. Comparing with fig. 3, it can be seen that a change of the spectral shape around the threshold region affects the Euclidean correlator at smaller τ than a change of the transport peak. (That said, we stress again that the results of the present section are meant as indicative only.)

7. Conclusions

The main purpose of this paper has been to compute the massive quark-number susceptibility and vector current correlator at next-to-leading order (NLO) in thermal QCD. The NLO results are shown in eqs. (4.1), (4.4), (4.5), and illustrated numerically in figs. 1, 2.

Our semi-analytic results can be directly compared with numerical lattice Monte Carlo simulations. Although no continuum limit has been reached for the massive vector current correlator [20], the agreement as seen in figs. 1, 2 is quite remarkable. (We have compared with quenched data, because these are “closest” to the continuum limit, but our analytic results are also valid for the unquenched case.)

The good agreement suggests that resummed perturbative NLO computations, through which the Minkowskian spectral function has been determined around the threshold region [48, 49], might be more accurate than sometimes assumed. A similar observation has also been made by comparing NLO computations to lattice data at spatial separations relevant for quarkonium physics [51].

The back side of a remarkable agreement is that the strict NLO result of the present paper reflects the physics of an infinitely narrow transport peak, rather than genuine heavy quark diffusion, and of a threshold singularity, rather than genuine quarkonium resonances — and yet it works well. This implies that even though impressive efforts to extract properties of the transport peak and quarkonium resonances from lattice data are being made, a very fine resolution is needed for getting systematic errors fully under control.

In order to quantify the resolution that lattice simulations should reach for observing substantial deviations from the NLO results, we have finally probed the significance of possible non-perturbative effects. The impact of a smeared transport peak is illustrated in fig. 3; the impact of resonance-like spectral weight below the threshold in fig. 4. Interpreting lattice results such as those in ref. [20] as a deviation from NLO, it appears that a diffusion coefficient $2\pi TD \sim 1 - 2$ could be observed in principle, but that larger values are hard to disentangle. Perhaps, a fruitful approach is to determine the diffusion coefficient by other means [13, 14], subtract the corresponding contribution from lattice data, and hope that any remaining deviations reflect the physics of the threshold region.

Ultimately, going beyond modelling, we suspect that systematic studies are only possible once a continuum extrapolation is available in a broad τ -range. At this stage vacuum physics can be subtracted, as outlined in ref. [26], and the non-divergent remainder subjected (at least in principle) to a model-independent analytic continuation [29].

Acknowledgements

We thank H.-T. Ding for helpful discussions and providing us with lattice data from ref. [20], and M. Vepsäläinen for collaboration at initial stages of this work. This work was partly supported by the Swiss National Science Foundation (SNF) under grant 200021-140234.

Appendix A. Results for individual master sum-integrals

In this appendix we list results for the 2-loop sum-integrals in eqs. (2.13), (2.17), after carrying out the Matsubara sums as well as the Fourier transformation in eq. (2.18). For brevity we refer to the sum-integrals with the notation

$$\mathcal{I}_{n_1 n_2 n_3 n_4 n_5}^{m_1 m_2 m_3}(\tau) \equiv T \sum_{\omega_n} e^{-i\omega_n \tau} \not\int_{K\{P\}} \frac{(M^2)^{m_1} (Q^2)^{m_2} (2K \cdot Q)^{m_3}}{(K^2)^{n_1} \Delta_P^{n_2} \Delta_{P-K}^{n_3} \Delta_{P-Q}^{n_4} \Delta_{P-K-Q}^{n_5}} \Bigg|_{Q=(\omega_n, \mathbf{0})}. \quad (\text{A.1})$$

In some cases the remaining integrands can be simplified via the symmetrization $\mathbf{p} \leftrightarrow \mathbf{k} - \mathbf{p}$. The index m_1 guarantees that all the masters have the same dimensionality. It is also convenient to introduce the shorthand notations

$$\Delta_{\sigma\tau} \equiv \epsilon_k + \sigma E_p + \tau E_{pk}, \quad \Delta_\sigma = E_p + \sigma E_{pk}, \quad (\text{A.2})$$

where the energies are defined as in eq. (2.11).

