ON THE MIXING TIME AND SPECTRAL GAP FOR BIRTH AND DEATH CHAINS

GUAN-YU CHEN¹ AND LAURENT SALOFF-COSTE²

ABSTRACT. For birth and death chains, we derive bounds on the spectral gap and mixing time in terms of birth and death rates. Together with the results of Ding *et al.* in [15], this provides a criterion for the existence of a cutoff in terms of the birth and death rates. A variety of illustrative examples are treated.

1. INTRODUCTION

Let Ω be a countable set and (Ω, K, π) be an irreducible Markov chain on Ω with transition matrix K and stationary distribution π . Let I be the identity matrix indexed by Ω and

$$H_t = e^{-t(I-K)} = \sum_{i=0}^{\infty} e^{-t} t^i K^i / i!$$

be the associated semigroup which describes the corresponding natural continuous time process on Ω . For $\delta \in (0, 1)$, set

(1.1)
$$K_{\delta} = \delta I + (1 - \delta)K.$$

Clearly, K_{δ} is similar to K but with an additional holding probability depending of δ . We call K_{δ} the δ -lazy walk or δ -lazy chain of K. It is well-known that if K is irreducible with stationary distribution π , then

$$\lim_{m \to \infty} K^m_{\delta}(x, y) = \lim_{t \to \infty} H_t(x, y) = \pi(y), \quad \forall x, y \in \Omega, \, \delta \in (0, 1).$$

In this paper, we consider convergence in total variation. The total variation between two probabilities μ, ν on Ω is defined by $\|\mu - \nu\|_{\text{TV}} = \sup\{\mu(A) - \nu(A) | A \subset \Omega\}$. For any irreducible K with stationary distribution π , the (maximum) total variation distance is defined by

(1.2)
$$d_{\rm TV}(m) = \sup_{x \in \Omega} \|K^m(x, \cdot) - \pi\|_{\rm TV},$$

and the corresponding mixing time is given by

(1.3)
$$T_{\rm TV}(\epsilon) = \inf\{m \ge 0 | d_{\rm TV}(m) \le \epsilon\}, \quad \forall \epsilon \in (0,1).$$

We write $d_{\text{TV}}^{(c)}, T_{\text{TV}}^{(c)}$ for the total variation distance and mixing time for the continuous semigroup and $d_{\text{TV}}^{(\delta)}, T_{\text{TV}}^{(\delta)}$ for the δ -lazy walk.

A birth and death chain on $\{0, 1, ..., n\}$ with birth rate p_i , death rate q_i and holding rate r_i is a Markov chain with transition matrix K given by

$$K(i,i+1) = p_i, \quad K(i,i-1) = q_i, \quad K(i,i) = r_i, \quad \forall 0 \le i \le n,$$

where $p_i + q_i + r_i = 1$ and $p_n = q_0 = 0$. It is obvious that K is irreducible if and only if $p_i q_{i+1} > 0$ for $0 \le i < n$. Under the assumption of irreducibility, the unique stationary distribution π of K is given by $\pi(i) = c(p_0 \cdots p_{i-1})/(q_1 \cdots q_i)$, where c is a positive constant such that $\sum_{i=0}^{n} \pi(i) = 1$. The following theorem provides a bound on the mixing time using the birth and death rates and is treated in Theorems 3.1 and 3.5.

Theorem 1.1. Let K be an irreducible birth and death chain on $\{0, 1, ..., n\}$ with birth, death and holding rates p_i, q_i, r_i . Let i_0 be a state satisfying $\pi([0, i_0]) \ge 1/2$ and $\pi([i_0, n]) \ge 1/2$, where $\pi(A) = \sum_{i \in A} \pi(i)$, and set

$$t = \max\left\{\sum_{k=0}^{i_0-1} \frac{\pi([0,k])}{\pi(k)p_k}, \sum_{k=i_0+1}^n \frac{\pi([k,n])}{\pi(k)q_k}\right\}.$$

Then, for any $\delta \in [1/2, 1)$,

$$\min\left\{T_{\rm TV}^{(c)}(1/10), T_{\rm TV}^{(\delta)}(1/20)\right\} \ge \frac{t}{6},$$

and

$$\max\left\{T_{\mathrm{TV}}^{(c)}(\epsilon), T_{\mathrm{TV}}^{(\delta)}(\epsilon)\right\} \le \frac{18t}{\epsilon^2}, \quad \forall \epsilon \in (0, 1).$$

The authors of [15] derive a similar upper bound. Note that if $(X_m)_{m=0}^{\infty}$ is a Markov chain on Ω_n with transition matrix K and $\tau_i := \min\{m \ge 0 | X_m = i\}$, then $t = \max\{\mathbb{E}_0 \tau_{i_0}, \mathbb{E}_n \tau_{i_0}\}$, where \mathbb{E}_i denotes the conditional expectation given $X_0 = i$. See Lemma 3.2 for details.

A sharp transition phenomenon, known as cutoff, was observed by Aldous and Diaconis in early 1980s. See e.g. [10, 5] for an introduction and a general review of cutoffs. In total variation, a family of irreducible Markov chains $(\Omega_n, K_n, \pi_n)_{n=1}^{\infty}$ is said to present a cutoff if

(1.4)
$$\lim_{n \to \infty} \frac{T_{n,\mathrm{TV}}(\epsilon)}{T_{n,\mathrm{TV}}(\eta)} = 1, \quad \forall 0 < \epsilon < \eta < 1.$$

The family is said to present a (t_n, b_n) cutoff if $b_n = o(t_n)$ and

$$|T_{n,\mathrm{TV}}(\epsilon) - t_n| = O(b_n), \quad \forall 0 < \epsilon < 1.$$

The cutoff for the associated continuous semigroups is defined in a similar way. Given a family \mathcal{F} of irreducible Markov chains, we write \mathcal{F}_c and \mathcal{F}_{δ} for the families of corresponding continuous time chain and δ -lazy discrete time chains.

Let $\mathcal{F} = \{(\Omega_n, K_n, \pi_n) | n = 1, 2, ...\}$ be a family of birth and death chains, where $\Omega_n = \{0, 1, ..., n\}$ and K_n has birth rate $p_{n,i}$, death rate $q_{n,i}$ and holding rate $r_{n,i}$. Suppose that K_n is irreducible with stationary distribution π_n . For the family $\{(\Omega_n, K_n, \pi_n) | n = 1, 2, ...\}$, Ding *et al.* [15] showed that, in the discrete time case and assuming $\inf_{i,n} r_{n,i} > 0$, the cutoff in total variation exists if and only if the product of the total variation mixing time and the spectral gap, i.e. the smallest non-zero eigenvalue of I - K, tends to infinity. There is also a similar version for the continuous time case. In [6], we use the results of [13, 15] to provide another criterion on the cutoff using the eigenvalues of K_n . In both cases, the spectral gap is needed to determine if there is a cutoff. The following theorem provides a bound on the spectral gap using the birth and death rates.

Theorem 1.2. Consider an irreducible birth and death chain K on $\{0, 1, ..., n\}$ with birth, death and holding rates, p_i, q_i, r_i . Let π and λ be the stationary distribution and spectral gap of K and set

$$\ell = \max\left\{\max_{j:ji_0} \sum_{k=i_0+1}^j \frac{\pi([j,n])}{\pi(k)q_k}\right\}$$

where i_0 is a state such that $\pi([0, i_0]) \ge 1/2$ and $\pi([i_0, n]) \ge 1/2$. Then, $1 \le i_0 \le 2$

$$\frac{1}{4\ell} \le \lambda \le \frac{1}{\ell}.$$

The above theorem is motivated by [16], where the author considers the spectral gap of birth and death chains on \mathbb{Z} . We refer the reader to [16] and the references therein for more information. Note that if t, ℓ are the constants in Theorem 1.1-1.2, then $t \geq \ell$. Based on the results in [15], we obtain a theorem regarding cutoffs for birth and death chains.

Theorem 1.3. Consider a family of irreducible birth and death chains

$$\mathcal{F} = \{ (\Omega_n, K_n, \pi_n) | n = 1, 2, \dots \},\$$

where $\Omega_n = \{0, 1, ..., n\}$ and K_n has birth, death and holding rates, $p_{n,i}, q_{n,i}, r_{n,i}$. For $n \geq 1$, let $i_n \in \{0, ..., n\}$ be a state satisfying $\pi_n([0, i_n]) \geq 1/2$ and $\pi_n([i_n + 1, n]) \geq 1/2$ and set

$$t_n = \max\left\{\sum_{k=0}^{i_n-1} \frac{\pi_n([0,k])}{\pi_n(k)p_{n,k}}, \sum_{k=i_n+1}^n \frac{\pi_n([k,n])}{\pi_n(k)q_{n,k}}\right\}.$$

and

$$\ell_n = \max\left\{\max_{j:j < i_n} \sum_{k=j}^{i_n-1} \frac{\pi_n([0,j])}{\pi_n(k)p_{n,k}}, \max_{j:j > i_n} \sum_{k=i_n+1}^j \frac{\pi_n([j,n])}{\pi_n(k)q_{n,k}}\right\},\$$

Then, for any $\epsilon \in (0, 1/2)$ and $\delta \in (0, 1)$, there is a constant $C = C(\epsilon, \delta) > 1$ such that

$$C^{-1}t_n \le \min\{T_{n,\mathrm{TV}}^{(c)}(\epsilon), T_{n,\mathrm{TV}}^{(\delta)}(\epsilon)\} \le \max\{T_{n,\mathrm{TV}}^{(c)}(\epsilon), T_{n,\mathrm{TV}}^{(\delta)}(\epsilon)\} \le Ct_n,$$

for n large enough. Moreover, the following are equivalent.

- (1) \mathcal{F}_c has a total variation cutoff.
- (2) For $\delta \in (0, 1)$, \mathcal{F}_{δ} has a total variation cutoff.
- (3) $t_n \ell_n \to \infty$.

The above theorem is immediate from Theorems 1.1, 1.2, 2.2 and 2.3. The selection of i_n can be relaxed. See Theorem 3.6 for a precise statement. By the results in [6], Theorem 1.3 also holds when t_n is replaced by the following constant

$$s_n = \frac{1}{\lambda_{n,1}} + \dots + \frac{1}{\lambda_{n,n}},$$

where $\lambda_{n,1}, ..., \lambda_{n,n}$ are nonzero eigenvalues of $I - K_n$. Furthermore, Theorem 1.3 also holds in separation with $\delta \in [1/2, 1)$. We will use Theorem 1.3 to study the cutoff of several examples including the following theorem which concerns random walks with bottlenecks. It is a special case of Theorem 4.8.

Theorem 1.4. For $n \ge 1$, let $\Omega_n = \{0, 1, ..., n\}$, $\pi_n \equiv 1/(n+1)$ and K_n be an irreducible birth and death chain on Ω_n satisfying

$$K_n(i-1,i) = K_n(i,i-1) = \begin{cases} 1/2 & \text{for } i \notin \{x_{n,1},...,x_{n,k_n}\} \\ \epsilon_n & \text{for } i = x_{n,j}, \ 1 \le j \le k_n \end{cases}$$

where $0 \leq k_n \leq n$, $\epsilon_n \in (0, 1/2]$, $x_{n,1}, ..., x_{n,k_n} \in \Omega_n$ are distinct and the holding rate at *i* is adjusted accordingly. Set $t_n = n^2 + a_n/\epsilon_n$, where

$$a_n = \sum_{i=1}^{k_n} \min\{x_{n,i}, n+1-x_{n,i}\},\$$

and set

$$b_n = \max_{j: j \le n/2} \{ (j+1) \times | \{ 1 \le i \le k_n : j < x_{n,i} \le n-j \} | \}.$$

Then, for any $\epsilon \in (0, 1/2)$ and $\delta \in (0, 1)$, there is $C = C(\epsilon, \delta) > 1$ such that

$$C^{-1}t_n \le \min\{T_{n,\mathrm{TV}}^{(c)}(\epsilon), T_{n,\mathrm{TV}}^{(\delta)}(\epsilon)\} \le \max\{T_{n,\mathrm{TV}}^{(c)}(\epsilon), T_{n,\mathrm{TV}}^{(\delta)}(\epsilon)\} \le Ct_n$$

for n large enough.

Moreover, the following are equivalent.

- (1) \mathcal{F}_c has a total variation cutoff.
- (2) For $\delta \in (0,1)$, \mathcal{F}_{δ} has a total variation cutoff.
- (3) $a_n/(n^2\epsilon_n) \to \infty$ and $a_n/b_n \to \infty$.

The remaining of this article is organized as follows. In Section 2, the concepts of cutoffs and mixing times and fundamental results are reviewed. In Section 3, we give a proof for Theorems 1.1 and 1.2. For illustration, we consider several nontrivial examples in Section 4, where the mixing time and cutoff are determined. Note that the assumption regarding birth and death rates in Sections 3 and 4 can be relaxed using the comparison technique in [11, 12].

2. Backgrounds

Throughout this paper, for any two sequences s_n, t_n of positive numbers, we write $s_n = O(t_n)$ if there are C > 0, N > 0 such that $|s_n| \leq C|t_n|$ for $n \geq N$. If $s_n = O(t_n)$ and $t_n = O(s_n)$, we write $s_n \approx t_n$. If $t_n/s_n \to 1$ as $n \to \infty$, we write $t_n \sim s_n$.

2.1. Cutoffs and mixing time. Consider the following definitions.

Definition 2.1. Referring to the notation in (1.2), a family $\mathcal{F} = \{(\Omega_n, K_n, \pi_n) | n = 1, 2, ...\}$ is said to present a total variation

(1) precutoff if there is a sequence t_n and B > A > 0 such that

$$\lim_{n \to \infty} d_{n,\mathrm{TV}}(\lceil Bt_n \rceil) = 0, \quad \liminf_{n \to \infty} d_{n,\mathrm{TV}}(\lfloor At_n \rfloor) > 0.$$

(2) cutoff if there is a sequence t_n such that, for all $\epsilon > 0$,

$$\lim_{n \to \infty} d_{n,\mathrm{TV}}(\lceil (1+\epsilon)t_n \rceil) = 0, \quad \lim_{n \to \infty} d_{n,\mathrm{TV}}(\lfloor (1-\epsilon)t_n \rfloor) = 1.$$

In definition 2.1(2), t_n is called a cutoff time. The definition of a cutoff for continuous semigroups is similar with $\lceil \cdot \rceil$ and $\lfloor \cdot \rfloor$ deleted.

