

Some remarks on Landau-Ginzburg potentials for odd-dimensional quadrics

Vassily Gorbounov, Maxim Smirnov

Abstract

We study the possibility of constructing a Frobenius manifold for the standard Landau-Ginzburg model of odd-dimensional quadrics Q_{2n+1} and matching it with the Frobenius manifold attached to the quantum cohomology of these quadrics. Namely, we show that the initial conditions of the quantum cohomology Frobenius manifold of the quadric can be obtained from the suitably modified standard Landau-Ginzburg model.

1 Introduction

The idea of the Landau-Ginzburg model, LG model from now on, of a variety originated in the work of physicists. In studying conformal field theories over projective hypersurfaces, the zeros of a certain function, they noticed that the function itself can be used to calculate various quantities in the theory of the hypersurface. This revealed a mysterious relation between smooth projective varieties and functions with isolated singularities, the superpotentials, as they are called in the literature. We cite, out of many references, the work of D. Gepner, E. Witten, and T. Eguchi and his school as being very influential for mathematicians [Ge], [Wi], [EgHoXi].

The LG models appeared in the mathematics literature for the first time probably in the work of A. Givental [Gi]. He has introduced the notion of the quantum differential equation associated to a smooth projective variety, and expressed its solutions for some classes of Fano varieties as oscillating integrals of a certain function, the "LG model" of these Fano varieties.

Later the concept of the LG model became a part of the Homological Mirror Symmetry Conjecture, which is due to M. Kontsevich.

Despite a large volume of serious work of many people there is no commonly accepted definition of the LG model for a given Fano variety. There is a number of examples of a LG model for Fano varieties but they are examples each in its own sense.

In developing the theory of Frobenius manifolds, B. Dubrovin used two main sources of examples. The first is the quantum cohomology of a smooth projective variety, just a variety from now on, and the other is the work of K. Saito [Sai], an important development of singularity theory, which produces a non-trivial example of a Frobenius manifold associated to a polynomial superpotential with an isolated singularity. This suggests another natural approach to finding the LG model for a variety X : one could look for a function on a non-compact manifold such that some generalization of the K. Saito construction would produce a Frobenius manifold isomorphic to the one the quantum cohomology of X produces. This approach to the LG model was detailed in the book of Yu. Manin [Ma]. It was actually made to work for the weighted projective spaces in the papers of A. Douai, C. Sabbah, and E. Mann [DoSa1], [DoSa2], [M].

In this note we expand [DoSa2] by considering varieties which are not toric. Namely, we take one of the known in the literature Laurent polynomials which is believed to be the LG model for an odd-dimensional quadric (see [HoVa], [Pr]), and investigate the possibility of making it an example of a LG model to the quadric in the sense of the Frobenius manifold structure. From now on we will refer to this potential as "the standard potential".

We attempted to formulate a rule for finding such a potential in general. In the case of the quadric as well as in some other examples available in the literature the partial derivatives of the standard potential reproduce partially the relations generated by the multiplications by the generator of the second cohomology. But here a problem arises: the standard potential may have fewer critical points than the rank of the cohomology of the variety it supposedly models, as is observed in the quadric setting. Therefore this LG potential has the wrong Jacobi ring and in terms of the corresponding Frobenius manifolds can't be the correct LG model. This problem for the LG model of the Grassmannians was pointed out in the paper [EgHoXi] a long time

ago. In the same paper it was suggested how to remedy the situation. One needs to search for a partial compactification of the domain of the standard potential to gain the required number of the critical points. There is no procedure for doing this in general at least as far as we know, but in the examples we have looked at, including the quadric, it was always possible to find such a compactification by trial and error. The compactification of the domain changes the superpotential and it is no longer a Laurent polynomial.

We follow the generalization due to C. Sabbah and A. Douai of the K. Saito work. This reduces the problem of construction of a Frobenius manifold to studying the Gauss-Manin system associated to the potential. The first step is to solve the Birkhoff problem for the Gauss-Manin system at one point of the parameter space for the potential, to make sure it matches the initial conditions of the quantum cohomology Frobenius manifold of the appropriate variety. In the case of the quadric this can be done but with bit of an effort. With the kind help of C. Sabbah and A. Nemethi we check a certain property for our potential, the so called cohomological tameness, which helped a lot with solving the Birkhoff problem.

For the final step, we need to build the Frobenius manifold in the neighbourhood of that one point in the parameter space which would automatically match the Frobenius manifold of the quadric. This amounts to finding a good deformation of our potential, and this in turn requires one to have a good hold on the behaviour of the potential at the infinity. It is not clear at the present time what the best method is to handle this purely analytic problem in its most general setting. There are, however, some sufficiency conditions – for example the so called M -tameness of the potential – that guarantee such behaviour. In the case of Laurent polynomial this property can be checked and is used in [DoSa1] [DoSa2]. For a general regular function it appears to be a difficult analytical problem. We fail to check the M -tameness for our potential, however it seems interesting to us that proving the existence of the LG model hinges on the delicate analytical properties of the potential.

Putting it all together, in this note we have proved that the standard potential for the quadric after a suitable modification defines the initial conditions of the quantum cohomology Frobenius manifold of the quadric.

Throughout the whole text we restrict ourselves to the case of a three-dimensional quadric Q_3 for the sake of making the exposition compact. In fact, all the results hold for an arbitrary odd-dimensional quadric.

Remark. After the first version of this preprint was posted on the arxiv an interesting preprint by C. Pech and K. Rietsch [PeRi] appeared where it is shown that the superpotential considered in this paper for an odd-dimensional quadric is a particular case of a general construction proposed by K. Rietsch [Ri] for a homogeneous space G/P . Some results of Section 4 are used in [PeRi] to establish a part of a conjecture made in [Ri] (see *loc.cit.* for details). It would be interesting to further bridge the work done in this preprint with the approach initiated by K. Rietsch.

Acknowledgements. First, we would like to thank Yu. I. Manin for initiating this project and sharing generously his ideas. We are indebted to C. Sabbah and A. Nemethi for the proof of Lemma 4.1.1, and help with general questions about the subject of this paper. Special thanks go to P. Bressler and to E. Shinder for various discussions related to this work.

Both authors benefited a lot from the excellent research environment of the MPIM, Bonn. Some part of this work was done while the second author visited the IHES, Paris whose hospitality is gratefully acknowledged.

2 Background and notation

2.1 Quantum cohomology. Here we very briefly recall some facts about quantum cohomology. For the general theory of Frobenius manifolds we refer to [Ma], [He], and references therein.

Let X be a smooth projective complex algebraic variety and $QH(X)$ its big quantum cohomology. If $\Delta_0, \dots, \Delta_r$ is a graded basis and x_0, \dots, x_r dual coordinates, then the quantum product is defined as

$$\Delta_i \circ \Delta_j = \sum_{k,l} \Phi_{ijk} g^{kl} \Delta_l, \tag{2.1}$$

where Φ is the Gromov-Witten potential, $\Phi_{ijk} = \frac{\partial^3 \Phi}{\partial x_i \partial x_j \partial x_k}$, and g is the Poincaré pairing on $H = H^*(X, \mathbb{C})$. The full structure of the quantum cohomology of X endows H with a structure of a Frobenius manifold. In fact, one needs to work with formal manifolds because Φ is not known to be convergent.

Disregarding convergence issues one can think of $QH(X)$ as a family of multiplications on H parametrized by H itself, i.e. it is a multiplication on \mathcal{T}_H , where we consider H as a complex manifold. Poincaré pairing on H defines a constant pairing on \mathcal{T}_H which is multiplication invariant and flat.

Under small quantum cohomology one means the restriction of the above picture to $H^2(X, \mathbb{C}) \subset H$. In terms of coordinates it means that we reduce all our formulas modulo an ideal generated by coordinates dual to Δ_i 's not lying in $H^2(X, \mathbb{C})$.

2.1.1 Spectral cover. Assume that $H = H^*(X, \mathbb{C})$ is of dimension one in each even degree and zero otherwise. In this situation one can consider an algebraic torus $\mathbf{T} \subset H^t$, which is a locally closed subvariety of H^t . Here H^t is the dual of H .

Namely, let $\Delta_0, \dots, \Delta_r$ be a graded basis of H , such that Δ_0 is the identity element, and consider

$$H^t = \text{Spec}(S^\bullet(H)) = \text{Spec}(\mathbb{C}[\Delta_0, \dots, \Delta_r]).$$

In H^t we have an affine subspace $\{\Delta_0 = 1\} \simeq \text{Spec}(\mathbb{C}[\Delta_1, \dots, \Delta_r])$, and inside this affine subspace we have the torus $\mathbf{T} = \text{Spec}(\mathbb{C}[\Delta_1^{\pm 1}, \dots, \Delta_r^{\pm 1}])$. This torus does not depend on the choice of $\Delta_1, \dots, \Delta_r$ and will play an important role in construction of LG models.

Equations that define the spectral cover $\text{Spec}(QH(X))$ as a subvariety of $H \times H^t$ are given just by the multiplication table. One of the equations is always $\Delta_0 = 1$. Hence, the spectral cover always lives inside the affine space $\{\Delta_0 = 1\} \simeq \text{Spec}(\mathbb{C}[\Delta_1, \dots, \Delta_r])$.

One can summarize it in the diagram

$$\begin{array}{ccccc} \text{Spec}(QH(X)) & \xrightarrow{i} & H \times H^t & \xleftarrow{j} & H \times \mathbf{T} \\ & & \downarrow & & \swarrow \\ & & H & & \end{array}$$

where i and j are embeddings.

In some cases $\text{Spec}(QH(X))$ lies in $H \times \mathbf{T}$. For example, it is true for projective spaces (at least in the small quantum cohomology). It is not true for the case of odd-dimensional quadrics that we consider.