Four of the masters appearing are independent of the external momentum Q , and therefore lead to contact terms:

$$\mathcal{I}_{12000}^{000}(\tau) = \delta_\beta(\tau) \not\int_{K\{P\}} \frac{1}{K^2 \Delta_P^2}, \quad (\text{A.3})$$

$$\mathcal{I}_{02100}^{000}(\tau) = \delta_\beta(\tau) \not\int_{K\{P\}} \frac{1}{\Delta_P^2 \Delta_{P-K}}, \quad (\text{A.4})$$

$$\mathcal{I}_{11100}^{000}(\tau) = \delta_\beta(\tau) \not\int_{K\{P\}} \frac{1}{K^2 \Delta_P \Delta_{P-K}}, \quad (\text{A.5})$$

$$\mathcal{I}_{12100}^{100}(\tau) = \delta_\beta(\tau) \not\int_{K\{P\}} \frac{M^2}{K^2 \Delta_P^2 \Delta_{P-K}}. \quad (\text{A.6})$$

No further details are given since these contact terms cancel against contributions from masters with $m_2 > 0$ (eqs. (A.9), (A.13), (A.16), (A.18), (A.24)). After carrying out the Matsubara sums the remaining masters can be represented as (with the notation of eq. (3.1))

$$\mathcal{I}_{11010}^{000}(\tau) = \int_{\mathbf{p},\mathbf{k}} \frac{1 + 2n_B(\epsilon_k)}{8\epsilon_k E_p^2} \left[D_{2E_p}(\tau) + 2T n'_F(E_p) \right], \quad (\text{A.7})$$

$$\begin{aligned} \mathcal{I}_{12010}^{100}(\tau) &= \int_{\mathbf{p},\mathbf{k}} \frac{M^2 [1 + 2n_B(\epsilon_k)]}{32\epsilon_k E_p^4} \left[2D_{2E_p}(\tau) - E_p \partial_{E_p} D_{2E_p}(\tau) \right. \\ &\quad \left. + 4T n'_F(E_p) - 2T E_p n''_F(E_p) \right], \end{aligned} \quad (\text{A.8})$$

$$\mathcal{I}_{12010}^{010}(\tau) = \mathcal{I}_{12000}^{000}(\tau) + \int_{\mathbf{p},\mathbf{k}} \frac{1 + 2n_B(\epsilon_k)}{8\epsilon_k E_p} \left[\partial_{E_p} D_{2E_p}(\tau) \right], \quad (\text{A.9})$$

$$\mathcal{I}_{10110}^{000}(\tau) = \int_{\mathbf{p},\mathbf{k}} \frac{1}{8\epsilon_k E_p E_{pk}} \left[D_{\epsilon_k E_p E_{pk}}(\tau) + D_{E_p E_{pk}}^{\epsilon_k}(\tau) - 2D_{\epsilon_k E_{pk}}^{E_p}(\tau) \right], \quad (\text{A.10})$$

$$\begin{aligned} \mathcal{I}_{11110}^{100}(\tau) &= \int_{\mathbf{p},\mathbf{k}} \frac{M^2}{8\epsilon_k E_p E_{pk}} \left\{ -\frac{D_{\epsilon_k E_p E_{pk}}(\tau)}{\Delta_{++}\Delta_{-+}} - \frac{D_{E_p E_{pk}}^{\epsilon_k}(\tau)}{\Delta_{+-}\Delta_{--}} + \frac{2\epsilon_k D_{\epsilon_k E_{pk}}^{E_p}(\tau)}{\Delta_{++}\Delta_{-+}\Delta_{--}} \right. \\ &\quad \left. + \frac{D_{2E_p}(\tau) + 2T n'_F(E_p)}{E_p} \left[\frac{\epsilon_k + E_{pk}}{\Delta_{++}\Delta_{-+}} \right. \right. \\ &\quad \left. \left. - \epsilon_k n_F(E_{pk}) \left(\frac{1}{\Delta_{++}\Delta_{--}} + \frac{1}{\Delta_{+-}\Delta_{-+}} \right) \right. \right. \\ &\quad \left. \left. - E_{pk} n_B(\epsilon_k) \left(\frac{1}{\Delta_{++}\Delta_{+-}} + \frac{1}{\Delta_{-+}\Delta_{--}} \right) \right] \right\}, \end{aligned} \quad (\text{A.11})$$

$$\begin{aligned} \mathcal{I}_{11110}^{001}(\tau) &= \int_{\mathbf{p},\mathbf{k}} \frac{1}{4E_p E_{pk}} \left\{ \frac{D_{\epsilon_k E_p E_{pk}}(\tau)}{\Delta_{-+}} + \frac{D_{E_p E_{pk}}^{\epsilon_k}(\tau)}{\Delta_{+-}} - \frac{2\epsilon_k D_{\epsilon_k E_{pk}}^{E_p}(\tau)}{\Delta_{++}\Delta_{--}} \right. \\ &\quad \left. - 2E_p D_{2E_p}(\tau) \left[\frac{1}{\Delta_{++}\Delta_{-+}} \right. \right. \\ &\quad \left. \left. - n_F(E_{pk}) \left(\frac{1}{\Delta_{++}\Delta_{--}} + \frac{1}{\Delta_{+-}\Delta_{-+}} \right) \right. \right. \\ &\quad \left. \left. + n_B(\epsilon_k) \left(\frac{1}{\Delta_{++}\Delta_{-+}} - \frac{1}{\Delta_{+-}\Delta_{--}} \right) \right] \right\}, \end{aligned} \quad (\text{A.12})$$