5

Remark 2.1. In Definition 2.1, if $t_n \to \infty$ (or equivalently $T_{n,\mathrm{TV}}(\epsilon) \to \infty$ for some $\epsilon \in (0,1)$), then the cutoff is consistent with (1.4). This is also true for cutoffs in continuous semigroups without the assumption $t_n \to \infty$. See [4, 5] for further discussions on cutoffs.

It is well-known that the mixing time can be bounded below by the reciprocal of the spectral gap up to a multiple constant. We cite the bound in [6] as follows.

Lemma 2.1. Let K be an irreducible transition matrix on a finite set Ω with stationary distribution π . For $\delta \in (0,1)$, let K_{δ} be the δ -lazy walk given by (1.1). Suppose (π, K) is reversible, that is, $\pi(x)K(x, y) = \pi(y)K(y, x)$ for all $x, y \in \Omega$ and let λ be the smallest non-zero eigenvalue of I - K. Then, for $\epsilon \in (0, 1/2)$,

$$T_{\rm TV}^{(c)}(\epsilon) \geq \frac{-\log(2\epsilon)}{\lambda}, \quad T_{\rm TV}^{(\delta)}(\epsilon) \geq \left\lfloor \frac{-\log(2\epsilon)}{2\max\{1-\delta,\log(2/\delta)\}\lambda} \right\rfloor,$$

where the second inequality requires $|\Omega| > 2/\delta$.

2.2. Cutoffs for birth and death chains. Consider a family of irreducible birth and death chains

$$\mathcal{F} = \{ (\Omega_n, K_n, \pi_n) | n = 1, 2, \dots \},\$$

where $\Omega_n = \{0, 1, ..., n\}$ and K_n has birth rate $p_{n,i}$, death rate $q_{n,i}$ and holding rate $r_{n,i}$. We write $\mathcal{F}_c, \mathcal{F}_\delta$ as families of the corresponding continuous time chains and δ -lazy discrete time chains in \mathcal{F} . A criterion on total variation cutoffs for families of birth and death chains was introduced in [15], which say that, for $\delta \in (0, 1)$, $\mathcal{F}_c, \mathcal{F}_\delta$ have total variation cutoffs if and only if the product of the mixing time and the spectral gap tends to infinity. As the total variation distance is comparable with the separation distance, the authors of [15] identify cutoffs in total variation and separation, where a criterion on separation cutoffs was proposed in [13]. In the recent work [6], the cutoffs for \mathcal{F}_c and \mathcal{F}_{δ} are proved to be equivalent and this leads to the following theorems.

Theorem 2.2. [6, Section 4] Let $\mathcal{F} = \{(\Omega_n, K_n, \pi_n) | n = 1, 2, ...\}$ be a family of irreducible birth and death chain with $\Omega_n = \{0, 1, ..., n\}$. For $n \ge 1$, let $\lambda_{n,1}, ..., \lambda_{n,n}$ be nonzero eigenvalues of $I - K_n$ and set

$$\lambda_n = \min_{1 \le i \le n} \lambda_{n,i}, \quad s_n = \frac{1}{\lambda_{n,1}} + \dots + \frac{1}{\lambda_{n,n}}.$$

Then, the following are equivalent.

- (1) \mathcal{F}_c has a total variation cutoff.
- (2) \mathcal{F}_{δ} has a total variation cutoff.
- (3) \mathcal{F}_c has a total variation precutoff.
- (4) \mathcal{F}_{δ} has a total variation precutoff. (5) $T_{n,\mathrm{TV}}^{(c)}(\epsilon)\lambda_n \to \infty$ for some $\epsilon \in (0,1)$.
- (6) $T_{n,\mathrm{TV}}^{(\delta)}(\epsilon)\lambda_n \to \infty \text{ for some } \epsilon \in (0,1).$
- (7) $s_n \lambda_n \to \infty$.

Theorem 2.3. [6, Section 4] Referring to Theorem 2.2, it holds true that, for $\epsilon, \eta \in (0, 1/2) \text{ and } \delta \in (0, 1),$

$$T_{n,\mathrm{TV}}^{(c)}(\epsilon) \asymp T_{n,\mathrm{TV}}^{(\delta)}(\eta).$$

Further, if there is $\epsilon_0 \in (0, 1/2)$ such that $T_{n, \text{TV}}^{(c)}(\epsilon_0)\lambda_n$ or $T_{n, \text{TV}}^{(\delta)}(\epsilon_0)\lambda_n$ is bounded, then, for any $\epsilon \in (0, 1/2)$ and $\delta \in (0, 1)$,

$$T_{n,\mathrm{TV}}^{(c)}(\epsilon) \simeq T_{n,\mathrm{TV}}^{(\delta)}(\epsilon) \simeq \lambda_n^{-1}.$$

2.3. A remark on the precutoff. Note that if there is no cutoff in total variation, the approximation in Theorem 2.3 may fail for $\epsilon \in (1/2, 1)$. This means that, for $0 < \epsilon < 1/2 < \eta < 1$, the orders of $T_{n,\text{TV}}^{(c)}(\epsilon)$ and $T_{n,\text{TV}}^{(c)}(\eta)$ can be different. Consider the following example. For $n \geq 3$, let $\Omega_n = \{0, 1, ..., n\}, M_n = \lfloor n/2 \rfloor$ and

(2.1)
$$\begin{cases} K_n(i, i+1) = K_n(i+1, i) = 1/2 & \text{for } 0 \le i < n, i \ne M_n \\ K_n(M_n, M_n+1) = K_n(M_n+1, M_n) = \epsilon_n \\ K_n(0, 0) = K_n(n, n) = 1/2 \\ K_n(M_n, M_n) = K_n(M_n+1, M_n+1) = 1/2 - \epsilon_n \end{cases}$$

with $\epsilon_n \leq 1/2$. Assume that $\epsilon_n = o(n^{-2})$. By Theorem 1.4, we have

$$T_{n,\mathrm{TV}}^{(c)}(\epsilon) \asymp T_{n,\mathrm{TV}}^{(\delta)}(\epsilon) \asymp n/\epsilon_n, \quad \forall \epsilon \in (0, 1/2), \, \delta \in (0, 1).$$

Next, we consider the δ -lazy discrete time case with $\delta = 1/2$. Let $K_{n,1/2} = (I + K_n)/2$ and K'_n be the 1/2-lazy simple random walk on $\{0, 1, ..., M_n\}$, that is,

$$\begin{cases} K'_n(i, i+1) = K'_n(i+1, i) = 1/4, & \forall 0 \le i < M_n \\ K'_n(i, i) = 1/2, & \forall 0 < i < M_n \\ K'_n(0, 0) = K'_n(M_n, M_n) = 3/4 \end{cases}$$

For $n \geq 3$, set

$$c_n = \min_{0 \le i,j \le M_n} \frac{K_{n,1/2}^{m_n}(i,j)}{(K'_n)^{m_n}(i,j)}, \quad C_n = \max_{0 \le i,j \le M_n} \frac{K_{n,1/2}^{m_n}(i,j)}{(K'_n)^{m_n}(i,j)}$$

Proposition 2.4. If $m_n \simeq n^2$, then

$$c_n \to 1$$
, $C_n \to 1$, as $n \to \infty$.

Proof. For $\ell \ge 1$, let $(i_0, i_1, ..., i_\ell)$ be a path in $\{0, 1, ..., M_n\}$. Note that

$$\prod_{k=1}^{\ell} K_{n,1/2}(i_{k-1}, i_k) \ge \left(\frac{3/4 - \epsilon_n/2}{3/4}\right)^{\ell} \prod_{k=1}^{\ell} K'_n(i_{k-1}, i_k)$$

This implies $c_n \ge (1 - 2\epsilon_n/3)^{m_n} \sim 1$ as $n \to \infty$. To see an upper bound of C_n , one may use Lemma 4.4 in [15] to conclude that, for $0 \le i \le n$ and $\ell \ge 0$,

$$\begin{cases} K_{n,1/2}^{\ell}(i,j) \ge K_{n,1/2}^{\ell}(i,j-1) & \forall 1 \le j \le i \\ K_{n,1/2}^{\ell}(i,j) \ge K_{n,1/2}^{\ell}(i,j+1) & \forall i \le j < n \end{cases},$$

and, for $0 \le i \le M_n$ and $\ell \ge 0$,

$$\begin{cases} (K'_n)^{\ell}(i,j) \ge (K'_n)^{\ell}(i,j-1) & \forall 1 \le j \le i \\ (K'_n)^{\ell}(i,j) \ge (K'_n)^{\ell}(i,j+1) & \forall i \le j < M_n \end{cases}$$

By the induction, the above observation implies that, for any probabilities μ, ν on $\{0, ..., n\}, \{0, ..., M_n\}$ satisfying $\mu(i) = \nu(i)$ for $0 \le i \le M_n$,

$$\mu K_{n,1/2}^{\ell}(j) \le \nu (K_n')^{\ell}(j), \quad \forall 0 \le j \le M_n, \, \ell \ge 0.$$

This yields $C_n \leq 1$ for all $n \geq 3$.

7

For $\epsilon \in (0,1)$, let $T'_{n,\mathrm{TV}}(\epsilon)$ be the total variation mixing time for K'_n . It is wellknown that, for $\epsilon \in (0,1)$, $T'_{n,\mathrm{TV}}(\epsilon) \simeq n^2$. Let $d^{(1/2)}_{n,\mathrm{TV}}$, $d'_{n,\mathrm{TV}}$ be the total variation distance for $K_{n,1/2}, K'_n$. As a consequence of the above discussion, we obtain, for $\epsilon \in (0,1)$,

$$\limsup_{n \to \infty} d_{n,\mathrm{TV}}^{(1/2)}(T'_{n,\mathrm{TV}}(\epsilon)) \le \frac{1}{2} \left(1 + \limsup_{n \to \infty} d'_{n,\mathrm{TV}}(T'_{n,\mathrm{TV}}(\epsilon)) \right) \le \frac{1+\epsilon}{2}.$$

Thus, for $\epsilon \in (1/2, 1)$, $T_{n, \text{TV}}^{(1/2)}(\epsilon) = O(n^2)$. Note that, for $m_n = o(n^2)$,

$$\lim_{n \to \infty} \sum_{i \le an} K_{n,1/2}^{m_n}(0,i) = 1, \quad \forall a > 0.$$

This yields $n^2 = O(T_{n,\text{TV}}^{(1/2)}(\epsilon))$ for $\epsilon > 0$. The above discussion is also valid for the continuous time case and any δ -lazy discrete time case. We summarizes the results in the following theorem.

Theorem 2.5. Let $\mathcal{F} = \{(\Omega_n, K_n, \pi_n) | n = 1, 2, ...\}$ be the family of birth and death chains in (2.1) and $\delta \in (0, 1)$. Suppose that $\epsilon_n = o(n^{-2})$. Then, there is no total variation cutoff for \mathcal{F}_c and \mathcal{F}_{δ} . Furthermore, for $\epsilon \in (0, 1/2)$,

$$T_{n,\mathrm{TV}}^{(c)}(\epsilon) \asymp T_{n,\mathrm{TV}}^{(\delta)}(\epsilon) \asymp n/\epsilon_n,$$

and, for $\epsilon \in (1/2, 1)$,

$$T_{n,\mathrm{TV}}^{(c)}(\epsilon) \asymp T_{n,\mathrm{TV}}^{(\delta)}(\epsilon) \asymp n^2.$$

Remark 2.2. Figure 1 displays the total variation distances of the birth and death chains on $\{1, 2, ..., 100\}$ with transition matrices K_1 and K_2 given by

$$\begin{cases} K_1(i,i) = 1/2, & \text{for } i \notin \{1,50,51,100\} \\ K_1(i,i+1) = K_1(i+1,i) = 1/4, & \text{for } i < 50 \text{ or } i > 51 \\ K_1(i,i) = 3/4 & \text{for } k \in \{1,100\} \\ K_1(i,i+1) = K_1(i+1,i) = 10^{-3} & \text{for } k = 50 \\ K_1(i,i) = K_1(i,i) = 3/4 - 10^{-3} & \text{for } i \in \{50,51\} \\ K_1(i,j) = 0 & \text{otherwise} \end{cases}$$

and

$$\begin{cases} K_2(i, i+1) = K_2(i+1, i) = 10^{-2} & \text{for } i = 25 \\ K_2(i, i) = 3/4 - 10^{-2} & \text{for } i \in \{25, 26\} \\ K_2(i, j) = K_1(i, j) & \text{otherwise} \end{cases}$$

Note that each curve has only one sharp transition for $d_{\rm TV}(t) \leq 1/2$. This is consistent with Theorem 1.3. These examples show that multiple sharp transitions may occur for $d_{\rm TV}(t) > 1/2$. Note also that the flat part of the curves occupy very large time regions. For instance, the left most curve stays near the value 1/2 for tbetween 10^3 and 10^6 .

3. Bounds for mixing time and spectral gap

This section is dedicated to proving Theorems 1.1 and 1.2. In the first two subsections, we treat respectively the upper and lower bounds of the total variation mixing time. This leads to Theorem 1.1. In the third subsection, we provide a

FIGURE 1. The curves display the total variation distance of the chains in Remark 2.2, where the left most curve is for K_1 and the right most curve is for K_2 . The curve consists of the points $(m, d_{\rm TV}(100^{\lfloor 0.1 \times m \rfloor}))$ with m = 1, 2, ..., 50. The right most point of each curve corresponds to $d_{\rm TV}(t)$ with $t = 10^{10}$.

relaxation of the choice of i_n in Theorem 1.3. In the last subsection, we introduce a bound on the spectral gap which includes Theorem 1.2.

