The detailed formulation of loop quantum cosmology with higher order holonomy corrections has been constructed recently in the homogeneous and isotropic spacetime, yet it is important to extend the higher order holonomy corrections to include the effects of anisotropy which typically grow during the collapsing phase. In this paper we investigate the Bianchi I model in $\bar{\mu}'$ scheme which truly captures the regularization of the Hamiltonian constraint. To compare with the earlier works and provide a comparison with the $\bar{\mu}'$ scheme, we also investigate the $\bar{\mu}$ scheme although it has many disadvantages. First we construct the effective dynamics with higher order holonomy corrections in a massless scalar field, then we extend it to the inclusion of arbitrary matter. Besides that, we also analyze the behavior of the anisotropy during the evolution of the universe. We find that in the $\bar{\mu}'$ scheme, the singularity is never approached and the quantum bounce is generic as in the isotropic case, regardless of the order of the holonomy corrections. Some differences in the bouncing phase of the two schemes are also found out. It is also shown that in the two schemes the behavior of the anisotropy is not the same before and after the bounce.

I. INTRODUCTION

loop quantum gravity (LQG) is a mathematically welldefined, nonperturbative, and background independent quantization of gravity [1]. The applications of LQG to homogeneous and isotropic spacetime results in loop quantum cosmology (LQC). The comprehensive formulation of LQC is constructed in the spatially flat, isotropic model in detail [2–4], which indicates that the classical big-bang singularity can be replaced by a big-bounce. With these successes, the methods can also be extended to Bianchi I model to include anisotropy [5–9].

The underlying dynamics in LQC is governed by the discreteness of the quantum geometry. With the achievements described above, the scheme of LQC is indeed attractive, while its rigorous quantum approach is difficult to afford due to the complexity. However, using semiclassical strategies we can construct an effective method which has captured to a very good approximation in the quantum dynamics [16]. With quantum corrections to the classical Hamiltonian, we can get the effective equations of the modified Hamiltonian which is an efficient approach to investigate the evolution of the early universe. In [17] the evolution of the universe is investigated in the form of effective approach, which indicates that the presence of a big-bounce is a generic feature of LQC and does not require any exotic matter that violates energy condition.

When the effective approach is extended to the anisotropic Bianchi I model, the scheme is ambiguous in the early investigations as there are two strategies: $\bar{\mu}$ scheme and $\bar{\mu}'$ scheme, each of which is of particular interest. In [7] and [8] the $\bar{\mu}$ scheme is investigated and in [9–14] the $\bar{\mu}'$ scheme is considered. The $\bar{\mu}$ scheme is just a simplifying assumption without a systematic justification [5, 8, 9]. However, this leads to drawbacks that the quantum dynamics depends on the choice of the fiducial cell[15]. There are also problems that expansion scalar and shear scalar are not bounded above [10], which point towards lack of generic resolution of singularities in this quantization. In [6] a more systematic procedure leads to the $\bar{\mu}'$ scheme, which is fiducial cell independent. This scheme also leads to the strong singularity resolution[10–12]. Not only do the results at the level of effective dynamics agree with the anticipations of the rigorous quantum approach but some details of quantum effects during the evolution are also obtained.

Despite the fascinating and attractive features, whether the quantum effects result from the discreteness of the spacetime geometry of LQC is still questionable, as some of the results through the rigorous quantum approach can also be obtained through the heuristic effective dynamics in continuum spacetime. In response to the deficiency, a new avenue of higher order holonomy corrections is investigated [18].

The approach of the higher order holonomy corrections is also a heuristic effective strategy that is more general than the conventional scheme, which takes the traditional

[†]Author to whom correspondence should be addressed; Electronic address: zhujy@bnu.edu.cn

one to be the situation where the order of the holonomy corrections is 0. In [18] it reveals that the big-bounce are a generic feature of LQC no matter whether the higher order holonomy corrections are included and the matter density remains finite with an upper bound. In [19] the rigorous quantum theory of LQC with higher order holonomy corrections is formulated and the anticipations of [18] are confirmed. It is also shown that the higher order holonomy corrections can be interpreted as a result of admitting generic SU(2) representations for the Hamiltonian constraint operators.

The heuristic analysis of higher order holonomy corrections is a very promising approach. However, the extension to the anisotropic case is still an open issue. In this paper we investigate the higher order holonomy corrections in Bianchi I model.

Firstly we construct the effective dynamics of Bianchi I model with higher order holonomy corrections. We extend the $\bar{\mu}$ scheme to the case of higher order holonomy corrections to compare with the early investigations and provide a comparison with the $\bar{\mu}'$ scheme. On the other hand, although the numerical simulations about the bouncing phase of $\bar{\mu}'$ scheme are abundant, the analytical investigations about the this phase are some limited due to the mathematical complexity, especially with the arbitrary matter case. In this paper, we investigate the effective dynamics with arbitrary matter analytically in detail and extend it to higher order holonomy corrections.

The anisotropy is also an important aspect as it grows in the contracting phase of the evolution. Besides that, it can also tell us some information of the universe before the big bounce. In this paper we also investigate the evolution of the anisotropy with higher order holonomy corrections and compare the differences of the behavior in the two schemes.

This paper is organized as follows. Firstly, we review briefly the classical dynamics in Bianchi I model in Sec. II, and then, in Sec. III, we introduce the effective loop quantum dynamics with higher order holonomy corrections and two sets of research schemes: $\bar{\mu}$ scheme and $\bar{\mu}'$ scheme. Next in Sec. IV and Sec. V, we investigate in detail the effective dynamics in the forms of $\bar{\mu}$ scheme and $\bar{\mu}'$ scheme, respectively. In Sec. VI, the anisotropies of the Bianchi I model in the two schemes are analyzed. Finally, we draw the conclusions in Sec. VII.

II. CLASSICAL DYNAMICS

In this section, we review briefly the classical dynamics in Bianchi I model. As a comparison of previous investigations, we first focus on the model with a massless scalar field. Then we will turn to the case where a general matter potential is considered. For a more complete description of the classical dynamics one can see, e.g. [7–9].

The spacetime metric of Bianchi I model is given as

$$ds^{2} = -N^{2}dt^{2} + a_{1}^{2}dx^{2} + a_{2}^{2}dy^{2} + a_{3}^{2}dz^{2}, \qquad (1)$$

where N is the lapse function. When we write the classical dynamics in the Ashtekar variables, we consider the spacetime with a manifold $\Sigma \times \mathbb{R}$ where the space supersurface Σ is flat. Because of the non-compactness of the spatial manifold, it is necessary to introduce a fiducial cell \mathcal{V} which has a fiducial volume $V_0 = l_1 l_2 l_3$. In Bianchi I model, the Ashtekar variables take a simple form where the phase space is given by the diagonal triad variables p_I and diagonal connection variables c_I (I = 1, 2, 3). The canonical conjugate phase space satisfies

$$\{c_I, p_J\} = \kappa \gamma \delta_{IJ},\tag{2}$$

where $\kappa = 8\pi G$ and γ is the Barbero-Immirzi parameter which was set to be $\gamma \simeq 0.2375$ by the black hole thermodynamics [26]. The triad p_I are related to the scale factors a_I by

$$|p_1| = l_2 l_3 a_2 a_3, |p_2| = l_1 l_3 a_1 a_3, |p_3| = l_1 l_2 a_1 a_2.$$
(3)

Thus the triad variables are the physical areas of the rectangular surface of \mathcal{V} which is invariant under the coordinate rescaling. The connection variables are given by

$$c_1 = \gamma l_1 \dot{a}_1, c_2 = \gamma l_2 \dot{a}_2, c_3 = \gamma l_3 \dot{a}_3, \tag{4}$$

that is the time change rates of the physical lengths of the edges of \mathcal{V} , which is also invariant under the coordinate rescaling [9]. Thus, the Hamiltonian constraint in the Ashtekar variables can be written as

$$\mathcal{H}_{cl} = -\frac{N}{\kappa \gamma^2 V} \left(c_1 p_1 c_2 p_2 + c_2 p_2 c_3 p_3 + c_3 p_3 c_1 p_1 \right) + \mathcal{H}_{matt},$$

where $V = l_1 l_2 l_3 a_1 a_2 a_3$ is the physical volume of the fiducial cell \mathcal{V} and \mathcal{H}_{matt} is the matter Hamiltonian. The form of the matter Hamiltonian is

$$\mathcal{H}_{matt} = N\sqrt{p_1 p_2 p_3} \rho_M.$$

Equations of motion are

$$\dot{p}_I = -\kappa \gamma \frac{\partial \mathcal{H}_{cl}}{\partial c_I}, \quad \dot{c}_I = \kappa \gamma \frac{\partial \mathcal{H}_{cl}}{\partial p_I}.$$
 (5)

A. for a massless scalar field

In order to compare with [5, 7] and [18], here we focus on a massless scalar field. For simplicity we choose the lapse function $N = \sqrt{p_1 p_2 p_3}$ and introduce a new time variable $dt' = (p_1 p_2 p_3)^{-1/2} dt$. The rescaled Hamiltonian is

$$\mathcal{H}_{cl} = -\frac{1}{\kappa\gamma^2} \left(c_1 p_1 c_2 p_2 + c_2 p_2 c_3 p_3 + c_3 p_3 c_1 p_1 \right) + \frac{p_{\phi}^2}{2}.$$

The equations of motion are:

$$\frac{d\phi}{dt'} = p_{\phi}, \quad \frac{dp_{\phi}}{dt'} = 0, \tag{6}$$

$$\frac{dc_1}{dt'} = -\gamma^{-1}c_1(c_2p_2 + c_3p_3),\tag{7}$$

$$\frac{dp_1}{dt'} = \gamma^{-1} p_1 (c_2 p_2 + c_3 p_3). \tag{8}$$

With Eq.(7) and Eq.(8) we have

$$\frac{d}{dt'}(c_I p_I) = 0 \Rightarrow c_I p_I = \kappa \gamma \hbar \mathcal{K}_I, \tag{9}$$

where \mathcal{K}_I are constants. Here we define

$$p_{\phi} = \hbar \sqrt{\kappa} \mathcal{K}_{\phi}. \tag{10}$$

Using Eq.(9), Eq.(10) and the Hamiltonian constraint $\mathcal{H}_{cl} = 0$ we have

$$\mathcal{K}_{\phi}^2 = 2(\mathcal{K}_2\mathcal{K}_3 + \mathcal{K}_3\mathcal{K}_1 + \mathcal{K}_1\mathcal{K}_2). \tag{11}$$