$$\begin{aligned} \mathcal{I}_{11110}^{010}(\tau) &= \mathcal{I}_{11100}^{000}(\tau) + \int_{\mathbf{p},\mathbf{k}} \frac{1}{8\epsilon_k E_p E_{pk}} \left\{ \frac{\Delta_{++}}{\Delta_{-+}} D_{\epsilon_k E_p E_{pk}}(\tau) + \frac{\Delta_{--}}{\Delta_{+-}} D_{E_p E_{pk}}^{\epsilon_k}(\tau) \right. \\ &\quad \left. - \left(\frac{\Delta_{-+}}{\Delta_{++}} + \frac{\Delta_{-+}}{\Delta_{--}} \right) D_{\epsilon_k E_{pk}}^{E_p}(\tau) - 4E_p D_{2E_p}(\tau) \left[\frac{\epsilon_k + E_{pk}}{\Delta_{++}\Delta_{-+}} \right. \right. \\ &\quad \left. \left. - \epsilon_k n_F(E_{pk}) \left(\frac{1}{\Delta_{++}\Delta_{--}} + \frac{1}{\Delta_{+-}\Delta_{-+}} \right) \right. \right. \\ &\quad \left. \left. - E_{pk} n_B(\epsilon_k) \left(\frac{1}{\Delta_{++}\Delta_{+-}} + \frac{1}{\Delta_{-+}\Delta_{--}} \right) \right] \right\}, \end{aligned} \quad (\text{A.13})$$

$$\mathcal{I}_{01110}^{000}(\tau) = \int_{\mathbf{p},\mathbf{k}} \frac{1 - 2n_{\text{F}}(E_{pk})}{8E_p^2 E_{pk}} \left[D_{2E_p}(\tau) + 2Tn'_{\text{F}}(E_p) \right], \quad (\text{A.14})$$

$$\begin{aligned} \mathcal{I}_{02110}^{100}(\tau) = & \int_{\mathbf{p},\mathbf{k}} \frac{M^2 [1 - 2n_{\text{F}}(E_{pk})]}{32E_p^4 E_{pk}} \left[2D_{2E_p}(\tau) - E_p \partial_{E_p} D_{2E_p}(\tau) \right. \\ & \left. + 4Tn'_{\text{F}}(E_p) - 2TE_p n''_{\text{F}}(E_p) \right], \end{aligned} \quad (\text{A.15})$$

$$\mathcal{I}_{02110}^{010}(\tau) = \mathcal{I}_{02100}^{000}(\tau) + \int_{\mathbf{p},\mathbf{k}} \frac{1 - 2n_{\text{F}}(E_{pk})}{8E_p E_{pk}} \left[\partial_{E_p} D_{2E_p}(\tau) \right], \quad (\text{A.16})$$

$$\begin{aligned} \mathcal{I}_{12110}^{200}(\tau) = & \int_{\mathbf{p},\mathbf{k}} \frac{M^4}{8\epsilon_k E_p E_{pk}} \left\{ \frac{D_{\epsilon_k E_p E_{pk}}(\tau)}{\Delta_{++}^2 \Delta_{-+}^2} + \frac{D_{E_p E_{pk}}^{\epsilon_k}(\tau)}{\Delta_{+-}^2 \Delta_{--}^2} - \frac{D_{\epsilon_k E_{pk}}^{E_p}(\tau)}{\Delta_{-+}^2} \left(\frac{1}{\Delta_{++}^2} + \frac{1}{\Delta_{--}^2} \right) \right. \\ & + \frac{D_{2E_p}(\tau) + 2Tn'_{\text{F}}(E_p)}{2E_p^3} \left[(\epsilon_k + E_{pk}) \left(\frac{\Delta_{++} \Delta_{-+} - 2E_p^2}{\Delta_{++}^2 \Delta_{-+}^2} \right) \right. \\ & - \epsilon_k n_{\text{F}}(E_{pk}) \left(\frac{\Delta_{++} \Delta_{--} - 2E_p \Delta_{+-}}{\Delta_{++}^2 \Delta_{--}^2} + \frac{\Delta_{+-} \Delta_{-+} - 2E_p \Delta_{-+}}{\Delta_{+-}^2 \Delta_{-+}^2} \right) \\ & - E_{pk} n_{\text{B}}(\epsilon_k) \left(\frac{\Delta_{++} \Delta_{+-} + 2E_p(\epsilon_k + E_p)}{\Delta_{++}^2 \Delta_{+-}^2} + \frac{\Delta_{-+} \Delta_{--} - 2E_p(\epsilon_k - E_p)}{\Delta_{-+}^2 \Delta_{--}^2} \right) \left. \right] \\ & - \frac{\partial_{E_p} D_{2E_p}(\tau) + 2Tn''_{\text{F}}(E_p)}{4E_p^2} \left[\frac{\epsilon_k + E_{pk}}{\Delta_{++} \Delta_{-+}} \right. \\ & - \epsilon_k n_{\text{F}}(E_{pk}) \left(\frac{1}{\Delta_{++} \Delta_{--}} + \frac{1}{\Delta_{+-} \Delta_{-+}} \right) \\ & \left. \left. - E_{pk} n_{\text{B}}(\epsilon_k) \left(\frac{1}{\Delta_{++} \Delta_{+-}} + \frac{1}{\Delta_{-+} \Delta_{--}} \right) \right] \right\}, \end{aligned} \quad (\text{A.17})$$