3.1. An upper bound of the mixing time. Let (Ω, K, π) be an irreducible birth and death chain, where $\Omega = \{0, 1, ..., n\}$ and K has birth rate p_i , death rate q_i and holding rate r_i . Let $(X_m)_{m=0}^{\infty}$ be a realization of the discrete time chain. Obviously, if N_t is a Poisson process with parameter 1 and independent of $(X_m)_{m=0}^{\infty}$, then $(X_{N_t})_{t\geq 0}$ is a realization of the continuous time chain. For $\delta \in [0, 1)$, if $(B_m^{(\delta)})_{m=1}^{\infty}$ is a sequence of independent Bernoulli $(1 - \delta)$ trials which are independent of $(X_m)_{m=0}^{\infty}$, then $Y_m^{(\delta)} = X_{B_1^{(\delta)}+\dots+B_m^{(\delta)}}$ is a realization of the δ -lazy chain. For $0 \leq i \leq n$, we define the first passage time to i by

(3.1)
$$\widetilde{\tau}_i := \inf\{t \ge 0 | X_{N_t} = i\}, \quad \tau_i^{(\delta)} := \min\{m \ge 0 | Y_m = i\},$$

and simply put $\tau_i := \tau_i^{(0)} = \min\{m \ge 0 | X_m = i\}$. Briefly, we write $\mathbb{P}_i(\cdot)$ for $\mathbb{P}(\cdot | X_0 = i)$ and write \mathbb{E}_i , Var_i as the expectation and variance under \mathbb{P}_i . The main result of this subsection is as follows.

Theorem 3.1 (Upper bound). Let (Ω, K, π) be an irreducible birth and death chain with $\Omega = \{0, 1, ..., n\}$. Let $\tau_i = \tau_i^{(0)}$ be the first passage time to i defined in (3.1). For $\epsilon \in (0, 1)$ and $\delta \in [1/2, 1)$,

(3.2)
$$\max\left\{T_{\mathrm{TV}}^{(c)}(\epsilon), (1-\delta)T_{\mathrm{TV}}^{(\delta)}(\epsilon)\right\} \leq \frac{9(\mathbb{E}_0\tau_{i_0} + \mathbb{E}_n\tau_{i_0})}{\epsilon^2},$$

where $i_0 \in \{0, ..., n\}$ satisfies $\pi([0, i_0 - 1]) \le 1/2$ and $\pi([i_0 + 1, n]) \le 1/2$.

Remark 3.1. The authors of [6] obtain a slightly improved upper bound similar to (3.2), which says that

$$\max\left\{T_{\mathrm{TV}}^{(c)}(\epsilon), (1-\delta)T_{\mathrm{TV}}^{(\delta)}(\epsilon)\right\} \le \frac{(\sqrt{\epsilon} + \sqrt{1-\epsilon})(\mathbb{E}_0\tau_{i_0} + \mathbb{E}_n\tau_{i_0})}{\sqrt{\epsilon}}$$

Comparing with (3.2), the above inequality has an improved dependence on ϵ .

To understand the right side of (3.2), we introduce the following lemma.

Lemma 3.2. Referring to the setting in (3.1), it holds true that, for i < j, $\mathbb{E}_i(\tau_j^{(\delta)}) = \mathbb{E}_i(\tau_j)/(1-\delta)$ and $\mathbb{E}_i(\tau_j) = \mathbb{E}_i(\widetilde{\tau}_j) = \sum_{k=i}^{j-1} \pi([0,k])/(p_k\pi(k))$.

Proof. The proof is based on the strong Markov property. See [2, Proposition 2] for a reference on the discrete time case, whereas the continuous time case is an immediate result of the fact $\{\tilde{\tau}_i > t\} = \{\tau_i > N_t\}$.

Remark 3.2. By Theorem 3.1 and Lemma 3.2, the total variation mixing time for the continuous time and the δ -lazy, with $\delta \geq 1/2$, discrete time birth and death chain on $\{0, 1, ..., n\}$ are bounded above by the following term up to a multiple constant.

$$\sum_{k=0}^{i_0-1} \frac{\pi([0,k])}{p_k \pi(k)} + \sum_{k=i_0+1}^n \frac{\pi([k,n])}{q_k \pi(k)},$$

where $i_0 \in \{0, ..., n\}$ satisfies $\pi([0, i_0 - 1]) \le 1/2$ and $\pi([i_0 + 1, n]) \le 1/2$.

Remark 3.3. In Theorem 3.1, i_0 is unique if $\pi([0,i]) \neq 1/2$ for all $0 \leq i \leq n$. If $\pi([0,j]) = 1/2$, then i_0 can be j or j+1, but the right side of (3.2) is the same in either case using Lemma 3.2.

Remark 3.4. Let K be an irreducible birth and death chain with birth, death and holding rates p_i, q_i, r_i and stationary distribution π . Let λ be the spectral gap of K. As a consequence of Lemma 2.1 and theorem 3.1, we obtain, for $\epsilon \in (0, 1/2)$,

$$\lambda \ge \frac{\epsilon^2 \log(1/(2\epsilon))}{9} \left(\sum_{k=0}^{i_0-1} \frac{\pi([0,k])}{p_k \pi(k)} + \sum_{k=i_0+1}^n \frac{\pi([k,n])}{q_k \pi(k)} \right)^{-1},$$

where i_0 is such that $\pi([0, i_0 - 1]) \leq 1/2$ and $\pi([i_0 + 1, n]) \leq 1/2$. The maximum of $\epsilon^2 \log(1/(2\epsilon))$ on (0, 1/2) is attained at $\epsilon = 1/(2\sqrt{e})$ and equal to 1/(8e). A similar lower bound of the spectral gap is also derived in [7] with improved constant.

As a simple application of Lemma 3.2, we have

Corollary 3.3. Referring to Lemma 3.2, for $i \leq j$,

$$\mathbb{E}_i \tau_j \le \left(\frac{1}{\pi([j,n])} - 1\right) \mathbb{E}_n \tau_i$$

Proof. By Lemma 3.2, one has

$$\mathbb{E}_i \tau_j = \sum_{k=i}^{j-1} \frac{\pi([0,k])}{p_k \pi(k)}, \quad \mathbb{E}_n(\tau_i) = \sum_{k=i}^{n-1} \frac{\pi([k+1,n])}{q_{k+1} \pi(k+1)} = \sum_{k=i}^{n-1} \frac{\pi([k+1,n])}{p_k \pi(k)}.$$

The inequality is then given by the fact $\pi([0,k])/\pi([k+1,n]) = 1/\pi([k+1,n]) - 1 \le 1/\pi([j,n]) - 1$ for k < j.

The following proposition is the main technique used to prove Theorem 3.1.

Proposition 3.4. Referring to the setting in (3.1), it holds true that, for j < k,

$$d_{\mathrm{TV}}^{(c)}(i,t) \le \mathbb{P}_i(\max\{\widetilde{\tau}_j,\widetilde{\tau}_k\} > t) + 1 - \pi([j,k]).$$

and

$$d_{\rm TV}^{(1/2)}(i,t) \le \mathbb{P}_i(\max\{\tau_j^{(1/2)}, \tau_k^{(1/2)}\} > t) + 1 - \pi([j,k]),$$

In particular,

$$d_{\rm TV}^{(c)}(t) \le \frac{\mathbb{E}_0 \tilde{\tau}_k + \mathbb{E}_n \tilde{\tau}_j}{t} + 1 - \pi([j,k])$$

and

$$d_{\rm TV}^{(1/2)}(t) \le \frac{2(\mathbb{E}_0 \tau_k^{(1/2)} + \mathbb{E}_n \tau_j^{(1/2)})}{t} + 1 - \pi([j,k]).$$

In the above proposition, the discrete time case is discussed in Lemma 2.3 in [15]. Our method to prove this proposition is to construct a no-crossing coupling. We give the proof of the continuous time case for completeness and refer to [15] for the discrete time case, where a heuristic idea on the construction of no-crossing coupling is proposed.

Proof of Proposition 3.4. Let $(Y_t)_{t\geq 0}$ be another process corresponding to H_t with $Y_0 \stackrel{d}{=} \pi$. Set $T := \inf\{t \geq 0 | X_t = Y_t\}$ and $Z_t := Y_t \mathbf{1}_{\{t\leq T\}} + X_t \mathbf{1}_{\{t>T\}}$. Clearly, $(X_t, Z_t)_{t\geq 0}$ is a coupling for the semigroup H_t and must be no-crossing according to the continuous time setting. Note that $T = \inf\{t \geq 0 | X_t = Z_t\}$ is the coupling time of X_t and Z_t . The classical coupling statement implies that

(3.3)
$$d_{\mathrm{TV}}^{(c)}(i,t) \leq \mathbb{P}_i(T>t).$$

See e.g. [1] for a reference. Note that $X_{\tau_i} = j$, $X_{\tau_k} = k$ and

$$\mathbb{P}_i(X_{\widetilde{\tau}_j} \le Y_{\widetilde{\tau}_j}) = \pi([j, n]), \quad \mathbb{P}_i(X_{\widetilde{\tau}_k} \ge Y_{\widetilde{\tau}_k}) = \pi([0, k]).$$

As X_t, Y_t can not cross each other without coalescing in advance, this implies

$$\mathbb{P}_{i}(T \leq \max\{\widetilde{\tau}_{j}, \widetilde{\tau}_{k}\}) \geq \mathbb{P}_{i}(\min\{\widetilde{\tau}_{j}, \widetilde{\tau}_{k}\}) \leq T \leq \max\{\widetilde{\tau}_{j}, \widetilde{\tau}_{k}\})$$
$$\geq \mathbb{P}_{i}(X_{\widetilde{\tau}_{i}} \leq Y_{\widetilde{\tau}_{i}}, X_{\widetilde{\tau}_{k}} \geq Y_{\widetilde{\tau}_{k}}) \geq \pi([j, k]).$$

Putting this back to (3.3) gives the desired result.

For the last part, note that if $i \leq j$, then $\tilde{\tau}_j < \tilde{\tau}_k$ and, by Markov's inequality, this implies

$$\mathbb{P}_i(\max\{\widetilde{\tau}_j,\widetilde{\tau}_k\}>t) \le \mathbb{P}_0(\widetilde{\tau}_k>t) \le \mathbb{E}_0\widetilde{\tau}_k/t.$$

Similarly, for $i \ge k$, one can show that

$$\mathbb{P}_i(\max\{\widetilde{\tau}_j,\widetilde{\tau}_k\}>t) \le \mathbb{P}_n(\widetilde{\tau}_j>t) \le \mathbb{E}_n\widetilde{\tau}_j/t.$$

For j < i < k, we have

$$\mathbb{P}_{i}(\max\{\widetilde{\tau}_{j},\widetilde{\tau}_{k}\} > t) \leq \mathbb{P}_{i}(\widetilde{\tau}_{j} > t) + \mathbb{P}_{i}(\widetilde{\tau}_{k} > t) \leq \frac{\mathbb{E}_{n}\widetilde{\tau}_{j} + \mathbb{E}_{0}\widetilde{\tau}_{k}}{t}.$$

Proof of Theorem 3.1. Set $j_{\epsilon} = \min\{i \geq 0 | \pi([0,i]) \geq \epsilon/3\}$ and $k_{\epsilon} = \min\{i \geq 0 | \pi([0,i]) \geq 1 - \epsilon/3\}$. By Proposition 3.4 and Lemma 3.2, the choice of $j = j_{\epsilon}$ and $k = k_{\epsilon}$ implies that

$$T_{\mathrm{TV}}^{(c)}(\epsilon) \leq \frac{3(\mathbb{E}_0 \tau_{k_{\epsilon}} + \mathbb{E}_n \tau_{j_{\epsilon}})}{\epsilon}.$$

By Corollary 3.3, one has

$$\mathbb{E}_0 \tau_{k_{\epsilon}} = \mathbb{E}_0 \tau_{i_0} + \mathbb{E}_{i_0} \tau_{k_{\epsilon}} \le \mathbb{E}_0 \tau_{i_0} + \left(\frac{3}{\epsilon} - 1\right) \mathbb{E}_n \tau_{i_0}$$

and

$$\mathbb{E}_n \tau_{j_{\epsilon}} = \mathbb{E}_n \tau_{i_0} + \mathbb{E}_{i_0} \tau_{j_{\epsilon}} \le \mathbb{E}_n \tau_{i_0} + \left(\frac{3}{\epsilon} - 1\right) \mathbb{E}_0 \tau_{i_0}$$

Adding up both terms gives the upper bound in continuous time case. The proof for the (1/2)-lazy discrete time case is similar and, by Proposition 3.4, we obtain

10

 $T_{\text{TV}}^{(1/2)}(\epsilon) \leq 18(\mathbb{E}_0 \tau_{i_0} + \mathbb{E}_n \tau_{i_0})/\epsilon^2$. For $\delta \in (1/2, 1)$, note that $K_{\delta} = (K_{2\delta-1})_{1/2}$. Since the birth and death rates of $K_{2\delta-1}$ are $2(1-\delta)p_i$ and $2(1-\delta)q_i$, the above result and Lemma 3.2 lead to $T_{\text{TV}}^{(\delta)}(\epsilon) \leq 9(\mathbb{E}_0 \tau_{i_0} + \mathbb{E}_n \tau_{i_0})/((1-\delta)\epsilon^2)$.

3.2. A lower bound of the mixing time. The goal of this subsection is to establish a lower bound on the total variation mixing time for birth and death chains. Recall the notations in the previous subsection. Let $(X_m)_{m=0}^{\infty}$ be an irreducible birth and death chain with transition matrix K and stationary distribution π . Let N_t be a Poisson process of parameter 1 that is independent of X_m . For $0 \le i \le n$, let $\tau_i = \min\{m \ge 0 | X_m = i\}$ and $\tilde{\tau}_i = \inf\{t \ge 0 | X_{N_t} = i\}$. Then, the total variation mixing time satisfies

(3.4)
$$d_{\text{TV}}(0,t) \ge K^t(0,[0,i-1]) - \pi([0,i-1]) \ge \mathbb{P}_0(\tau_i > t) - \pi([0,i-1])$$

and

(3.5)
$$d_{\mathrm{TV}}^{(c)}(0,t) \ge H_t(0,[0,i-1]) - \pi([0,i-1]) \ge \mathbb{P}_0(\widetilde{\tau}_i > t) - \pi([0,i-1]).$$

Brown and Shao discuss the distribution of $\tilde{\tau}_i$ in [3], of which proof also works for the discrete time case. In detail, if $-1 < \beta_1 < \cdots < \beta_i < 1$ are the eigenvalues of the submatrix of K indexed by $\{0, ..., i-1\}$ and $\lambda_j = 1 - \beta_j$, then

(3.6)
$$\mathbb{P}_0(\tau_i > t) = \sum_{j=1}^i \left(\prod_{k \neq j} \frac{\lambda_k}{\lambda_k - \lambda_j} \right) (1 - \lambda_j)^t$$

and

(3.7)
$$\mathbb{P}_0(\tilde{\tau}_i > t) = \sum_{j=1}^i \left(\prod_{k \neq j} \frac{\lambda_k}{\lambda_k - \lambda_j} \right) e^{-t\lambda_j}.$$

Note that, under \mathbb{P}_0 , $\tilde{\tau}_i$ is the sum of independent exponential random variables with parameters $\lambda_1, ..., \lambda_i$. If $\beta_1 > 0$, then τ is the sum of independent geometric random variables with parameters $\lambda_1, ..., \lambda_i$. In discrete time case, the requirement $\beta_1 > 0$ holds automatically for the δ -lazy chain with $\delta \ge 1/2$. The above formula leads to the following theorem.