2.2 Landau-Ginzburg models. Let X be a Fano variety and $QH(X)$ its quantum cohomology.

A Saito's framework (see [Ma, III.8]) is called a Landau-Ginzburg model for X iff it is isomorphic to $QH(X)$ as a Frobenius manifold.

Consider a pair (U, f) consisting of a complex smooth affine variety and a regular function on it. It is called a Landau-Ginzburg model for X iff there exists a deformation of (U, f) and a Saito's framework attached to it which is isomorphic to $QH(X)$ as a Frobenius manifold.

These definitions are quite restrictive. One can relax both of them as follows. We require the existence of a point in $QH(X)$ and a point in Saito's framework such that the germs of Frobenius manifolds at these points are isomorphic.

2.3 Gauss-Manin systems. Here we will give a brief account on Gauss-Manin systems, Brieskorn lattices, higher residue pairings and Birkhoff problems. Mainly we will be setting up notation that we will use in Section 4 and refer to [Do1], [Do2] for details.

Consider a projective line with a chosen coordinate θ . We will denote it by \mathbb{P}_θ^1 . Let $\mathbb{P}_\theta^1 = U_0 \cup U_\infty$ be the standard open cover, i.e. $U_0 = \mathbb{A}_\theta^1$, $U_1 = \mathbb{A}_{\theta^{-1}}^1$, and $W = U_0 \cap U_\infty = \mathbb{A}_\theta^1 - \{0\}$. Here \mathbb{A}_θ^1 stands for $\text{Spec}(\mathbb{C}[\theta])$ and $\{0\}$ for $\{\theta = 0\}$. Sometimes we will write τ for θ^{-1} . We will use this notation when working with Gauss-Manin systems throughout the article.

2.3.1 Definition. Let X be a smooth affine variety of dimension n with a regular function h on it. The main example relevant for mirror symmetry: $X = (\mathbf{G}_m)^n$ and h is a Laurent polynomial. To such a function h one can attach its *Gauss-Manin system*

$$G = \Omega^n(X)[\theta, \theta^{-1}] / (\theta d - dh \wedge) \Omega^{n-1}(X)[\theta, \theta^{-1}],$$

which is a free $\mathbb{C}[\theta, \theta^{-1}]$ -module of finite rank with a flat connection ∇ defined as follows. Let $\sum_i \omega_i \theta^i$ be a representative of some class $\gamma \in G$, i.e. $\gamma = [\sum_i \omega_i \theta^i]$. Then

$$\theta^2 \nabla_{\frac{\partial}{\partial \theta}}(\gamma) = \left[\sum_i h \omega_i \theta^i + \sum_i i \omega_i \theta^{i+1} \right],$$

where the brackets $[\]$ denote taking class in G .

It is a general fact that (G, ∇) always has a regular singularity at $\theta = \infty$ and possibly irregular singularity at $\theta = 0$ of rank 2.

2.3.2 Brieskorn lattice. At $\theta = 0$ the Gauss-Manin system (G, ∇) has a natural lattice

$$G_0 = \Omega^n(X)[\theta] / (\theta d - dh \wedge) \Omega^{n-1}(X)[\theta], \quad (2.2)$$

the *Brieskorn lattice* of h . This means that G_0 is a $\mathbb{C}[\theta]$ -module such that $G_0 \otimes_{\mathbb{C}[\theta]} \mathbb{C}[\theta, \theta^{-1}] \simeq G$.

The connection ∇ naturally restricted (or extended) to G_0 has a pole of order 2 at $\theta = 0$, i.e.

$$\theta^2 \nabla_{\frac{\partial}{\partial \theta}}(G_0) \subset G_0.$$

Abusing notation we will denote this meromorphic connection again by ∇ .

In general G_0 does not have torsion but may be not finitely generated. If h is *cohomologically tame* (see Section 2.3.6 and [Sa2]), then it is finitely generated and free. Therefore, in the cohomologically tame case the pair (G_0, ∇) gives a meromorphic extension of (G, ∇) to \mathbb{A}_θ^1 with a pole of order 2 at the origin.

2.3.3 Extension to \mathbb{P}_θ^1 . The aim is to find an extension of (G_0, ∇) to a free $\mathcal{O}_{\mathbb{P}_\theta^1}$ -module with a meromorphic connection on \mathbb{P}_θ^1 with a pole of order less or equal to 1 at infinity. We will denote such an extension (\mathcal{F}, ∇) . This type of question is known as *the Birkhoff problem* (cf. [Sa1, Ch. 4]).

More concretely it means that we need to find a $\mathbb{C}[\theta^{-1}]$ -module $G_\infty \subset G$ such that:

- $G_\infty \otimes_{\mathbb{C}[\theta^{-1}]} \mathbb{C}[\theta, \theta^{-1}] \simeq G$
- $G_0 = (G_0 \cap G_\infty) \oplus \theta G_0$
- $\tau \nabla_{\frac{\partial}{\partial \tau}}(G_\infty) \subset G_\infty$

(recall that $\tau = \theta^{-1}$).

Even more concretely, and this is the way we will do it in Section 4, it can be done as follows. We need to find a $\mathbb{C}[\theta]$ -basis of G_0 such that the connection matrix in this basis takes the form

$$\left(\frac{A_0}{\theta} + A_\infty \right) \frac{d\theta}{\theta}, \quad (2.3)$$

where A_0 and A_∞ are constant matrices. To get the desired extension one just needs to consider these basis elements inside G and define G_∞ as a $\mathbb{C}[\theta^{-1}]$ -submodule generated by them.

2.3.4 Pairing. If h is a cohomologically tame function, then there exists a non-degenerate bilinear pairing (cf. [DoSa1])

$$S_W: G \otimes j^*G \rightarrow \mathbb{C}[\theta, \theta^{-1}], \quad (2.4)$$

where $j: W \rightarrow W$ is given by $\theta \mapsto -\theta$.¹

It satisfies

$$\frac{d}{d\theta} S_W(g_1, g_2) = S_W(\partial_\theta g_1, g_2) + S_W(g_1, \partial_\theta g_2), \quad (2.5)$$

i.e. it is a horizontal section of the sheaf $\mathcal{H}om_{\mathcal{O}_W}(\mathcal{F}_W \otimes j^*\mathcal{F}_W, \mathcal{O}_W)$ equipped with its natural connection, and

$$S_W(g_1, g_2) = (-1)^n \overline{S_W(g_2, g_1)}, \quad (2.6)$$

where we used the notation $\overline{P(\theta, \theta^{-1})} := P(-\theta, -\theta^{-1})$ for a Laurent polynomial $P(\theta, \theta^{-1})$.

Moreover, (2.4) has the property

$$S_W(G_0, j^*G_0) \subset \theta^n \mathbb{C}[\theta] \subset \mathbb{C}[\theta, \theta^{-1}], \quad (2.7)$$

and therefore we get a natural extension

$$S_{U_0}: G_0 \otimes j^*G_0 \rightarrow \mathbb{C}[\theta]. \quad (2.8)$$

On G_0 we can write

$$S_{U_0} = \sum_{i \geq n} S_i \theta^i,$$

where $S_i: G_0 \otimes j^*G_0 \rightarrow \mathbb{C}\theta^i$ are *higher residue pairings* of K. Saito; S_n is the Grothendieck residue pairing. For a modern overview of K. Saito's works on this subject we refer to [SaiTa].

Let (\mathcal{F}, ∇) be an extension as in Section 2.3.3. We would like to extend (2.8) to a pairing

$$S: \mathcal{F} \otimes j^*\mathcal{F} \rightarrow \mathcal{O}_{\mathbb{P}_\theta^1}.$$

There exists $d \in \mathbb{Z}$ such that $S_W(G_\infty, j^*G_\infty) \subset \tau^{-d} \mathcal{O}_{U_\infty}$ and therefore (2.8) always extends to

$$S: \mathcal{F} \otimes j^*\mathcal{F} \rightarrow \mathcal{O}_{\mathbb{P}_\theta^1}(-n \cdot \{0\} + d \cdot \{\infty\}). \quad (2.9)$$

Here $\mathcal{O}_{\mathbb{P}_\theta^1}(-n \cdot \{0\} + d \cdot \{\infty\})$ is an invertible subsheaf of $K_{\mathbb{P}_\theta^1}$ which consists of rational functions of \mathbb{P}_θ^1 , generated by θ^n and τ^{-d} . It is isomorphic to $\mathcal{O}_{\mathbb{P}_\theta^1}$ if and only if $d = n$. The choice of d in (2.9) is not unique but there exists the minimal possible d .

By (2.7) we know that $d \geq n$ and therefore (2.9) produces a pairing with values in $\mathcal{O}_{\mathbb{P}_\theta^1}$ iff $d = n$. The latter condition is equivalent to the existence of a global basis e_1, \dots, e_μ of \mathcal{F} such that $S_{U_0}(e_i|_{U_0}, e_j|_{U_0}) \in \theta^n \mathbb{C}$.

2.3.5 V-filtration. Let X be a smooth algebraic variety, Y its closed smooth subvariety of codimension one, and I the ideal sheaf of Y in X . First define an increasing filtration $V_\bullet \mathcal{O}_X$ by putting $V_i \mathcal{O}_X = \mathcal{O}_X$ if $i \geq 0$ and $V_i \mathcal{O}_X = I^{-i}$ if $i < 0$. Now let $V_\bullet \mathcal{D}_X$ be an increasing filtration defined as

$$V_i \mathcal{D}_X = \{P \in \mathcal{D}_X \mid P(V_m \mathcal{O}_X) \subset V_{m+i} \mathcal{O}_X, \quad \forall m \in \mathbb{Z}\}.$$

¹The morphism j extends uniquely to a morphism $\mathbb{P}_\theta^1 \rightarrow \mathbb{P}_\theta^1$. Abusing notation we will denote this morphism again by j , and we will use the same notation for its restrictions if it does not lead to confusion.