\end{aligned}$$

Appendix B. Renormalization of the complete result

Inserting the expressions for the master sum-integrals from appendix A into eqs. (2.12), (2.13), (2.15), (2.17), we obtain renormalized results for the correlators considered. Like in sec. 3, the result can be divided into τ -dependent and constant terms. The former reads

$$\begin{aligned}
& \frac{G_{\text{V}}^{\text{NLO}}|_{\tau\text{-dep.}}}{4g^2 C_A C_F} = \\
& = \int_{\mathbf{p}, \mathbf{k}} \frac{D_{\epsilon_k E_p E_{pk}}(\tau)}{\epsilon_k E_p E_{pk} \Delta_{+-} \Delta_{-+}} \left\{ -E_p^2 - E_{pk}^2 + M^2 \left[\frac{\Delta_{--}}{\Delta_{++}} + \frac{2\epsilon_k^2}{\Delta_{+-} \Delta_{-+}} \right] + \frac{4\epsilon_k^2 M^4}{\Delta_{++} \Delta_{+-} \Delta_{--}} \right\} \\
& + \int_{\mathbf{p}, \mathbf{k}} \frac{D_{E_p E_{pk}}^{\epsilon_k}(\tau)}{\epsilon_k E_p E_{pk} \Delta_{+-} \Delta_{-+}} \left\{ -E_p^2 - E_{pk}^2 + M^2 \left[\frac{\Delta_{++}}{\Delta_{--}} + \frac{2\epsilon_k^2}{\Delta_{+-} \Delta_{-+}} \right] + \frac{4\epsilon_k^2 M^4}{\Delta_{--} \Delta_{+-} \Delta_{-+}} \right\} \\
& + \int_{\mathbf{p}, \mathbf{k}} \frac{2D_{\epsilon_k E_p E_{pk}}^{E_p}(\tau)}{\epsilon_k E_p E_{pk} \Delta_{++} \Delta_{--}} \left\{ +E_p^2 + E_{pk}^2 - M^2 \left[\frac{\Delta_{+-}}{\Delta_{-+}} + \frac{2\epsilon_k^2}{\Delta_{++} \Delta_{--}} \right] - \frac{4\epsilon_k^2 M^4}{\Delta_{-+} \Delta_{++} \Delta_{--}} \right\} \\
& + \int_{\mathbf{p}} D_{2E_p}(\tau) \left\{ \text{“eq. (B.4)”} \right. \\
& \quad + \int_{\mathbf{k}} \frac{n_{\text{B}}(\epsilon_k)}{\epsilon_k} \left[-\frac{1}{E_p^2} + \frac{M^2}{E_p^4} + \frac{M^2(2E_p^2 + M^2)}{2E_p^3 E_{pk}} \left(\frac{1}{\Delta_{++}^2} + \frac{1}{\Delta_{--}^2} - \frac{1}{\Delta_{+-}^2} - \frac{1}{\Delta_{-+}^2} \right) \right. \\
& \quad \quad - \frac{2(E_p^2 + E_{pk}^2 - M^2)}{E_p E_{pk}} \left(\frac{1}{\Delta_{++} \Delta_{--}} - \frac{1}{\Delta_{+-} \Delta_{-+}} \right) \\
& \quad \quad \left. + \frac{M^2(2E_p^2 - M^2)}{E_p^4} \left(\frac{1}{\Delta_{++} \Delta_{--}} + \frac{1}{\Delta_{+-} \Delta_{-+}} \right) \right] \\
& \quad + \int_{\mathbf{k}} \frac{n_{\text{F}}(E_{pk})}{E_{pk}} \mathbb{P} \left[\frac{1}{2E_p^2} + \frac{M^2}{E_p^4} + \frac{M^2(2E_p^2 + M^2)}{2E_p^3 \epsilon_k} \left(\frac{1}{\Delta_{-+}^2} + \frac{1}{\Delta_{--}^2} - \frac{1}{\Delta_{+-}^2} - \frac{1}{\Delta_{++}^2} \right) \right. \\
& \quad \quad - \frac{2(E_p^2 + E_{pk}^2 - M^2)}{E_p} \left(\frac{1}{\Delta_+ \Delta_{++} \Delta_{--}} + \frac{1}{\Delta_- \Delta_{+-} \Delta_{-+}} \right) + \frac{4(E_p^2 + E_{pk}^2) - \epsilon_k^2}{2E_p^2 \Delta_+ \Delta_-} \\
& \quad \quad \left. \left. + \frac{E_{pk} M^2(2E_p^2 - M^2)}{E_p^4} \left(\frac{1}{\Delta_+ \Delta_{++} \Delta_{--}} - \frac{1}{\Delta_- \Delta_{+-} \Delta_{-+}} \right) \right] \right\} \\
& + \int_{\mathbf{p}} E_p \partial_{E_p} D_{2E_p}(\tau) \left\{ 0 \right. \\
& \quad \left. + \int_{\mathbf{k}} \frac{n_{\text{B}}(\epsilon_k)}{\epsilon_k} \left[-\frac{1}{E_p^2} - \frac{M^2}{2E_p^4} + \frac{M^2(2E_p^2 + M^2)}{2E_p^4} \left(\frac{1}{\Delta_{++} \Delta_{+-}} + \frac{1}{\Delta_{--} \Delta_{-+}} \right) \right] \right\}
\end{aligned}$$