Theorem 3.5 (Lower bound). Let K be the transition matrix of an irreducible birth and death chain on $\{0, 1, ..., n\}$. Let $\tau_i = \tau_i^{(0)}$ be the first passage time to i defined in (3.1). For $\delta \in [1/2, 1)$,

$$\min\{T_{\mathrm{TV}}^{(c)}(1/10), 2(1-\delta)T_{\mathrm{TV}}^{(\delta)}(1/20)\} \ge \frac{\max\{\mathbb{E}_0\tau_{i_0}, \mathbb{E}_n\tau_{i_0}\}}{6}$$

where $i_0 \in \{0, ..., n\}$ satisfies $\pi([0, i_0 - 1]) \le 1/2$ and $\pi([i_0 + 1, n]) \le 1/2$.

Proof of Theorem 3.5. First, we consider the continuous time case. Let $\lambda_1, ..., \lambda_i$ be eigenvalues of the submatrix of I - K indexed by 0, ..., i - 1 and $\tilde{\tau}_{i,1}, ..., \tilde{\tau}_{i,i}$ be independent exponential random variables with parameters $\lambda_1, ..., \lambda_i$. By (3.7), $\tilde{\tau}_i$ and $\tilde{\tau}_{i,1} + \cdots + \tilde{\tau}_{i,i}$ are identically distributed under \mathbb{P}_0 and, by (3.5), this implies

$$d_{\mathrm{TV}}^{(c)}(0,t) \ge \mathbb{P}(\widetilde{\tau}_{i,1} + \dots + \widetilde{\tau}_{i,i} > t) - \pi([0,i-1]).$$

It is easy to see that

$$\mathbb{E}_0 \widetilde{\tau}_i = \frac{1}{\lambda_1} + \dots + \frac{1}{\lambda_i}, \quad \operatorname{Var}_0(\widetilde{\tau}_i) = \frac{1}{\lambda_1^2} + \dots + \frac{1}{\lambda_i^2}$$

Let $a \in (0,1)$ and consider the following two cases. If $1/\lambda_j > a\mathbb{E}_0 \tilde{\tau}_i$ for some $1 \leq j \leq i$, then

$$\mathbb{P}_0(\widetilde{\tau}_i > t) \ge \mathbb{P}(\widetilde{\tau}_{i,j} > t) > e^{-t/(a\mathbb{E}_0\widetilde{\tau}_i)}.$$

If $1/\lambda_j \leq a\mathbb{E}_0\widetilde{\tau}_i$ for all $1 \leq j \leq i$, then $\operatorname{Var}_0(\widetilde{\tau}_i) \leq a(\mathbb{E}_0\widetilde{\tau}_i)^2$ and, by the one-sided Chebyshev inequality, we have

$$\mathbb{P}_{0}(\widetilde{\tau}_{i} > t) \geq \frac{(t - \mathbb{E}_{0}\widetilde{\tau}_{i})^{2}}{\operatorname{Var}_{0}(\widetilde{\tau}_{i}) + (t - \mathbb{E}_{0}\widetilde{\tau}_{i})^{2}} \geq \frac{(t - \mathbb{E}_{0}\widetilde{\tau}_{i})^{2}}{a(\mathbb{E}_{0}\widetilde{\tau}_{i})^{2} + (t - \mathbb{E}_{0}\widetilde{\tau}_{i})^{2}} = \frac{(1 - b)^{2}}{a + (1 - b)^{2}},$$

for $t = b\mathbb{E}_0 \tilde{\tau}_i$ with $b \in (0, 1)$. Combining both cases and setting $i = i_0$ in (3.5) yields that, for $a, b \in (0, 1)$,

(3.8)
$$d_{\mathrm{TV}}^{(c)}(0, b\mathbb{E}_0 \tilde{\tau}_{i_0}) \ge \min\left\{e^{-b/a}, \frac{(1-b)^2}{a+(1-b)^2}\right\} - \frac{1}{2}.$$

Putting a = 1/3 and b = 1/6 gives $T_{\text{TV}}^{(c)}(0, 1/10) \ge \mathbb{E}_0 \tilde{\tau}_{i_0}/6$.

For the discrete time case, note that the eigenvalues of the submatrix of $I - K_{1/2} = \frac{1}{2}(I - K)$ indexed by 0, ..., i - 1 are $\lambda_1/2, ..., \lambda_i/2$. Let $\tau_{i,1}, ..., \tau_{i,i}$ be independent geometric random variables with success probabilities $\lambda_1/2, ..., \lambda_i/2$. Replacing K with $K_{1/2}$ in (3.4), we obtain

$$d_{\mathrm{TV}}^{(1/2)}(0,t) \ge \mathbb{P}_0(\tau_{i,1} + \dots + \tau_{i,i} > t) - \pi([0,i-1]).$$

Note that, under \mathbb{P}_0 , $\tau_i^{(1/2)}$ has the same distribution as $\tau_{i,1} + \cdots + \tau_{i,i}$ and this implies

$$\mathbb{E}_0 \tau_i^{(1/2)} = \frac{2}{\lambda_1} + \dots + \frac{2}{\lambda_i}, \quad \text{Var}_0(\tau_i^{(1/2)}) = \sum_{j=1}^i \frac{4(1-\lambda_j/2)}{\lambda_j^2} \le \sum_{j=1}^i \frac{4}{\lambda_j^2}$$

Using the same analysis as before, one may derive, for $1/\mathbb{E}_0 \tau_i^{(1/2)} < a < 1$ and $t < \mathbb{E}_0 \tau_i^{(1/2)}$,

$$\mathbb{P}_{0}(\tau_{i}^{(1/2)} > t) \ge \min\left\{ \left(1 - \frac{1}{a\mathbb{E}_{0}\tau_{i}^{(1/2)}}\right)^{t}, \frac{\left(t - \mathbb{E}_{0}\tau_{i}^{(1/2)}\right)^{2}}{a\left(\mathbb{E}_{0}\tau_{i}^{(1/2)}\right)^{2} + \left(t - \mathbb{E}_{0}\tau_{i}^{(1/2)}\right)^{2}}\right\}.$$

By Lemma 3.2, $\mathbb{E}_0 \tau_i^{(1/2)} \ge 2i$. Obviously, if $i_0 = 0$, then $T_{\text{TV}}^{(1/2)}(0, 1/20) \ge 0 = \mathbb{E}_0 \tau_{i_0}^{(1/2)}$. For $i_0 \ge 1$, $\mathbb{E}_0 \tau_{i_0}^{(1/2)} \ge 2$ and the setting, a = 2/3 and $t = \left\lfloor \mathbb{E}_0 \tau_{i_0}^{(1/2)} / 12 \right\rfloor$, implies

$$d_{\rm TV}^{(1/2)}\left(0, \left\lfloor \mathbb{E}_0 \tau_{i_0}^{(1/2)} / 12 \right\rfloor \right) \ge \min\left\{ 2^{-1/3}, \frac{(11/12)^2}{2/3 + (11/12)^2} \right\} - \frac{1}{2} > \frac{1}{20}$$

where the first inequality use the fact that $s \log(1 - 3/(2s))$ is increasing on $[2, \infty)$. Hence, we have $T_{\text{TV}}^{(1/2)}(0, 1/20) \geq \mathbb{E}_0 \tau_{i_0}^{(1/2)}/12 = \mathbb{E}_0 \tau_{i_0}/6$. For $\delta > 1/2$, the combination of the above result and the observation $K_{\delta} = (K_{2\delta-1})_{1/2}$ implies that $T_{\text{TV}}^{(\delta)}(0, 1/20) \geq \mathbb{E}_0 \tau_{i_0}/(12(1 - \delta))$.

The analysis from the other end point gives the other lower bound. This finishes the proof. $\hfill \Box$

3.3. Relaxation of the median condition. In some cases, it is not easy to determine the value of i_n in Theorem 1.3. Let t_n be the constants in Theorem 3.1. For $c \in (0,1)$, let $i_n(c) \in \{0,...,n\}$ be the state such that $\pi_n([0,i_n(c)-1]) \leq c$, $\pi_n([i_n(c)+1,n]) \leq 1-c$ and let $t_n(c)$ be the following constant

$$t_n(c) = \sum_{k=0}^{i_n(c)-1} \frac{\pi_n([0,k])}{\pi_n(k)p_{n,k}} + \sum_{k=i_n(c)+1}^n \frac{\pi_n([k,n])}{\pi_n(k)q_{n,k}}$$

Assume that $c \ge 1/2$. In this case, if i_n is the smallest median, then $i_n \le i_n(c)$ and

$$\sum_{k=i_n}^{i_n(c)-1} \frac{\pi([0,k])}{\pi_n(k)p_{n,k}} = \sum_{k=i_n+1}^{i_n(c)} \frac{\pi_n([0,k-1])}{\pi_n(k)q_{n,k}}$$

Note that, for $i_n < k \leq i_n(c)$,

$$\frac{1}{2} \le \pi_n([0, i_n]) \le \frac{\pi_n([0, k - 1])}{\pi_n([k, n])} \le \frac{1}{\pi_n([i_n(c), n])} \le \frac{1}{1 - c}$$

This implies $t_n/2 \le t_n(c) \le t_n/(1-c)$. Similarly, for $c \le 1/2$, one can show that $t_n/2 \le t_n(c) \le t_n/c$. Combining both cases gives

(3.9)
$$t_n/2 \le t_n(c) \le t_n/\min\{c, 1-c\}.$$

As a consequence of the above discussion, we obtain the following theorem.

Theorem 3.6. Referring to Theorem 1.3. For $n \ge 1$, let $j_n \in \{0, 1, ..., n\}$ and set

$$t'_{n} = \max\left\{\sum_{k=0}^{j_{n}-1} \frac{\pi_{n}([0,k])}{\pi_{n}(k)p_{n,k}}, \sum_{k=j_{n}+1}^{n} \frac{\pi_{n}([k,n])}{\pi_{n}(k)q_{n,k}}\right\}.$$

Suppose that

$$0 < \liminf_{n \to \infty} \pi_n([0, j_n]) \le \limsup_{n \to \infty} \pi_n([0, j_n]) < 1.$$

Then, Theorem 1.3 remains true if t_n is replaced by t'_n .

Proof. The proof comes immediately from (3.9) with $c = \pi_n([0, j_n])$.

We use this observation to bound the cutoff time in the following theorem.

Theorem 3.7. Referring to Theorem 1.3. Suppose that \mathcal{F}_c has a total variation cutoff. Then, for any $\epsilon \in (0, 1)$,

$$\frac{2\log 2}{5} \leq \liminf_{n \to \infty} \frac{T_{n,\mathrm{TV}}^{(c)}(\epsilon)}{t_n} \leq \limsup_{n \to \infty} \frac{T_{n,\mathrm{TV}}^{(c)}(\epsilon)}{t_n} \leq 2$$

Proof of Theorem 3.7. The upper bound is given by Remark 3.1 and the fact, $\max\{s,t\} \ge (s+t)/2$, whereas the lower bound is obtained by applying a = 2/5 and $b = a \log(2/(1+2\epsilon))$ in (3.8) with $\epsilon \to 0$.

3.4. Bounding the spectral gap. This subsection is devoted to poviding bounds on the specral gap for birth and death chains. As the graph associated with a birth and death chain is a path, weighted Hardy's inequality can be used to bound the spectral gap. We refer to the Appendix for a detailed discussion of the following results. See Theorems A.1-A.3.

Theorem 3.8. Consider an irreducible birth and death chain on $\{0, ..., n\}$ with birth, death and holding rates p_i, q_i, r_i and stationary distribution π . Let λ be the spectral gap and set, for $0 \le i \le n$,

$$C(i) = \max\left\{\max_{j:j < i} \sum_{k=j}^{i-1} \frac{\pi([0,j])}{\pi(k)p_k}, \max_{j:j > i} \sum_{k=i+1}^{j} \frac{\pi([j,n])}{\pi(k)q_k}\right\}$$

Then, for $0 \leq m \leq n$,

$$\frac{1}{4C(m)} \leq \lambda \leq \frac{1}{\min\{\pi([0,m]),\pi([m,n])\}C(m)}$$

In particular, if M is a median of π , that is, $\pi([0, M]) \ge 1/2$ and $\pi([M, n]) \ge 1/2$, then

$$\frac{1}{4C(M)} \le \lambda \le \frac{2}{C(M)}$$

Theorem 3.9. Consider an irreducible birth and death chain on $\{0, ..., n\}$ with birth, death and holding rates p_i, q_i, r_i and stationary distribution π . Let λ be the spectral gap and set $N = \lceil n/2 \rceil$. Suppose that $p_i = q_{n-i}$ for $0 \le i \le n$. Then,

$$\frac{1}{4C} \le \lambda \le \frac{1}{C},$$

where

$$C = \max_{0 \le i \le N-1} \left\{ \pi([0,i]) \sum_{j=i}^{N-1} \frac{1}{\pi(j)p_j} \right\} \quad if \ n \ is \ even,$$

and

$$C = \max_{0 \le i \le N-1} \left\{ \pi([0,i]) \left(\sum_{j=i}^{N-2} \frac{1}{\pi(j)p_j} + \frac{1}{2\pi(N-1)p_{N-1}} \right) \right\} \quad if \ n \ is \ odd.$$

Remark 3.5. In [18], the author also obtained bounds similar to Theorem 3.9 for the case $\pi(i) \geq \pi(i+1)$ with $0 \leq i < n/2$ using the path technique. For more information on path techniques, see [11, 12, 14] and the references therein.

4. Examples

In this section, we will apply the theory developed in the previous section to examples of special interest. First, we give a criterion on the cutoff using the birth and death rates.

