# ON ORNSTEIN-UHLENBECK DRIVEN BY ORNSTEIN-UHLENBECK PROCESSES

BERNARD BERCU, FRÉDÉRIC PROIA, AND NICOLAS SAVY

Abstract. We investigate the asymptotic behavior of the maximum likelihood estimators of the unknown parameters of positive recurrent Ornstein-Uhlenbeck processes driven by Ornstein-Uhlenbeck processes.

## 1. INTRODUCTION AND MOTIVATION

Since the seminal work of Ornstein and Uhlenbeck [\[17\]](#page-12-0), a wide literature is available on Ornstein-Uhlenbeck processes driven by Brownian or fractional Brownian motions [\[12\]](#page-12-1), [\[14\]](#page-12-2). Many interesting papers are also available on Ornstein-Uhlenbeck processes driven by Lévy processes

$$
(1.1) \t\t dX_t = \theta X_t dt + dL_t
$$

where  $\theta < 0$  and  $(L_t)$  is a continuous-time stochastic process starting from zero with stationary and independent increments. We refer the reader to Barndorff-Nielsen and Shephard [\[2\]](#page-12-3) for the mathematical foundation on Ornstein-Uhlenbeck processes driven by Lévy processes, and also to  $[1]$  for a recent extension to fractional Lévy processes. Parametric estimation results for Ornstein-Uhlenbeck driven by  $\alpha$ -stable Lévy processes are established in [\[10\]](#page-12-5) whereas nonparametric estimation results are given in [\[11\]](#page-12-6). Two interesting applications related to money exchange rates and stock prices may be found in [\[2\]](#page-12-3) and [\[15\]](#page-12-7), see also the references therein.

To the best of our knowledge, no results are available on Ornstein-Uhlenbeck driven by Ornstein-Uhlenbeck processes defined, over the time interval  $[0, T]$ , by

<span id="page-0-0"></span>(1.2) 
$$
\begin{cases} dX_t = \theta X_t dt + dV_t \\ dV_t = \rho V_t dt + dW_t \end{cases}
$$

where  $\theta < 0$ ,  $\rho \leq 0$  and  $(W_t)$  is a standard Brownian motion. For the sake of simplicity and without loss of generality, we choose the initial values  $X_0 = 0$  and  $V_0 = 0$ . Our motivation for studying  $(1.2)$  comes from two observations. On the one hand, the increments of Ornstein-Uhlenbeck processes are not independent which means that the weighted maximum likelihood estimation approach of [\[10\]](#page-12-5) does not apply directly to our situation. On the other hand, Ornstein-Uhlenbeck driven by Ornstein-Uhlenbeck processes are clearly related with stochastic volatility models in financial mathematics [\[16\]](#page-12-8). Furthermore, [\(1.2\)](#page-0-0) is the continuous-time version of

Key words and phrases. Ornstein-Uhlenbeck process, Maximum likelihood estimation, Continuous-time Durbin-Watson statistic, Almost sure convergence, Asymptotic normality.

the first-order stable autoregressive process driven by a first-order autoregressive process recently investigated in [\[3\]](#page-12-9).

The paper organizes as follows. Section [2](#page-1-0) is devoted to the maximum likelihood estimation for  $\theta$  and  $\rho$ . We also introduce the continuous-time Durbin-Watson statistic which will allow us to propose a serial correlation test for Ornstein-Uhlenbeck driven by Ornstein-Uhlenbeck processes. In Section [3,](#page-2-0) we establish the almost sure convergence as well as the asymptotic normality of our estimates. One shall realize that there is a radically different behavior of the estimator of  $\rho$  in the two situations where  $\rho < 0$  and  $\rho = 0$ . Our analysis relies on technical tools postponed to Section [4.](#page-8-0) Finally, in Section [5,](#page-10-0) we propose a statistical procedure based on the continuous-time Durbin-Watson statistic, in order to test whether or not  $\rho = 0$ .

## <span id="page-1-1"></span>2. MAXIMUM LIKELIHOOD ESTIMATION

<span id="page-1-0"></span>The maximum likelihood estimator of  $\theta$  is given by

(2.1) 
$$
\widehat{\theta}_T = \frac{\int_0^T X_t \, dX_t}{\int_0^T X_t^2 \, dt} = \frac{X_T^2 - T}{2 \int_0^T X_t^2 \, dt}.
$$

In the standard situation where  $\rho = 0$ , it is well-known that  $\widehat{\theta}_T$  converges to  $\theta$  almost surely. Moreover, as  $\theta < 0$ , the process  $(X_T)$  is positive recurrent and we have the asymptotic normality

<span id="page-1-2"></span>
$$
\sqrt{T}\left(\widehat{\theta}_T - \theta\right) \stackrel{\mathcal{L}}{\longrightarrow} \mathcal{N}(0, -2\theta).
$$

We shall see in Section [3](#page-2-0) that the almost sure limiting value of  $\theta_T$  and its asymptotic variance will change as soon as  $\rho < 0$ . The estimation of  $\rho$  requires the evaluation of the residuals generated by the estimation of  $\theta$  at stage T. For all  $0 \le t \le T$ , denote

$$
\widehat{V}_t = X_t - \widehat{\theta}_T \Sigma_t
$$

where

(2.3) 
$$
\Sigma_t = \int_0^t X_s \, \mathrm{d}s.
$$

By analogy with [\(2.1\)](#page-1-1) and on the basis of the residuals [\(2.2\)](#page-1-2), we estimate  $\rho$  by