$$+ \int_{\mathbf{k}} \frac{n_{\text{F}}(E_{pk})}{E_{pk}} \left[-\frac{1}{E_p^2} - \frac{M^2}{2E_p^4} + \frac{M^2(2E_p^2 + M^2)}{2E_p^4} \left(\frac{1}{\Delta_{++}\Delta_{--}} + \frac{1}{\Delta_{+-}\Delta_{-+}} \right) \right] \}. \quad (\text{B.1})$$

The constant contribution, in turn, can be expressed as

$$\begin{aligned} & \frac{G_{\text{V}}^{\text{LO}}|_{\text{const.}}}{4g^2 C_A C_F} = \\ & = \int_{\mathbf{p}, \mathbf{k}} \frac{T n'_{\text{F}}(E_p) n'_{\text{F}}(E_{pk})}{2E_p^2 E_{pk}^2} \left\{ -\epsilon_k^2 + E_p^2 + E_{pk}^2 + 2M^4 \left(\frac{1}{\Delta_{++}\Delta_{--}} + \frac{1}{\Delta_{+-}\Delta_{-+}} \right) \right\} \\ & + \int_{\mathbf{p}} 2T n'_{\text{F}}(E_p) \left\{ \text{“eq. (B.5)”} \right. \\ & + \int_{\mathbf{k}} \frac{n_{\text{B}}(\epsilon_k)}{\epsilon_k} \left[-\frac{1}{E_p^2} + \frac{M^2}{E_p^4} - \frac{2\epsilon_k M^4}{E_p^3} \left(\frac{1}{\Delta_{++}\Delta_{+-}} - \frac{1}{\Delta_{--}\Delta_{-+}} \right) \right. \\ & \quad \left. \left. + \frac{M^2(2E_p^2 - M^2)}{E_p^4} \left(\frac{1}{\Delta_{++}\Delta_{+-}} + \frac{1}{\Delta_{--}\Delta_{-+}} \right) \right] \right. \\ & + \int_{\mathbf{k}} \frac{n_{\text{F}}(E_{pk})}{E_{pk}} \left[-\frac{1}{E_p^2} + \frac{M^2}{E_p^4} + \frac{\epsilon_k^2 - E_p^2 - E_{pk}^2}{2E_p^2 E_{pk}^2} + \frac{2M^4}{E_p^3 E_{pk}} \left(\frac{\Delta_+^2}{\Delta_{++}\Delta_{--}} - \frac{\Delta_-^2}{\Delta_{+-}\Delta_{-+}} \right) \right. \\ & \quad \left. \left. + \left(\frac{M^2(2E_p^2 - M^2)}{E_p^4} - \frac{M^4}{E_p^2 E_{pk}^2} \right) \left(\frac{1}{\Delta_{++}\Delta_{--}} + \frac{1}{\Delta_{+-}\Delta_{-+}} \right) \right] \right\} \\ & + \int_{\mathbf{p}} 2TE_p n''_{\text{F}}(E_p) \left\{ 0 \right. \\ & + \int_{\mathbf{k}} \frac{n_{\text{B}}(\epsilon_k)}{\epsilon_k} \left[-\frac{M^2}{2E_p^4} + \frac{M^4}{2E_p^4} \left(\frac{1}{\Delta_{++}\Delta_{+-}} + \frac{1}{\Delta_{--}\Delta_{-+}} \right) \right] \\ & \left. \left. + \int_{\mathbf{k}} \frac{n_{\text{F}}(E_{pk})}{E_{pk}} \left[-\frac{M^2}{2E_p^4} + \frac{M^4}{2E_p^4} \left(\frac{1}{\Delta_{++}\Delta_{--}} + \frac{1}{\Delta_{+-}\Delta_{-+}} \right) \right] \right] \right\}. \quad (\text{B.2}) \end{aligned}$$