One can locally describe it more explicitly as follows (cf. [PeSt]). Let (y_1, \dots, y_n, x) be a local coordinate system on X such that in this neighbourhood Y is given by the equation $x = 0$. Then $V_0\mathcal{D}_X$ is a subsheaf of rings of \mathcal{D}_X locally generated by \mathcal{O}_X , vector fields $\frac{\partial}{\partial y_1}, \dots, \frac{\partial}{\partial y_n}$ and $x\frac{\partial}{\partial x}$. If we denote $\partial_x = \frac{\partial}{\partial x}$, then $V_i\mathcal{D}_X$ is a $V_0\mathcal{D}_X$ -module generated by $x^i\partial_x^j$ with $i - j \geq -k$.

Let \mathcal{M} be a (left) \mathcal{D}_X -module and $V_\bullet\mathcal{M}$ a discrete exhaustive increasing filtration indexed by \mathbb{Q} . It is called *V-filtration* iff

1. it is compatible with the filtration $V_\bullet\mathcal{D}_X$, i.e. $(V_i\mathcal{D}_X)(V_\alpha\mathcal{M}) \subset V_{\alpha+i}\mathcal{M}$ for all α and i ; furthermore, the inclusion $I(V_\alpha\mathcal{M}) \subset V_{\alpha-1}\mathcal{M}$ should be an equality for $\alpha < 0$.
2. the action of $x\partial_x + \alpha$ on $\text{Gr}_\alpha^V\mathcal{M}$ is nilpotent.

If such a filtration exists, then it is unique (cf. [Bu]).

The Gauss-Manin system G considered as a $\mathbb{C}[\tau]\langle\partial_\tau\rangle$ -module² always has a *V-filtration* along $\{\tau = 0\}$, and pairing (2.4) satisfies

$$S_W(V_0G, \overline{V_{<1}G}) \subset \mathbb{C}[\tau]. \quad (2.10)$$

For more details we refer to [DoSa1].

2.3.6 Tameness. Let X be a smooth algebraic variety and $h: X \rightarrow \mathbb{A}^1$ a morphism. By a partial compactification we mean a commutative diagram

$$\begin{array}{ccc} X & \xrightarrow{j} & \overline{X} \\ \downarrow h & \swarrow \bar{h} & \\ \mathbb{A}^1 & & \end{array}$$

where \overline{X} is an algebraic variety (not necessarily smooth), j is an open embedding, and \bar{h} is proper.

The morphism h is called *cohomologically tame* iff there exists a partial compactification such that the support of $\Phi_{\bar{h}-a}(Rj_*\mathbb{C}_X)$ is finite and contained in X_a , for all $a \in \mathbb{A}^1$. We refer to [Sa2] for more details.

2.4 Initial conditions. Let (M, \circ, e, g, E) be a Frobenius manifold with an Euler field. In this setting one defines two endomorphisms of \mathcal{T}_M as

$$\mathcal{U}(X) = E \circ X, \quad \mathcal{V}(X) = \nabla_X(E) - \frac{D}{2}X, \quad (2.11)$$

where D is defined by $\text{Lie}_E(g) = Dg$ (see [Ma, II.1]).

If $p \in M$ is a semi-simple point of M , i.e. the algebra (T_pM, \circ_p) is semi-simple (isomorphic to \mathbb{C}^n), then in a neighborhood of this point the tuple (M, \circ, e, g, E) is uniquely determined by the data

$$(T, \mathcal{U}, \mathcal{V}, g, e), \quad (2.12)$$

where $T = T_pM$, \mathcal{U} and \mathcal{V} are endomorphisms of T induced by (2.11), g is a non-degenerate symmetric bilinear pairing on T induced by the metric, and e is an element in T induced by the identity vector field. This follows from [Du, Main Th., p.188] or [Sa1, Th. VII.4.2].

3 Construction of Landau-Ginzburg potentials

We start by summarizing some facts about quantum cohomology of a smooth three-dimensional quadric Q_3 (see [BaMa] for details). Then we explain how to obtain the standard LG potential for Q_3 from its quantum cohomology. As we already mentioned, this LG potential does not have enough critical points to be an honest LG model in the sense of Section 2.2, and we present its *ad hoc* partial compactification.

²This just means that we consider not G itself but its push-forward as a D -module with respect to the open inclusion $U_0 \cap U_\infty \rightarrow U_\infty$.

3.1 Quantum cohomology of Q_3 . Let $V = Q_3$ be a smooth Fano hypersurface in \mathbb{P}^4 which is given by a non-degenerate homogeneous polynomial of degree 2. The singular cohomology groups $H^i(V, \mathbb{Z})$ are free of rank one in each even degree and vanish in odd degrees. Consider a graded basis $\Delta_0, \Delta_1, \Delta_2, \Delta_3$ of $H^*(V, \mathbb{Z})$, such that Δ_0 is the identity, Δ_1 is the hyperplane class, $\Delta_1 \cup \Delta_2 = \Delta_3$, where Δ_3 is Poincaré dual to the class of a point.

The table of quantum multiplication by Δ_1 in the small quantum cohomology is

$$\begin{aligned}\Delta_1 \Delta_0 &= \Delta_1 \\ \Delta_1 \Delta_1 &= 2\Delta_2 \\ \Delta_1 \Delta_2 &= \Delta_3 + q\Delta_0 \\ \Delta_1 \Delta_3 &= q\Delta_1.\end{aligned}\tag{3.1}$$

Hence, the spectral cover consists of 4 reduced points

$$\begin{aligned}P_0 &= (1, 0, 0, -q) \\ P_i &= (1, \xi_i, \frac{\xi_i^2}{2}, q),\end{aligned}$$

where ξ_i are roots of $\xi^3 = 4q$, and $1 \leq i \leq 3$. The point P_0 does not lie on the torus \mathbf{T} (cf. Section 2.1.1).

3.1.1 Initial conditions. We can express the anti-canonical class as

$$-K_V = 3\Delta_1.$$

In the basis of the Δ_i 's the initial conditions take the form

$$\mathcal{U} = \begin{pmatrix} 0 & 0 & 3q & 0 \\ 3 & 0 & 0 & 3q \\ 0 & 6 & 0 & 0 \\ 0 & 0 & 3 & 0 \end{pmatrix}$$

and

$$\mathcal{V} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -2 \end{pmatrix} + \frac{1}{2}.$$

3.2 Standard LG potential. Restricting to the torus \mathbf{T} we can rewrite system (3.1) as

$$\begin{aligned}\Delta_1 &= \frac{2\Delta_2}{\Delta_1} \\ \Delta_1 &= \frac{\Delta_3 + q}{\Delta_2} \\ \Delta_1 &= \frac{q\Delta_1}{\Delta_3}.\end{aligned}$$

The above system can be rewritten as

$$\begin{aligned}\Delta_1 &= \frac{2\Delta_2}{\Delta_1} \\ \frac{\Delta_2}{\Delta_1} &= \frac{(\Delta_3 + q)^2}{2\Delta_2\Delta_3} \\ \frac{\Delta_3^2}{2\Delta_2\Delta_3} &= \frac{q^2}{2\Delta_2\Delta_3}.\end{aligned}\tag{3.2}$$

It is easy to see that if we define

$$f = \Delta_1 + \frac{2\Delta_2}{\Delta_1} + \frac{(\Delta_3 + q)^2}{2\Delta_2\Delta_3}, \quad (3.3)$$

then the system $\Delta_i \frac{\partial f}{\partial \Delta_i} = 0$ coincides with (3.2). In this sense f "integrates" the multiplication table.

We claim that (3.3) is the standard LG potential for Q_3 proposed in [EgHoXi]. Indeed, consider another coordinate system on the torus $\mathbf{T} = \{\Delta_1\Delta_2\Delta_3 \neq 0\}$ given by

$$Y_1 = \Delta_1, \quad Y_2 = \frac{2\Delta_2}{\Delta_1}, \quad Y_3 = \Delta_3.$$

Rewriting (3.3) in terms of these coordinates we get

$$f = Y_1 + Y_2 + \frac{(Y_3 + q)^2}{Y_1 Y_2 Y_3}. \quad (3.4)$$

which is exactly the LG potential proposed in loc.cit..

3.3 Compactification. By construction (3.3) has 3 critical points but a Landau-Ginzburg potential for Q_3 in the sense of Section 2.2 must necessarily have 4 critical points. Below we will give an *ad hoc* partial compactification of f to a new LG potential \tilde{f} which has the correct number of critical points. In Section 4 we will study the Gauss-Manin system of \tilde{f} and show that it deserves the name LG potential.

Consider the affine space $\mathbb{A}^3 = \text{Spec } \mathbb{C}[Y_1, Y_2, Y_3]$. Expression (3.4) gives a regular function on the torus $\{Y_1 Y_2 Y_3 \neq 0\} \subset \mathbb{A}^3$. Functions x, y, z given by

$$\begin{aligned} x &= \frac{Y_3 + q}{qY_1} \\ y &= Y_1 \\ z &= \frac{Y_2}{Y_1} - 1 \end{aligned} \quad (3.5)$$

define another coordinate system on this torus. Rewriting f in terms of these coordinates we get

$$\tilde{f} = y(2 + z) + \frac{qx^2}{(xy - 1)(1 + z)}. \quad (3.6)$$

One can interpret (3.6) as a regular function on an open subvariety of $\mathbb{A}^3 = \text{Spec } \mathbb{C}[x, y, z]$ defined by $\{(xy - 1)(1 + z) \neq 0\}$. The torus $\{Y_1 Y_2 Y_3 \neq 0\}$ is embedded into this space by formulas (3.5).

It is easy to check that the critical locus of \tilde{f} consists of 4 points

$$P_0 = (0, 0, -2) \quad \text{and} \quad P_i = \left(\frac{2}{\xi_i}, \xi_i, 0\right),$$

where $\xi_i^3 = 4q$.