<span id="page-1-3"></span>(2.4) 
$$
\widehat{\rho}_T = \frac{\widehat{V}_T^2 - T}{2 \int_0^T \widehat{V}_t^2 dt}.
$$

Therefore, we are in the position to define the continuous-time version of the discretetime Durbin-Watson statistic [\[3\]](#page-12-9), [\[5\]](#page-12-10), [\[6\]](#page-12-11), [\[7\]](#page-12-12),

<span id="page-1-4"></span>(2.5) 
$$
\widehat{D}_T = \frac{2 \int_0^T \widehat{V}_t^2 dt - \widehat{V}_T^2 + T}{\int_0^T \widehat{V}_t^2 dt},
$$

which clearly means that  $\widehat{D}_T = 2(1 - \widehat{\rho}_T)$ . In Section [3,](#page-2-0) we shall make use of  $\widehat{D}_T$ to build a serial correlation statistical test for the Ornstein-Uhlenbeck driven noise, that is to test whether or not  $\rho = 0$ .

#### <span id="page-2-2"></span>3. MAIN RESULTS

<span id="page-2-0"></span>The almost sure convergences of our estimates are as follows.

<span id="page-2-6"></span>**Theorem 3.1.** We have the almost sure convergences

(3.1) 
$$
\lim_{T \to \infty} \widehat{\theta}_T = \theta^*, \qquad \lim_{T \to \infty} \widehat{\rho}_T = \rho^* \qquad \text{a.s.}
$$

where

(3.2) 
$$
\theta^* = \theta + \rho \quad \text{and} \quad \rho^* = \frac{\theta \rho(\theta + \rho)}{(\theta + \rho)^2 + \theta \rho}.
$$

Proof. We immediately deduce from [\(1.2\)](#page-0-0) that

<span id="page-2-1"></span>(3.3) 
$$
\int_0^T X_t \, dX_t = \theta S_T + \rho P_T + M_T^X
$$

where

<span id="page-2-7"></span>(3.4) 
$$
S_T = \int_0^T X_t^2 dt, \qquad P_T = \int_0^T X_t V_t dt, \qquad M_T^X = \int_0^T X_t dW_t.
$$

We shall see in Corollary [4.1](#page-9-0) below that

<span id="page-2-5"></span>(3.5) 
$$
\lim_{T \to \infty} \frac{1}{T} S_T = -\frac{1}{2(\theta + \rho)} \quad \text{a.s.}
$$

and in the proof of Corollary [4.2](#page-9-1) that

<span id="page-2-9"></span>(3.6) 
$$
\lim_{T \to \infty} \frac{1}{T} P_T = -\frac{1}{2(\theta + \rho)} \quad \text{a.s.}
$$

Moreover, if  $(\mathcal{F}_t)$  stands for the natural filtration of the standard Brownian motion  $(W_t)$ , then  $(M_t^X)$  is a continuous-time  $(\mathcal{F}_t)$ −martingale with quadratic variation  $S_t$ . Hence, it follows from the strong law of large numbers for continuous-time martingales given e.g. in [\[8\]](#page-12-13) or [\[13\]](#page-12-14), that  $M_T^X = o(T)$  a.s. Consequently, we obtain from  $(3.3)$  that

<span id="page-2-4"></span>(3.7) 
$$
\lim_{T \to \infty} \frac{1}{T} \int_0^T X_t dX_t = -\frac{\theta}{2(\theta + \rho)} - \frac{\rho}{2(\theta + \rho)} = -\frac{1}{2} \quad \text{a.s.}
$$

which leads, via  $(2.1)$ , to the first convergence in  $(3.1)$ . The second convergence in [\(3.1\)](#page-2-2) is more difficult to handle. We infer from [\(1.2\)](#page-0-0) that

<span id="page-2-3"></span>(3.8) 
$$
\int_0^T V_t \, \mathrm{d}V_t = \rho L_T + M_T^V
$$

where

<span id="page-2-8"></span>(3.9) 
$$
L_T = \int_0^T V_t^2 dt \quad \text{and} \quad M_T^V = \int_0^T V_t dW_t.
$$

On the one hand, if  $\rho < 0$ , it is well-known, see e.g. [\[8\]](#page-12-13) page 728, that

<span id="page-2-10"></span>(3.10) 
$$
\lim_{T \to \infty} \frac{1}{T} L_T = -\frac{1}{2\rho} \quad \text{a.s.}
$$

In addition,  $(M_t^V)$  is a continuous-time  $(\mathcal{F}_t)$ −martingale with quadratic variation  $L_t$ . Consequently,  $M_T^V = o(T)$  a.s. and we find from [\(3.8\)](#page-2-3) that

(3.11) 
$$
\lim_{T \to \infty} \frac{1}{T} \int_0^T V_t \, dV_t = -\frac{1}{2} \quad \text{a.s.}
$$

However, we know from Itô's formula that

<span id="page-3-1"></span><span id="page-3-0"></span>
$$
\frac{1}{T} \int_0^T X_t \, dX_t = \frac{1}{2} \left( \frac{X_T^2}{T} - 1 \right) \quad \text{and} \quad \frac{1}{T} \int_0^T V_t \, dV_t = \frac{1}{2} \left( \frac{V_T^2}{T} - 1 \right).
$$

Then, we deduce from  $(3.7)$  and  $(3.11)$  that

(3.12) 
$$
\lim_{T \to \infty} \frac{X_T^2}{T} = 0
$$
 and  $\lim_{T \to \infty} \frac{V_T^2}{T} = 0$  a.s.