Finally, for the susceptibility, the NLO term amounts to

$$\begin{aligned} \frac{G_{00}^{\text{NLO}}}{4g^2 C_A C_F} & = \int_{\mathbf{p}, \mathbf{k}} \frac{T n'_{\text{F}}(E_p) n'_{\text{F}}(E_{pk})}{E_p E_{pk}} \left\{ -M^2 \left(\frac{1}{\Delta_{++}\Delta_{--}} - \frac{1}{\Delta_{+-}\Delta_{-+}} \right) \right\} \\ & + \int_{\mathbf{p}} 2TE_p n''_{\text{F}}(E_p) \left\{ 0 \right. \\ & + \int_{\mathbf{k}} \frac{n_{\text{B}}(\epsilon_k)}{\epsilon_k} \left[-\frac{1}{2E_p^2} + \frac{M^2}{2E_p^2} \left(\frac{1}{\Delta_{++}\Delta_{+-}} + \frac{1}{\Delta_{--}\Delta_{-+}} \right) \right] \\ & \left. \left. + \int_{\mathbf{k}} \frac{n_{\text{F}}(E_{pk})}{E_{pk}} \left[-\frac{1}{2E_p^2} + \frac{M^2}{2E_p^2} \left(\frac{1}{\Delta_{++}\Delta_{--}} + \frac{1}{\Delta_{+-}\Delta_{-+}} \right) \right] \right] \right\}. \quad (\text{B.3}) \end{aligned}$$

The “0”s in eqs. (B.1), (B.2), (B.3) represent vacuum contributions that vanish after renormalization. The coefficients of $\partial_{E_p} D_{2E_p}(\tau)$ and $T n''_{\text{F}}(E_p)$ vanish already when eqs. (2.12), (2.13) are summed together, but the coefficients of $D_{2E_p}(\tau)$ and $T n'_{\text{F}}(E_p)$ not. They can be

expressed as

$$\begin{aligned}
\text{“eq. (B.4)”} &= \int_{\mathbf{k}} \left\{ \frac{1-\epsilon}{2E_p^2 E_{pk}} - \frac{(4-4\epsilon + \frac{M^2}{E_p^2})(\epsilon_k + E_{pk})}{\epsilon_k E_{pk} [(\epsilon_k + E_{pk})^2 - E_p^2]} + \frac{2(1-\epsilon)^2}{E_{pk} [(\epsilon_k + E_{pk})^2 - E_p^2]} \right. \\
&\quad - \frac{2(2-2\epsilon + \frac{M^2}{E_p^2})(\epsilon_k + E_{pk})M^2}{\epsilon_k E_{pk} [(\epsilon_k + E_{pk})^2 - E_p^2]^2} + \frac{2(1-\epsilon)(2+\epsilon) + \frac{\epsilon M^2}{E_p^2}}{2E_{pk}(E_{pk}^2 - E_p^2)} \\
&\quad \left. - \frac{(1-\epsilon)(\epsilon_k^2 + E_{pk}^2 - E_p^2)}{4E_p^2 E_{pk}(E_{pk}^2 - E_p^2)} - \frac{(4-4\epsilon + \frac{2\epsilon M^2}{E_p^2} - \frac{M^4}{E_p^4})(\epsilon_k + 2E_{pk})E_p^2}{\epsilon_k E_{pk} [(\epsilon_k + E_{pk})^2 - E_p^2](E_{pk}^2 - E_p^2)} \right\}, \quad (\text{B.4})
\end{aligned}$$

$$\begin{aligned}
\text{“eq. (B.5)”} &= \int_{\mathbf{k}} \left\{ \frac{1-\epsilon}{2E_p^2 E_{pk}} - \frac{(\epsilon_k + E_{pk})M^2}{\epsilon_k E_p^2 E_{pk} [(\epsilon_k + E_{pk})^2 - E_p^2]} \right. \\
&\quad - \frac{2(\epsilon_k + E_{pk})M^4}{\epsilon_k E_p^2 E_{pk} [(\epsilon_k + E_{pk})^2 - E_p^2]^2} + \frac{\epsilon M^2}{2E_p^2 E_{pk}^3} \\
&\quad \left. - \frac{(1-\epsilon)(\epsilon_k^2 + E_{pk}^2 - E_p^2)}{4E_p^2 E_{pk}^3} + \frac{[(\epsilon_k + 2E_{pk})(\epsilon_k + E_{pk})^2 - \epsilon_k E_p^2]M^4}{\epsilon_k E_p^2 E_{pk}^3 [(\epsilon_k + E_{pk})^2 - E_p^2]^2} \right\}. \quad (\text{B.5})
\end{aligned}$$