3.4 General case. The above considerations work for an arbitrary smooth odd-dimensional quadric Q_{2n+1} of dimension $2n + 1$. Let $\Delta_0, \dots, \Delta_{2n+1}$ be a graded basis of $H^*(Q_{2n+1}, \mathbb{Z})$, such that Δ_0 is the identity, Δ_1 is the hyperplane class, $\Delta_i = \Delta_1^{\cup i}$ for $i \leq n$, and $\Delta_i \cup \Delta_{2n+1-i} = \Delta_{2n+1}$, where Δ_{2n+1} is Poincaré dual to the class of a point.

One can write down the quantum multiplication by Δ_1 . Then one can show that

$$f = \Delta_1 + \frac{\Delta_2}{\Delta_1} + \dots + \frac{\Delta_n}{\Delta_{n-1}} + \frac{2\Delta_{n+1}}{\Delta_n} + \frac{\Delta_{n+2}}{\Delta_{n+1}} + \dots + \frac{\Delta_{2n}}{\Delta_{2n-1}} + \frac{(\Delta_{2n+1} + q)^2}{2\Delta_{2n}\Delta_{2n+1}}$$

is the analogue of (3.3), and

$$\tilde{f} = \sum_{i=1}^n y_i(2 + z_i) + \frac{qx^2}{(xy_1 \dots y_n - 1)(1 + z_1) \dots (1 + z_n)}.$$

is the analogue of (3.6).

4 Gauss-Manin system of \tilde{f}

4.1 Notation. For convenience we repeat the partial compactification in a somewhat backwards order. Namely, consider $\mathbb{A}^3 = \text{Spec } \mathbb{C}[x, y, z]$ and let \tilde{U} be the open subvariety defined by $\{(xy - 1)(1 + z) \neq 0\}$. On \tilde{U} we have the regular function

$$\tilde{f} = y(2 + z) + \frac{qx^2}{(xy - 1)(1 + z)}, \quad (4.1)$$

which is our partially compactified potential (3.6).

Consider functions $\Delta_1, \Delta_2, \Delta_3$ on \mathbb{A}^3 given by

$$\Delta_1 = y, \quad \Delta_2 = \frac{y^2}{2}(z + 1), \quad \Delta_3 = qxy - q, \quad (4.2)$$

which form a coordinate system on the subset $\{y \neq 0\} \subset \mathbb{A}^3$. The inverse coordinate change is given by

$$x = \frac{\Delta_3 + q}{q\Delta_1}, \quad y = \Delta_1, \quad z = \frac{2\Delta_2}{\Delta_1^2} - 1. \quad (4.3)$$

Let U be the intersection $\tilde{U} \cap \{y \neq 0\}$. On U function (4.1) can be rewritten in terms of $\Delta_1, \Delta_2, \Delta_3$ as

$$f := \tilde{f}|_U = \Delta_1 + \frac{2\Delta_2}{\Delta_1} + \frac{(\Delta_3 + q)^2}{2\Delta_2\Delta_3}. \quad (4.4)$$

Formulas (4.2) give an isomorphism of U with the algebraic torus $\mathbf{G}_m^3 = \text{Spec } \mathbb{C}[t_1^{\pm 1}, t_2^{\pm 1}, t_3^{\pm 1}]$, such that t_i 's correspond to Δ_i 's. Formula (4.4) gives the LG potential before the compactification as in (3.3).

4.1.1 Lemma. *Function (4.1) is cohomologically tame.*³

Proof. See Appendix A. ■

4.1.2 Lemma. *The Gauss-Manin system $G^{\tilde{f}}$ has the following properties:*

- (i) $G^{\tilde{f}}$ is a free $\mathbb{C}[\theta, \theta^{-1}]$ -module of rank 4;
- (ii) $G_0^{\tilde{f}}$ is a free $\mathbb{C}[\theta]$ -module of rank 4.

Proof. For both properties it is essential that \tilde{f} is cohomologically tame.

(i) For a function with isolated critical points the module G is always free of finite rank. If, moreover, the function is cohomologically tame, then the rank is equal to the Milnor number ([Do2], Th. 5.2.3). In our case it is 4.

(ii) For a function with (cohomologically) isolated critical points at infinity Corollary 5.2.6 of [Do2] states, that G_0 is free and of finite type iff the function is cohomologically tame.

Applying this corollary to \tilde{f} we get that $G_0^{\tilde{f}}$ is a free $\mathbb{C}[\theta]$ -module of finite rank. Hence, its rank equals to the dimension of the fiber at zero. Using Proposition 5.1.1 of [Do2] we see that the rank is equal to the Milnor number. ■

4.1.3 Lemma. *The natural morphism of \mathcal{D}_W -modules $G^{\tilde{f}} \rightarrow G^f$ given by the restriction of differential forms from \tilde{U} to U is an isomorphism.*⁴

Proof. Restriction of differential forms from \tilde{U} to U defines the morphism

$$\Omega^i(\tilde{U}) \rightarrow \Omega^i(U),$$

³It is also true that f has isolated singularities at infinity in the sense of [Do2].

⁴Recall from Section 2.3 that $W = \mathbb{A}_\theta^1 - \{0\}$

which is injective but not surjective; it is the localization morphism given by inverting Δ_1 . One can check directly that the induced morphism $G^{\tilde{f}} \rightarrow G^f$ on the Gauss-Manin systems is also injective.

By Theorem 5.2.3 of [Do2] the rank of G^f is 4 (we use here that f has one isolated singularity at infinity). Consider the short exact sequence of \mathcal{O}_W -coherent \mathcal{D}_W -modules

$$0 \rightarrow G^{\tilde{f}} \rightarrow G^f \rightarrow G^f/G^{\tilde{f}} \rightarrow 0.$$

Since $\text{rk } G^{\tilde{f}} = \text{rk } G^f$ the quotient is an \mathcal{O}_W -module of rank zero. Therefore, by the standard fact that for a smooth algebraic variety X any \mathcal{O}_X -coherent \mathcal{D}_X -module is a locally free \mathcal{O}_X -module (see [Be], Lect. 2, 1.a), we get that $G^f/G^{\tilde{f}}$ is locally free of rank zero and hence vanishes. ■

4.2 Birkhoff problem. Consider the following 3-form on \tilde{U}

$$\omega_0 = \frac{dx \wedge dy \wedge dz}{(xy-1)(z+1)},$$

and let $\omega_i = \Delta_i \omega_0$. Note also that

$$\omega_{0|U} = \frac{d\Delta_1}{\Delta_1} \wedge \frac{d\Delta_2}{\Delta_2} \wedge \frac{d\Delta_3}{\Delta_3}.$$

If ω is a 3-form, then let $[\omega]$ denote its class in G_0 . In the above formulas by Δ_i we mean $\Delta_i|_{\tilde{U}}$ and $\Delta_i|_U$ respectively. We will continue to use this notation, if it does not lead to confusion.

4.2.1 Lemma. *In G^f we have the following identities*

$$\begin{aligned} [\Delta_i f'_{\Delta_i} \omega_0] &= 0 \\ [\Delta_i \Delta_j f'_{\Delta_i} \omega_0] &= 0 \\ [\Delta_i^2 f'_{\Delta_i} \omega_0] &= \theta[\omega_i]. \end{aligned}$$

Proof. Let us only prove the third identity for $i = 2$. The other cases are analogous. We have the following equality of differential forms

$$\Delta_2^2 f'_{\Delta_2} \omega_0 = -df \wedge \left(\Delta_2 \frac{d\Delta_1}{\Delta_1} \wedge \frac{d\Delta_3}{\Delta_3} \right),$$

hence $[\Delta_2^2 f'_{\Delta_2} \omega_0] = \theta[\omega_2]$ in G^f . ■

4.2.2 Lemma. *Elements $[\omega_0], \dots, [\omega_3]$ are $\mathbb{C}[\theta]$ -linearly independent in $G_0^{\tilde{f}}$.*

Proof. The vector space $G_0^{\tilde{f}}/\theta G_0^{\tilde{f}}$ can be identified with the Milnor ring by mapping 1 to the class of $[\omega_0]$. Under this isomorphism the class of Δ_i goes to the class of $[\omega_i]$. Since $1, \Delta_1, \Delta_2, \Delta_3$ form a basis in the Milnor ring, classes of $[\omega_0], \dots, [\omega_3]$ form a basis in $G_0^{\tilde{f}}/\theta G_0^{\tilde{f}}$. This implies the statement. ■

4.2.3 Lemma. (i) *Elements $[\omega_0], \dots, [\omega_3]$ freely generate in $G^{\tilde{f}}$ an \mathcal{O}_W -submodule $H^{\tilde{f}}$ of rank 4;*
(ii) *The following identities hold*

$$\begin{aligned} \theta^2 \partial_\theta [\omega_0] &= 3[\omega_1] \\ \theta^2 \partial_\theta [\omega_1] &= 6[\omega_2] + \theta[\omega_1] \\ \theta^2 \partial_\theta [\omega_2] &= 3[\omega_3] + 3q[\omega_0] + 2\theta[\omega_2] \\ \theta^2 \partial_\theta [\omega_3] &= 3q[\omega_1] + 3\theta[\omega_3], \end{aligned}$$

and therefore $H^{\tilde{f}}$ is a \mathcal{D}_W -submodule;

(iii) $G^{\tilde{f}} = H^{\tilde{f}}$.

(iv) The connection matrix in the basis $[\omega_0], \dots, [\omega_3]$ takes the form

$$\left(\frac{A_0}{\theta} + A_\infty \right) \frac{d\theta}{\theta},$$

where

$$A_0 = \begin{pmatrix} 0 & 0 & 3q & 0 \\ 3 & 0 & 0 & 3q \\ 0 & 6 & 0 & 0 \\ 0 & 0 & 3 & 0 \end{pmatrix}$$

and

$$A_\infty = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 3 \end{pmatrix}$$

Proof. (i) By Lemma 4.2.2 $[\omega_0], \dots, [\omega_3]$ are linearly independent in $G_0^{\tilde{f}}$, and hence also in $G^{\tilde{f}}$ and G^f . Therefore, they generate a submodule of rank 4 in $G^{\tilde{f}}$ (and in G^f).