Theorem 4.1 (Cutoffs from birth and death rates). Let $\mathcal{F} = \{(\Omega_n, K_n, \pi_n) | n = 1, 2, ...\}$ be a family of irreducible birth and death chains on $\Omega_n = \{0, 1, ..., n\}$ with

birth rate, $p_{n,i}$, death rate $q_{n,i}$ and holding rate $r_{n,i}$. Let λ_n be the spectral gap of K_n . For $n \geq 1$, let $j_n \in \{0, ..., n\}$ and set

$$t_n = \max\left\{\sum_{k=0}^{j_n-1} \frac{\pi_n([0,k])}{\pi_n(k)p_{n,k}}, \sum_{k=j_n+1}^n \frac{\pi_n([k,n])}{\pi_n(k)q_{n,k}}\right\}$$

and

$$\ell_n = \max\left\{\max_{j:j < j_n} \sum_{k=j}^{j_n-1} \frac{\pi_n([0,j])}{\pi_n(k)p_{n,k}}, \max_{j:j>j_n} \sum_{k=j_n+1}^j \frac{\pi_n([j,n])}{\pi_n(k)q_{n,k}}\right\}.$$

Suppose that

$$0 < \liminf_{n \to \infty} \pi_n([0, j_n]) \le \limsup_{n \to \infty} \pi_n([0, j_n]) < 1.$$

Then, for $\epsilon \in (0, 1/2)$ and $\delta \in (0, 1)$,

$$\lambda_n \approx 1/\ell_n, \quad T_{n,\mathrm{TV}}^{(c)}(\epsilon) \approx t_n \approx T_{n,\mathrm{TV}}^{(\delta)}(\epsilon).$$

Furthermore, the following are equivalent.

- (1) \mathcal{F}_c has a cutoff in total variation.
- (2) For $\delta \in (0,1)$, \mathcal{F}_{δ} has a cutoff in total variation.
- (3) \mathcal{F}_c has precutoff in total variation.
- (4) For $\delta \in (0,1)$, \mathcal{F}_{δ} has a precutoff in total variation.
- (5) $t_n/\ell_n \to \infty$.

The above theorem is obvious from Theorems 2.2, 3.6 and 3.8. We use two classical examples, simple random walks and Ehrenfest chains, to illustrate how to apply Theorem 4.1 to determine the total variation cutoff and mixing times.

Example 4.1 (Simple random walks on finite paths). For $n \ge 1$, the simple random walk on $\{0, ..., n\}$ is a birth and death chain with $p_{n,i} = q_{n,i+1} = 1/2$ for $0 \le i < n$ and $r_{n,0} = r_{n,n} = 1/2$. It is clear that K_n is irreducible and aperiodic with uniform stationary distribution. Let t_n, ℓ_n be the constants in Theorem 4.1. It is an easy exercise to show that $\ell_n \simeq n^2 \simeq t_n$. By Theorem 4.1, neither \mathcal{F}_c nor \mathcal{F}_δ has total variation precutoff, but $T_{n,\mathrm{TV}}^{(c)}(\epsilon) \simeq n^2 \simeq T_{n,\mathrm{TV}}^{(\delta)}(\epsilon)$ for $\epsilon \in (0, 1/2)$ and $\delta \in (0, 1)$. In fact, one may use a hitting time statement to prove that the mixing time has order at least n^2 , when $\epsilon \in [1/2, 1)$. This implies that the above approximation of mixing time holds for $\epsilon \in (0, 1)$.

Example 4.2 (Ehrenfest chains). Consider the Ehrenfest chain on $\{0, ..., n\}$, which is a birth and death chain with rates $p_{n,i} = 1 - i/n$ and $q_{n,i} = i/n$. It is obvious that K_n is irreducible and periodic with stationary distribution $\pi_n(i) = 2^{-n} {n \choose i}$. An application of the representation theory shows that, for $0 \le i \le n$, 2i/n is an eigenvalue of $I - K_n$. Let λ_n, s_n be the constants in Theorem 2.2. Clearly, $\lambda_n = 2/n$ and $s_n \asymp n \log n$ and, by Theorem 2.2, both \mathcal{F}_c and \mathcal{F}_{δ} have a total variation cutoff. Note that, as a simple corollary, one obtains the non-trivial estimates

$$\sum_{i=0}^{\left\lceil \frac{n}{2} \right\rceil - 1} \frac{\binom{n}{0} + \dots + \binom{n}{i}}{\binom{n}{i}} \asymp n \log n, \quad \max_{0 \le i < n/2} \sum_{j=0}^{i} \binom{n}{j} \times \sum_{j=i}^{\left\lceil \frac{n}{2} \right\rceil - 1} \binom{n}{i}^{-1} \asymp n.$$

For a detailed computation on the total variation and the L^2 -distance, see e.g. [9].

In the next subsections, we consider birth and death chains of special types.

4.1. Chains with valley stationary distributions. In this subsection, we consider birth and death chains with valley stationary distribution. For $n \ge 1$, let $\Omega_n = \{0, 1, ..., n\}$ and K_n be an irreducible birth and death chain on Ω_n with birth, death and holding rates, $p_{n,i}, q_{n,i}, r_{n,i}$. Suppose that there is $j_n \in \Omega_n$ such that

$$(4.1) p_{n,i} \le q_{n,i+1}, \forall i < j_n, \quad p_{n,i} \ge q_{n,i+1}, \forall i \ge j_n.$$

Obviously, the stationary distribution π_n of K_n satisfies $\pi_n(i) \ge \pi_n(i+1)$ for $i < j_n$ and $\pi_n(i) \le \pi_n(i+1)$ for $i \ge j_n$.

Let t_n, ℓ_n be the constants in Theorem 4.1 and write

$$\ell_n = \max\left\{ \max_{j: j < j_n} \sum_{k=j+1}^{j_n} \frac{\pi_n([0,j])}{\pi_n(k)q_{n,k}}, \max_{j: j > j_n} \sum_{k=j_n}^{j-1} \frac{\pi_n([j,n])}{\pi_n(k)p_{n,k}} \right\}$$

 Set

$$M_L = \max_{0 < i \le j_n} q_{n,i}, \ m_L = \min_{0 < i \le j_n} q_{n,i}, \ M_R = \max_{j_n \le i < n} p_{n,i}, \ m_R = \min_{j_n \le i < n} p_{n,i}.$$

Clearly,

ł

$$\ell_n \le \max\left\{\frac{\pi_n([0,j_n])}{m_L}\sum_{i=0}^{j_n}\frac{1}{\pi_n(i)}, \frac{\pi_n([j_n,n])}{m_R}\sum_{i=j_n}^n\frac{1}{\pi_n(i)}\right\}.$$

Let j'_n be such that $\pi_n([0, j'_n]) \ge \pi_n([0, j_n])/2$ and $\pi_n([j'_n, j_n]) \ge \pi_n([0, j_n])/2$. Note that if $j_n \ge 1$, then $j_n \ge \max\{2j'_n, j'_n + 1\}$. By (4.1), this implies

$$\sum_{k=j'_n+1}^{j_n} \frac{\pi_n([0,j'_n])}{\pi_n(k)} \ge \frac{\pi_n([0,j_n])}{4} \sum_{k=j'_n}^{j_n} \frac{1}{\pi_n(k)} \ge \frac{\pi_n([0,j_n])}{8} \sum_{k=0}^{j_n} \frac{1}{\pi_n(k)}$$

One can derive a similar inequality from the other end point and this yields

$$\ell_n \ge \frac{1}{8} \min\left\{\frac{\pi_n([0, j_n])}{M_L} \sum_{i=0}^{j_n} \frac{1}{\pi_n(i)}, \frac{\pi_n([j_n, n])}{M_R} \sum_{i=j_n}^n \frac{1}{\pi_n(i)}\right\}.$$

For t_n , note that

$$\frac{\pi_n([0,j_n-1])}{2} \sum_{k=0}^{j_n-1} \frac{1}{\pi_n(k)} \le \sum_{k=0}^{j_n-1} \frac{\pi_n([0,k])}{\pi_n(k)} \le \pi_n([0,j_n-1]) \sum_{k=0}^{j_n-1} \frac{1}{\pi_n(k)}$$

and

$$\frac{\pi_n([j_n+1,n])}{2} \sum_{k=j_n+1}^n \frac{1}{\pi_n(k)} \le \sum_{k=j_n+1}^n \frac{\pi_n([k,n])}{\pi_n(k)} \le \pi_n([j_n+1,n]) \sum_{k=j_n+1}^n \frac{1}{\pi_n(k)}$$

This implies

$$t_n \le \max\left\{\frac{\pi_n([0,j_n])}{m_L}\sum_{i=0}^{j_n}\frac{1}{\pi_n(i)}, \frac{\pi_n([j_n,n])}{m_R}\sum_{i=j_n}^n\frac{1}{\pi_n(i)}\right\}$$

and

$$t_n \ge \frac{1}{8} \max\left\{\frac{\pi_n([0, j_n])}{M_L} \sum_{i=0}^{j_n} \frac{1}{\pi_n(i)}, \frac{\pi_n([j_n, n])}{M_R} \sum_{i=j_n}^n \frac{1}{\pi_n(i)}\right\}$$

The following theorem is an immediate consequence of the above discussion and Theorem 4.1.

Theorem 4.2. Let $\mathcal{F} = \{(\Omega_n, K_n, \pi_n) | n = 1, 2, ...\}$ be a family of birth and death chains satisfying (4.1). Assume that $\pi_n([0, j_n]) \approx \pi_n([j_n, n])$ and

$$\max_{0 < i \le j_n} q_{n,i} \asymp \min_{0 < i \le j_n} q_{n,i}, \quad \max_{j_n \le i < n} p_{n,i} \asymp \min_{j_n \le i < n} p_{n,i}$$

Then, there is no cutoff for $\mathcal{F}_c, \mathcal{F}_\delta$ and, for $\epsilon \in (0, 1/2)$ and $\delta \in (0, 1)$,

$$T_{n,\mathrm{TV}}^{(c)}(\epsilon) \asymp T_{n,\mathrm{TV}}^{(\delta)}(\epsilon) \asymp \frac{1}{\lambda_n} \asymp \max\left\{\frac{1}{q_{n,j_n}} \sum_{i=0}^{j_n} \frac{1}{\pi_n(i)}, \frac{1}{p_{n,j_n}} \sum_{i=j_n}^n \frac{1}{\pi_n(i)}\right\}$$

For an illustration of the above theorem, we consider the following Markov chains. For $n \ge 1$, let $\Omega_n = \{0, 1, ..., n\}$, π_n be a non-uniform probability distribution on Ω_n satisfying (4.1) and M_n be a transition matrix given by

$$(4.2) M_n(i,j) = \begin{cases} 1/2 & \text{for } j = i - 1, i \leq j_n, \\ 1/2 & \text{for } j = i + 1, i \geq j_n, \\ \pi_n(i+1)/(2\pi_n(i)) & \text{for } j = i + 1, i < j_n, \\ \pi_n(i-1)/(2\pi_n(i)) & \text{for } j = i - 1, i > j_n, \\ 1/2 - \pi_n(i+1)/(2\pi_n(i)) & \text{for } j = i < j_n, \\ 1/2 - \pi_n(i-1)/(2\pi_n(i)) & \text{for } j = i > j_n. \end{cases}$$

Note that M_n is the Metropolis chain for π_n associated to the simple random walk on Ω_n . For more information on the Metropolis chain, see [8] and the references therein. The next theorem is a corollary of Theorem 4.2.

Theorem 4.3. Let $\mathcal{F} = \{(\Omega_n, M_n, \pi_n) | n = 1, 2, ..\}$ be the family of Metropolis chains satisfying (4.1)-(4.2). Suppose $\pi_n([0, j_n]) \approx \pi_n([j_n, n])$. Then, neither \mathcal{F}_c nor \mathcal{F}_{δ} has a total variation precutoff but, for $\epsilon \in (0, 1/2)$ and $\delta \in (0, 1)$,

$$T_{n,\mathrm{TV}}^{(c)}(\epsilon) \asymp \sum_{i=0}^{n} \frac{1}{\pi_n(i)} \asymp T_{n,\mathrm{TV}}^{(\delta)}(\epsilon).$$

Example 4.3. Let a > 0 and $\check{\pi}_{n,a}, \hat{\pi}_{n,a}$ be probability measures on $\{0, \pm 1, ..., \pm n\}$ given by

(4.3)
$$\check{\pi}_{n,a}(i) = \check{c}_{n,a}(|i|+1)^a, \quad \hat{\pi}_{n,a}(i) = \hat{c}_{n,a}(n-|i|+1)^a,$$

where $\check{c}_{n,a}, \hat{c}_{n,a}$ are normalizing constants. Let $\check{\mathcal{F}}, \hat{\mathcal{F}}$ be families of the Metropolis chains for $\check{\pi}_{n,a}, \hat{\pi}_{n,a}$ associated to the simple random walks on $\{0, \pm 1, ..., \pm n\}$, that is,

$$\check{M}_{n,a}(i,j) = \check{M}_{n,a}(-i,-j), \quad \hat{M}_{n,a}(i,j) = \hat{M}_{n,a}(-i,-j)$$

and

$$\check{M}_{n,a}(i,j) = \begin{cases} \frac{1}{2} & \text{if } j = i+1, i \in [0, n-1] \\ \frac{i^a}{2(i+1)^a} & \text{if } j = i-1, i \in [1, n] \\ \frac{(i+1)^a - i^a}{2(i+1)^a} & \text{if } j = i, i \notin \{0, n\} \\ 1 - \frac{n^a}{2(n+1)^a} & \text{if } i = j = n \end{cases}$$

and

$$\hat{M}_{n,a}(i,j) = \begin{cases} \frac{1}{2} & \text{if } j = i-1, i \in [1,n] \\ \frac{2(n-i)^a}{2(n-i+1)^a} & \text{if } j = i+1, i \in [0,n-1] \\ \frac{(n-i+1)^a - (n-i)^a}{2(n-i+1)^a} & \text{if } j = i \neq 0 \\ 1 - \frac{n^a}{(n+1)^a} & \text{if } i = j = 0 \end{cases}.$$

Let $\lambda_{n,a}$, $\hat{\lambda}_{n,a}$ and $\tilde{T}_{n,a}$, $\hat{T}_{n,a}$ be the spectral gaps and total variation mixing times of $\tilde{M}_{n,a}$, $\hat{M}_{n,a}$. It has been proved in [7, 18] that there is C > 1 such that, for all a > 0 and $n \ge 1$,

$$\frac{1}{C\check{\lambda}_{n,a}} \asymp n^a \left(\left(1 + \frac{1}{n} \right)^a + \frac{n}{1+a} \right) (1 + v(n,a)) \le \frac{C}{\check{\lambda}_{n,a}}$$

and

$$\frac{1}{C\hat{\lambda}_{n,a}} \leq \frac{(n+a)^2}{(1+a)^2} \leq \frac{C}{\hat{\lambda}_{n,a}},$$

where $v(n,1) = \log n$ and $v(n,a) = (n^{1-a} - 1)/(1-a)$ for $a \neq 1$. By Theorem 4.2, $\check{\mathcal{F}}_c$ and $\check{\mathcal{F}}_\delta$ have no cutoff in total variation but, for fixed a > 0, $\epsilon \in (0, 1/2)$ and $\delta \in (0, 1)$,

$$\check{T}_{n,a}^{(c)}(\epsilon) \asymp \check{T}_{n,a}^{(\delta)}(\epsilon) \asymp \begin{cases} n^2 & \text{if } a \in (0,1) \\ n^2 \log n & \text{if } a = 1 \\ n^{1+a} & \text{if } a \in (1,\infty) \end{cases}$$

The above result in continuous time case is also obtained in [18].