Combining Eq.(9) and Eq.(8) gives

$$\frac{1}{p_1}\frac{dp_1}{dt'} = \kappa\hbar \left(\mathcal{K}_2 + \mathcal{K}_3\right). \tag{12}$$

With Eq.(6) the above equation can be written to be

$$\frac{1}{p_1}\frac{dp_1}{d\phi} = \kappa\hbar\frac{\mathcal{K}_2 + \mathcal{K}_3}{p_\phi} = \sqrt{8\pi G}\left(\frac{1-\kappa_1}{\kappa_\phi}\right),\qquad(13)$$

where $\mathcal{K}_I = \mathcal{K}\kappa_I$, $\mathcal{K}_{\phi} = \mathcal{K}\kappa_{\phi}$ and

$$\kappa_1 + \kappa_2 + \kappa_3 = 1, \kappa_1^2 + \kappa_2^2 + \kappa_3^2 + \kappa_\phi^2 = 1.$$
 (14)

B. for an arbitrary matter field

Now we consider the inclusion of an arbitrary matter field. Here we also choose the lapse function $N = \sqrt{p_1 p_2 p_3}$ and the Hamiltonian takes the form

$$\mathcal{H}_{cl} = -\frac{1}{\kappa\gamma^2} \left(c_1 p_1 c_2 p_2 + c_2 p_2 c_3 p_3 + c_3 p_3 c_1 p_1 \right) + p_1 p_2 p_3 \rho_M.$$

The equations of motion are:

$$\frac{dp_1}{dt'} = \gamma^{-1} p_1 \left(c_2 p_2 + c_3 p_3 \right), \tag{15}$$

$$\frac{dc_1}{dt'} = -\gamma^{-1}c_1 \left(c_2 p_2 + c_3 p_3\right) + \kappa \gamma p_2 p_3 \left(\rho_M + p_1 \frac{\partial \rho_M}{\partial p_1}\right).$$
(16)

One can see that when the energy density $\rho_M = p_{\phi}^2/2(p_1p_2p_3)$ Eq.(16) turns out to be Eq.(7). Combining Eq.(15) and Eq.(16) gives the relation

$$\frac{d}{dt'}(p_I c_I) = \kappa \gamma p_1 p_2 p_3 \left(\rho_M + p_I \frac{\partial \rho_M}{\partial p_I}\right).$$
(17)

If we assume that the matter has zero anisotropy, namely $\rho_M(p_1, p_2, p_3) = \rho_M(p_1 p_2 p_3)$, we can get $p_I \frac{\partial \rho_M}{\partial p_I} = p_J \frac{\partial \rho_M}{\partial p_J}$, which yields

$$\frac{d}{dt'}\left(p_Ic_I - p_Jc_J\right) = 0. \tag{18}$$

The above equation can be integrated to be:

$$p_I c_I - p_J c_J = \gamma V \left(H_I - H_J \right) = \gamma V_0 \alpha_{IJ}. \tag{19}$$

where α_{IJ} is a constant anti-symmetric matrix. From the constraint $\mathcal{H}_{cl} = 0$ we can get the relation

$$H_1H_2 + H_2H_3 + H_3H_1 = \kappa \rho_M.$$

We can also define the mean scale factor a as

$$a = (a_1 a_2 a_3)^{1/3}, \qquad (20)$$

then

$$H = \frac{\dot{a}}{a} = \frac{1}{3} \left(H_1 + H_2 + H_3 \right) \tag{21}$$

is the mean Hubble rate. In some literatures the expansion scalar is also defined to be $\theta = \frac{1}{V} \frac{dV}{dt} = 3H$ to describe the expansion rate of the whole volume.

The Friedmann equation with the inclusion of anisotropy is

$$H^{2} = \frac{1}{3} (H_{1}H_{2} + H_{2}H_{3} + H_{3}H_{1}) + \frac{1}{18} \left[(H_{1} - H_{2})^{2} + (H_{2} - H_{3})^{2} + (H_{3} - H_{1})^{2} \right] = \frac{\kappa}{3} \rho_{M} + \frac{\Sigma^{2}}{a^{6}},$$
(22)

The shear parameter is

$$\Sigma^2 = \frac{1}{18} \left(\alpha_{12}^2 + \alpha_{23}^2 + \alpha_{31}^2 \right), \tag{23}$$

which is a constant in the classical case. The anisotropic shear scalar $\sigma^2 = \sigma_{\mu\nu}\sigma^{\mu\nu}$ is given by

$$\sigma^{2} = \frac{1}{3} \left[(H_{1} - H_{2})^{2} + (H_{2} - H_{3})^{2} + (H_{3} - H_{1})^{2} \right]$$
$$= \frac{6\Sigma^{2}}{a^{6}}.$$
 (24)

III. EFFECTIVE LOOP QUANTUM DYNAMICS

In the effective dynamics of LQC, the connection variables c_I (I = 1, 2, 3) should be replaced by holonomies, i.e.,

$$c_I \to \frac{\sin\left(\bar{\mu}_I c_I\right)}{\bar{\mu}_I},$$
 (25)

where $\bar{\mu}_I$ are real valued functions of p_I which are measures of the discreteness in the quantum gravity. When $\bar{\mu}_I \ll 1$, $\sin(\bar{\mu}_I c_I)/\bar{\mu}_I \approx c_I$.

By choosing this, the Hamiltonian can be written as

$$\mathcal{H} = -\frac{N}{\kappa\gamma^2 V} \left[\frac{\sin(\bar{\mu}_1 c_1)}{\bar{\mu}_1} \frac{\sin(\bar{\mu}_2 c_2)}{\bar{\mu}_2} p_1 p_2 + \frac{\sin(\bar{\mu}_2 c_2)}{\bar{\mu}_2} \frac{\sin(\bar{\mu}_3 c_3)}{\bar{\mu}_3} p_2 p_3 + \frac{\sin(\bar{\mu}_3 c_3)}{\bar{\mu}_3} \frac{\sin(\bar{\mu}_1 c_1)}{\bar{\mu}_1} p_3 p_1 \right] + \mathcal{H}_{matt}.$$
 (26)

In this paper we consider the effective dynamics with higher order holonomy corrections. In fact, it is possible to approximate c_I in terms of $\sin(\bar{\mu}_I c_I)$ to arbitrary accuracy

$$c_{I} = \frac{1}{\bar{\mu}_{I}} \sum_{k=0}^{\infty} \frac{(2k)!}{2^{2k} (k!)^{2} (2k+1)} \left[\sin\left(\bar{\mu}_{I} c_{I}\right) \right]^{2k+1}.$$
 (27)

This inspires us to define the nth order holonomized connection variables as

$$c_I^{(n)} := \frac{1}{\bar{\mu}_I} \sum_{k=0}^n \frac{(2k)!}{2^{2k} (k!)^2 (2k+1)} \left[\sin(\bar{\mu}_I c_I) \right]^{2k+1}, \quad (28)$$

which remains a periodic and bounded function of c_I . The conventional holonomy correction corresponds to n = 0.

The remarkable point is that in fact it is only when $-\pi/2 \leq \bar{\mu}_I c_I \leq \pi/2$ does the power series give back to c_I . As $c_I^{(n)}$ is a periodic function of c_I , when $\bar{\mu}_I c_I$ exceeds this regime, the $c_I^{(n)}$ does not blow up as c_I , it is still bounded, even if $n \to \infty$. In the following we will see that it is the $\bar{\mu}_I c_I$ goes through the point $\pi/2$ that makes the cosine function flip its sign, which leads to the big bounce. This interprets the reason that when $n \to \infty$ the dynamics does not reduce to the classical case, as after the bouncing point $\bar{\mu}_I c_I > \pi/2$ the variable $c_I^{(\infty)}$ does not reduce to c_I , the classical dynamics is still modified drastically in the limit $n \to \infty$.

With this, the Hamiltonian with holonomy corrections up to the nth order can be written as

$$\mathcal{H}_{eff} = -\frac{N}{\kappa \gamma^2 V} \left[c_1^{(n)} p_1 c_2^{(n)} p_2 + c_2^{(n)} p_2 c_3^{(n)} p_3 + c_3^{(n)} p_3 c_1^{(n)} p_1 \right] + \mathcal{H}_{matt}.$$
(29)

Using the canonical relation (2) we can get the relation

$$\left\{c_{I}, c_{J}^{(n)}\right\} = \frac{\kappa\gamma}{\bar{\mu}_{J}} \frac{\partial\bar{\mu}_{J}}{\partial p_{I}} \left[\cos\left(\bar{\mu}_{J}c_{J}\right)\mathfrak{S}_{n}\left(\bar{\mu}_{J}c_{J}\right)c_{J} - c_{J}^{(n)}\right]$$
(30)

$$\left\{p_I, c_J^{(n)}\right\} = -\kappa\gamma \cos(\bar{\mu}_J c_J)\mathfrak{S}_n(\bar{\mu}_J c_J)\delta_{IJ},\qquad(31)$$

where

$$\mathfrak{S}_{n}(\bar{\mu}_{I}c_{I}) := \sum_{k=0}^{n} \frac{(2k)!}{2^{2k} (k!)^{2}} \sin(\bar{\mu}_{I}c_{I})^{2k}$$
$$\stackrel{n \to \infty}{\to} |\cos(\bar{\mu}_{I}c_{I})|^{-1}.$$
(32)

A. The meaning of higher order holonomy corrections

The initial motivation of introducing higher order holonomy corrections is to provide further evidence that the quantum bounce is a consequence of the intrinsic discreteness of geometry in LQC[18], but the implication is not just limited to the heuristic effective level. In [19] the rigorous quantum theory with higher order holonomy corrections is formulated in the isotropic model. Until now the quantum theory of higher order holonomy corrections in Bianchi I model is not completed, and this construction is not the focus of this paper, but taking a look at the quantum theory in the isotopic model can still provide us a taste of the meaning of the higher order holonomy corrections. The detailed analysis can be found in [19].