(ii) Because of the natural isomorphism $G^{\tilde{f}} \rightarrow G^f$ we can check these identities in G^f .

First, note that the following identities hold in the ring of functions on U

$$\begin{aligned} f &= 3\Delta_1 - 2\Delta_1 f'_{\Delta_1} - \Delta_2 f'_{\Delta_2} \\ \Delta_1 \Delta_1 &= 2\Delta_2 + \Delta_1^2 f'_{\Delta_1} \\ \Delta_1 \Delta_2 &= (\Delta_3 + q) + \Delta_2(\Delta_1 f'_{\Delta_1} + \Delta_2 f'_{\Delta_2} - \Delta_3 f'_{\Delta_3}) \\ \Delta_1 \Delta_3 &= q\Delta_1 + \Delta_3(\Delta_1 f'_{\Delta_1} + \Delta_2 f'_{\Delta_2} + \Delta_3 f'_{\Delta_3}) - q(\Delta_1 f'_{\Delta_1} + \Delta_2 f'_{\Delta_2} - \Delta_3 f'_{\Delta_3}). \end{aligned}$$

These identities can be checked by direct computations.

Using the first identity we get

$$\begin{aligned} \theta^2 \partial_\theta [\omega_0] &= [f \omega_0] = [(3\Delta_1 - 2\Delta_1 f'_{\Delta_1} - \Delta_2 f'_{\Delta_2}) \omega_0] = \\ &= 3[\Delta_1 \omega_0] - 2[\Delta_1 f'_{\Delta_1} \omega_0] - [\Delta_2 f'_{\Delta_2} \omega_0]. \end{aligned}$$

Applying Lemma 4.2.1 we get

$$\theta^2 \partial_\theta [\omega_0] = 3[\Delta_1 \omega_0] = 3[\omega_1].$$

Using the first two identities and Lemma 4.2.1 we get

$$\theta^2 \partial_\theta [\omega_1] = [f \Delta_1 \omega_0] = [6\Delta_2 \omega_0 + \Delta_1^2 f'_{\Delta_1} \omega_0 - \Delta_1 \Delta_2 f'_{\Delta_2} \omega_0] = 6[\omega_2] + \theta[\omega_1].$$

The remaining two formulas are obtained analogously.

(iii) Since $H^{\tilde{f}}$ and $G^{\tilde{f}}$ are \mathcal{O}_W -coherent \mathcal{D}_W -modules of the same rank, they coincide (as in the proof of Lemma 4.1.3).

(iv) It follows from (ii). ■

4.2.4 Lemma. *The classes $[\omega_0], \dots, [\omega_3]$ form a $\mathbb{C}[\theta]$ -basis in $G_0^{\tilde{f}}$.*

Proof. Let $H_0^{\tilde{f}}$ be the $\mathcal{O}_{\mathbb{A}_\theta^1}$ -submodule of $G_0^{\tilde{f}}$ generated by $[\omega_0], \dots, [\omega_3]$. We have the short exact sequence of $\mathcal{O}_{\mathbb{A}_\theta^1}$ -modules

$$0 \rightarrow H_0^{\tilde{f}} \rightarrow G_0^{\tilde{f}} \rightarrow Q_0^{\tilde{f}} \rightarrow 0, \quad (4.5)$$

and we need to show that $Q_0^{\tilde{f}} = 0$.

Since $Q_0^{\tilde{f}}|_{\mathbb{A}_\theta^1 - \{0\}} = 0$ by Lemma 4.2.3, and $Q_0^{\tilde{f}}$ is finitely generated, it is enough to prove that the fiber at zero vanishes, i.e. $Q_0^{\tilde{f}} \otimes_{\mathbb{C}[\theta]} \mathbb{C}[\theta]/(\theta) = 0$.

Tensoring (4.5) with $\mathbb{C}[\theta]/(\theta)$ we get a short exact sequence (tensor product is right exact)

$$H_0^{\tilde{f}} \otimes_{\mathbb{C}[\theta]} \mathbb{C}[\theta]/(\theta) \rightarrow G_0^{\tilde{f}} \otimes_{\mathbb{C}[\theta]} \mathbb{C}[\theta]/(\theta) \rightarrow Q_0^{\tilde{f}} \otimes_{\mathbb{C}[\theta]} \mathbb{C}[\theta]/(\theta) \rightarrow 0,$$

which can be rewritten as

$$H_0^{\tilde{f}} \otimes_{\mathbb{C}[\theta]} \mathbb{C}[\theta]/(\theta) \rightarrow \Omega^n(\tilde{U})/d\tilde{f} \wedge \Omega^{n-1}(\tilde{U}) \rightarrow Q_0^{\tilde{f}} \otimes_{\mathbb{C}[\theta]} \mathbb{C}[\theta]/(\theta) \rightarrow 0.$$

Since classes of $[\omega_0], \dots, [\omega_3]$ generate $\Omega^n(\tilde{U})/d\tilde{f} \wedge \Omega^{n-1}(\tilde{U})$, the first map is surjective. Therefore, $Q_0^{\tilde{f}} \otimes_{\mathbb{C}[\theta]} \mathbb{C}[\theta]/(\theta) = 0$, and, finally, $Q_0^{\tilde{f}} = 0$. ■

4.3 Pairing. In this section we study pairing (2.4) in our setup. Since it will make no difference here, we are dropping the subscripts in the notation of the Gauss-Manin systems, and just write G .

4.3.1 Lemma. *The V -filtration on G along $\{\tau = 0\}$ is given by*

$$\begin{aligned} V_0 G &= \bigoplus_{i=0}^3 \mathbb{C}[\tau] e_i \\ V_p G &= \tau^{-p} V_0 G, \end{aligned}$$

where $e_i = \tau^i[\omega_i]$.

Proof. This lemma, as well as most of the results of this article, first appeared in [Sm]. There the proof of this lemma has a mistake which is corrected here.

It is enough to show that this filtration satisfies the conditions of Section 2.3.5.

1. *Compatibility of filtrations.*

1a. It is clear that $\tau(V_p G) \subset V_{p-1} G$, and using that $\partial_\tau = -\theta^2 \partial_\theta$ and applying Lemma 4.2.3 it is not difficult to see that $\partial_\tau(V_p G) \subset V_{p+1} G$.

These two facts imply that $(V_m \mathcal{D}_{\mathbb{A}_\tau})(V_p G) \subset V_{p+m} G$.

1b. It is clear that the condition $\tau V_p G = V_{p-1} G$ for $p < 0$ holds.

2. *Nilpotence.* Classes of $\tau^{-p} e_0, \dots, \tau^{-p} e_3$ form a basis in $\text{Gr}_p^V G$. Using Lemma 4.2.3 one can see that in this basis the operator induced by $\tau \partial_\tau + p$ on $\text{Gr}_p^V G$ is given by the matrix

$$\begin{pmatrix} 0 & 0 & 0 & 0 \\ -3 & 0 & 0 & 0 \\ 0 & -6 & 0 & 0 \\ 0 & 0 & -3 & 0 \end{pmatrix}$$

It is clearly nilpotent. ■

4.3.2 Lemma. *The pairing S_W satisfies⁵*

$$S_W([\omega_k], \overline{[\omega_l]}) = \begin{cases} S_W([\omega_0], \overline{[\omega_3]}) & \text{if } k+l=3 \\ 0 & \text{otherwise} \end{cases} \quad (4.6)$$

and $S_W([\omega_0], \overline{[\omega_3]}) \in \tau^{-3}\mathbb{C}$.

Proof. To simplify the notation we will be writing S instead of S_W . By (2.7) we know that

$$S([\omega_k], \overline{[\omega_l]}) \in \tau^{-3}\mathbb{C}[\tau^{-1}].$$

On the other hand, by (2.10) we get

$$S(e_k, \overline{e_l}) = \tau^k(-\tau)^l S([\omega_k], \overline{[\omega_l]}) \in \mathbb{C}[\tau],$$

therefore $S([\omega_k], \overline{[\omega_l]}) \in \tau^{-(k+l)}\mathbb{C}[\tau]$. Hence

$$\begin{aligned} S([\omega_k], \overline{[\omega_l]}) &= 0 & \text{if } k+l < 3, \\ S([\omega_k], \overline{[\omega_l]}) &\in \tau^{-3}\mathbb{C} & \text{if } k+l = 3. \end{aligned} \quad (4.7)$$

To show vanishing in the remaining 4 cases with $k+l > 3$ one just combines (2.5) and (4.7). Let us consider the case $k=1, l=3$ only. Applying (2.5) to $S([\omega_0], \overline{[\omega_3]}) \in \tau^{-3}\mathbb{C}$ and using (4.7) we get

$$\begin{aligned} -3\tau^{-1}S([\omega_0], \overline{[\omega_3]}) &= \frac{d}{d\tau}S([\omega_0], \overline{[\omega_3]}) = S(\partial_\tau[\omega_0], \overline{[\omega_3]}) - S([\omega_0], \overline{\partial_\tau[\omega_3]}) = \\ &= -S(3[\omega_1], \overline{[\omega_3]}) + S([\omega_0], \overline{3q[\omega_1] + 3\theta[\omega_3]}) = \\ &= -3S([\omega_1], \overline{[\omega_3]}) - 3\tau^{-1}S([\omega_0], \overline{[\omega_3]}), \end{aligned}$$

and therefore $S([\omega_1], \overline{[\omega_3]}) = 0$.