As  $X_T = \theta \Sigma_T + V_T$ , it clearly follows from [\(2.2\)](#page-1-2) and [\(3.12\)](#page-3-1) that

(3.13) 
$$
\lim_{T \to \infty} \frac{1}{2} \left( \frac{\hat{V}_T^2}{T} - 1 \right) = -\frac{1}{2} \quad \text{a.s.}
$$

Hereafter, we have from [\(2.4\)](#page-1-3) the decomposition

(3.14) 
$$
\widehat{\rho}_T = \frac{T}{2\widehat{L}_T} \left( \frac{\widehat{V}_T^2}{T} - 1 \right)
$$

where

<span id="page-3-4"></span><span id="page-3-3"></span><span id="page-3-2"></span>
$$
\widehat{L}_T = \int_0^T \widehat{V}_t^2 \, \mathrm{d}t.
$$

We shall see in Corollary [4.2](#page-9-1) below that

(3.15) 
$$
\lim_{T \to \infty} \frac{1}{T} \widehat{L}_T = -\frac{1}{2\rho^*} \quad \text{a.s.}
$$

Therefore, [\(3.14\)](#page-3-2) together with [\(3.13\)](#page-3-3) and [\(3.15\)](#page-3-4) directly imply [\(3.1\)](#page-2-2). On the other hand, if  $\rho = 0$ , it is clear from [\(1.2\)](#page-0-0) that for all  $t \geq 0$ ,  $V_t = W_t$ . Hence, we have from  $(2.2)$  and Itô's formula that

<span id="page-3-6"></span>(3.16) 
$$
\widehat{V}_T^2 - T = 2M_T^W - 2W_T \Sigma_T (\widehat{\theta}_T - \theta) + \Sigma_T^2 (\widehat{\theta}_T - \theta)^2
$$

and

(3.17) 
$$
\widehat{L}_T = L_T - 2(\widehat{\theta}_T - \theta) \int_0^T W_t \Sigma_t dt + (\widehat{\theta}_T - \theta)^2 \int_0^T \Sigma_t^2 dt
$$

where

<span id="page-3-7"></span>
$$
L_T = \int_0^T W_t^2 dt \quad \text{and} \quad M_T^W = \int_0^T W_t dW_t
$$

.

It is now necessary to investigate the a.s. asymptotic behavior of  $L<sub>T</sub>$ . We deduce from the self-similarity of the Brownian motion  $(W_t)$  that

<span id="page-3-5"></span>(3.18) 
$$
L_T = \int_0^T W_t^2 dt = T \int_0^T W_{t/T}^2 dt = T^2 \int_0^1 W_s^2 ds = T^2 L
$$

Consequently, it clearly follows from  $(3.18)$  that for any power  $0 < a < 2$ ,

(3.19) 
$$
\lim_{T \to \infty} \frac{1}{T^a} L_T = +\infty \quad \text{a.s.}
$$

As a matter of fact, since  $L$  is almost surely positive, it is enough to show that

(3.20) 
$$
\lim_{T \to \infty} \mathbb{E}\left[\exp\left(-\frac{1}{T^a}L_T\right)\right] = 0.
$$

However, we have from standard Gaussian calculations, see e.g. [\[14\]](#page-12-2) page 232, that

<span id="page-4-1"></span><span id="page-4-0"></span>
$$
\mathbb{E}\left[\exp\left(-\frac{1}{T^a}L_T\right)\right] = \mathbb{E}\left[\exp\left(-\frac{T^2}{T^a}L\right)\right] = \frac{1}{\sqrt{\cosh(v_T(a))}}
$$

where  $v_T(a) = \sqrt{2T^{2-a}}$  goes to infinity, which clearly leads to [\(3.20\)](#page-4-0). Furthermore,  $(M_t^W)$  is a continuous-time  $(\mathcal{F}_t)$ −martingale with quadratic variation  $L_t$ . We already saw that  $L_T$  goes to infinity a.s. which implies that  $M_T^W = o(L_T)$  a.s. In addition, we obviously have  $\Sigma_T^2 \leq TS_T$ . One can observe that convergence [\(3.5\)](#page-2-5) still holds when  $\rho = 0$ , which ensures that  $\Sigma_T^2 \leq T^2$  a.s. Moreover, we deduce from the strong law of large numbers for continuous-time martingales that

$$
(\hat{\theta}_T - \theta)^2 = O\left(\frac{\log T}{T}\right)
$$
 a.s.

which implies that  $\Sigma^2_T(\hat{\theta}_T - \theta)^2 = O(T \log T) = o(L_T)$  a.s. By the same token, as  $X_T^2 = o(T)$  and  $W_T^2 = o(T \log T)$  a.s., we find that

$$
W_T \Sigma_T(\hat{\theta}_T - \theta) = o(L_T) \quad \text{a.s.}
$$

Consequently, we obtain from [\(3.16\)](#page-3-6) that

(3.21) 
$$
\hat{V}_T^2 - T = o(L_T) \quad \text{a.s.}
$$

It remains to study the a.s. asymptotic behavior of  $\widehat{L}_T$ . One can easily see that