It was shown that the higher order holonomy corrections is related to the j ambiguity. We know that in LQC the classical variable c should be replaced by the holonomy

$$h_l^{(\bar{\mu})} := \mathcal{P}exp \int_0^{\bar{\mu}L} \tau_i A_a^i dx^a = exp(\bar{\mu}c\tau_i),$$

which is the holonomy along the edge of coordinate length $\bar{\mu}L$. Here τ_i are the SU(2) generators with $[\tau_i, \tau_j] = \epsilon_{ij}^k \tau_k$. In standard convention $2i\tau_i = \sigma_i$ are the Pauli matrices. In fact, the Lie algebra generators τ_i in the j representation of the SU(2) group are represented as $(2j+1) \times (2j+1)$ matrices ${}^{(j)}\tau_i$, which satisfy

$$Tr(^{(j)}\tau_i^{(j)}\tau_j) = -\frac{1}{3}j(j+1)(2j+1)\delta_{ij}$$

where j is a half integer and the conventional choice is j = 1/2. The holonomies $h_i^{(\bar{\mu})}$ can also be promoted to ${}^{(j)}h_i^{(\bar{\mu})}$ in the j representation. We write ${}^{(j)}\widehat{C}'_{grav}$ to be the Hamiltonian operator in generic j representations, which consists of even powers of $\widehat{\sin(\bar{\mu}c)}$. When j = 1/2,

$$^{1/2)}\widehat{C}'_{grav} = -\frac{3}{\kappa\gamma^2\bar{\mu}^2}\widehat{\sin(\bar{\mu}c)}^2|\widehat{p}|^2$$

(

which leads to the conventional holonomy corrections $(c^{(n=0)})$.

In [19] it was proved that the gravitational part of Hamiltonian operator with higher order holonomy corrections $\hat{C}_{grav}^{\prime(n)}$ can be represented as a linear superposition of the Hamiltonian operators in generic j representations:

$$\widehat{C}_{grav}^{'(n)} = \sum_{j=1/2}^{n/2} c_j^{(n)(j)} \widehat{C}_{grav}'$$

where $c_j^{(n)}$ are constants. In the limit $n \to \infty$, we have to include all the *j* representations.

There is a problem that although the linear superposition coefficients $c_j^{(n)}$ are constants for a definite n, they diverge as $n \to \infty$. However, the computed data has shown that comparatively only the contributions from the moderate j are appreciable. If we compose a regularization to supress the high j contributions, the coefficients $c_j^{(n)}$ can be made to converge. With a suitable regularization, the $\widehat{C}_{grav}^{'(\infty)}$ can be obtained.

In [19] the relation between higher order holonomy corrections and spin-foams is discussed briefly. The peculiar feature of the divergence of $c_j^{(n)}$ is reminiscent to the infrared divergence in many spin-foam models[20–22], and the regularization may correspond to a nonzero cosmological constant[23]. It's reasonable to speculate that the higher order holonomy corrections comes out from the spin-foam models more naturally. The research about this issue may help us to find out the link between LQC and the spin-foam formalism.

In [24] and [25] it was shown that the j > 1/2 representations will lead to the ill-behaving spurious solutions. However, the investigation in [19] has shown that the expectation values of Dirac observables are well behaved when we consider $\hat{C}_{grav}^{'(n)}$, at least for the case $n = \infty$. The reason may be that the spurious solutions come out only in a definite j representation and suppressed when all j representations are included to match the expression $\hat{C}_{grav}^{'(n)}$. There are also signs which bolster that it may be more natural to include all j representations, although no theory suggests it in first principle.

The detailed quantum theory in Bianchi I model with j = 1/2 is also formulated in [6], but the construction of the quantum theory with higher order holonomy corrections in Bianchi I model is still an open issue. It is very probable that in the Bianchi I model the higher order holonomy corrections can also be interpreted as a result of admitting generic SU(2) representations for the Hamiltonian operator.

In [6] a semiheuristic consideration of the wellmotivated correspondence between kinematic states in LQG and LQC suggests that j = 1/2. The reason is that although the macroscopic geometry is spatially homogeneous, the microscopic is not exactly homogeneous. To achieve the best possible coarse that constitute the large scale geometry, the edges should be packed as tightly as possible. However, if we focus our attention on the precisely homogeneous Bianchi I model, the former requirement seems unnecessary. This is the question that whether the investigations for the theory of LQC are derived from LQG or within the confines of LQC. As a systematic formulation to derive LQC from LQG is still an open issue, it is logically legitimate to reduce the theory to homogeneous level first and then quantize.

The implications of the higher order holonomy corrections in the quantum level is still not conclusive, the linear superposition of generic j representations is just one possibility. This issue still requires future researches, which is not the focus of this paper. In the following we only focus upon the effective dynamics.

B. The $\bar{\mu}$ and $\bar{\mu}'$ schemes

We can see from Eq. (30) that the equation is different for different expressions of $\bar{\mu}_I$. In the isotropic case, the discreteness variable $\bar{\mu}$ has the form $\bar{\mu} \propto 1/\sqrt{p}$.

In Bianchi I model, the schemes are more ambiguous. When the anisotropy is considered, there are three p_I and three different $\bar{\mu}_I$ should be introduced. Generally speaking there are two schemes which can reduce to the the consistent isotropic case:

• $\bar{\mu}$ scheme:

$$\bar{\mu}_1 = \sqrt{\frac{\triangle}{p_1}}, \bar{\mu}_2 = \sqrt{\frac{\triangle}{p_2}}, \bar{\mu}_3 = \sqrt{\frac{\triangle}{p_3}}$$
(33)

• $\bar{\mu}'$ scheme:

$$\bar{\mu}_1' = \sqrt{\frac{\Delta p_1}{p_2 p_3}}, \ \bar{\mu}_2' = \sqrt{\frac{\Delta p_2}{p_3 p_1}}, \ \bar{\mu}_3' = \sqrt{\frac{\Delta p_3}{p_1 p_2}}.$$
 (34)

Here \triangle is the area gap in LQG. However, as will be seen the $\bar{\mu}$ scheme has the drawbacks that its effective dynamics is dependent of the choice of $\mathcal{V}[15]$. In [6] the $\bar{\mu}'$ scheme was introduced by a more systematic procedure, which is fiducial cell independent. This can be easily seen from the simplest form of Hamiltonian, Eq.(26), which corresponds to $H_{eff}^{(n=0)}$. In this form, the $\sin(\bar{\mu}_I c_I)$ is actually related to the shift operator in the full quantum theory. When $\bar{\mu}_I c_I$ changes, the volume shift corresponding to the shift operator varies. Considering $\bar{\mu}$ scheme, we have $\bar{\mu}_1 c_1 = \frac{\sqrt{\Delta}c_1}{p_1^{1/2}}$. If we choose a different fiducial volume

$$V_0 = l_1 l_2 l_3 \to V_0' = L_1 l_1 L_2 l_2 L_3 l_3 = L_1 L_2 L_3 V_0,$$

it can be seen from Eq.(3) and Eq.(4) that

$$\bar{\mu}_1 c_1 \to \bar{\mu}_1 c_1 \frac{L_1}{\sqrt{L_2 L_3}}$$

which changes its value. On the other hand, when we consider $\bar{\mu}'$ scheme with $\bar{\mu}'_1 c_1 = \frac{\sqrt{\Delta} p_1^{1/2} c_1}{(p_2 p_3)^{1/2}}$, one can verify that this problem disappears.

In addition to the problem of rescaling under shape of the fiducial cell, the $\bar{\mu}$ scheme has other problems, including the expansion and shear scalar are not bounded above as documented in[10]. This means that even when there might be solutions of 'bounce' to the effective equations of motion, there is no universal 'quantum gravity scale', which leads to the lack of resolution of the strong singularity. Nowadays all kinds of signs indicate that the $\bar{\mu}'$ scheme is much more preferable.

IV. EFFECTIVE DYNAMICS IN $\bar{\mu}$ SCHEME

In this section, we will construct the effective dynamics in $\bar{\mu}$ scheme with higher order holonomy corrections in a massless scalar field and in an arbitrary scalar field respectively.

In $\bar{\mu}$ scheme, Eq.(30) turns out to be

$$\left\{c_{I}, c_{J}^{(n)}\right\} = -\kappa \gamma \frac{1}{2p_{J}} \left[\cos\left(\bar{\mu}_{J}c_{J}\right)\mathfrak{S}_{n}\left(\bar{\mu}_{J}c_{J}\right)c_{J} - c_{J}^{(n)}\right]\delta_{IJ}.$$
(35)

In the effective dynamics we also choose the lapse function to be $N = \sqrt{p_1 p_2 p_3}$ and Eq.(29) becomes

$$\mathcal{H}_{\bar{\mu}} = -\frac{1}{\kappa \gamma^2} \left[c_2^{(n)} p_2 c_3^{(n)} p_3 + c_3^{(n)} p_3 c_1^{(n)} p_1 + c_1^{(n)} p_1 c_2^{(n)} p_2 \right] + p_1 p_2 p_3 \rho_M.$$
(36)

The equations of motion are

$$\frac{dp_1}{dt'} = \frac{1}{\gamma} \cos\left(\bar{\mu}_1 c_1\right) \mathfrak{S}_n\left(\bar{\mu}_1 c_1\right) p_1\left[c_3^{(n)} p_3 + c_2^{(n)} p_2\right], \quad (37)$$

$$\frac{dc_1}{dt'} = -\frac{1}{\gamma} \left[\frac{3}{2} c_1^{(n)} - \frac{1}{2} \cos(\bar{\mu}_1 c_1) \mathfrak{S}_n(\bar{\mu}_1 c_1) c_1 \right] \\
\times \left[p_2 c_2^{(n)} + p_3 c_3^{(n)} \right] + \kappa \gamma p_2 p_3 \left[\rho_M + p_1 \frac{\partial \rho_M}{\partial p_1} \right].$$
(38)

We also have

$$\frac{dc_1^{(n)}}{dt'} = -\frac{1}{\gamma} c_1^{(n)} \cos\left(\bar{\mu}_1 c_1\right) \mathfrak{S}_n\left(\bar{\mu}_1 c_1\right) \left(c_2^{(n)} p_2 + c_3^{(n)} p_3\right)
+ \kappa \gamma \cos(\bar{\mu}_1 c_1) \mathfrak{S}_n\left(\bar{\mu}_1 c_1\right) p_2 p_3 \left(\rho_M + p_1 \frac{\partial \rho_M}{\partial p_1}\right).$$
(39)