Similarly one can show that $S([\omega_0], \overline{[\omega_3]}) = S([\omega_2], \overline{[\omega_1]})$. Moreover, by (2.6) we have $S([\omega_0], \overline{[\omega_3]}) = S([\omega_3], \overline{[\omega_0]})$ and $S([\omega_2], \overline{[\omega_1]}) = S([\omega_1], \overline{[\omega_2]})$. ■

4.4 Canonical solution to the Birkhoff problem. The problem of extending (G_0, ∇) to \mathbb{P}_θ^1 described in Section 2.3 has a canonical solution given by Hodge theory. Here we will show that our solution given by the basis $\omega_0, \dots, \omega_3$ is canonical in this sense. We more or less keep notation of [DoSa2, Sec. 5]. Details can be found in loc. cit. and references therein.

It is a general fact (see [Sa2]) that the vector space

$$H = \bigoplus_{\alpha \in [0,1]} \text{Gr}_\alpha^V G \quad (4.8)$$

carries a mixed Hodge structure, i.e. H has a rational structure $H_{\mathbb{Q}}$, an increasing weight filtration $W_\bullet H_{\mathbb{Q}}$, a decreasing Hodge filtration $F^\bullet H$, s.t. the Hodge filtration induces a pure Hodge structure of weight m on $\text{Gr}_m^W H$ for all m .

For the function \tilde{f} we have

$$\begin{aligned} H &= \text{Gr}_0^V G = \bigoplus_{i=0}^3 \mathbb{C} e_i \\ F^p H &= \bigoplus_{i=0}^{3-p} \mathbb{C} e_i, \end{aligned}$$

⁵The overline over the second argument of S_W stresses that the element is considered as a section of $j^*\mathcal{F}_W$. Therefore, τ and $\nabla_{\frac{\partial}{\partial \tau}}$ act with the opposite sign.

where abusing notation we write e_i 's meaning classes of e_i 's in H . The complexification of the weight filtration is

$$0 \subset \mathbb{C}e_3 \subset \mathbb{C}e_3 \subset \mathbb{C}e_2 \oplus \mathbb{C}e_3 \subset \mathbb{C}e_2 \oplus \mathbb{C}e_3 \subset \mathbb{C}e_1 \oplus \mathbb{C}e_2 \oplus \mathbb{C}e_3 \subset \mathbb{C}e_1 \oplus \mathbb{C}e_2 \oplus \mathbb{C}e_3 \subset H, \quad (4.9)$$

where the first term on the left is $W_{-1}H$. The only non-trivial associated graded objects are $\text{Gr}_0^W H$, $\text{Gr}_2^W H$ and $\text{Gr}_4^W H$.

In the case of the function \tilde{f} Saito's canonical opposite filtration (it is a filtration on H) is defined as

$$H_{\text{Saito}}^\bullet = \sum_q \overline{F^q H} \cap W_{3+q-\bullet} H.$$

From (4.9) and the fact that the weight filtration is stable under conjugation we have

$$\bar{e}_i = \sum_{r=i}^3 a_{ri} e_r, \quad (4.10)$$

with $a_{ii} \neq 0$. Using (4.10) one can show that

$$H_{\text{Saito}}^p = \bigoplus_{i=0}^{3-p} \mathbb{C}e_{3-i}. \quad (4.11)$$

To any solution of the Birkhoff problem one can attach a filtration H^\bullet on H by the formula

$$H^i := G_\infty^i \cap V_0 G / G_\infty^i \cap V_{-1} G,$$

where $G_\infty^k = \tau^k G_\infty$. To prove that this solution of the Birkhoff problem is canonical one needs to show that the filtrations H^\bullet and H_{Saito}^\bullet coincide.

In our case it is easy to see that

$$H^i = \bigoplus_{i=0}^{3-p} \mathbb{C}e_{3-i},$$

which coincides with (4.11). Hence, our solution to the Birkhoff problem is canonical.

4.5 Frobenius manifold. Ideally one would like to show the existence of (or to exhibit) a deformation of \tilde{f} producing a Saito's framework isomorphic to $QH(Q_3)$. We have not been able to achieve this goal so far.

There is a general construction of such Saito's frameworks due to A. Douai and C. Sabbah (see [DoSa1]) but it requires some additional properties of \tilde{f} that we have not been able to check. Namely, one needs to show that \tilde{f} is M -tame. We refer to loc.cit. for details.

Assume that such Saito's framework $(M, \circ, e, g_\omega, E)$ exists. Then the initial conditions for M at the origin are

$$T = T_{x_0} M, \quad \mathcal{U} = A_0, \quad \mathcal{V} = -A_\infty + \frac{3}{2} \text{Id}, \quad g_\omega, \quad e.$$

Therefore, by Lemmas 4.2.3 and 4.3.2 we see that these initial conditions coincide with those of Section 3.1.1.

A Proof of Lemma 4.1.1

The proof of Lemma 4.1.1 given here has been kindly explained to us by Claude Sabbah and András Némethi.

A.1 Vanishing cycles. Here we recall some basic facts about functors of vanishing cycles. For a complex algebraic variety X we denote by $D_c^b(X)$ the bounded derived category of $\mathbb{C}_{X^{an}}$ -modules with constructible cohomology, where X^{an} is the associated analytic space.

A.1.1 Functor of vanishing cycles. Let X be a complex algebraic variety and $g: X \rightarrow \mathbb{A}_t^1$ a morphism. The functor of vanishing cycles to the fiber over 0 of the morphism g is denoted Φ_g . If one considers the fiber over a , then one shifts g and considers Φ_{g-a} .

If we denote X_0 the fiber of g over 0, then the functor of vanishing cycles to this fiber is a triangulated functor

$$\Phi_g: D_c^b(X) \rightarrow D_c^b(X_0),$$

i.e. it maps distinguished triangles to distinguished triangles. See [Di] for a precise definition.

Below we collect some basic properties of these functors. They are standard and can be found in [Di].

A.1.2 Proper morphism. Let $\pi: X \rightarrow Y$ be a morphism of algebraic varieties and consider the following commutative diagram

$$\begin{array}{ccc} X_0 & \longrightarrow & X \\ \downarrow \widehat{\pi} & & \downarrow \pi \\ Y_0 & \longrightarrow & Y \\ \downarrow & & \downarrow g \\ \{0\} & \longrightarrow & \mathbb{A}^1 \end{array}$$

where X_0 and Y_0 are fibers over 0. Naturally one can attach to it the diagram of derived categories and functors between them

$$\begin{array}{ccc} D_c^b(X_0) & \xleftarrow{\Phi_{g \circ \pi}} & D_c^b(X) \\ \downarrow R\widehat{\pi}_* & & \downarrow R\pi_* \\ D_c^b(Y_0) & \xleftarrow{\Phi_g} & D_c^b(Y) \end{array}$$

Fact: if π is *proper*, then the above diagram is commutative (e.g. this is true if π is a closed embedding).

A.1.3 Restriction to an open subset. Let $U \subset X$ be an open subset and let j be the natural inclusion. We have a commutative diagram

$$\begin{array}{ccc} U_0 & \longrightarrow & U \\ \downarrow \widehat{j} & & \downarrow j \\ X_0 & \longrightarrow & X \\ \downarrow & & \downarrow g \\ \{0\} & \longrightarrow & \mathbb{A}^1 \end{array}$$

with U_0 and X_0 being fibers over 0. Consider the associated diagram of derived categories and functors between them

$$\begin{array}{ccc} D_c^b(U_0) & \xleftarrow{\Phi_{g \circ j}} & D_c^b(U) \\ \widehat{j}^{-1} \uparrow & & \uparrow j^{-1} \\ D_c^b(X_0) & \xleftarrow{\Phi_g} & D_c^b(X) \end{array}$$

Fact: the above diagram is commutative.

A.1.4 Duality. For any complex algebraic variety Y there exists a functor $\mathbf{D}_Y: D^b(Y) \rightarrow D^b(Y)$ defined by

$$\mathbf{D}_Y(\mathcal{F}^\bullet) := R\mathcal{H}om(\mathcal{F}^\bullet, \omega_Y),$$

where ω_Y is the dualizing complex. It has the property $\mathbf{D}_Y \circ \mathbf{D}_Y \simeq \text{Id}_{D^b(Y)}$. Moreover, this functor restricts to $D_c^b(Y)$ and we will use the same notation for this restriction. If we do not want specify the space, we will just denote it \mathbf{D} .

One can show that the following properties hold:

1. For an arbitrary morphism $f: X \rightarrow Y$ of algebraic varieties we have

$$\mathbf{D}_Y \circ Rf_* \circ \mathbf{D}_X \simeq Rf_!$$

and

$$Rf_* \simeq \mathbf{D}_Y \circ Rf_! \circ \mathbf{D}_X. \quad (\text{A.1})$$

One can be obtained from the other using $\mathbf{D} \circ \mathbf{D} \simeq \text{Id}$.

2. If $g: Y \rightarrow \mathbb{A}^1$ is a morphism, then there exists a non-functorial isomorphism

$$\mathbf{D} \circ \Phi_g(\mathcal{F}^\bullet) \simeq (\Phi_g \circ \mathbf{D}(\mathcal{F}^\bullet))[-2]. \quad (\text{A.2})$$

3. Duality commutes with restriction to an open subvariety.

4. If Y is smooth, then

$$\omega_Y \simeq \mathbb{C}_Y[2 \dim Y]. \quad (\text{A.3})$$

Hence, $\mathbf{D}_Y(\mathbb{C}_Y) \simeq \mathbb{C}_Y[2 \dim Y]$. Here $\dim Y$ is the complex dimension.