To see the cutoff for $\hat{\mathcal{F}}$, let

$$t_n = \sum_{k=0}^{n-1} \frac{\hat{\pi}_{n,a}([-n, -n+k])}{\hat{\pi}_{n,a}(-n+k)} = \sum_{k=1}^n k^{-a} \sum_{j=1}^k j^a.$$

By Theorems 3.1-3.5, we have

$$\frac{2t_n}{3} \le \hat{T}_{n,a}^{(c)}(1/10) \le 3600t_n.$$

Note that, for $k \ge 1$ and a > 0,

$$\frac{k^a(k+a)}{2(1+a)} \le \sum_{j=1}^k j^a \le \frac{2k^a(k+a)}{1+a}.$$

This implies

$$\frac{n(n+a)}{6(1+a)} \le \hat{T}_{n,a}^{(c)}(1/10) \le \frac{14400n(n+a)}{1+a}$$

We collect the above results in the following theorem.

Theorem 4.4. For $n \geq 1$, let $a_n > 0$ and $\check{\pi}_{n,a_n}, \hat{\pi}_{n,a_n}$ be probability measures given by (4.3). Let $\check{\mathcal{F}}, \hat{\mathcal{F}}$ be the families of Metropolis chains for $\check{\pi}_{n,a_n}, \hat{\pi}_{n,a_n}$ as above with total variation mixing time $\check{T}_{n,\mathrm{TV}}, \hat{T}_{n,\mathrm{TV}}$. Then, for $\epsilon \in (0, 1/2)$ and $\delta \in (0, 1)$,

$$\hat{T}_{n,\mathrm{TV}}^{(c)}(\epsilon) \asymp \hat{T}_{n,\mathrm{TV}}^{(\delta)}(\epsilon) \asymp \frac{n(n+a_n)}{1+a_n}$$

and

$$\check{T}_{n,\mathrm{TV}}^{(c)}(\epsilon) \asymp \check{T}_{n,\mathrm{TV}}^{(\delta)}(\epsilon) \asymp n^{a_n} \left(\left(1 + \frac{1}{n} \right)^{a_n} + \frac{n}{1 + a_n} \right) (1 + v(n, a_n)),$$

where $v(n, 1) = \log n$ and $v(n, a) = (n^{1-a} - 1)/(1 - a)$ for $a \neq 1$.

Moreover, neither $\check{\mathcal{F}}_c$ nor $\check{\mathcal{F}}_\delta$ has a total variation cutoff. Also, $\hat{\mathcal{F}}_c$ and $\hat{\mathcal{F}}_\delta$ have a total variation cutoff if and only if $a_n \to \infty$.

4.2. Chains with monotonic stationary distributions. In this subsection, we consider birth and death chains with monotonic stationary distributions. For $n \ge 1$, let $\Omega_n = \{0, 1, ..., n\}$ and K_n be a birth and death chain on Ω_n with birth, death and holding rates, $p_{n,i}, q_{n,i}, r_{n,i}$. Suppose that

$$(4.4) p_{n,i} \ge q_{n,i+1}, \quad \forall 0 \le i < n.$$

If K_n is irreducible, then the stationary distribution π_n satisfying $\pi_n(i) \leq \pi_n(i+1)$ for $0 \leq i < n$. Let $j_n \in \Omega_n$ and t_n, ℓ_n be the constants in Theorem 4.1. Assume that $\pi_n([0, j_n]) \approx \pi_n([j_n, n])$ and

(4.5)
$$\max_{0 \le i < j_n} p_{n,i} \asymp \min_{0 \le i < j_n} p_{n,i}, \quad \max_{j_n \le i < n} p_{n,i} \asymp \min_{j_n \le i < n} p_{n,i}.$$

Using a discussion similar to that in front of Theorem 4.2, one can show that

$$t_n \asymp \max\left\{\frac{1}{p_{n,1}}\sum_{k=0}^{j_n-1}\frac{\pi_n([0,k])}{\pi_n(k)}, \frac{1}{p_{n,j_n}}\sum_{k=j_n}^n\frac{1}{\pi_n(k)}\right\}$$

and

$$\ell_n \asymp \max\left\{\frac{1}{p_{n,1}} \max_{0 \le j < j_n} \sum_{k=j}^{j_n-1} \frac{\pi_n([0,j])}{\pi_n(k)}, \frac{1}{p_{n,j_n}} \sum_{k=j_n}^n \frac{1}{\pi_n(k)}\right\}.$$

This leads to the following theorem.

Theorem 4.5. Let $\mathcal{F} = \{(\Omega_n, K_n, \pi_n) | n = 1, 2, ...\}$ be a family of irreducible birth and death chains with $\Omega_n = \{0, 1, ..., n\}$ and birth, death and holding rates $p_{n,i}, q_{n,i}, r_{n,i}$. Let $\lambda_n, T_{n,\mathrm{TV}}$ be the spectral gap and total variation mixing time of K_n and set

$$u_n = \sum_{k=0}^{j_n-1} \frac{\pi_n([0,k])}{\pi_n(k)}, \quad v_n = \max_{0 \le j < j_n} \sum_{k=j}^{j_n-1} \frac{\pi_n([0,j])}{\pi_n(k)}, \quad w_n = \sum_{k=j_n}^n \frac{1}{\pi_n(k)}.$$

Assume that $\pi_n([0, j_n]) \approx \pi_n([j_n, n])$ and (4.5) holds. Then, for $\epsilon \in (0, 1/2)$ and $\delta \in (0, 1)$,

$$\lambda_n^{-1} \asymp \max\left\{\frac{v_n}{p_{n,1}}, \frac{w_n}{p_{n,j_n}}\right\}, \quad T_{n,\mathrm{TV}}^{(c)}(\epsilon) \asymp T_{n,\mathrm{TV}}^{(\delta)}(\epsilon) \asymp \max\left\{\frac{u_n}{p_{n,1}}, \frac{w_n}{p_{n,j_n}}\right\}.$$

Moreover, \mathcal{F}_c and \mathcal{F}_{δ} have a total variation cutoff if and only if

$$u_n/v_n \to \infty$$
, $(u_n p_{n,j_n})/(w_n p_{n,1}) \to \infty$.

For $n \geq 1$, let f_n be a non-decreasing function on [0,n] and set $F_n(x) = \int_0^x f_n(t)dt$ and $G_n(x,m) = \int_x^m 1/f_n(t)dt$. Note that if there is C > 1 such that

$$C^{-1}f_n(i)\pi_n(0) \le \pi_n(i) \le Cf_n(i)\pi_n(0), \quad \forall 0 \le i \le n, n \ge 1,$$

then

$$\frac{1}{2C^2} \left(\frac{F_n(k)}{f_n(k)} + 1 \right) \le \frac{\pi_n([0,k])}{\pi_n(k)} \le C^2 \left(\frac{F_n(k)}{f_n(k)} + 1 \right)$$

and

$$\frac{1}{2C} \left(G_n(j, j_n) + \frac{1}{f_n(j)} \right) \le \pi_n(0) \sum_{k=j}^{j_n-1} \frac{1}{\pi_n(k)} \le C \left(G_n(j, j_n) + \frac{1}{f_n(j)} \right).$$

This implies

$$\pi_n([0,j]) \sum_{k=j}^{j_n-1} \frac{1}{\pi_n(k)} \le C^2 \left(G_n(j,j_n) + \frac{1}{f_n(j)} \right) \left(F_n(j) + f_n(j) \right)$$

and

$$\pi_n([0,j]) \sum_{k=j}^{j_n-1} \frac{1}{\pi_n(k)} \ge \frac{1}{4C^2} \left(G_n(j,j_n) + \frac{1}{f_n(j)} \right) \left(F_n(j) + f_n(j) \right)$$

Let u_n, v_n, w_n be the constants in Theorem 4.5 and assume that

$$\min_{0 \le i < n} p_{n,i} \asymp \max_{0 \le i < n} p_{n,i} \asymp 1.$$

Consider the following cases.

Case 1: $f_n(x) = \exp\{\alpha_n x^{\beta_n}\}$ with $\inf_n \alpha_n > 0$ and $\inf_n \beta_n \ge 1$. In this case, $F_n(x) = O(f_n(x))$ and $G_n(x,m) = O(1/f_n(x))$ for $1 \le x < m$. By setting $j_n = n$, we obtain

$$\pi_n([0, j_n]) \asymp \pi_n([j_n, n]), \quad u_n \asymp n, \quad v_n \asymp w_n \asymp 1.$$

By Theorem 4.5, $\lambda_n \approx 1$ and, for $\epsilon \in (0, 1/2)$ and $\delta \in (0, 1)$,

$$T_{n,\mathrm{TV}}^{(c)}(\epsilon) \asymp T_{n,\mathrm{TV}}^{(\delta)}(\epsilon) \asymp n$$

There is a total variation cutoff for \mathcal{F}_c or \mathcal{F}_{δ} .

Case 2: $f_n(x) = \exp\{\alpha_n x^{\beta_n}\}$ with $0 < \inf_n \alpha_n \leq \sup_n \alpha_n < \infty$ and $0 < \inf_n \beta_n \leq \sup_n \beta_n < 1$. Note that, for $\alpha \in \mathbb{R}$ and $\beta \in (0, 1)$,

$$\frac{d}{dx}\left(x^{1-\beta}e^{\alpha x^{\beta}}\right) = \left(\alpha\beta + (1-\beta)x^{-\beta}\right)e^{\alpha x^{\beta}}.$$

This implies that, uniformly for $n/2 \le x$ and $1 + x \le m \le n$,

$$F_n(x) \asymp x^{1-\beta_n} f_n(x), \quad G_n(x,m) \asymp \left(\frac{x^{1-\beta_n}}{f_n(x)} - \frac{m^{1-\beta_n}}{f_n(m)}\right).$$

Letting $j_n = \lfloor n - n^{1-\beta_n} \rfloor$ yields

$$\pi_n([0,j_n]) \asymp \pi_n([j_n,n]), \quad u_n \asymp n^{2-\beta_n}, \quad v_n \asymp n^{2-2\beta_n} \asymp w_n.$$

By Theorem 4.5, \mathcal{F}_c and \mathcal{F}_{δ} have a total variation cutoff and

$$\lambda_n \asymp n^{2\beta_n - 2}, \quad T_{n, \mathrm{TV}}^{(c)}(\epsilon) \asymp T_{n, \mathrm{TV}}^{(\delta)}(\epsilon) \asymp n^{2 - \beta_n}, \quad \forall \epsilon \in (0, 1/2), \, \delta \in (0, 1).$$

Case 3: $f_n(x) = \exp\{\alpha_n [\log(x+1)]^{\beta_n}\}$ with $0 < \inf_n \alpha_n \le \sup_n \alpha_n < \infty$ and $1 < \inf_n \beta_n \le \sup_n \beta_n < \infty$. Note that, for $\alpha \in \mathbb{R}$ and $\beta > 1$,

$$\frac{d}{dx}\left(\frac{(x+1)e^{\alpha[\log(x+1)]^{\beta}}}{[\log(x+1)]^{\beta-1}}\right) = \left(\alpha\beta + \frac{1 - (\beta-1)/\log(x+1)}{[\log(x+1)]^{\beta-1}}\right)e^{\alpha[\log(x+1)]^{\beta}}.$$

This implies that, uniformly for $n/2 \le x < m \le n$,

$$F_n(x) \simeq \frac{(x+1)}{[\log(x+1)]^{\beta_n-1}} e^{\alpha_n [\log(x+1)]^{\beta_n}}$$

and

$$G_n(x,m) \asymp \left(\frac{(x+1)e^{-\alpha_n [\log(x+1)]^{\beta_n}}}{[\log(x+1)]^{\beta_n-1}} - \frac{(m+1)e^{-\alpha_n [\log(m+1)]^{\beta_n}}}{[\log(m+1)]^{\beta_n-1}}\right).$$

20

Set $j_n = n[1 - (\log n)^{1-\beta_n}]$. The above computation leads to

$$\pi_n([0,j_n]) \asymp \pi_n([j_n,n]), \quad u_n \asymp n^2 (\log n)^{1-\beta_n}, \quad v_n \asymp n^2 (\log n)^{2-2\beta_n} \asymp w_n.$$

By Theorem 4.5, both \mathcal{F}_c and \mathcal{F}_{δ} have a total variation cutoff and, for $\epsilon \in (0, 1/2)$ and $\delta \in (0, 1)$,

$$\lambda_n \asymp n^{-2} (\log n)^{2\beta_n - 2}, \quad T_{n, \mathrm{TV}}^{(c)}(\epsilon) \asymp n^2 (\log n)^{1 - \beta_n} \asymp T_{n, \mathrm{TV}}^{(\delta)}(\epsilon).$$

Case 4: $f_n(x) = \exp\{\alpha_n [\log(x+1)]^{\beta_n}\}$ with $\sup_n \alpha_n < \infty$ and $\sup_n \beta_n \leq 1$. Note that, as a consequence of the mean values theorem, one may choose, for each 0 < a < 1, a constant $b \in (a, 1)$ such that

$$1 < \frac{f_n(n)}{f_n(an)} = \exp\left\{\alpha_n \left[(\log(n+1))^{\beta_n} - (\log(an+1))^{\beta_n} \right] \right\}$$
$$= \exp\left\{\alpha_n \beta_n (1-a)n \frac{(\log(bn+1))^{\beta_n-1}}{bn+1} \right\}$$
$$\leq \exp\left\{\frac{1-a}{a} \sup_n \alpha_n\right\} < \infty.$$

This implies that, for $a \in (0, 1)$, one may choose a constant A > 1 (depending on a) such that

$$\frac{1}{An} \le \pi_n(x) \le \frac{A}{n}, \quad \forall x \ge an, \ n \ge 1.$$

Choosing $j_n = \lfloor n/2 \rfloor$ yields $\pi_n([0, j_n]) \approx \pi_n([j_n, n])$ and $u_n \approx v_n \approx w_n \approx n^2$. By Theorem 4.5, there is no total variation cutoff for \mathcal{F}_c or \mathcal{F}_{δ} and

$$T_{n,\mathrm{TV}}^{(c)}(\epsilon) \asymp T_{n,\mathrm{TV}}^{(\delta)}(\epsilon) \asymp \lambda_n^{-1} \asymp n^2, \quad \forall \epsilon \in (0, 1/2), \, \delta \in (0, 1).$$

4.3. Chains with symmetric stationary distributions. This subsection is dedicated to the study of birth and death chains with symmetric stationary distributions. Let K be an irreducible birth and death chain on $\{0, ..., n\}$ with stationary distribution π . Note that π is symmetric at n/2, that is, $\pi(n - i) = \pi(i)$ for $0 \le i \le n/2$, if and only if

$$p_i p_{n-i-1} = q_{i+1} q_{n-i}, \quad \forall 0 \le i \le n/2.$$

By the symmetry of π , we will fix $j_n = \lfloor n/2 \rfloor$ when applying Theorem 4.1.