With Eq.(37) and Eq.(39) we can get

$$\frac{d}{dt'}\left(p_1c_1^{(n)}\right) = \kappa\gamma\mathfrak{S}_n(\bar{\mu}_1c_1)\cos(\bar{\mu}_1c_1) \\ \times p_1p_2p_3\left(\rho_M + p_1\frac{\partial\rho_M}{\partial p_1}\right). \quad (40)$$

A. for a massless scalar field

In the case of a massless scalar field, the energy density is $\rho_M = \frac{p_{\phi}^2}{2p_1p_2p_3}$. We can get

$$\frac{dp_{\phi}}{dt'} = \{p_{\phi}, \mathcal{H}_{eff}\} = 0, \qquad (41)$$

and

$$\frac{d\phi}{dt'} = \{\phi, \mathcal{H}_{eff}\} = p_{\phi}.$$
(42)

Eq.(41) means that p_{ϕ} is a constant and Eq.(42) shows that ϕ can be regarded as an emergent time. With a massless scalar field Eq.(40) has the form

$$\frac{d}{dt'}\left(p_I c_I^{(n)}\right) = 0,\tag{43}$$

which means

$$p_I c_I^{(n)} = \kappa \gamma \hbar \mathcal{K}_I \tag{44}$$

(35) where \mathcal{K}_I is a constant. Comparing Eq.(44) with Eq.(9) it can be seen that the classical connection c_I is replaced by $c_I^{(n)}$. From the constraint $\mathcal{H}_{eff} = 0$ we can get the relation

$$p_{\phi}^{2} = \frac{2}{\kappa\gamma^{2}} \left[c_{1}^{(n)} p_{1} c_{2}^{(n)} p_{2} + c_{2}^{(n)} p_{2} c_{3}^{(n)} p_{3} + c_{3}^{(n)} p_{3} c_{1}^{(n)} p_{1} \right].$$

$$(45)$$

As in the classical case, by defining $p_{\phi} = \hbar \sqrt{\kappa} \mathcal{K}_{\phi}$, we can get Eq.(11) and Eq.(14). Combining Eq. (37) and Eq. (44) yields

$$\frac{1}{p_1}\frac{dp_1}{dt'} = \kappa\hbar\cos(\bar{\mu}_1c_1)\mathfrak{S}_n(\bar{\mu}_1c_1)\left(\mathcal{K}_2 + \mathcal{K}_3\right).$$
(46)

By regarding ϕ as an emergent time, via Eq.(42) we can obtain

$$\frac{1}{p_1}\frac{dp_1}{d\phi} = \sqrt{\kappa}\cos(\bar{\mu}_1c_1)\mathfrak{S}_n(\bar{\mu}_1c_1)\frac{1-\kappa_1}{\kappa_\phi}.$$
 (47)

When $\bar{\mu}_1 c_1 \ll 1$, $\cos(\bar{\mu}_1 c_1) \to 1$, $\sin(\bar{\mu}_1 c_1) \to 0$, $\mathfrak{S}_n \to 1$ and $c_I^{(n)} \to c_I$, Eq.(37), Eq.(38) and Eq.(39) all turn out to be the classical form. On the other hand, when $\bar{\mu}_I c_I$ is significant, the quantum corrections are more and more appreciable. When $\cos(\bar{\mu}_1 c_1) = 0$ (i.e., $\bar{\mu}_1 c_1 = \pi/2$), the quantum bounce occurs. From Eq.(28) this happens when

$$c_1^{(n)}\bar{\mu}_1 = \sum_{k=0}^n \frac{(2k)!}{2^{2k} (k!)^2 (2k+1)} =: \mathfrak{F}_n, \qquad (48)$$

where $\mathfrak{F}_n \to \pi/2$ as $n \to \infty$. From Eq.(44) and Eq.(28), we can also get

$$p_1^{3/2} = \sqrt{\Delta} \frac{\kappa \gamma \hbar \mathcal{K}_1}{\sum_{k=0}^n \frac{(2k)!}{2^{2k} (k!)^2 (2k+1)} \left[\sin\left(\bar{\mu}_1 c_1\right)\right]^{2k+1}} \\ \geqslant \sqrt{\Delta} \frac{\kappa \gamma \hbar \mathcal{K}_1}{\mathfrak{F}_n}.$$
(49)

In the second step the equality holds when $\bar{\mu}_1 c_1 = \pi/2$, which is just the bounce point. One can see that the classical singularity is never approached and the bounce is robust under the inclusion of anisotropies. We can define the directional density:

$$\rho_I := \frac{p_\phi^2}{p_I^3} \tag{50}$$

for the *I*-direction and its critical value is

$$\rho_{I,crit} := \frac{p_{\phi}^2}{p_{I,bounce}^3} = \mathfrak{F}_n^2 \left(\frac{\kappa_{\phi}}{\kappa_I}\right)^2 \rho_{Pl}, \qquad (51)$$

where $\rho_{Pl} := (\kappa \gamma^2 \Delta)^{-1}$. It shows that the evolutions of p_I are decoupled in three different directions. Thus the bounces occur up to three times, whenever each of the directional density reaches its critical density, which is the same as the conventional holonomy corrected case (corresponding to n = 0 in higher order holonomy corrections). But the critical value of directional density is different from the previous case.

The mean scale factor a(t) is depicted in Fig.1(a). It demonstrates that the nonsingular bouncing scenario is robust regardless of n. The quantum bounce of a(t)occurs more abruptly as n increases, and if $n \to \infty$, the bounce takes place so abruptly that it only imprints a kink, which does not reduce to the classical form. This can be seen from Eq.(47). When $n \to \infty$, the term $\mathfrak{S} \to |\cos(\bar{\mu}_I c_I)|^{-1}$, and the product $\cos(\bar{\mu}_I c_I)\mathfrak{S}(\mu_I c_I) \to sgn(\cos(\bar{\mu}_I c_I))$. When $\bar{\mu}_I c_I = \pi/2$, the cosine function flips its sign and the big-bounce happens abruptly.

B. for an arbitrary matter field

In this section we consider the dynamics with arbitrary matter. Here we use the method provided in [8]. We can assume that the matter density is in the form

$$\rho_M = A \left(p_1 p_2 p_3 \right)^{-(1+w)/2}, \tag{52}$$

with A a constant and w the state parameter. When $a \to \infty$, the derivation in [8] has shown that the effective dynamics reduces to the classical form when -1 < w < 1. Although here we use the higher order holonomy corrections, this conclusion is still correct.

Then we consider the other limit $a \to 0$. When we consider the arbitrary matter, Eq.(43) is not satisfied, but we can still write it to be a simple form. We know that in the classical limit, $c_I^{(n)} \to c_I$, and we have Eq.(18), which leads to $p_I c_I - p_J c_J = \gamma V_0 \alpha_{IJ}$ as Eq.(19). Now for convenience we can write the integration constant $\gamma V_0 \alpha_{IJ}$ to be $\gamma V_0 \alpha_{IJ} = \kappa \gamma \hbar (\mathcal{K}_I - \mathcal{K}_J)$, where \mathcal{K}_I and \mathcal{K}_J are constants. With this, in the semiclassical regime, we can assume that

$$p_I c_I^{(n)} = \kappa \gamma \hbar \left[\mathcal{K}_I + f_I(t) \right]. \tag{53}$$

The first term is a constant introduced in the classical case and the second term is time-dependent. From Eq.(40) and the expression of ρ_M we can get

$$\frac{d}{dt'} \left(p_I c_I^{(n)} - p_J c_J^{(n)} \right)$$

$$= \kappa \gamma \frac{1 - w}{2} A \left[\mathfrak{S}_n(\bar{\mu}_I c_I) \cos(\bar{\mu}_I c_I) - \mathfrak{S}_n(\bar{\mu}_J c_J) \cos(\bar{\mu}_J c_J) \right] \left(p_1 p_2 p_3 \right)^{\frac{1 - w}{2}}.$$
(54)

One can see when $\bar{\mu}_I c_I \to 0$ the above equation reduces to Eq.(18). When $a \to 0$, we also have $p_I \to 0$. If w < 1, the above equation turns out to be $\frac{d}{dt'} \left(p_I c_I^{(n)} - p_J c_J^{(n)} \right) \approx 0$, which means that $f_I(t)$ in Eq.(53) has the same value near the bouncing point: $f_1(t) = f_2(t) = f_3(t) = f(t)$. The Hamiltonian constraint $\mathcal{H}_{eff} = 0$ with \mathcal{H}_{eff} given by Eq.(36) then yields

$$3f^{2}(t) + 2\left(\mathcal{K}_{1} + \mathcal{K}_{2} + \mathcal{K}_{3}\right)f(t) + \mathcal{K}_{2}\mathcal{K}_{3} + \mathcal{K}_{3}\mathcal{K}_{1} + \mathcal{K}_{1}\mathcal{K}_{2} = \frac{A}{\kappa\hbar^{2}}\left(p_{1}p_{2}p_{3}\right)^{\frac{1-w}{2}}.(55)$$

The time-independent part satisfies

$$\mathcal{K}_2\mathcal{K}_3 + \mathcal{K}_3\mathcal{K}_1 + \mathcal{K}_1\mathcal{K}_2 = 0, \tag{56}$$

and the time-dependent part is given by:

$$f(t) = -\frac{\mathcal{K}_1 + \mathcal{K}_2 + \mathcal{K}_3}{3} \\ \pm \frac{1}{3} \left[\left(\mathcal{K}_1 + \mathcal{K}_2 + \mathcal{K}_3 \right)^2 + \frac{3A \left(p_1 p_2 p_3 \right)^{\frac{1-w}{2}}}{\kappa \hbar^2} \right]^{1/2} \\ = -\frac{\mathcal{K}}{3} \pm \frac{1}{3} \left[\mathcal{K}^2 + \frac{3A \left(p_1 p_2 p_3 \right)^{\frac{1-w}{2}}}{\kappa \hbar^2} \right]^{1/2}.$$
(57)

In the second step we scale the constants $\mathcal{K}_I = \mathcal{K}\kappa_I$ such that Eq.(56) gives

$$\kappa_1 + \kappa_2 + \kappa_3 = 1, \kappa_1^2 + \kappa_2^2 + \kappa_3^2 = 1.$$
(58)

In Eq.(57) we can choose the + sign only without losing any generality [8]. When we discuss the bounces in the Bianchi I model, we follow [8] to separate three cases: (i) the Kasner phase, (ii) the isotropized phase, and (iii) the transition phase.