5. The functor \mathbf{D} preserves the support.

A.2 Setup I. Let X be smooth complex algebraic variety, U an open smooth subvariety, and Z the complement to U . Let $\bar{f}: X \rightarrow \mathbb{A}^1$ be a proper morphism. Then we have a commutative diagram

$$\begin{array}{ccccc} U & \xrightarrow{j} & X & \xleftarrow{i} & Z \\ & \searrow f_U & \downarrow \bar{f} & \swarrow f_Z & \\ & & \mathbb{A}^1 & & \end{array} \quad (\text{A.4})$$

- (i) By (A.1) we have the isomorphism

$$Rj_*(\mathbb{C}_U) \simeq \mathbf{D}_X \circ Rj_! \circ \mathbf{D}_U(\mathbb{C}_U).$$

Applying $\Phi_{\bar{f}}$ to both sides and using (A.3) we get

$$\Phi_{\bar{f}} \circ Rj_*(\mathbb{C}_U) \simeq \Phi_{\bar{f}} \circ \mathbf{D}_X \circ Rj_!(\mathbb{C}_U[2 \dim U]).$$

Using (A.2) we can rewrite it as

$$\Phi_{\bar{f}} \circ Rj_*(\mathbb{C}_U) \simeq \left(\mathbf{D}_X \circ \Phi_{\bar{f}} \circ Rj_!(\mathbb{C}_U[2 \dim U]) \right)[-2].$$

If the support of the complex $\Phi_{\bar{f}} \circ Rj_!(\mathbb{C}_U)$ is contained in U , then the same is true for $\Phi_{\bar{f}} \circ Rj_*(\mathbb{C}_U)$ (cf. Property 5 from Section A.1.4). Therefore, it does not matter which one to consider for cohomological tameness, since we are interested only in the support.

(ii) There exists a standard short exact sequence (see [Ha], Chapter II, exercise 1.19.c)

$$0 \rightarrow Rj_! \mathbb{C}_U \rightarrow \mathbb{C}_X \rightarrow i_* \mathbb{C}_Z \rightarrow 0.$$

Applying $\Phi_{\bar{f}}$ to it we get a distinguished triangle

$$\Phi_{\bar{f}} \circ Rj_!(\mathbb{C}_U) \rightarrow \Phi_{\bar{f}}(\mathbb{C}_X) \rightarrow \Phi_{\bar{f}} \circ i_*(\mathbb{C}_Z) \rightarrow \Phi_{\bar{f}} \circ Rj_!(\mathbb{C}_U)[1].$$

Since i is *proper*, we can rewrite it as

$$\Phi_{\bar{f}} \circ Rj_!(\mathbb{C}_U) \rightarrow \Phi_{\bar{f}}(\mathbb{C}_X) \rightarrow \hat{i}_* \circ \Phi_{\bar{f} \circ i}(\mathbb{C}_Z) \rightarrow \Phi_{\bar{f}} \circ Rj_!(\mathbb{C}_U)[1],$$

where $\hat{i}: Z_0 \rightarrow X_0$ is the natural closed embedding.

In the future applications we will need to prove that $\Phi_{\bar{f}} \circ Rj_!(\mathbb{C}_U)$ is supported on U_0 . This would follow if we prove that $\Phi_{\bar{f}}(\mathbb{C}_X)$ is supported on U_0 and $\Phi_{\bar{f} \circ i}(\mathbb{C}_Z)$ has empty support (since \hat{i}_* does not change support).

Complexes $\Phi_{\bar{f}}(\mathbb{C}_X)$ and $\Phi_{\bar{f} \circ i}(\mathbb{C}_Z)$ compute vanishing cycles of \bar{f} and f_Z with values in \mathbb{C}_X and \mathbb{C}_Z respectively. Therefore, their support can be computed geometrically.

A.3 Setup II. It is clear that proving cohomological tameness of (4.1) is equivalent to proving cohomological tameness of

$$g(x, y, z) = y(z + 1) + \frac{qx^2}{(xy - 1)z}.$$

Here x, y, z are coordinates on $\mathbb{A}^3 = \text{Spec}(\mathbb{C}[x, y, z])$ and g is defined on $U \subset \mathbb{A}^3$ given by the equation $(xy - 1)z \neq 0$. By a simple computation of partial derivatives one can see that all critical points of g lie in the subset $\{xy - z - 1 = 0\}$.

Consider the map $U \rightarrow U \times \mathbb{A}_t^1$ given by the graph of g and denote its image $\Gamma_g \subset U \times \mathbb{A}_t^1$. Further, consider the natural embedding of $U \times \mathbb{A}_t^1$ into $\mathbb{A}^3 \times \mathbb{A}_t^1 \subset (\mathbb{P}^1)^3 \times \mathbb{A}_t^1$. Let $\bar{\Gamma}_g$ be the closure of Γ_g in $(\mathbb{P}^1)^3 \times \mathbb{A}_t^1$. Thus, we have a commutative diagram completely analogous to (A.4)

$$\begin{array}{ccc} \Gamma_g & \xrightarrow{j} & \bar{\Gamma}_g \xleftarrow{i} \bar{\Gamma}_g \setminus \Gamma_g \\ & \searrow g_U & \downarrow \bar{g} \\ & & \mathbb{A}_t^1 \\ & & \swarrow g_Z \end{array} \quad (\text{A.5})$$

where \bar{g} is induced by projection $(\mathbb{P}^1)^3 \times \mathbb{A}_t^1 \rightarrow \mathbb{A}_t^1$, and we will identify g_U with g .

It is easy to see that $\Gamma_g \subset \mathbb{A}^3 \times \mathbb{A}_t^1$ is defined by the equation

$$y(z + 1) + \frac{qx^2}{(xy - 1)z} = t,$$

and $\bar{\Gamma}_g \subset (\mathbb{P}^1)^3 \times \mathbb{A}_t^1$ is given by the homogeneous equation

$$x_0 z_1 (x_1 y_1 - x_0 y_0) [y_1 (z_1 + z_0) - t y_0 z_0] + q z_0^2 x_1^2 y_0^2 = 0. \quad (\text{A.6})$$

A.4 Open cover. Consider an open cover of $(\mathbb{P}^1)^3 \times \mathbb{A}_t^1$ by 8 open subsets

$$V_{i,j,k} = \{x_i y_j z_k \neq 0\},$$

each of which is just $\mathbb{A}^3 \times \mathbb{A}_t^1$. As standard local coordinates on these open subsets we will be always using fractions $\frac{x_{i+1}}{x_i}, \frac{y_{j+1}}{y_j}, \frac{z_{k+1}}{z_k}$ and t (in the subscripts here we mean mod 2 sum: $1 + 1 = 0$).

On each $V_{i,j,k}$ one can write down the equation of $\bar{\Gamma}_g \cap V_{i,j,k}$ in terms of local coordinates and we will be referring to this equation simply as "the equation of $\bar{\Gamma}_g$ in the chart $V_{i,j,k}$ ".

A.5 How to compute $\Phi_{\bar{g}}(\mathbb{C}_{\bar{\Gamma}_g})$? Decompose $\bar{\Gamma}_g$ into the disjoint union

$$\bar{\Gamma}_g = W \sqcup S,$$

where S is the singular locus of $\bar{\Gamma}_g$ and W is the smooth locus; S is a closed subvariety of codimension at least 1, W is open in $\bar{\Gamma}_g$ and smooth.

According to Section A.1.3, computing vanishing cycles commutes with restriction to an open subset, and therefore, to investigate the support at points of W , we can restrict to it from the beginning. Since W is smooth the support of $\Phi_{\bar{g}|_W}(\mathbb{C}_W)$ can be non-zero only in singular points of fibers of $\bar{g}|_W$ (by the implicit function theorem). Thus, on W we just need to worry about critical points of $\bar{g}|_W$.

There exists a decomposition into disjoint union

$$(\mathbb{P}^1)^3 \times \mathbb{A}_t^1 = V_{0,0,0} \sqcup \{x_0 y_0 z_0 = 0\}.$$

A.5.1 Lemma. *Let $Q \in \bar{\Gamma}_g$ be a smooth point, i.e. $Q \in W$. If $Q \in \{x_0 y_0 z_0 = 0\}$, then Q is not a critical point of $\bar{g}|_W$.*

Proof. Consider a chart $V_{i,j,k}$ and temporarily denote the local coordinates just by x, y, z . Let $P(x, y, z, t) = 0$ be equation (A.6) written in these coordinates.

In this notation the intersection $V_{i,j,k} \cap S$ is defined by the system

$$\begin{aligned} x_0 z_1 (x_1 y_1 - x_0 y_0) y_0 z_0 &= 0 & (A.7) \\ P_x(x, y, z, t) &= 0 \\ P_y(x, y, z, t) &= 0 \\ P_z(x, y, z, t) &= 0 \\ P(x, y, z, t) &= 0, \end{aligned}$$

where we have written the first equation, which comes from the derivative with respect to t , in the original homogeneous coordinates.

On the other hand, the intersection of the fiber of \bar{g} over the point $d \in \mathbb{A}_t^1$ with $V_{i,j,k}$ is given by the equation $P(x, y, z, d) = 0$. Therefore, on $V_{i,j,k}$ the singular locus of this fiber is given by the system

$$\begin{aligned} P_x(x, y, z, d) &= 0 & (A.8) \\ P_y(x, y, z, d) &= 0 \\ P_z(x, y, z, d) &= 0 \\ P(x, y, z, d) &= 0. \end{aligned}$$

From (A.6) it is easy to see that if a point $Q \in \{x_0 y_0 z_0 = 0\}$ with coordinates (a, b, c, d) satisfies (A.8), then it satisfies it for arbitrary d , i.e. we get singular points simultaneously in all fibers. Thus, on the locus $\{x_0 y_0 z_0 = 0\}$ systems (A.8) and (A.7) coincide.

Therefore, if $Q \in \{x_0 y_0 z_0 = 0\}$ is a smooth point of $\bar{\Gamma}_g$, then it is also a smooth point in the respective fiber of \bar{g} (and $\bar{g}|_W$). ■

A.5.2 Strategy. In the rest of this section we will treat points in $V_{0,0,0}$ and in $\{x_0 y_0 z_0 = 0\}$ separately. In the latter case, by the above lemma, it is enough to look at vanishing cycles at singular points of $\bar{\Gamma}_g$.