The various structures here can be identified as specific vacuum integrals:

$$\int_{\mathbf{k}} \frac{1}{2\epsilon_k} = \int_K \frac{1}{K^2}, \quad (\text{B.6})$$

$$\int_{\mathbf{k}} \frac{1}{2E_{pk}} = \int_K \frac{1}{\Delta_{P-K}}, \quad (\text{B.7})$$

$$\int_{\mathbf{k}} \frac{1}{2\epsilon_k E_{pk}} \frac{\epsilon_k + E_{pk}}{(\epsilon_k + E_{pk})^2 - E_p^2} = \left[\int_K \frac{1}{K^2 \Delta_{P-K}} \right]_{p_0=iE_p}, \quad (\text{B.8})$$

$$\int_{\mathbf{k}} \frac{-E_p^2}{2E_{pk} [(\epsilon_k + E_{pk})^2 - E_p^2]} = \left[p_0 \int_K \frac{k_0}{K^2 \Delta_{P-K}} \right]_{p_0=iE_p}, \quad (\text{B.9})$$

$$\int_{\mathbf{k}} \frac{-E_p^2(\epsilon_k + E_{pk})}{2\epsilon_k E_{pk} [(\epsilon_k + E_{pk})^2 - E_p^2]^2} = \left[p_0 \int_K \frac{p_0 - k_0}{K^2 \Delta_{P-K}^2} \right]_{p_0=iE_p}, \quad (\text{B.10})$$

$$\int_{\mathbf{k}} \frac{1}{4E_{pk}^3} = \left[\int_K \frac{1}{\Delta_{P-K}^2} \right]_{p_0=iE_p}, \quad (\text{B.11})$$

$$\int_{\mathbf{k}} \frac{1}{4E_{pk}(E_{pk}^2 - E_p^2)} = \left[\int_K \frac{1}{\Delta_{P-K} \Delta_{P-K-Q}} \right]_{Q=(2iE_p, \mathbf{0})}, \quad (\text{B.12})$$

$$\int_{\mathbf{k}} \frac{\epsilon_k^2 + E_{pk}^2 - E_p^2}{4E_{pk}^3} = \left[\int_K \frac{K^2}{\Delta_{P-K}^2} \right]_{p_0=iE_p}, \quad (\text{B.13})$$

$$\int_{\mathbf{k}} \frac{\epsilon_k^2 + E_{pk}^2 - E_p^2}{4E_{pk}(E_{pk}^2 - E_p^2)} = \left[\int_K \frac{K^2}{\Delta_{P-K} \Delta_{P-K-Q}} \right]_{p_0=iE_p, Q=(2iE_p, \mathbf{0})}, \quad (\text{B.14})$$

$$\int_{\mathbf{k}} \frac{(\epsilon_k + 2E_{pk})(\epsilon_k + E_{pk})^2 - \epsilon_k E_p^2}{4\epsilon_k E_{pk}^3 [(\epsilon_k + E_{pk})^2 - E_p^2]^2} = \left[\int_K \frac{1}{K^2 \Delta_{P-K}^2} \right]_{p_0=iE_p}, \quad (\text{B.15})$$

$$\int_{\mathbf{k}} \frac{\epsilon_k + 2E_{pk}}{4\epsilon_k E_{pk} [(\epsilon_k + E_{pk})^2 - E_p^2] (E_{pk}^2 - E_p^2)} = \left[\int_K \frac{1}{K^2 \Delta_{P-K} \Delta_{P-K-Q}} \right]_{p_0=iE_p, Q=(2iE_p, \mathbf{0})} . \quad (\text{B.16})$$

After having expressed the integrals in these forms, we can make use of Lorentz invariance in order to remove redundant structures:

$$(\text{B.9}) = \frac{E_p^2}{2M^2} [(\text{B.7}) - (\text{B.6})] , \quad (\text{B.17})$$

$$(\text{B.10}) = \frac{E_p^2}{2M^2} [(\text{B.8}) - (\text{B.11}) - 2M^2 (\text{B.15})] , \quad (\text{B.18})$$

$$(\text{B.13}) = (\text{B.7}) - 2M^2 (\text{B.11}) , \quad (\text{B.19})$$

$$(\text{B.14}) = (\text{B.7}) + 2(E_p^2 - M^2) (\text{B.12}) . \quad (\text{B.20})$$

Inserting these relations, eq. (B.5) vanishes exactly. The coefficient of $D_{2E_p}(\tau)$, eq. (B.4), does not vanish; after the transformation of eqs. (B.17)–(B.20) it can be written as