The distinction between the Kasner phase, the isotropized phase and the transition phase is due to the classical dynamics in Bianchi I model. The detailed dynamics in classical case is investigated in Appendix A of [8]. Here we just cite the conclusions in general terms. In the classical case of Bianchi I model with arbitrary matter, the evolutions of different p_I are dominated by two parts: the anisotropic part \mathcal{K} and the matter part ρ_M . If the matter part is negligible compared to the anisotropic part, the evolutions of p_I are like the Kasner solution, which is called the Kasner phase. On the other hand, if the matter part is dominant, the variation rates of different p_I are nearly the same, which is called the isotropized phase. The situation in between is called the transition phase. Here we have to note that even if in the isotropized phase, the universe is not exactly isotopic. It is just more isotropic than the Kasner phase. Only if the initial conditions of the three directions are all the same does the Bianchi I model reduce to the isotropic model. In the following we will see that in LQC the case is the same.

In case (i)(the Kasner phase), the contribution from the matter sector is negligible and the evolution is dominated by the constant \mathcal{K} . Thereby

$$f(t) \approx -\frac{\mathcal{K}}{3} + \frac{\mathcal{K}}{3} \left[1 + \frac{3A(p_1p_2p_3)^{\frac{1-w}{2}}}{2\mathcal{K}^2\kappa\hbar^2} \right]$$
$$\approx \frac{A}{2\kappa\mathcal{K}\hbar^2} (p_1p_2p_3)^{\frac{1-w}{2}}.$$
 (59)

Applying it to Eq.(53) we can get

$$p_{I}c_{I}^{(n)} \approx \kappa\gamma\hbar \left[\mathcal{K}_{I} + \frac{A}{2\kappa\mathcal{K}\hbar^{2}}(p_{1}p_{2}p_{3})^{\frac{1-w}{2}}\right]$$
$$\approx \kappa\gamma\hbar\mathcal{K}_{I}.$$
 (60)

In the second step we use the condition that $\mathcal{K}_I \gg \frac{A}{2\kappa \kappa \hbar^2} (p_1 p_2 p_3)^{\frac{1-w}{2}}$. Substituting the above equation to Eq.(37) we have

$$\frac{1}{p_1}\frac{dp_1}{dt'} \approx \kappa \hbar \cos(\bar{\mu}_1 c_1)\mathfrak{S}_n(\bar{\mu}_1 c_1)(\mathcal{K}_2 + \mathcal{K}_3).$$

In the backward evolution, the $\bar{\mu}_1 c_1$ gets more and more significant, at some point $\cos(\bar{\mu}_1 c_1) = 0$ and the big bounce occurs. Combining Eq.(28) and Eq.(60) we can get

$$p_1^{3/2} = \sqrt{\Delta} \frac{\kappa \gamma \hbar \mathcal{K}_1}{\sum_{k=0}^n \frac{(2k)!}{2^{2k} (k!)^2 (2k+1)} \left[\sin\left(\bar{\mu}_1 c_1\right)\right]^{2k+1}} \\ \geqslant \sqrt{\Delta} \frac{\kappa \gamma \hbar \mathcal{K}_1}{\mathfrak{F}_n}.$$
(61)

In the second step the equality holds at the bouncing point, which is the same as the massless scalar field. As a result the critical value of p_I is

$$p_{I,crit} = \left[\sqrt{\bigtriangleup} \frac{\kappa \gamma \hbar \mathcal{K}_1}{\mathfrak{F}_n}\right]^{2/3}.$$
 (62)

We can also define the directional density ρ_I as

$$\rho_I := \frac{\kappa \hbar^2 \mathcal{K}_I^2}{3 p_I^3},\tag{63}$$

with the expression of ρ_I we can say that the big bounces take place whenever each of the directional density reaches the critical value

$$\rho_{I,crit} = \frac{1}{3} \mathfrak{F}_n^2 (\kappa \gamma^2 \triangle)^{-1} \sim \rho_{pl}.$$
 (64)

Plugging $p_{I,crit}$ to the condition $\mathcal{K}_I \gg \frac{A}{2\kappa\mathcal{K}\hbar^2}(p_1p_2p_3)^{\frac{1-w}{2}}$ it can be found that for case (i) the constant A has to satisfy

$$A \ll \mathfrak{F}_n^{1-w} \frac{|\kappa_I| \gamma^{w-1}}{|\kappa_1 \kappa_2 \kappa_3|^{(1-w)}} \mathcal{K}^{1+w} \kappa^w \hbar^{1+w} \triangle^{\frac{w-1}{2}}.$$
(65)

Now we consider case (ii)(the isotropized phase), where the matter sector dominates and the universe is isotropized. In this case Eq.(57) turns out to be

$$f(t) \approx \sqrt{\frac{A}{3\kappa\hbar^2}} (p_1 p_2 p_3)^{\frac{1-w}{4}}.$$
 (66)

Then Eq.(53) becomes

$$p_I c_I^{(n)} \approx \gamma \sqrt{\frac{\kappa A}{3}} (p_1 p_2 p_3)^{\frac{1-w}{4}}, \qquad (67)$$

where we use the condition $\mathcal{K}_I \ll \frac{A}{2\kappa \mathcal{K}\hbar^2} (p_1 p_2 p_3)^{\frac{1-w}{2}}$. From Eq.(37) we can get

$$\frac{1}{p_1}\frac{dp_1}{dt'} \approx 2\sqrt{\frac{\kappa A}{3}}\cos(\bar{\mu}_1 c_1)\mathfrak{S}(\bar{\mu}_1 c_1)(p_1 p_2 p_3)^{\frac{1-w}{4}}.$$
 (68)

We can see that once again when $\cos(\bar{\mu}_1 c_1) = 0$, the bounce occurs. Applying Eq.(28) to Eq.(67) we have

$$p_{1,crit}^{3/2} = \frac{\gamma}{\mathfrak{F}_n} \sqrt{\frac{\kappa A \triangle}{3}} (p_{1,crit} p_2 p_3)^{\frac{1-w}{4}}.$$
 (69)

It can be seen that the critical value of p_I is coupled with other directions. If we assume in the isotropized case the bouncing points in different directions are roughly at only slightly different moments, we can get the approximated critical value for different p_I :

$$p_{crit} = \left[\frac{\kappa A \triangle \gamma^2}{3\mathfrak{F}_n^2}\right]^{\frac{2}{3+3w}}.$$
 (70)

This means that the critical density of the bouncing point is

$$\rho_{crit} = A p_{crit}^{-3(1+w)/2} = 3\mathfrak{F}_n^2 (\kappa \Delta \gamma^2)^{-1} \sim \rho_{pl}.$$
 (71)

And in this case the criterion is

$$A \gg \gamma^{w-1} \mathcal{K}^{1+w} \kappa_I^{\frac{1+w}{2}} \hbar^{1+w} \kappa^w \triangle^{\frac{w-1}{2}} \mathfrak{F}_n^{1-w}.$$
(72)

Finally, we turn to case (iii)(the transition phase). We can see that the order of magnitude of the right hand side of Eq.(65) and Eq.(72) is nearly the same. So in the transition phase, the criterion is also between the one in the two phases:

$$A \sim \gamma^{w-1} \mathcal{K}^{1+w} \kappa_I^{\frac{1+w}{2}} \hbar^{1+w} \kappa^w \triangle^{\frac{w-1}{2}} \mathfrak{F}_n^{1-w}, \qquad (73)$$

and the bouncing points of p_I is between the critical value of p_I given in Eq.(62) and Eq.(70).

The mean scale factor a(t) of the three cases with w = 1/3 (radiation field) in $\bar{\mu}$ scheme is depicted in Fig.1(b),(c), and (d). In each case the singularity is replaced by the big bounce regardless of the order of holonomy corrections. As the matter contribution is more and more dominant, the difference of the evolution with different holonomy orders is more and more inconspicuous.

In [10] it was shown that in the $\bar{\mu}$ scheme the critical value of energy density fails to have an upper bound. This can be seen as follows. In the traditional holonomy corrections, it was derived that the energy density has the form $\rho_M = \frac{1}{\kappa \gamma^2 \bigtriangleup} \left(\frac{\sqrt{p_1 p_2}}{p_3} \sin(\bar{\mu}_1 c_1) \sin(\bar{\mu}_2 c_2) + cyclic terms\right)$. As the prefactors such as $\frac{\sqrt{p_1 p_2}}{p_3}$ are not bounded, ρ_M are not bounded above. In this paper our analysis is consistent with this conclusion. Although the p_I has the lower bound Eq.(62), it has no upper bound. As a result the factor $\frac{\sqrt{p_1p_2}}{p_3}$ can diverge when $p_2 \to \infty$ or $p_3 \to \infty$. The numerical simulations in Fig.1 shows the solutions of the bounce, but the bounce is not generic.