A.6 Chart $V_{0,0,0}$. Recall that $\Gamma_g \subset V_{0,0,0}$ and in this chart we need to prove that the support is contained in Γ_g . In this chart $\bar{\Gamma}_g$ is given by

$$z(xy - 1)[y(1 + z) - t] + qx^2 = 0$$

and Γ_g is defined by the intersection with $z(xy - 1) \neq 0$. Consider functions

$$\begin{aligned} x_1 &= x \\ y_1 &= y(1 + z) - t \\ z_1 &= z(xy - 1) \\ t_1 &= t. \end{aligned} \tag{A.9}$$

Computing the Jacobian we get

$$J = xy - z - 1,$$

and hence on the complement to the closed subset $\{xy - z - 1 = 0\}$ formulas (A.9) define a new coordinate system. Notice that $(\bar{\Gamma}_g \setminus \Gamma_g) \cap V_{0,0,0} = \{x = 0, z = 0\}$ lies in this open set.

On this open set the equation for $\bar{\Gamma}_g$ can be rewritten as

$$y_1 z_1 + q x^2 = 0, \tag{A.10}$$

and hence the restriction of \bar{g} to this open set is a projection and therefore has no vanishing cycles. Thus, we conclude that in this chart all vanishing cycles of \bar{g} with coefficients in $\mathbb{C}_{\bar{\Gamma}_g}$ live in Γ_g .

Using (A.10) it is easy to see that

$$V_{0,0,0} \cap S = \{x = 0, z = 0, y = t\}.$$

A.7 The set $\{x_0 y_0 z_0 = 0\}$. To check vanishing of stalks of $\Phi_{\bar{g}}(\mathbb{C}_{\bar{\Gamma}_g})$ at points of S we will be restricting to different charts and work in local coordinates. The whole chart $V_{0,0,0}$ has already been considered. Hence, there are seven charts left to be checked.

A.7.1 Charts $V_{1,0,0}, V_{0,1,0}, V_{0,0,1}$. In the chart $V_{0,1,0}$ the equation of $\bar{\Gamma}_g$ takes the form

$$z(x - y')[(z + 1) - y't] + q x^2 y'^2 = 0. \tag{A.11}$$

Finding singular points of $\bar{\Gamma}_g$ with $y' = 0$ (we need to check only them) we get that there are two singular lines given by

$$\begin{aligned} x = 0, y' = 0, z = 0 \\ x = 0, y' = 0, z = -1. \end{aligned} \tag{A.12}$$

By computing the Jacobian it is easy to see that functions

$$x_1 = x, \quad y_1 = y', \quad z_1 = (1 + z - ty')z, \quad t_1 = t. \tag{A.13}$$

form a coordinate system in a neighborhood of (A.12). In terms of these coordinates (A.11) takes the form

$$z_1(x_1 - y_1) + q x_1^2 y_1^2 = 0,$$

and is independent of t . Hence, there are no vanishing cycles.

It is easy to check that the sets $S \cap V_{1,0,0} \cap \{x_0 = 0\}$ and $S \cap V_{0,0,1} \cap \{z_0 = 0\}$ are empty.

A.7.2 Charts $V_{1,1,0}, V_{0,1,1}$. In the previous section we have considered the charts $V_{1,0,0}, V_{0,1,0}, V_{0,0,1}$. Therefore, in the chart $V_{1,1,0}$ we only need to look at points in $S \cap V_{1,1,0} \cap \{x_0 = 0\} \cap \{y_0 = 0\}$. Keeping in mind this remark one can treat the chart $V_{1,1,0}$ completely similarly to $V_{0,1,0}$ just replacing x by x' everywhere; the conclusion is also similar.

An analogous remark applies to $V_{1,0,1}$ and $V_{0,1,1}$ as well. Looking for points in $S \cap V_{0,1,1} \cap \{y_0 = 0\} \cap \{z_0 = 0\}$ it is easy to see that this set is empty. The chart $V_{1,0,1}$ will be considered in the next section.

A.7.3 Chart $V_{1,0,1}$. This is the only case where the argument is a bit more involved. In this chart the equation of $\overline{\Gamma}_g$ takes form

$$x'(y - x')[y(1 + z') - tz'] + qz'^2 = 0,$$

and the singular locus with $x' = 0$ and $z' = 0$ is the line

$$x' = 0, y = 0, z' = 0.$$

It is not clear if one can find such a simple argument via coordinate changes as above. Therefore, we proceed differently.

For each value of t the fiber over it has an isolated singularity at the origin, and we need to prove that there are no vanishing cycles to this point. Note that the family is of the form

$$\alpha(x', y, z') + t\beta(x', y, z') = 0,$$

where

$$\begin{aligned}\alpha(x', y, z') &= x'(y - x')y(1 + z') + qz'^2 \\ \beta(x', y, z') &= -x'(y - x')z'.\end{aligned}$$

According to Corollary 2.1 of [Pa], if this family of isolated hypersurface singularities is μ -constant (i.e. Milnor numbers coincide for all fibers), then it is topologically locally trivial over the base. In particular, this implies the absence of vanishing cycles.

Let us compute the Milnor numbers. Consider the polynomial $P(x', y, z') = x'(y - x')[y(1 + z') - tz'] + qz'^2$. Its partial derivatives are

$$\begin{aligned}P_{x'} &= (y - 2x')[y(1 + z') - tz'] \\ P_y &= x'[y(1 + z') - tz'] + x'(y - x')(1 + z') = x'[(2y - x')(1 + z') - tz'] \\ P_{z'} &= x'(y - x')[y - t] + 2qz'.\end{aligned}\tag{A.14}$$

By definition the Milnor number is

$$\mu = \dim_{\mathbb{C}}(\mathbb{C}\{x', y, z'\}/(P_{x'}, P_y, P_{z'})),$$

and we need to show that it does not depend on t .

From (A.14) we see that $2qz' = -x'(y - x')[y - t]$ in the quotient $\mathbb{C}\{x', y, z'\}/(P_{x'}, P_y, P_{z'})$. Hence, the latter can be rewritten as

$$\mathbb{C}\{x', y\}/(\tilde{P}_{x'}, \tilde{P}_y),\tag{A.15}$$

where

$$\begin{aligned}\tilde{P}_{x'} &= (y - 2x')[y(1 - \frac{x'(y - x')[y - t]}{2q}) + t\frac{x'(y - x')[y - t]}{2q}] \\ \tilde{P}_y &= x'[(2y - x')(1 - \frac{x'(y - x')[y - t]}{2q}) + t\frac{x'(y - x')[y - t]}{2q}].\end{aligned}$$

Note that we can write

$$\tilde{P}_{x'} = f_1 f_2, \quad \tilde{P}_y = f_3 f_4,$$

where

$$\begin{aligned}f_1 &= (y - 2x'), & f_2 &= [y(1 - \frac{x'(y - x')[y - t]}{2q}) + t\frac{x'(y - x')[y - t]}{2q}] \\ f_3 &= x', & f_4 &= [(2y - x')(1 - \frac{x'(y - x')[y - t]}{2q}) + t\frac{x'(y - x')[y - t]}{2q}].\end{aligned}$$

It is easy to check that any pair out of f_1, f_2, f_3, f_4 forms a coordinate system around the origin in the x', y' -plane. Let $u = f_1, v = f_2$ be such a coordinate system. Then (A.15) can be rewritten as

$$\mathbb{C}\{u, v\}/(uv, \tilde{P}_y), \quad (\text{A.16})$$

where \tilde{P}_y is written as a power series in u and v ; it starts from terms quadratic in u and v , since $\tilde{P}_y = f_3 f_4$. Moreover, as a vector space (A.16) can be further rewritten as

$$\mathbb{C}\{u\}/(u^2) \oplus \mathbb{C}\{v\}/(v^2).$$

Thus,

$$\mu = 4,$$

and is independent of t .

A.7.4 Chart $V_{1,1,1}$. It is easy to check that the set $S \cap V_{1,1,1} \cap \{x_0 = 0\} \cap \{y_0 = 0\} \cap \{z_0 = 0\}$ is empty.

A.8 Computation of $\Phi_{\bar{F}_{oi}}(\mathbb{C}_Z)$. Recall that $Z = \bar{\Gamma}_g \setminus \Gamma_g$ and $\bar{\Gamma}_g \subset (\mathbb{P}^1)^3 \times \mathbb{C}$ is given by the homogeneous equation

$$x_0 z_1 (x_1 y_1 - x_0 y_0) [y_1 (z_1 + z_0) - t y_0 z_0] + q z_0^2 x_1^2 y_0^2 = 0.$$

The subvariety Γ_g is defined by additionally putting

$$\begin{aligned} x_0 y_0 z_0 &\neq 0 \\ z_1 (x_1 y_1 - x_0 y_0) &\neq 0. \end{aligned}$$

Thus, $\bar{\Gamma}_g \setminus \Gamma_g$ is defined by the system

$$\begin{aligned} x_0 z_1 (x_1 y_1 - x_0 y_0) [y_1 (z_1 + z_0) - t y_0 z_0] + q z_0^2 x_1^2 y_0^2 &= 0 \\ x_0 y_0 z_0 z_1 (x_1 y_1 - x_0 y_0) &= 0. \end{aligned}$$

This system is equivalent to

$$\begin{aligned} x_0 z_1 y_1 (x_1 y_1 - x_0 y_0) (z_1 + z_0) + q z_0^2 x_1^2 y_0^2 &= 0 \\ x_0 y_0 z_0 z_1 (x_1 y_1 - x_0 y_0) &= 0, \end{aligned}$$

which is independent of t . Therefore $Z = \bar{\Gamma}_g \setminus \Gamma_g$ is a product and $\Phi_{\bar{F}_{oi}}(\mathbb{C}_Z)$ has empty support.