“eq. (B.4)” =

$$\begin{aligned} & \left\{ \int_K \mathbb{P} \left[\frac{2(1-2\epsilon)}{M^2} \left(\frac{1}{K^2} - \frac{1}{\Delta_K} \right) - \frac{4(1-\epsilon)}{K^2 \Delta_{P-K}} + \frac{2(1+\epsilon)}{\Delta_K^2} + \left(3 + \frac{M^2}{E_p^2} \right) \frac{2}{\Delta_K} \left(\frac{1}{\Delta_{K-Q}} - \frac{1}{\Delta_K} \right) \right. \right. \\ & \quad \left. \left. - \left(1 + \frac{M^2}{2E_p^2} \right) \frac{8M^2}{K^2 \Delta_{P-K}^2} - \left(1 - \frac{M^4}{4E_p^4} \right) \frac{16E_p^2}{K^2 \Delta_{P-K} \Delta_{P-K-Q}} \right] \right\}_{p_0=iE_p, Q=(2iE_p, \mathbf{0})} + \mathcal{O}(\epsilon) \\ & = \frac{1}{4\pi^2} \left[\left(3 + \frac{M^2}{E_p^2} \right) \left(1 - \frac{p}{2E_p} \ln \frac{E_p + p}{E_p - p} \right) - 1 \right] \\ & \quad + \left(2 + \frac{M^2}{E_p^2} \right) \int_{\mathbf{k}} \mathbb{P} \left\{ \frac{M^2}{E_{pk}} \left[\frac{1}{2\epsilon_k (\epsilon_k + E_p) \Delta_{++}^2} + \frac{1}{2\epsilon_k (\epsilon_k - E_p) \Delta_{-+}^2} - \frac{1}{(\epsilon_k^2 - E_p^2) E_{pk}^2} \right] \right. \\ & \quad \left. + \frac{2E_p^2 - M^2}{2\epsilon_k^2 E_p E_{pk}} \left(\frac{1}{\Delta_+} + \frac{1}{\Delta_-} - \frac{1}{\Delta_{++}} + \frac{1}{\Delta_{-+}} \right) \right\} + \mathcal{O}(\epsilon) , \quad (\text{B.21}) \end{aligned}$$

where the first row represents the result of the ultraviolet sensitive integrals containing single or double propagators. The remaining \mathbf{k} -integral is infrared (IR) divergent and needs to be evaluated together with the other terms of eq. (B.1). Its form after angular integration can be found in eq. (4.4), as the structure preceding $\theta(k)$.

It may be interesting to note that regulating the IR through a “gluon mass” λ , we obtain³

$$\left\{ \int_K \mathbb{P} \left[\frac{8M^2}{(K^2 + \lambda^2) \Delta_{P-K}^2} \right] \right\}_{p_0=iE_p} = \frac{8}{(4\pi)^2} \ln \frac{M}{\lambda} + \mathcal{O}(\lambda) , \quad (\text{B.22})$$

³For eq. (B.23) a Feynman parameter s can be used for combining Δ_{P-K} and Δ_{P^*-K} . Subsequently the integral $\left\{ \int_K \frac{1}{(K^2 + \lambda^2) \Delta_{P-K}^2} \right\}_{P^2=-M^2} = \frac{1}{(4\pi)^2} \frac{1}{2M^2} \ln \frac{M^2}{\lambda^2} + \mathcal{O}\left(\frac{\lambda^2}{M^4}\right)$ can be used in both cases for determining the IR divergence. It is not enough for determining the term of $\mathcal{O}(1)$ in the latter case, because the effective mass parameter appearing, $\tilde{M}^2 = M^2 - 4s(1-s)E_p^2$, crosses zero. Fortunately the relevant integral over s can be carried out without an expansion in λ .

$$\begin{aligned}
\left\{ \int_K \mathbb{P} \left[\frac{16E_p^2}{(K^2 + \lambda^2)\Delta_{P-K}\Delta_{P^*-K}} \right] \right\}_{p_0=iE_p} &= \frac{8}{(4\pi)^2} \frac{E_p}{p} \left\{ \ln\left(\frac{E_p-p}{E_p+p}\right) \ln\left(\frac{2p}{\lambda}\right) + \frac{\pi^2}{3} \right. \\
&\quad \left. + \text{Li}_2\left(\frac{E_p-p}{E_p+p}\right) + \frac{1}{4} \ln^2\left(\frac{E_p-p}{E_p+p}\right) \right\} + \mathcal{O}(\lambda).
\end{aligned}
\tag{B.23}$$

Here $P^* \equiv (-iE_p, \mathbf{p})$. The sum of these (with the proper coefficients) amounts to a particular choice of $\int_0^\infty dk \theta(k)/k$, appearing on the first row of eq. (4.4); a corresponding subtraction of $\theta(k)$ on the sixth row of eq. (4.4) would remove all powerlike terms at large k , with the price of inserting more structure into the infrared regime $k \sim \lambda$.