FIG. 1: Mean scale factor a(t) in $\bar{\mu}$ scheme corresponding to different orders of holonomy corrections. (a) for a massless scalar field with $\kappa_1 = -1/4$, $\kappa_2 = 3/4$, $\kappa_3 = 1/2$, and $\kappa_{\phi} = 1/\sqrt{8}$, $p_1(0) = p_2(0) = p_3(0) = 10^4 l_{pl}$, and $p_{\phi} = 2 \times 10^3 \hbar \sqrt{\pi G}$. (b),(c), and (d) all for the radiation field with w = 1/3, $\kappa_1 = -2/7$, $\kappa_2 = 3/7$, $\kappa_3 = 6/7$, and $\mathcal{K} = 1 \times 10^3$; (b) Kasner phase: $A = 0.1\hbar l_{pl}^2$, $p_1(0) = 3 \times 10^4 l_{pl}$, $p_2(0) = 2 \times 10^4 l_{pl}$, and $p_3(0) = 1 \times 10^4 l_{pl}$. (c) Isotropized phase: $A = 10^4 \hbar l_{pl}^2$, $p_1(0) = 9 \times 10^4 l_{pl}$, $p_2(0) = 6 \times 10^4 l_{pl}$, and $p_3(0) = 3 \times 10^4 l_{pl}$. (d)Transition phase: $A = 10^2 \hbar l_{pl}^2$, $p_1(0) = 3 \times 10^4 l_{pl}$, $p_2(0) = 2 \times 10^4 l_{pl}$, and $p_3(0) = 1 \times 10^4 l_{pl}$.

v. EFFECTIVE DYNAMICS IN $\bar{\mu}'$ SCHEME

 $(p_1p_2p_3)^{1/2}dt$. We also define a new variable

$$b_I^{(n)} = \bar{\mu}_I' c_I^{(n)}. \tag{74}$$

From the canonical relations we can get

$$\left\{ c_I, b_J^{(n)} \right\} = \kappa \gamma \frac{\bar{\mu}'_J}{2p_I} \mathfrak{S}_n \left(\bar{\mu}'_J c_J \right) \cos \left(\bar{\mu}'_J c_J \right) c_J$$

$$for \quad I = J,$$

$$(75)$$

$$\left\{ c_I, b_J^{(n)} \right\} = -\kappa \gamma \frac{\bar{\mu}'_J}{2p_I} \mathfrak{S}_n \left(\bar{\mu}'_J c_J \right) \cos \left(\bar{\mu}'_J c_J \right) c_J,$$

for $I \neq J$ (76)

In this section we consider an alternative quantization scheme called $\bar{\mu}'$ scheme. Previous works about $\bar{\mu}'$ scheme focus on a massless scalar field as it is difficult to get the analytical solution with arbitrary matter. Here we extend the effective dynamics to arbitrary matter. The method used here is exactly the same as the $\bar{\mu}$ scheme and to avoid repetition we does not introduce it again in detail. As it has no difference from the arbitrary matter case, we won't discuss the massless scalar field separately.

For simplicity, we choose the lapse function N = $1/\sqrt{p_1p_2p_3}$ and introduce a new time variable dt'' =

$$\left\{p_I, b_J^{(n)}\right\} = -\kappa \gamma \bar{\mu}'_J \mathfrak{S}_n\left(\bar{\mu}'_J c_J\right) \cos\left(\bar{\mu}'_J c_J\right) \delta_{IJ}.$$
 (77)

The Hamiltonian can be written as

$$\mathcal{H}_{\bar{\mu}'} = -\frac{1}{\kappa \gamma^2 \triangle} \left[b_1^{(n)} b_2^{(n)} + b_2^{(n)} b_3^{(n)} + b_3^{(n)} b_1^{(n)} \right] + \rho_M.$$
(78)

The equations of motion are

$$\frac{dc_{1}}{dt''} = -\frac{\mathfrak{S}_{n}(\bar{\mu}_{1}'c_{1})\cos(\bar{\mu}_{1}'c_{1})\bar{\mu}_{1}'c_{1}\left[b_{2}^{(n)}+b_{3}^{(n)}\right]}{2\gamma\Delta p_{1}} + \frac{\mathfrak{S}_{n}(\bar{\mu}_{2}'c_{2})\cos(\bar{\mu}_{2}'c_{2})\bar{\mu}_{2}'c_{2}\left[b_{3}^{(n)}+b_{1}^{(n)}\right]}{2\gamma\Delta p_{1}} + \frac{\mathfrak{S}_{n}(\bar{\mu}_{3}'c_{3})\cos(\bar{\mu}_{3}'c_{3})\bar{\mu}_{3}'c_{3}\left[b_{1}^{(n)}+b_{2}^{(n)}\right]}{2\gamma\Delta p_{1}} + \kappa\gamma\frac{\partial\rho_{M}}{\partial p_{1}},$$
(79)

$$\frac{dp_1}{dt''} = \frac{\mathfrak{S}_n(\bar{\mu}_1'c_1)\cos(\bar{\mu}_1'c_1)\bar{\mu}_1'(b_2^{(n)} + b_3^{(n)})}{\gamma\Delta}.$$
 (80)

Combining Eq.(79) and Eq.(80) we can get

$$\frac{d}{dt''}\left(p_Ic_I - p_Jc_J\right) = 0\tag{81}$$

In the above equation we used the assumption that the matter has zero anisotropy as in Sec.II B. As in the classical theory, $p_I c_I - p_J c_J$ is a constant. However, unlike the classical case Eq.(4) is no longer satisfied. From Eq.(80) we can get the relation

$$\frac{1}{p_1}\frac{dp_1}{dt''} = \frac{1}{\gamma\sqrt{\Delta p_1 p_2 p_3}}\mathfrak{S}_n(\bar{\mu}_1'c_1)\cos(\bar{\mu}_1'c_1)\left[b_2^{(n)} + b_3^{(n)}\right].$$
(82)

The above equation has shown that as in the $\bar{\mu}$ case, when $\cos(\bar{\mu}'_1c_1) = 0$ the big bounce occurs. Now we investigate the bouncing regime. From Eq.(81), we can assume the relation

$$p_I c_I = \kappa \gamma \hbar \left[\mathcal{K}_I + f(t) \right]. \tag{83}$$

Note that in this equation the time-dependent part is the same for all of $p_I c_I$, which is different from the $\bar{\mu}$ case. The energy density is also assumed to be Eq.(52). Following the same derivation as in Sec.IV A we can get Eq.(56), Eq.(57) and Eq.(58). Here we also consider three cases separately.

(i) The Kasner phase:

In this phase Eq.(59) holds and we have

$$p_I c_I \approx \kappa \gamma \hbar \mathcal{K}_I.$$
 (84)

At the bouncing point, $\cos(\bar{\mu}'_I c_I) = 0$, which corresponds to $\bar{\mu}'_I c_I = \pi/2$. Applying this equation to Eq.(84) we can get the criterion of the bouncing point of p_I :

$$\sqrt{p_1 p_2 p_3} = \frac{2}{\pi} \kappa \gamma \hbar \sqrt{\Delta} \mathcal{K}_I. \tag{85}$$

The critical energy density at this point is

$$\rho_{crit,I} = A \left[\frac{2}{\pi} \kappa \gamma \hbar \sqrt{\Delta} \mathcal{K}_I \right]^{-(1+w)}.$$
 (86)

As in the $\bar{\mu}$ case, the criterion for the Kasner case is also $\mathcal{K}_I \gg \frac{A}{\mathcal{K}\kappa\hbar^2} (p_1p_2p_3)^{\frac{1-w}{2}}$. Applying the critical value of $\sqrt{p_1p_2p_3}$ to this condition we can get

$$A \ll (2/\pi)^{w-1} \kappa^w \gamma^{w-1} \mathcal{K}^{w+1} \kappa_I^w \hbar^{w+1} \triangle^{\frac{w-1}{2}}.$$
 (87)

Applying it to Eq.(86) we have

$$\rho_{M,crit} \ll \left(\frac{\pi}{2}\right)^2 \kappa_I^{-1} \rho_{pl}.$$
(88)

(ii) The isotropized phase:

In this case, Eq.(66) holds and we have

$$p_I c_I = \gamma \sqrt{\frac{\kappa A}{3}} \left(p_1 p_2 p_3 \right)^{\frac{1-w}{4}}.$$
 (89)

Applying the bouncing condition $\cos(\bar{\mu}'_I c_I) = 0$ as in the Kasner phase we can get

$$\sqrt{p_1 p_2 p_3} = \left(\frac{\pi}{2}\right)^{\frac{2}{1+w}} \left(\frac{\gamma^2 \kappa A \triangle}{3}\right)^{\frac{1}{1+w}}.$$
 (90)

One can see that for different p_I the condition at the bouncing point is the same, which means that all p_I at three directions bounce at the same time. The criterion for this case is

$$A \gg (2/\pi)^{w-1} \kappa^{w} \gamma^{w-1} \mathcal{K}^{w+1} \kappa_I^{(1+w)/2} \hbar^{w+1} \triangle^{\frac{w-1}{2}}.$$
 (91)

The critical value of energy density is

$$\rho_{crit} = \left(\frac{\pi}{2}\right)^2 \left(\gamma^2 \frac{\kappa \Delta}{3}\right)^{-1} = 3 \left(\frac{\pi}{2}\right)^2 \rho_{Pl} \sim 10 \rho_{pl}.$$
 (92)

(iii) The transition phase:

Here $A \sim (2/\pi)^{w-1} \kappa^w \gamma^{w-1} \mathcal{K}^{w+1} \kappa_I^{(1+w)/2} \hbar^{w+1} \Delta^{(w-1)/2}$ and the critical value of energy density is between the one got in Eq.(88) and Eq.(92).

The numerical solutions of mean scale factor a(t) is depicted in Fig.2. The singularity is never approached and the big bounce of a(t) occurs at any case. As the order of holonomy corrections increases, the big bounce takes place more and more abruptly.

In previous investigations about the $\bar{\mu}'$ scheme, it was shown that there is a generic strong singularity resolution[10–12, 14]. Here we can extend the conclusion to the case of higher order holonomy corrections. The vanishing of the Hamiltonian constraint Eq.(78) leads to the expression of the energy density:

$$\rho_M = \frac{1}{\kappa \gamma^2 \Delta} \left[b_1^{(n)} b_2^{(n)} + b_2^{(n)} b_3^{(n)} + b_3^{(n)} b_1^{(n)} \right]$$
(93)

Since the $b_I^{(n)}$ in the parenthesis are all bounded functions, the maximum value of the energy density is

$$\rho_{max} = \frac{3\mathfrak{F}_n^2}{\kappa\gamma^2 \Delta} \tag{94}$$

where the \mathfrak{F}_n is defined in Eq.(48). When $n \to \infty$, the

(a) for a massless scalar field case with $\kappa_1 = -1/4$, $\kappa_2 = 3/4$, $\kappa_3 = 1/2$, $\kappa_{\phi} = 1/\sqrt{8}$, $p_1(0) = p_2(0) = p_3(0)10^4 l_{pl}$, and $p_{\phi} = 2 \times 10^3 \hbar \sqrt{\pi G}$. (b), (c), and (d) all for the radiation field with $w = 1/3, \kappa_1 = -2/7, \kappa_2 = 3/7, \kappa_3 = 6/7; \mathcal{K} = 1 \times 10^3$; (b)Kasner phase. With $A = 0.1 \hbar l_{pl}^2$; $p_1(0) = 3 \times 10^4 l_{pl}$, $p_2(0) = 2 \times 10^4 l_{pl}$, $p_3(0) = 1 \times 10^4 l_{pl}$. (c)Isotropized phase. With $A = 10^4 \hbar l_{pl}^2$; $p_1(0) = 9 \times 10^4 l_{pl}$, $p_2(0) = 6 \times 10^4 l_{pl}$, $p_3(0) = 3 \times 10^4 l_{pl}$. (d)Transition phase. With $A = 10^2 \hbar l_{pl}^2$; and $p_1(0) = 3 \times 10^4 l_{pl}$, $p_2(0) = 2 \times 10^4 l_{pl}$, $p_3(0) = 1 \times 10^4 l_{pl}$.