<span id="page-4-4"></span><span id="page-4-2"></span>
$$
\int_0^T \Sigma_t^2 dt \le \frac{2}{\theta^2} (S_T + L_T).
$$

However, it follows from [\(3.5\)](#page-2-5) and [\(3.19\)](#page-4-1) that  $S_T = o(L_T)$  a.s. which ensures that

(3.22) 
$$
(\widehat{\theta}_T - \theta)^2 \int_0^T \Sigma_t^2 dt = o(L_T) \quad \text{a.s.}
$$

Via the same arguments,

<span id="page-4-3"></span>(3.23) 
$$
(\widehat{\theta}_T - \theta) \int_0^T W_t \Sigma_t dt = o(L_T) \quad \text{a.s.}
$$

Then, we find from [\(3.17\)](#page-3-7), [\(3.22\)](#page-4-2) and [\(3.23\)](#page-4-3) that

<span id="page-4-5"></span>(3.24) 
$$
\hat{L}_T = L_T(1 + o(1))
$$
 a.s.

Finally, the second convergence in [\(3.1\)](#page-2-2) follows from [\(3.21\)](#page-4-4) and [\(3.24\)](#page-4-5) which achieves the proof of Theorem [3.1.](#page-2-6)

Our second result deals with the asymptotic normality of our estimates

<span id="page-5-3"></span>**Theorem 3.2.** If  $\rho < 0$ , we have the joint asymptotic normality

<span id="page-5-2"></span>(3.25) 
$$
\sqrt{T} \begin{pmatrix} \widehat{\theta}_T - \theta^* \\ \widehat{\rho}_T - \rho^* \end{pmatrix} \stackrel{\mathcal{L}}{\longrightarrow} \mathcal{N}(0, \Gamma)
$$

where the asymptotic covariance matrix

(3.26) 
$$
\Gamma = \begin{pmatrix} \sigma_{\theta}^2 & \ell \\ \ell & \sigma_{\rho}^2 \end{pmatrix}
$$

with 
$$
\sigma_{\theta}^2 = -2\theta^*
$$
,  $\ell = \frac{2\rho^* ((\theta^*)^2 - \theta \rho)}{(\theta^*)^2 + \theta \rho}$  and  

$$
\sigma_{\rho}^2 = -\frac{2\rho^* ((\theta^*)^6 + \theta \rho ((\theta^*)^4 - \theta \rho (2(\theta^*)^2 - \theta \rho)))}{((\theta^*)^2 + \theta \rho)^3}.
$$

In particular, we have

(3.27) 
$$
\sqrt{T}\left(\widehat{\theta}_T - \theta^*\right) \xrightarrow{\mathcal{L}} \mathcal{N}(0, \sigma_\theta^2),
$$

and

(3.28) 
$$
\sqrt{T} \left( \widehat{\rho}_T - \rho^* \right) \stackrel{\mathcal{L}}{\longrightarrow} \mathcal{N}(0, \sigma_\rho^2).
$$

Proof. We obtain from  $(2.1)$  the decompostion

(3.29) 
$$
\widehat{\theta}_T - \theta^* = \frac{M_T^X}{S_T} + \frac{R_T^X}{S_T}
$$

where

<span id="page-5-4"></span><span id="page-5-1"></span>
$$
R_T^X = \rho \int_0^T X_t (V_t - X_t) dt = -\theta \rho \int_0^T \Sigma_t d\Sigma_t = -\frac{\theta \rho}{2} \Sigma_T^2.
$$

We shall now establish a similar decomposition for  $\hat{\rho}_T - \rho^*$ . It follows from [\(2.2\)](#page-1-2) that for all  $0 \le t \le T$ ,

$$
\begin{split} \widehat{V}_t &= X_t - \widehat{\theta}_T \Sigma_t = V_t - (\widehat{\theta}_T - \theta) \Sigma_t = V_t - (\widehat{\theta}_T - \theta^*) \Sigma_t - \rho \Sigma_t, \\ &= V_t - \frac{\rho}{\theta} (X_t - V_t) - \frac{1}{\theta} (\widehat{\theta}_T - \theta^*) (X_t - V_t) = \frac{\theta^*}{\theta} V_t - \frac{\rho}{\theta} X_t - \frac{1}{\theta} (\widehat{\theta}_T - \theta^*) (X_t - V_t), \end{split}
$$

which leads to

(3.30) 
$$
\widehat{L}_T = I_T + (\widehat{\theta}_T - \theta^*) \left( J_T + (\widehat{\theta}_T - \theta^*) K_T \right),
$$

where

<span id="page-5-0"></span>
$$
I_T = \frac{1}{\theta^2} \Big( \rho^2 S_T + (\theta^*)^2 L_T - 2\theta^* \rho P_T \Big),
$$
  
\n
$$
J_T = \frac{1}{\theta^2} \Big( 2\rho S_T + 2\theta^* L_T - 2(\theta + 2\rho) P_T \Big),
$$
  