Consider a family of irreducible birth and death chains, $\mathcal{F} = \{(\Omega_n, K_n, \pi_n) | n = 1, 2, ...\}$ with $\Omega_n = \{0, 1, ..., n\}$. Let $p_{n,i}, q_{n,i}, r_{n,i}$ be respectively the birth, death and holding rates of K_n and t_n, ℓ_n be constants in Theorem 4.1. Assume that π_n is symmetric at n/2. Continuously using the fact $(a+b)/2 \leq \max\{a,b\} \leq a+b$ for $a \geq 0, b \geq 0$, we obtain

$$t_n \asymp \sum_{k:k \le n/2} \frac{\pi_n([0,k])}{\pi_n(k) \min\{p_{n,k}, q_{n,n-k}\}}$$

and

$$\ell_n \asymp \max_{j: j \le n/2} \sum_{k: j \le k \le n/2} \frac{\pi_n([0, j])}{\pi_n(k) \min\{p_{n,k}, q_{n,n-k}\}}$$

Theorem 4.1 can be rewritten as follows.

Theorem 4.6. Let $\mathcal{F} = \{(\Omega_n, K_n, \pi_n) | n = 1, 2, ...\}$ be a family of irreducible birth and death chains with $\Omega_n = \{0, 1, ..., n\}$. Let λ_n and $p_{n,i}, q_{n,i}, r_{n,i}$ be the spectral gap and the birth, death and holding rates of K_n . Assume that

$$p_{n,i}p_{n,n-i-1} = q_{n,i+1}q_{n,n-i}, \quad \forall 0 \le i \le n/2.$$

Then, for $\epsilon \in (0, 1/2)$ and $\delta \in (0, 1)$,

$$\lambda_n \simeq 1/\ell_n, \quad T_{n,\mathrm{TV}}^{(c)}(\epsilon) \simeq T_{n,\mathrm{TV}}^{(\delta)}(\epsilon) \simeq t_n,$$

where

$$t_n = \sum_{k:k \le n/2} \frac{\pi_n([0,k])}{\pi_n(k) \min\{p_{n,k}, q_{n,n-k}\}}$$

and

$$\ell_n = \max_{j: j \le n/2} \left\{ \pi_n([0, j]) \sum_{k: j \le k \le n/2} \frac{1}{\pi_n(k) \min\{p_{n,k}, q_{n,n-k}\}} \right\}.$$

Moreover, the following are equivalent.

- (1) \mathcal{F}_c has a cutoff in total variation.
- (2) For $\delta \in (0,1)$, \mathcal{F}_{δ} has a cutoff in total variation.
- (3) \mathcal{F}_c has a precutoff in total variation.
- (4) For $\delta \in (0,1)$, \mathcal{F}_{δ} has a precutoff in total variation.
- (5) $t_n/\ell_n \to \infty$.

The next theorem considers a perturbation of birth and death chains which has the same stationary distribution as the original chains. The new chains keep the order of mixing time and spectral gap unchanged.

Theorem 4.7. Consider the family in Theorem 4.6 and assume that

 $p_{n,i}p_{n,n-i-1} = q_{n,i+1}q_{n,n-i}, \quad \forall 0 \le i \le n/2.$

For $n \geq 1$, let $A_n \subset \{0, ..., n-1\}$, $c_{n,i} \in [0,1]$ for $i \in A_n$ and \widetilde{K}_n be a birth and death chain on Ω_n with birth and death rates, $\widetilde{p}_{n,i}, \widetilde{q}_{n,i}$, satisfying

$$\begin{cases} \widetilde{p}_{n,i} = c_{n,i} p_{n,i} + (1 - c_{n,i}) \min\{p_{n,i}, q_{n,n-i}\} & \text{for } i \in A_n, \\ \widetilde{q}_{n,i+1} = q_{n,i+1} \widetilde{p}_{n,i} / p_{n,i} & \text{for } i \in A_n, \\ \widetilde{p}_{n,i} = p_{n,i}, & \widetilde{q}_{n,i+1} = q_{n,i+1} & \text{for } i \notin A_n. \end{cases}$$

Let $\lambda_n, \widetilde{\lambda}_n$ and $T_{n,\mathrm{TV}}(\epsilon), \widetilde{T}_{n,\mathrm{TV}}(\epsilon)$ be the spectral gaps and total variation mixing times of K_n, \widetilde{K}_n . Then, given $\epsilon \in (0, 1/2)$ and $\delta \in (0, 1)$,

$$\widetilde{\lambda}_n \asymp \lambda_n, \quad \widetilde{T}_{n,\mathrm{TV}}^{(c)}(\epsilon) \asymp T_{n,\mathrm{TV}}^{(c)}(\epsilon) \asymp \widetilde{T}_{n,\mathrm{TV}}^{(\delta)}(\epsilon) \asymp T_{n,\mathrm{TV}}^{(\delta)}(\epsilon)$$

where the approximation is uniform on the choice of $A_n, c_{n,i}$.

Proof. The approximation of the spectral gap and the total variation mixing time is immediate from Theorem 4.6, whereas the uniformity of the approximation is given by Theorems 3.1, 3.5 and 3.8.

Example 4.4. For $n \ge 1$, let K_n be a birth and death chain on $\{0, 1, ..., 2n\}$ given by

$$K_n(i, i+1) = K_n(i+1, i) = \begin{cases} 1/2 & \text{for even } i\\ 1/(2n) & \text{for odd } i \end{cases}$$

By Theorem 4.7, the mixing time and spectral gap of K_n are comparable with those of \widetilde{K}_n , where $\widetilde{K}_n(i, i+1) = \widetilde{K}_n(i+1, i) = 1/(2n)$ for $0 \le i < 2n$. Let \mathcal{F} be the family consisting of K_n . By Theorem 4.6, neither \mathcal{F}_c nor \mathcal{F}_{δ} has a total variation precutoff and $T_{n,\mathrm{TV}}^{(c)}(\epsilon) \simeq T_{n,\mathrm{TV}}^{(\delta)}(\epsilon) \simeq \lambda_n^{-1} \simeq n^3$ for all $\epsilon \in (0, 1/2)$ and $\delta \in (0, 1)$, which is nontrivial.

Next, we consider simple random walks on finite paths with bottlenecks. For $n \ge 1$, let $k_n \le n$ and $x_{n,1}, ..., x_{n,k_n}$ be positive integers satisfying $1 \le x_{n,i} < x_{n,i+1} \le n$ for $i = 1, ..., k_n - 1$. Let K_n be the birth and death chain on $\{0, 1, ..., n\}$ of which birth, death and holding rates are given by

(4.6)
$$p_{n,i-1} = q_{n,i} = \begin{cases} 1/2 & \text{for } i \notin \{x_{n,1}, ..., x_{n,k_n}\} \\ \epsilon_{n,j} & \text{for } i = x_{n,j}, 1 \le j \le k_n \end{cases}$$

where $\epsilon_{n,j} \in (0, 1/2]$ for $1 \leq j \leq k_n$. Clearly, K_n is irreducible and the stationary distribution, say π_n , is uniform on $\{0, 1, ..., n\}$. The following theorem is immediate from Theorems 4.6.

Theorem 4.8. Let \mathcal{F} be a family of birth and death chains given by (4.6) and λ_n be the spectral gap of K_n . For $n \geq 1$, set

$$t_n = n^2 + \sum_{i=1}^{k_n} \frac{\min\{x_{n,i}, n+1-x_{n,i}\}}{\epsilon_{n,i}}$$

and

$$\ell_n = n^2 + \max_{j:j \le n/2} \left\{ \sum_{i:|x_{n,i}-n/2| \le j} \frac{n/2 + 1 - j}{\epsilon_{n,i}} \right\}$$

Then, for all $\epsilon \in (0, 1/2)$ and $\delta \in (0, 1)$,

$$T_{n,\mathrm{TV}}^{(c)}(\epsilon) \simeq T_{n,\mathrm{TV}}^{(\delta)}(\epsilon) \simeq t_n, \quad \lambda_n \simeq 1/\ell_n.$$

Furthermore, the following are equivalent.

- (1) \mathcal{F}_c has a cutoff in total variation.
- (2) For $\delta \in (0, 1)$, \mathcal{F}_{δ} has a cutoff in total variation.
- (3) \mathcal{F}_c has precutoff in total variation.

 t_r

- (4) For $\delta \in (0, 1)$, \mathcal{F}_{δ} has a precutoff in total variation.
- (5) $t_n/\ell_n \to \infty$.

Remark 4.1. Let t_n, ℓ_n be the constants in Theorem 4.8. Then,

$$n \approx n^2 + \sum_{j \in L_n} \frac{x_{n,j}}{\epsilon_{n,j}} + \sum_{j \in R_n} \frac{n+1-x_{n,j}}{\epsilon_{n,j}}$$

and

$$\ell_n \asymp n^2 + \max_{i \in L_n} \sum_{j \in L_n: j \ge i} \frac{x_{n,i}}{\epsilon_{n,j}} + \max_{i \in R_n} \sum_{j \in R_n: j \le i} \frac{n+1-x_{n,i}}{\epsilon_{n,j}}.$$

where $L_n = \{i : x_{n,i} \le n/2\}$ and $R_n = \{i : x_{n,i} > n/2\}.$

Theorem 1.4 considers a special case of Theorem 4.8 with $\epsilon_{n,i} = \epsilon_n$ for $1 \le i \le k_n$. It is clear from Theorem 1.4 that if k_n is bounded, then no cutoff exists for \mathcal{F}_c or \mathcal{F}_{δ} . The following example shows a case of cutoffs for the family in Theorem 1.4. *Example* 4.5. Let \mathcal{F} be the family in Theorem 1.4, with $k_n = \lfloor n^{1/3} \rfloor - 1$ and

$$x_{n,i} = \left\lfloor \frac{n^{5/6}}{n^{1/3} - i} \right\rfloor, \quad \forall 1 \le i \le k_n.$$

Clearly, for n large enough, $x_{n,i} \neq x_{n,j}$ when $i \neq j$. Let a_n, b_n be the constant in Theorem 1.4. It is not hard to show that

$$a_n \asymp n^{5/6} \log n, \quad b_n \asymp n^{5/6}.$$

By Theorem 1.4, \mathcal{F}_c and \mathcal{F}_{δ} , with $\delta \in (0, 1)$, have a total variation cutoff if and only if $\epsilon_n = o(n^{-7/6} \log n)$. Furthermore, if $\epsilon_n = o(n^{-7/6} \log n)$, then

$$T_{n,\mathrm{TV}}^{(c)}(\epsilon) \asymp \frac{n^{5/6} \log n}{\epsilon_n} \asymp T_{n,\mathrm{TV}}^{(\delta)}(\epsilon), \quad \forall \epsilon, \delta \in (0,1).$$

The following two theorems treat special cases of Theorem 4.8.

Theorem 4.9. Let \mathcal{F} be a family of birth and death chains satisfying (4.6). Let N be a positive constant. Suppose, for $n \geq 1$, there are constants $J_1^{(n)}, ..., J_N^{(n)}$ and a partition of $\{1, ..., k_n\}$, say $I_1^{(n)}, ..., I_N^{(n)}$, such that, for $1 \leq k \leq N$,

$$\max_{i \in I_k^{(n)}} \{ x_{n,i} \land (n+1-x_{n,i}) \} \asymp \min_{i \in I_k^{(n)}} \{ x_{n,i} \land (n+1-x_{n,i}) \} \asymp J_k^{(n)},$$

where $a \wedge b = \min\{a, b\}$. Then, neither \mathcal{F}_c nor \mathcal{F}_{δ} has a total variation cutoff. Moreover,

$$T_{n,\mathrm{TV}}^{(c)}(\epsilon) \asymp T_{n,\mathrm{TV}}^{(\delta)}(\epsilon) \asymp \lambda_n^{-1} \asymp t_n, \quad \forall \epsilon \in (0, 1/2), \, \delta \in (0, 1)$$

where

$$t_n = n^2 + \max_{1 \le k \le N} \left\{ J_k^{(n)} \sum_{l \in I_k^{(n)}} \frac{1}{\epsilon_{n,l}} \right\}.$$

The next theorem gives an example that no total variation cutoff exists for $\mathcal{F}_c, \mathcal{F}_\delta$ even when the constant N in Theorem 4.9 tends to infinity.