In [6],[8] and [9], it was shown that in the $\bar{\mu}'$ scheme there is no directional dependence on the critical energy density, which seems contrary to our conclusions in this section, at least at the Kasner phase. This problem comes from the confusing definition of the critical energy density. If we define it to be the critical value at the bouncing point of the whole volume(corresponding to the bouncing point of *a* defined in Eq.(20)), it is indeed directional independent. On the other hand, if we define the critical energy density to be the value at the bouncing point of directional Hubble parameter H_I , it is directional dependent. In general, in the Bianchi I model, there are

three bounces of different directions, which occur at distinct times. The criterion of bounce of a definite directional p_I is Eq.(86), but this is not the bouncing point of the whole volume. As a simplest example, supposing $\rho_{crit,1} < \rho_{crit,2} < \rho_{crit,3}$, when the whole energy density reaches $\rho_{crit,1}$, the p_1 bounces, but p_2 and p_3 are still contracting, which is still leading to the contraction of the whole volume. Similarly, when $\rho = \rho_{crit,2}$, the p_2 bounces, but the whole volume is still contracting with p_3 . Only at the bouncing point of p_3 does the whole volume bounce, namely in this case the critical energy density of the whole volume is just $\rho_{crit,3}$. Eq.(86) shows

 $\rho_{max} \rightarrow \frac{3\pi^2}{4\kappa\gamma^2\Delta}$. For different *n* the specific value of ρ_{max}

is different but still finite. The ρ_{max} is the largest value of energy density in theory, but the real evolution of the

universe may not attain it.

that the magnitude of the critical energy densities of different p_I are dominated by \mathcal{K}_I , which are the integration constants that only relate to the initial conditions.

In [9], the critical energy densities of three directions are nearly the same, but the result is under the isotropic approximation which corresponds to our 'isotropized phase'. In that paper it is also approved that when the solution is far from isotropic and the approximation is violated, the matter density is still the indication of the bounce occurrence, with the critical value quite different from each other. Fig.2 actually depicts the bounce of the whole volume.

In fact, the case that the whole volume bounces at the point $\rho_{bounce} = \rho_{crit,3}$ as described above is the simplest situation. Comparing the value of ρ_{bounce} to the three values of $\rho_{crit,I}$ can lead to an insight about an interesting phenomena called the 'Kasner transition' as investigated in [12]. Generally speaking, the Kasner transition is to describe the transition of the geometry structure of space before and after the big bounce of the whole volume. For example, in the pre-bounce phase when all the three scale factors a_I contracting or in the post-bounce phase all three a_I expanding, it's called the point like structure, as the evolution forward in time in the prebounce phase or backward in the post-bounce phase will structure a point singularity in classical dynamics. Another structure is called cigar like when a_1 expanding but a_2 and a_3 contracting in the pre-bounce phase or a_1 contracting but a_2 and a_3 expanding in the post-bounce phase as the physical evolution forward in time in the prebounce or backward in the post-bounce phase will lead to an infinite cigar like sigularity in classical dynamics.

With the analytical investigations provided in this section, the Kasner transition described in [12] can be interpreted as follows. Supposing $\rho_{crit,1} < \rho_{crit,2} < \rho_{crit,3}$ in the point like structure of pre-bounce phase, if the bouncing point of the whole volume is at $\rho_{bounce} = \rho_{crit,3}$ as described above, after the bounce all three a_I expanding, which is also the point like structure. This is the so-called point-point transition. If in the pre-bounce phase the structure is cigar like, one can verify that the bouncing point at $\rho_{bounce} = \rho_{crit,3}$ can also lead to the cigar-cigar transition.

The same as before, supposing $\rho_{crit,1} < \rho_{crit,2} < \rho_{crit,3}$ in the point like structure of pre-bounce phase, but this time the bouncing point is at $\rho_{crit,1} < \rho_{bounce} < \rho_{crit,2}$. After the bounce, the p_1 increases but p_2 and p_3 still decrease. After the bounce, the scale factor $a_2 = \frac{\sqrt{p_1 p_2 p_3}}{p_2}$ and $a_3 = \frac{\sqrt{p_1 p_2 p_3}}{p_3}$ expanding as the denominator decrease but the molecular increase. The only contracting scale factor is a_1 as $a_1 \propto \frac{p_2}{a_3}$, which leads to the cigar like structure. This is the so-called point-cigar transition, which means that the spatial structures before and after the bounce are not the same. In this case, the $\rho_{crit,2}$ and $\rho_{crit,3}$ are never attained as after the bounce the energy desity will decrease. But this does not mean the physical evolution would lead to a piece like structure. In [13] it was shown that in the cigar like structure of post-bounce phase the inflation model can lead the contracting direction to undergo a turn around in the forward evolution. But this procedure is not due to quantum bounce.

VI. ANISOTROPY

In Bianchi I model the anisotropy is included. Here we use the shear parameter Σ to describe the anisotropy.

In classical case, the anisotropy is discussed in Sec. II B. We can see from Eq.(23) that in this case the shear parameter is a constant, which does not vary when the universe evolves. However, Eq.(24) shows that when the singularity is reached, the shear scalar blows up as a approaches 0.

In the effective dynamics with higher order holonomy corrections, the shear parameter Σ is

$$\Sigma^{2} = \frac{a^{6}}{18} \left[(H_{1} - H_{2})^{2} + (H_{2} - H_{3})^{2} + (H_{3} - H_{1})^{2} \right]$$
(95)

From Eq.(3) we have

$$a_1 = \frac{1}{l_1} \left(\frac{p_2 p_3}{p_1}\right)^{\frac{1}{2}} \tag{96}$$

and its cyclic permutations. As a result

$$H_1 = \frac{\dot{a_1}}{a_1} = -\frac{\dot{p_1}}{2p_1} + \frac{\dot{p_2}}{2p_2} + \frac{\dot{p_3}}{2p_3} \tag{97}$$

Here the \dot{a} is the derivative of a with cosmic time t which have the lapse function N = 1. From the definition of the Hamiltonian Eq.(29) we can see when N = 1 we have

$$\mathcal{H}_{eff} = -\frac{1}{\kappa \gamma^2 \sqrt{p_1 p_2 p_3}} \left[c_1^{(n)} p_1 c_2^{(n)} p_2 + c_2^{(n)} p_2 c_3^{(n)} p_3 + c_3^{(n)} p_3 c_1^{(n)} p_1 \right] + \sqrt{p_1 p_2 p_3} \rho_M.$$
(98)

As a result

$$\dot{p_1} = -\kappa \gamma \frac{\partial \mathcal{H}_{eff}}{\partial c_1} \\ = \frac{1}{\sqrt{p_1 p_2 p_3}} \frac{1}{\gamma} \cos(\bar{\mu}_1 c_1) \mathfrak{S}(\bar{\mu}_1 c_1) p_1 \left(c_2^{(n)} p_2 + c_3^{(n)} p_3 \right)$$
(99)

Applying Eq.(99) to Eq.(97) and then substitute the re-

sult to Eq.(95) we can get the following result:

$$\Sigma^{2} = \frac{1}{6\gamma^{2}} \left\{ \left[\cos(\bar{\mu}_{2}c_{2})\mathfrak{S}_{n}(\bar{\mu}_{2}c_{2}) \left(p_{1}c_{1}^{(n)} + p_{3}c_{3}^{(n)} \right) \right]^{2} \\ - \cos(\bar{\mu}_{1}c_{1})\mathfrak{S}_{n}(\bar{\mu}_{1}c_{1}) \left(p_{2}c_{2}^{(n)} + p_{3}c_{3}^{(n)} \right) \right]^{2} \\ + \left[\cos(\bar{\mu}_{3}c_{3})\mathfrak{S}_{n}(\bar{\mu}_{3}c_{3}) \left(p_{1}c_{1}^{(n)} + p_{2}c_{2}^{(n)} \right) \right]^{2} \\ - \cos(\bar{\mu}_{2}c_{2})\mathfrak{S}_{n}(\bar{\mu}_{2}c_{2}) \left(p_{3}c_{3}^{(n)} + p_{1}c_{1}^{(n)} \right) \right]^{2} \\ + \left[\cos(\bar{\mu}_{1}c_{1})\mathfrak{S}_{n}(\bar{\mu}_{1}c_{1}) \left(p_{2}c_{2}^{(n)} + p_{3}c_{3}^{(n)} \right) \right]^{2} \\ - \cos(\bar{\mu}_{3}c_{3})\mathfrak{S}_{n}(\bar{\mu}_{3}c_{3}) \left(p_{1}c_{1}^{(n)} + p_{2}c_{2}^{(n)} \right) \right]^{2} \right\}.$$

$$(100)$$

Contrary to the classical case, the shear is not a constant because of the holonomy corrections. Besides that, different orders of holonomy corrections correspond to different values of shear. In the classical regime, $\bar{\mu}_I c_I \to 0$, which means $\cos(\bar{\mu}_I c_I) = 1$, $\mathfrak{S}_n(\bar{\mu}_I c_I) = 1$ and $c_I^{(n)} \to c_I$, the shear parameter turns out to be

$$\Sigma^{2} = \frac{1}{6\gamma^{2}} \left[\left(p_{1}c_{1} - p_{2}c_{2} \right)^{2} + \left(p_{2}c_{2} - p_{3}c_{3} \right)^{2} + \left(p_{3}c_{3} - p_{1}c_{1} \right)^{2} \right], \qquad (101)$$

which goes back to the classical form.