\n
$$
K_T = \frac{1}{\theta^2} \Big( S_T + L_T - 2P_T \Big).
$$

Then, we deduce from [\(2.4\)](#page-1-3) and [\(3.30\)](#page-5-0) that

(3.31) 
$$
\widehat{L}_T \left( \widehat{\rho}_T - \rho^* \right) = \frac{I_T^V}{2} + \frac{1}{2} (\widehat{\theta}_T - \theta^*) \left( J_T^V + (\widehat{\theta}_T - \theta^*) K_T^V \right)
$$

in which  $I_T^V = \hat{V}_T^2 - T - 2\rho^* I_T$ ,  $J_T^V = -2\rho^* J_T$ , and  $K_T^K = -2\rho^* K_T$ . At this stage, in order to simplify the complicated expression [\(3.31\)](#page-6-0), we make repeatedly use of Itô's formula. For all  $0 \le t \le T$ , we have

<span id="page-6-0"></span>
$$
L_t = \frac{1}{2\rho} V_t^2 - \frac{1}{\rho} M_t^V - \frac{t}{2\rho},
$$
  
\n
$$
P_t = \frac{1}{\theta^*} X_t V_t - \frac{1}{2\theta^*} V_t^2 - \frac{1}{\theta^*} M_t^X - \frac{t}{2\theta^*},
$$
  
\n
$$
S_t = \frac{1}{2\theta} X_t^2 + \frac{\rho}{2\theta^*\theta} V_t^2 - \frac{\rho}{\theta^*\theta} X_t V_t - \frac{1}{\theta^*} M_t^X - \frac{t}{2\theta^*}
$$

where the continuous-time martingales  $M_t^X$  and  $M_t^V$  were previously defined in [\(3.4\)](#page-2-7) and [\(3.9\)](#page-2-8). Therefore, it follows from tedious but straightforward calculations that

,

.

(3.32) 
$$
\widehat{L}_T(\widehat{\rho}_T - \rho^*) = C_X M_T^X + C_V M_T^V + \frac{J_T^V}{2} (\widehat{\theta}_T - \theta^*) + R_T^V
$$

where

<span id="page-6-1"></span>
$$
C_V = \frac{(\theta^*)^2 \rho^*}{\theta^2 \rho} \quad \text{and} \quad C_X = -\frac{\rho (2\theta + \rho) \rho^*}{\theta^2 \theta^*}
$$

The remainder  $R_T^V$  is similar to  $R_T^X$  and they play a negligible role. The combination of [\(3.29\)](#page-5-1) and [\(3.32\)](#page-6-1) leads to the vectorial expression

(3.33) 
$$
\sqrt{T} \begin{pmatrix} \widehat{\theta}_T - \theta^* \\ \widehat{\rho}_T - \rho^* \end{pmatrix} = \frac{1}{\sqrt{T}} A_T Z_T + \sqrt{T} R_T
$$

where

<span id="page-6-2"></span>
$$
A_T = \begin{pmatrix} S_T^{-1}T & 0 \\ B_T \hat{L}_T^{-1}T & C_V \hat{L}_T^{-1}T \end{pmatrix}, \qquad R_T = \begin{pmatrix} S_T^{-1}R_T^X \\ \hat{L}_T^{-1}D_T \end{pmatrix}
$$

with  $B_T = C_X + J_T^V (2S_T)^{-1}$  and  $D_T = R_T^V + J_T^V (2S_T)^{-1} R_T^X$ . The leading term in [\(3.33\)](#page-6-2) is the continuous-time vector  $(\mathcal{F}_t)$ −martingale  $(Z_t)$  with predictable quadratic variation  $\langle Z \rangle_t$  given by

$$
Z_t = \begin{pmatrix} M_t^X \\ M_t^V \end{pmatrix} \quad \text{and} \quad \langle Z \rangle_t = \begin{pmatrix} S_t & P_t \\ P_t & L_t \end{pmatrix}.
$$

We deduce from  $(3.5)$ ,  $(3.6)$  and  $(3.10)$  that

(3.34) 
$$
\lim_{T \to \infty} A_T = A \quad \text{a.s.}
$$

where  $A$  is the limiting matrix given by

<span id="page-6-4"></span><span id="page-6-3"></span>
$$
A = \begin{pmatrix} -2\theta^* & 0\\ -2\rho^*(C_X - 2(\theta \rho)^{-1}\theta^* \rho^*) & -2\rho^* C_V \end{pmatrix}.
$$

By the same token, we immediately have from [\(3.5\)](#page-2-5), [\(3.6\)](#page-2-9) and [\(3.10\)](#page-2-10) that

(3.35) 
$$
\lim_{T \to \infty} \frac{\langle Z \rangle_T}{T} = \Lambda = -\frac{1}{2\theta^*} \begin{pmatrix} 1 & 1 \\ 1 & \theta^* \rho^{-1} \end{pmatrix} \quad \text{a.s.}
$$

Furthermore, it clearly follows from Corollary [4.3](#page-10-1) below that

<span id="page-7-0"></span>(3.36) 
$$
\frac{X_T^2}{\sqrt{T}} \xrightarrow{\mathcal{P}} 0 \quad \text{and} \quad \frac{V_T^2}{\sqrt{T}} \xrightarrow{\mathcal{P}} 0.
$$