Theorem 4.10. Let \mathcal{F} be a family of birth and death chains satisfying (4.6). Suppose that $\min_j \epsilon_{n,j} \asymp \max_j \epsilon_{n,j}$ and $x_{n,i} = \lfloor in/k_n \rfloor$ with $k_n \leq n/2$, then neither \mathcal{F}_c nor \mathcal{F}_{δ} has a total variation cutoff, but

$$T_{n,\mathrm{TV}}^{(c)}(\epsilon) \asymp T_{n,\mathrm{TV}}^{(\delta)}(\epsilon) \asymp \lambda_n^{-1} \asymp \max\{n^2, nk_n/\epsilon_{n,1}\}, \quad \forall \epsilon \in (0, 1/2), \, \delta \in (0, 1).$$

Remark 4.2. Note that the assumption regarding the birth and death rates in this section can be relaxed using the comparison technique in [11, 12].

APPENDIX A. SPECTRAL GAPS OF FINITE PATHS

This section is devoted to finding the correct order of spectral gaps of finite paths. Let G = (V, E) be the undirected finite graph with vertex set $V = \{0, 1, 2, ..., n\}$ and edge set $E = \{\{i, i + 1\} : i = 0, 1, ..., n - 1\}$. Given two positive measures π, ν on V, E with $\pi(V) = 1$, the Dirichlet form and variance associated with ν and π are defined by

$$\mathcal{E}_{\nu}(f,g) := \sum_{i=1}^{n-1} [f(i) - f(i+1)][g(i) - g(i+1)]\nu(i,i+1)$$

and

$$\operatorname{Var}_{\pi}(f) := \pi(f^2) - \pi(f)^2,$$

where f, g are functions on V. The spectral gap of G with respect to π, ν is defined as

$$\lambda_{\pi,\nu}^G := \min\left\{ \frac{\mathcal{E}_{\nu}(f,f)}{\operatorname{Var}_{\pi}(f)} \middle| f \text{ is non-constant} \right\}.$$

To bound the spectral gap, we need the following notations. Let $C_+(i)$ and $C_-(i)$ be constants defined by

(A.1)
$$C_{+}(i) = \max_{j:j>i} \sum_{k=i+1}^{j} \frac{\pi([j,n])}{\nu(k-1,k)}, \quad C_{-}(i) = \max_{j:j$$

where $\max \emptyset := 0$.

Theorem A.1. Let G = (V, E) be a path on $\{0, 1, ..., n\}$ and π, ν be positive measures on V, E with $\pi(V) = 1$. Referring to (A.1), set $C(m) = \max\{C_+(m), C_-(m)\}$. Then, for $0 \le m \le n$,

$$\frac{1}{4C(m)} \le \lambda^G_{\pi,\nu} \le \frac{1}{\min\{\pi([0,m]),\pi([m,n])\}C(m)}$$

In particular, if M is a median of π , that is, $\pi([0, M]) \ge 1/2$ and $\pi([M, n]) \ge 1/2$, then

$$\frac{1}{4C(M)} \le \lambda^G_{\pi,\nu} \le \frac{2}{C(M)}$$

Remark A.1. Referring to the setting in Theorem A.1, the authors of [7] obtained $\lambda_{\pi,\nu}^G \geq 1/C'$, where

$$C' = \min_{0 \le j \le n} \max\left\{ \sum_{k=0}^{j-1} \frac{\pi([0,k])}{\nu(k,k+1)}, \sum_{k=j+1}^{n} \frac{\pi([k,n])}{\nu(k-1,k)} \right\}$$

Theorem A.1 indicates that 1/C(M) is always of the same order as the spectral gap and provides an estimate that can be significantly better than 1/C'.

The proof of Theorem A.1 is based on the following proposition, which is related to weighted Hardy's inequality on $\{1, ..., n\}$.

Proposition A.2. Fix $n \ge 1$. Let μ, π be positive measures on $\{1, ..., n\}$ and A be the smallest constant such that

(A.2)
$$\sum_{i=1}^{n} \left(\sum_{j=1}^{i} g(j) \right)^2 \pi(i) \le A \sum_{i=1}^{n} g^2(i) \mu(i), \quad \forall g \neq \mathbf{0}$$

Then, $B \leq A \leq 4B$, where

$$B = \max_{1 \le i \le n} \left\{ \pi([i, n]) \sum_{j=1}^{i} \frac{1}{\mu(j)} \right\}.$$

Remark A.2. Miclo [16] discussed the infinity case $\{1, 2, ...\}$ using the method in [17], which was introduced by Muckenhoupt to study the continuous case $[0, \infty)$. For more information on the weighted Hardy inequality, see [16] and the references therein.

Proof of Theorem A.1. We first consider the lower bound of $\lambda_{\pi,\nu}^G$. Let f be any function defined on V and set $f_+ = [f - f(m)]\mathbf{1}_{\{m,\dots,n\}}$ and $f_- = [f - f(m)]\mathbf{1}_{\{0,\dots,m\}}$. Then,

(A.3)
$$\frac{\mathcal{E}_{\nu}(f,f)}{\operatorname{Var}_{\pi}(f)} \ge \frac{\mathcal{E}_{\nu}(f,f)}{\pi(f-f(m))^2} = \frac{\mathcal{E}_{\nu}(f_+,f_+) + \mathcal{E}_{\nu}(f_-,f_-)}{\pi(f_+^2) + \pi(f_-^2)}$$

Set g(j) = f(m+j) - f(m+j-1) for $1 \le j \le n-m$ and h(i) = f(m-i) - f(m-i+1) for $1 \le i \le m$. Note that

$$\mathcal{E}_{\nu}(f_{+},f_{+}) = \sum_{j=1}^{n-m} g^{2}(j)\nu(m+j-1,m+j), \ \pi(f_{+}^{2}) = \sum_{j=1}^{n-m} \left(\sum_{k=1}^{j} g(k)\right)^{2} \pi(m+j),$$

and

$$\mathcal{E}_{\nu}(f_{-},f_{-}) = \sum_{i=1}^{m} h^{2}(i)\nu(m-i,m-i+1), \ \pi(f_{-}^{2}) = \sum_{j=1}^{m} \left(\sum_{k=1}^{j} h(k)\right)^{2} \pi(m-j).$$

By Proposition A.2, the above computation implies that

$$\frac{\mathcal{E}_{\nu}(f_+, f_+)}{\pi(f_+^2)} \ge \frac{1}{4C_+(m)}, \quad \frac{\mathcal{E}_{\nu}(f_-, f_-)}{\pi(f_-^2)} \ge \frac{1}{4C_-(m)}$$

Putting this back to (A.3) gives the desired lower bound.

For the upper bound, we first consider the case $C = C_+(m)$. By Proposition A.2, $C_+(m) \leq A$, where A is the smallest constant A such that, for any function ϕ defined on $\{1, 2, ..., n - m + 1\}$,

$$\sum_{j=1}^{n-m} \left(\sum_{k=1}^{j} \phi(k)\right)^2 \pi(m+j) \le A \sum_{j=1}^{n-m} \phi^2(j)\nu(m+j-1,m+j).$$

Let ϕ be a minimizer for A, which must exist, and define ψ by setting

$$\psi(i) = \begin{cases} \phi(1) + \dots + \phi(i-m) & \text{for } m < i \le n \\ 0 & \text{for } 0 \le i \le m \end{cases}.$$

Clearly, $1/C_+(m) \geq 1/A = \mathcal{E}_{\nu}(\psi,\psi)/\pi(\psi^2)$. Without loss of generality, we may assume further that ϕ is nonnegative. Note that $\pi(\{\psi = 0\}) \geq \pi([0,m])$. By the Cauchy-Schwartz inequality, this implies $\pi(\psi)^2 \leq \pi(\{\psi > 0\})\pi(\psi^2) \leq \pi([m + 1,n])\pi(\psi^2)$ and, then, $\operatorname{Var}_{\pi}(\psi) \geq \pi([0,m])\pi(\psi^2)$. This leads to $1/C = 1/C_+(m) \geq \pi([0,m])\lambda_{\pi,\nu}^G$. Similarly, if $C = C_-(m)$, one can prove that $1/C \geq \pi([m,n])\lambda_{\pi,\nu}^G$. This yields the upper bound of the spectral gap.

Proof of Proposition A.2. The proofs of Theorem A.1 and Proposition A.2 are very similar to those in [16]. Note that A is attained at functions of the same sign and we assume that g is non-negative. As A is attainable, the minimizer g for A satisfies the following Euler-Lagrange equations.

(A.4)
$$Ag(i)\mu(i) = \sum_{j=i}^{n} (g(1) + \dots + g(j))\pi(j), \quad \forall 1 \le i \le n.$$

This is equivalent to the following system of equations.

$$A[g(i)\mu(i) - g(i+1)\mu(i+1)] = (g(1) + \dots + g(i))\pi(i), \quad \forall 1 \le i \le n,$$

with the convention that $\mu(n+1) := 0$. Inductively, one can show that g > 0. Summing up (A.4) over $\{1, ..., \ell\}$ yields

$$A\sum_{i=1}^{\ell} g(i) = \sum_{i=1}^{\ell} \frac{1}{\mu(i)} \sum_{j=i}^{n} (g(1) + \dots + g(j))\pi(j)$$

$$\geq \sum_{i=1}^{\ell} \sum_{j=\ell}^{n} \frac{(g(1) + \dots + g(j))\pi(j)}{\mu(i)}$$

$$\geq \left(\sum_{i=1}^{\ell} g(i)\right) \left(\sum_{i=1}^{\ell} \frac{1}{\mu(i)}\right)\pi([\ell, n]).$$

This leads to $A \ge B$.

To see the upper bound, we use Miclo's method in [16]. Set $N(j) = \sum_{i=1}^{j} 1/\mu(i)$. By the Cauchy inequality, the left side of (A.2) is bounded above by

$$\sum_{i=1}^{n} \pi(i) \sum_{j=1}^{i} g^{2}(j) \mu(j) N^{1/2}(j) \sum_{l=1}^{i} \frac{1}{\mu(l) N^{1/2}(l)}.$$

Note that, for $s > 0, t > 0, t^{1/2} - s^{1/2} \ge (t - s)/(2t^{1/2})$. This implies $2(N^{1/2}(l) - N^{1/2}(l-1)) \ge 1/(\mu(l)N^{1/2}(l))$ with the convention that N(0) := 0. Consequently, we have

$$\sum_{l=1}^{i} \frac{1}{\mu(l)N^{1/2}(l)} \le 2N^{1/2}(i) \le \left(\frac{4B}{\pi([i,n])}\right)^{1/2},$$

and, thus,

$$\sum_{i=1}^{n} \left(\sum_{j=1}^{i} g(j) \right)^{2} \pi(i) \leq \sqrt{4B} \sum_{i=1}^{n} \frac{\pi(i)}{\pi([i,n])^{1/2}} \sum_{j=1}^{i} g^{2}(j) \mu(j) N^{1/2}(j)$$
$$\leq \sqrt{4B} \sum_{j=1}^{n} g^{2}(j) \mu(j) N^{1/2}(j) \sum_{i=j}^{n} \frac{\pi(i)}{\pi([i,n])^{1/2}}.$$

Again, the inequality for s, t implies

$$\sum_{i=j}^{n} \frac{\pi(i)}{\pi([i,n])^{1/2}} \leq 2\pi([j,n])^{1/2} \leq \frac{\sqrt{4B}}{N^{1/2}(j)}.$$

This gives the desired upper bound.

Next, we consider a special case. Let π,ν are measures on $V=\{0,1,...,n\}, E=\{\{i,i+1\}|0\leq i< n\}$ with $\pi(V)=1.$ Suppose

(A.5)
$$\pi(i) = \pi(n-i), \quad \nu(i,i+1) = \nu(n-i-1,n-i), \quad \forall 0 \le i \le n/2.$$

By the symmetry of π and ν , if ψ is a minimizer for $\lambda_{\pi,\nu}^G$ with $\pi(\psi) = 0$, then ψ is either symmetric or anti-symmetric at n/2. The former is set aside because ψ is known to be monotonic and this leads to the case $\psi(n-i) = -\psi(i)$ for $0 \le i \le n/2$. If n is even with n = 2k, then $\psi(k) = 0$ and this implies

$$\lambda_{\pi,\nu}^{G} = \inf \left\{ \frac{\sum_{i=1}^{k} (f(i) - f(i-1))^{2} \nu(i-1,i)}{\sum_{i=0}^{k-1} f^{2}(i) \pi(i)} \middle| f(k) = 0, f \neq \mathbf{0} \right\}.$$

Equivalently, if one sets g(i) = f(k-i) - f(k-i+1) and $\mu(i) = \nu(k-i, k-i+1)$ for $1 \le i \le k$, then $1/\lambda_{\pi,\nu}^G$ is the smallest constant A such that

(A.6)
$$\sum_{i=1}^{k} \left(\sum_{j=1}^{i} g(j) \right)^2 \pi(k-i) \le A \sum_{i=1}^{k} g^2(i) \mu(i), \quad \forall g \neq \mathbf{0}$$

Similarly, if n is odd with n = 2k - 1, one has

$$\lambda_{\pi,\nu}^{G} = \min\left\{\frac{\sum_{i=1}^{k-1} (f(i) - f(i-1))^2 \nu(i-1,i) + 2f^2(k-1)\nu(k-1,k)}{\sum_{i=0}^{k-1} f^2(i)\pi(i)} \middle| f \neq \mathbf{0}\right\},\$$

and this leads to (A.6) with g(1) = f(k-1), $\mu(1) = 2\nu(k-1,k)$ and, for $2 \le i \le k$, g(i) = f(k-i) - f(k-i+1) and $\mu(i) = \nu(k-i,k-i+1)$. A direct application of Proposition A.2 implies the following theorem.

Theorem A.3. Let G = (V, E) be the graph with $V = \{0, 1, ..., n\}$, $E = \{\{i, i + 1\} | i = 0 \le i < n\}$ and let π, ν be positive measures on V, E satisfying $\pi(V) = 1$ and (A.5). Set $N = \lceil n/2 \rceil$. Then, $1/(4C) \le \lambda_{\pi,\nu}^G \le 1/C$, where

$$C = \max_{0 \le i < N} \left\{ \pi([0,i]) \sum_{j=i}^{N-1} \frac{1}{\nu(j,j+1)} \right\} \quad if \ n \ is \ even$$

and

$$C = \max_{0 \le i < N} \left\{ \pi([0,i]) \left(\sum_{j=i}^{N-2} \frac{1}{\nu(j,j+1)} + \frac{1}{2\nu(N-1,N)} \right) \right\} \quad if \ n \ is \ odd.$$

Remark A.3. The symmetry of π, ν in Theorems A.3 can be relaxed using the comparison technique.