A. Anisotropy in $\bar{\mu}$ scheme

In $\bar{\mu}$ scheme with a massless scalar field, when we consider the pre-bounce classical regime, the shear parameter turns out to be

$$\Sigma^{2} = \frac{\kappa^{2}\hbar^{2}}{6} \left[(\mathcal{K}_{1} - \mathcal{K}_{2})^{2} + (\mathcal{K}_{2} - \mathcal{K}_{3})^{2} + (\mathcal{K}_{3} - \mathcal{K}_{1})^{2} \right]$$
(102)

which is a constant. At the bouncing regime, although the shear parameter changes its value, the $p_I c_I^{(n)}$ keeps its constant value through the bounce. After the bounce occurs and the classical behavior is recovered, the constant $p_I c_I^{(n)}$ is the same as the pre-bounce value. So we can conclude that the shear does not change its value after the bounce. The shear for massless scalar field is depicted in Fig.3(a). One can see the shear parameter in the pre-bounce and post-bounce regime is the same. As n increases, the shear parameter also changes more abruptly.

In the Kasner phase, the shear parameter is also given by Eq.(100). In the pre-bounce classical case, the shear is in the form of Eq.(102). During the bouncing regime, although Σ varies as $\bar{\mu}_I c_I$ gets more and more significant, the $p_I c_I^{(n)} \approx \mathcal{K}_I$, which is nearly a constant. When the evolution approaches the classical regime again, its value comes back to Eq.(102). As a result, we can conclude that in the Kasner phase, we have $\Sigma^2(post \ bounce) \approx$ $\Sigma^2(pre \ bounce)$.

Now we discuss the shear in the isotropized case. In this case, the expression is also Eq.(100). However, we can see from Eq.(67) that the $p_I c_I^{(n)} \approx \gamma \sqrt{\frac{\kappa A}{3}} (p_1 p_2 p_3)^{(1-w)/4}$, which can not keep its value as a constant as p_I varies. So in general the shear parameter Σ is not the same in the post-bounce and pre-bounce regimes as the information of anisotropy is smeared.

The shear parameter with arbitrary matter in $\bar{\mu}$ scheme is depicted in Fig.3(b). It shows that when the order of holonomy corrections increases, the variation of the shear value between post-bounce and pre-bounce regimes gets more and more smaller. When $n \to \infty$, we have $\Sigma^2(post \ bounce) = \Sigma^2((pre \ bounce))$.

We have to note the case where the order of holonomy corrections $n = \infty$. In this case, $c_I^{(n)} = c_I$, $\mathfrak{S}_n(\bar{\mu}_I c_I) =$ $1/|\cos(\mu_I c_I)|$, one may have the idea that the quantum form of shear parameter Σ turns out to be the classical form ,which may mean that the shear parameter Σ is a constant not only in the classical regime but also in the bouncing regime. However, Fig.3(a) shows that it's not the case. The reason is that different p_I bounce at different moments, as a result different $\cos(\bar{\mu}_I c_I)$ flip signs at different time. From Eq.(100) one can see that if $\cos(\mu_I c_I)$ have different signs, the form of Σ can't reduce to the classical form. So even in the case where $n = \infty$ the shear parameter does vary its value at the bouncing regime, although the change is abrupt.

B. Anisotropy in $\bar{\mu}'$ Scheme

At last we discuss the shear in the $\bar{\mu}'$ scheme. The expression of the shear Σ^2 is also Eq.(100). In the classical regime, it reduces to Eq.(101). From Eq.(81) we know that $p_I c_I - p_J c_J$ is a constant all around the evolution process, including the bouncing regime. As a result, the shear is the same in the pre-bounce classical regime and the post-bounce classical regime in any case.

The shear parameter with a massless scalar field and arbitrary matter is depicted in Fig.3(c) and Fig.3(d). We can see the value of pre-bounce regime is the same as post-bounce regime, regardless of the order of holonomy corrections. When $n \to \infty$, the shear does change its value in the bouncing regime as the $\bar{\mu}$ scheme.

FIG. 3: Shear term in $\bar{\mu}$ and $\bar{\mu}'$ schemes for different orders of holonomy corrections. (a)Massless scalar field in $\bar{\mu}$ scheme. (b)Arbitrary matter in $\bar{\mu}$ scheme. (c)Massless scalar field in $\bar{\mu}'$ scheme. (c)Arbitrary matter in $\bar{\mu}'$ scheme.

VII. SUMMARY AND CONCLUSIONS

In this paper we investigate the Bianchi I model in LQC with higher order holonomy corrections in the heuristic effective level.

The focus of this paper is to construct the effective dynamics with higher order holonomy corrections in the form of $\bar{\mu}'$ scheme. In this scheme, due to the mathematical complexity most of previous investigations have focused on the numerical simulations. Here we try to study this scheme with analytical method. To compare with the $\bar{\mu}'$ scheme and the earlier works in Bianchi I model we also investigate the $\bar{\mu}$ scheme, respectively. The $\bar{\mu}$ scheme has been proven to be a problematic scheme as it's fiducial cell dependent and fails to solve the strong singularity. Here we find that in this scheme with higher order holonomy corrections, we can really find out the solutions of the big bounce, but even so the energy density has no generic upper bound, which means in the $\bar{\mu}$ scheme the strong singularity is not resolved. Contrary to this, in the $\bar{\mu}'$ scheme the strong singularity is never reached and the big bounce is robust regardless of the order of the holonomy corrections, even when the order is ∞ , which is consistent with the recent investigations [10– 12, 14].

Besides that, we also find out some detailed difference in the two schemes. In the case of $\bar{\mu}$ scheme with a massless scalar field and with an arbitrary matter field in the Kasner phase, different p_I bounce at different time, and the critical values of p_I can be found out. We use the directional density ρ_I to describe the bounces. When a directional density ρ_I reaches its critical value, the p_I bounces. In $\bar{\mu}$ scheme with isotropized phase, the three directions of p_I bounce roughly at the same time. When the energy density reaches the critical value the bounces occur at all three directions. When the higher order holonomy corrections are considered, the critical value is given by the one in the conventional case times a numerical factor \mathfrak{F} . For different orders of holonomy corrections the numerical factor is also different.

Different from the $\bar{\mu}$ scheme, we find that in the $\bar{\mu}'$ scheme the critical values of p_I are not clear but we can find out the critical energy densities, and if the energy density reaches one of the critical values a bounce happens. In the Kasner phase different directions correspond to different critical densities while for the isotropized phase all three directions have the same critical density and the bounces happen at the same time. We also find that in the Kasner case the critical energy densities are far less than the Planck density. In the isotropized case the value approaches the Planck density, which is the same as the result in [9]. Besides that, it is shown that the critical densities are not depend on the order of holonomy corrections, which is different from the $\bar{\mu}$ scheme.

In the $\bar{\mu}'$ scheme we also find out an interesting phenomena that given the criterion of the three directions of $p_I(\text{Eq.}(86))$, weather the physical evolution can attain all of them dominates the spatial structure after the big bounce. This leads to the so-called 'Kasner transition' as investigated in [12]. We find that when the largest value of the three critical energy density can be attained, the point-point transition or cigar-cigar transition comes into being. When just the minimum of the three critical energy densities can be attained, the point-cigar transition can be formed. In [12], with the numerical simulations it was found that the Kasner transition follows selection rules which are determined by the initial relative strenth of the matter and anisotropy. In this paper we just attempt to interpret it analytically and this is not the focus of this paper. Our following works would be investigating this issue systematically in the analytical method and find out the exact condition for every Kasner transition case and compare with the numerical simulations.

We use the shear parameter Σ to describe the anisotropy. In the classical case, the shear parameter is a constant. In the semiclassical regime the shear parameter is not a constant, which is a kind of quantum effects. In the $\bar{\mu}$ scheme under the condition that the order of holonomy corrections is finite, generically the shear parameter can not keep its constant value before and after the bounce unless at the massless scalar field case. Contrary to the $\bar{\mu}$ scheme, in the $\bar{\mu}'$ scheme the shear parameter can hold its value in classical regimes before and after the bounce in all cases. When we consider the case where $n = \infty$, the shear parameter does change its value in the bouncing regime, which indicates that the variation of the shear parameter is a real quantum effect which does not depend on the artificial choice of the order of the holonomy corrections.

It's interesting when the order of holonomy corrections approaches ∞ . In this case, the expression of the moving equations turn out to be the classical form, even in the bouncing regime, but the dynamics is not the same as the classical case. The reason is shown in Sec.III that the power series $c_I^{(\infty)}$ gives back to c_I only when $-\pi/2 \leq \bar{\mu}_I c_I \leq \pi/2$, and out of this regime $c_I^{(n)}$ does not equal to c_I . When $n \to \infty$, in the contracting phase before bounce, the directional Hubble parameter H_I never gets to be 0, at the bouncing point the H_I changes its sign abruptly and the p_I transforms from the contracting phase to the expanding phase. In other words, the Hubble parameter is discontinuous at this point. This is the picture of motion in the semiclassical level, which is different from previous investigations. Surely we know that at the bouncing point the semiclassical dynamics is only an approximation, this picture is closer to the quantum picture than before.

It is worth noting that we can have $c_I^{(n)} \to c_I$ no matter when $\bar{\mu}_I \to 0$ or $n \to \infty$, but the two cases are not the same. The first reduces the dynamics to the classical case while the second one has a kink at the bounce point $\bar{\mu}_I c_I = \pi/2$.

The method of higher order holonomy corrections is a promising approach. In fact, some other problems may be solved when the order of holonomy corrections approaches ∞ , i.e. the anomaly free problem in the perturbation theory of LQC [27–30]. The previous solution is to add counter terms to the Hamiltonian to eliminate the anomaly terms, but when we consider the infinite orders of holonomy corrections the anomaly terms disappear spontaneously. Whether there are other qualitative changes when all orders of holonomy corrections are considered still requires future investigations.

Now it seems that at the effective level the order of the holonomy corrections can vary from 0 to ∞ and the definite value of n is not clear. In [19] the quantum approach is constructed in homogeneous and isotropic cosmology, which shows that the higher order holonomy corrections is related to the j ambigurity. In Bianchi I model, what is the definite meaning of higher order holonomy corrections has not been thoroughly studied and we can only speculate from the isotropic case. In addition, whether nhas to approach ∞ are still questionable. The construction of the rigorous quantum theory with higher order holonomy corrections in Bianchi I model is necessary to answer these questions, which is still an open issue. As well as this, even in the isotropic case the higher order holonomy corrections is still not conclusive. The investigations about this may shed light to the issue of j ambiguity and the link between LQC and spin-foams.