Finally, as  $\Gamma = A\Lambda A'$ , the joint asymptotic normality [\(3.25\)](#page-5-2) follows from the conjunction of [\(3.33\)](#page-6-2), [\(3.34\)](#page-6-3), [\(3.35\)](#page-6-4), [\(3.36\)](#page-7-0) together with Slutsky's lemma and the central limit theorem for continuous-time vector martingales given e.g. in [\[8\]](#page-12-13), which achieves the proof of Theorem [3.2.](#page-5-3)

**Theorem 3.3.** If  $\rho = 0$ , we have the convergence in distribution

<span id="page-7-2"></span>
$$
(3.37) \t\t T\hat{\rho}_T \xrightarrow{\mathcal{L}} \mathcal{W}
$$

where the limiting distribution  $\mathcal W$  is given by

<span id="page-7-5"></span>(3.38) 
$$
\mathcal{W} = \frac{\int_0^1 B_s \, \mathrm{d}B_s}{\int_0^1 B_s^2 \, \mathrm{d}s} = \frac{B_1^2 - 1}{2 \int_0^1 B_s^2 \, \mathrm{d}s}
$$

and  $(B_t)$  is a standard Brownian motion.

Proof. Via the same reasoning as in Section 2 of [\[9\]](#page-12-15), it follows from the self-similarity of the Brownian motion  $(W_t)$  that

<span id="page-7-3"></span>
$$
\left(\int_0^T W_t^2 dt, \frac{1}{2} (W_T^2 - T)\right) \stackrel{\mathcal{L}}{=} \left(T \int_0^T W_{t/T}^2 dt, \frac{T}{2} (W_1^2 - 1)\right),
$$
\n(3.39)\n
$$
= \left(T^2 \int_0^1 W_s^2 ds, \frac{T}{2} (W_1^2 - 1)\right).
$$

Moreover, we obtain from [\(3.30\)](#page-5-0) that

(3.40) 
$$
\widehat{L}_T = \alpha_T S_T + \beta_T P_T + \gamma_T L_T
$$

where

<span id="page-7-4"></span><span id="page-7-1"></span>
$$
\alpha_T = \frac{1}{\theta^2} (\hat{\theta}_T - \theta)^2,
$$
  
\n
$$
\beta_T = -\frac{2}{\theta} (\hat{\theta}_T - \theta) - \frac{2}{\theta^2} (\hat{\theta}_T - \theta)^2,
$$
  
\n
$$
\gamma_T = 1 + \frac{2}{\theta} (\hat{\theta}_T - \theta) + \frac{1}{\theta^2} (\hat{\theta}_T - \theta)^2.
$$

By Theorem [3.1,](#page-2-6)  $\theta_T$  converges a.s. to  $\theta$  which implies that  $\alpha_T$ ,  $\beta_T$ , and  $\gamma_T$  converge a.s. to  $0, 0$  and 1. Hence, we deduce from  $(3.5)$ ,  $(3.6)$  and  $(3.40)$  that

(3.41) 
$$
\widehat{L}_T = L_T(1 + o(1)) \quad \text{a.s.}
$$

Furthermore, one can observe that  $\widehat{V}_T^2/T$  shares the same asymptotic distribution as  $W_T^2/T$ . Finally, [\(3.37\)](#page-7-2) follows from [\(3.39\)](#page-7-3) and [\(3.41\)](#page-7-4) together with the continuous mapping theorem.  $\Box$  **Remark 3.1.** The asymptotic behavior of  $\hat{\rho}_T$  when  $\rho < 0$  and  $\rho = 0$  is closely related to the results previously established for the unstable discrete-time autoregressive process, see [\[4\]](#page-12-16), [\[9\]](#page-12-15), [\[18\]](#page-12-17). According to Corollary 3.1.3 of [4], we can express

$$
\mathcal{W} = \frac{\mathcal{T}^2 - 1}{2\mathcal{S}}
$$

where  $\mathcal T$  and  $\mathcal S$  are given by the Karhunen-Loeve expansions

$$
\mathcal{T} = \sqrt{2} \sum_{n=1}^{\infty} \gamma_n Z_n \qquad \text{and} \qquad \mathcal{S} = \sum_{n=1}^{\infty} \gamma_n^2 Z_n^2
$$

with  $\gamma_n = 2(-1)^n/((2n-1)\pi)$  and  $(Z_n)$  is a sequence of independent random variables with  $\mathcal{N}(0,1)$  distribution.

**Remark 3.2.** For all  $0 \le t \le T$ , the residuals  $V_t$  given by  $(2.2)$  depend on  $\theta_T$ . It would have been more natural to make use of the estimator of  $\theta$  at stage t instead of stage T, in order to produce a recursive estimate. In this situation, Theorem [3.1](#page-2-6) still holds but we have been unable to prove Theorem [3.2.](#page-5-3)

### 4. SOME TECHNICAL TOOLS

<span id="page-8-0"></span>First of all, most of our results rely on the following keystone lemma.

<span id="page-8-2"></span>**Lemma 4.1.** The process  $(X_t)$  is geometrically ergodic.

Proof. It follows from [\(1.2\)](#page-0-0) that

(4.1) 
$$
dX_t = (\theta + \rho)X_t dt - \theta \rho \Sigma_t dt + dW_t
$$

where we recall that

<span id="page-8-1"></span>
$$
\Sigma_t = \int_0^t X_s \, \mathrm{d} s.
$$

Consequently, if

$$
\Phi_t = \begin{pmatrix} X_t \\ \Sigma_t \end{pmatrix},
$$

we clearly deduce from [\(4.1\)](#page-8-1) that

$$
\mathrm{d}\Phi_t = A\Phi_t \,\mathrm{d}t + \,\mathrm{d}B_t
$$

where

$$
A = \begin{pmatrix} \theta + \rho & -\theta \rho \\ 1 & 0 \end{pmatrix} \quad \text{and} \quad B_t = \begin{pmatrix} W_t \\ 0 \end{pmatrix}.
$$

The geometric ergodicity of  $(\Phi_t)$  only depends on the sign of  $\lambda_{\text{max}}(A)$ , *i.e.* the largest eigenvalue of A, which has to be negative. An immediate calculation shows that

$$
\lambda_{\max}(A) = \max(\theta, \, \rho)
$$

which ensures that  $\lambda_{\max}(A) < 0$  as soon as  $\rho < 0$ . Moreover, if  $\rho = 0$ ,  $(X_t)$  is an ergodic Ornstein-Uhlenbeck process since  $\theta < 0$ , which completes the proof of Lemma [4.1.](#page-8-2)  $\Box$ 

<span id="page-9-0"></span>Corollary 4.1. We have the almost sure convergence

(4.2) 
$$
\lim_{T \to \infty} \frac{1}{T} S_T = -\frac{1}{2(\theta + \rho)} \quad \text{a.s.}
$$

Proof. According to Lemma [4.1,](#page-8-2) it is only necessary to establish the asymptotic behavior of  $\mathbb{E}[X_t^2]$ . Denote  $\alpha_t = \mathbb{E}[X_t^2]$ ,  $\beta_t = \mathbb{E}[\Sigma_t^2]$  and  $\gamma_t = \mathbb{E}[X_t \Sigma_t]$ . One obtains from Itô's formula that

<span id="page-9-2"></span>
$$
\frac{\partial U_t}{\partial t} = CU_t + I
$$

where

$$
U_t = \begin{pmatrix} \alpha_t \\ \beta_t \\ \gamma_t \end{pmatrix}, \quad C = \begin{pmatrix} 2(\theta + \rho) & 0 & -2\theta\rho \\ 0 & 0 & 2 \\ 1 & -\theta\rho & \theta + \rho \end{pmatrix}, \quad I = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}.
$$

It is not hard to see that  $\lambda_{\max}(C) = \max(\theta + \rho, 2\theta, 2\rho)$ . On the one hand, if  $\rho < 0$ ,  $\lambda_{\max}(C) < 0$  which implies that

$$
\lim_{t \to \infty} U_t = -C^{-1}I.
$$

It means that

$$
\lim_{t \to \infty} \alpha_t = -\frac{1}{2(\theta + \rho)}, \quad \lim_{t \to \infty} \beta_t = -\frac{1}{2\theta\rho(\theta + \rho)}, \quad \lim_{t \to \infty} \gamma_t = 0.
$$

Hence, [\(4.2\)](#page-9-2) follows from Lemma [4.1](#page-8-2) together with the ergodic theorem. On the other hand, if  $\rho = 0$ ,  $(X_t)$  is a positive recurrent Ornstein-Uhlenbeck process and convergence  $(4.2)$  is well-known.

<span id="page-9-1"></span>**Corollary 4.2.** If  $\rho < 0$ , we have the almost sure convergence

$$
\lim_{T \to \infty} \frac{1}{T} \widehat{L}_T = -\frac{(\theta + \rho)^2 + \theta \rho}{2\theta \rho (\theta + \rho)}
$$
 a.s.

*Proof.* If  $\rho < 0$ ,  $(V_t)$  is a positive recurrent Ornstein-Uhlenbeck process and it is well-known that

$$
\lim_{T \to \infty} \frac{1}{T} L_T = -\frac{1}{2\rho} \quad \text{a.s.}
$$

In addition, as  $X_t = \theta \Sigma_t + V_t$ ,

$$
\int_0^T X_t \Sigma_t dt = \frac{1}{\theta} (S_T - P_T).
$$

However, we already saw in the proof of Corollary [4.1](#page-9-0) that

$$
\lim_{T \to \infty} \frac{1}{T} \int_0^T X_t \Sigma_t dt = 0 \quad \text{a.s.}
$$

which leads, via [\(4.2\)](#page-9-2), to the almost sure convergence

$$
\lim_{T \to \infty} \frac{P_T}{T} = -\frac{1}{2(\theta + \rho)} \quad \text{a.s.}
$$

Consequently, we deduce from [\(3.1\)](#page-2-2) together with [\(3.30\)](#page-5-0) that

$$
\lim_{T \to \infty} \frac{1}{T} \widehat{L}_T = \lim_{T \to \infty} \frac{1}{T} I_T = -\frac{(\theta + \rho)^2 + \theta \rho}{2\theta \rho (\theta + \rho)}
$$
 a.s.

which achieves the proof of Corollary [4.2.](#page-9-1)  $\Box$ 

<span id="page-10-1"></span>**Corollary 4.3.** If  $\rho < 0$ , we have the asymptotic normalities

$$
X_T \xrightarrow{\mathcal{L}} \mathcal{N}\left(0, -\frac{1}{2(\theta + \rho)}\right) \quad \text{and} \quad V_T \xrightarrow{\mathcal{L}} \mathcal{N}\left(0, -\frac{1}{2\rho}\right).
$$

The asymptotic normality of  $X_T$  still holds in the particular case where  $\rho = 0$ .

Proof. This asymptotic normality is a well-known result for the Ornstein-Uhlenbeck process  $(V_t)$  with  $\rho < 0$ . In addition, one can observe that for all  $t \geq 0$ ,  $\mathbb{E}[X_t] = 0$ . The end of the proof is a direct consequence of the Gaussianity of  $(X_t)$  together with Lemma [4.1](#page-8-2) and Corollary [4.1.](#page-9-0)

## 5. A STATISTICAL TESTING PROCEDURE

<span id="page-10-0"></span>Our purpose is now to propose a statistical procedure in order to test

$$
\mathcal{H}_0: \text{``}\rho=0\text{''} \qquad \text{against} \qquad \mathcal{H}_1: \text{``}\rho<0\text{''}.
$$

We shall make use of the Durbin-Watson statistic given by [\(2.5\)](#page-1-4). Its asymptotic properties are as follows.

<span id="page-10-2"></span>Theorem 5.1. We have the almost sure convergence

(5.1) 
$$
\lim_{T \to \infty} \widehat{D}_T = D^* \quad \text{a.s.}
$$

where  $D^* = 2(1 - \rho^*)$ . In addition, if  $\rho < 0$ , we have the asymptotic normality

(5.2) 
$$
\sqrt{T}\left(\widehat{D}_T - D^*\right) \xrightarrow{\mathcal{L}} \mathcal{N}(0, \sigma_D^2)
$$

where

$$
\sigma_D^2 = 4 \sigma_\rho^2 = -\frac{8\rho^* ((\theta^*)^6 + \theta\rho ((\theta^*)^4 - \theta\rho (2(\theta^*)^2 - \theta\rho)))}{((\theta^*)^2 + \theta\rho)^3}.
$$

while, if  $\rho = 0$ ,

(5.3) 
$$
T(\hat{D}_T - 2) \xrightarrow{\mathcal{L}} -2\mathcal{W}
$$

with  $W$  given by  $(3.38)$ .

*Proof.* The proof of Theorem [5.1](#page-10-2) is a straightforward application of  $(3.1)$ ,  $(3.28)$  and [\(3.37\)](#page-7-2) since  $\widehat{D}_T = 2(1 - \widehat{\rho}_T).$ 

From now on, let us define the test statistic

$$
\widehat{Z}_T = T^2 \left( \widehat{D}_T - 2 \right)^2
$$

.

It follows from Theorem [5.1](#page-10-2) that under  $\mathcal{H}_0$ ,

$$
\widehat{Z}_T \stackrel{\mathcal{L}}{\longrightarrow} 4\mathcal{W}^2
$$

while, under  $\mathcal{H}_1$ ,

$$
\lim_{T \to \infty} \widehat{Z}_T = +\infty \quad \text{a.s.}
$$

From a practical point of view, for a significance level  $\alpha$  where  $0 < \alpha < 1$ , the acceptance and rejection regions are given by  $\mathcal{A} = [0, z_{\alpha}]$  and  $\mathcal{R} = [z_{\alpha}, +\infty]$  where  $z_{\alpha}$  stands for the  $(1 - \alpha)$ -quantile of the distribution of  $4\mathcal{W}^2$ . The null hypothesis  $\mathcal{H}_0$  will not be rejected if the empirical value

$$
\widehat{Z}_T\leq z_\alpha,
$$

and will be rejected otherwise. Assume to conclude that  $\mathcal{H}_0$  is rejected, which means that we admit the existence of a serial correlation  $\rho < 0$ . Then, the best way to produce unbiased estimates is to study the process given by [\(4.1\)](#page-8-1). As a matter of fact, for all  $t \geq 0$ ,

$$
X_t = (\theta + \rho)\Sigma_t - \theta \rho \Pi_t + W_t
$$

where

$$
\Sigma_t = \int_0^t X_s \, \mathrm{d}s \qquad \text{and} \qquad \Pi_t = \int_0^t \Sigma_s \, \mathrm{d}s.
$$

The maximum likelihood estimator of the vector

$$
\vartheta=\begin{pmatrix}\theta+\rho\\-\theta\rho\end{pmatrix}
$$

is given by

$$
\widehat{\vartheta}_T = \left(\int_0^T \Phi_t \Phi_t' \, \mathrm{d}t\right)^{-1} \int_0^T \Phi_t \, \mathrm{d}X_t
$$

where  $\Phi_t = (X_t \Sigma_t)'$ . We can show the almost sure convergence

$$
\lim_{T \to \infty} \widehat{\vartheta}_T = \vartheta \qquad \text{a.s.}
$$

as well as the asymptotic normality

$$
\sqrt{T}\left(\widehat{\vartheta}_T-\vartheta\right)\xrightarrow{\mathcal{L}}\mathcal{N}(0,\Delta)
$$

where the asymptotic covariance matrix is given by

$$
\Delta = \begin{pmatrix} -2\theta^* & 0 \\ 0 & -2\theta\rho\,\theta^* \end{pmatrix}.
$$

Accordingly, the maximum likelihood estimator  $\vartheta_T$  is strongly consistent and one can see that its components are asymptotically independent.
