

DEGENERATE EISENSTEIN SERIES FOR $Sp(4)$

MARCELA HANZER AND GORAN MUIĆ

to Steve Rallis, in memoriam

ABSTRACT. In this paper we obtain a complete description of images and poles of degenerate Eisenstein series attached to maximal parabolic subgroups of $Sp_4(\mathbb{A})$, where \mathbb{A} is the ring of adeles of \mathbb{Q} .

1. INTRODUCTION

The degenerate Eisenstein series attached to Siegel parabolic subgroups of symplectic and metaplectic groups has been studied extensively for various applications such for example explicit construction of automorphic L -functions [3], and application in the Siegel–Weil formula [10, 11, 12, 13, 8]. On the other hand, we have used a more general type of degenerate Eisenstein series to construct and prove unitarity of various significant classes of unitary representations of local (real or p -adic groups) and to construct various families of square-integrable automorphic forms [17, 18, 5]. In [6] we study degenerate Eisenstein series for GL_n , their restriction to archimedean place and images (this improves in part results of [10]).

The problem of getting complete information about poles of Eisenstein series and their images for classical groups is mostly related to our insufficient understanding of various types of degenerate principal series representations and standard intertwining operators especially for real groups that appear in the constant term of Eisenstein series. For Siegel Eisenstein series this problem is solved in [12]. In the current literature, there are also some other works which deal with various types of "Siegel-like" degenerate principal series (see for example [7, 14, 15, 16, 4]) but more complicated ones appear in the theory of automorphic forms (see the last section in [18] for simple examples or [5] for more sophisticated examples).

1991 Mathematics Subject Classification. 11F70, 22E50.

Key words and phrases. automorphic forms, degenerate Eisenstein series, normalized intertwining operators.

For the group $Sp_4(\mathbb{R})$, there is a description (see [19]) of all generalized and degenerate principal series in terms of the Langlands classification as well as some information about the images and poles of the local intertwining operators. This is used in the present paper along with the local information on p -adic places [21] to get the complete description of the images and poles of degenerate Eisenstein series for Siegel and Heisenberg parabolic subgroups of adelic Sp_4 . The description of the residual spectrum and square-integrable non-cuspidal automorphic forms is well-known [9].

Now, we will describe the paper by sections. In Section 2 we state notation regarding the group Sp_4 , we define degenerate Eisenstein series, and recall basic procedure of computing their poles thorough the constant term and local normalized intertwining operators. In Section 3 we deal with the Eisenstein series attached to the Heisenberg parabolic subgroup. The main results are Theorems 3.6 and 3.7. In Section 4 we deal with the Eisenstein series attached to the Siegel parabolic subgroup. The main results are Theorems 4.3 and 4.4. As we explain above, this last part has an overlap with the results of [12], but we have a different approach to the archimedean components [19] which gives us the answer in terms of the Langlands classification which is hard to see from [12].

In the future papers we plan to extend this work beyond Sp_4 (see also the last Section of [18]). One of the obstacles that we need to overcome is better understanding certain degenerate principal series which are induced from non-Siegel parabolic subgroups of $Sp_{2n}(\mathbb{R})$ (see also the last Section of [18]).

2. PRELIMINARIES

For $n \in \mathbb{Z}_{\geq 1}$, we define J_n as a $n \times n$ matrix with 1's on the opposite diagonal, and zeroes everywhere else. We realize the group Sp_4 as a matrix group in the following way:

$$Sp_4(\mathbb{F}) = \left\{ g \in GL_4(\mathbb{F}) : g^t \begin{bmatrix} 0 & J_2 \\ -J_2 & 0 \end{bmatrix} g = \begin{bmatrix} 0 & J_2 \\ -J_2 & 0 \end{bmatrix} \right\}.$$

For us $\mathbb{F} \in \{\mathbb{Q}, \mathbb{Q}_p, \mathbb{R}, \mathbb{A}\}$, where \mathbb{A} is the ring of adeles of \mathbb{Q} .

The upper triangular matrices in Sp_4 form a Borel subgroup B , which we fix. The standard parabolic subgroups are those containing this Borel subgroup. The diagonal matrices in the Borel subgroup form a maximal torus, which we denote by T . Thus

$$T(\mathbb{F}) = \{diag(t_1, t_2, t_2^{-1}, t_1^{-1}); t_1, t_2 \in \mathbb{F}^*\}.$$

The unipotent matrices in B form the unipotent radical of B . Let W be the Weyl group of Sp_4 with respect to T . We define the action of the Weyl group elements with respect to the elementary reflections:

$$s(\text{diag}(t_1, t_2, t_2^{-1}, t_1^{-1})) = \text{diag}(t_2, t_1, t_1^{-1}, t_2^{-1})$$

and

$$c_2(\text{diag}(t_1, t_2, t_2^{-1}, t_1^{-1})) = \text{diag}(t_1, t_2^{-1}, t_2, t_1^{-1}).$$

All other elements of W are generated by s and c_2 . The set of roots of Sp_4 with respect to T is denoted by Σ , and Σ^+ denotes the set of positive roots with respect to the above choice of Borel subgroup. Let Δ denote the set of simple roots in Σ^+ . Then $\Delta = \{e_1 - e_2, 2e_2\}$ with obvious meaning of e_i , $i = 1, 2$.

Let χ denote a unitary Grössencharacter of $\mathbb{Q}^\times \backslash \mathbb{A}^\times \rightarrow \mathbb{C}^\times$. We study the degenerate Eisenstein series on Sp_4 acting on the holomorphic sections associated with the global representations of $Sp_4(\mathbb{A})$ (more precisely, of its Hecke algebra) induced from the characters of the maximal standard parabolic subgroups of Sp_4 . Thus, we have the Heisenberg and the Siegel case. We denote by $P_1 = M_1U_1$ the Heisenberg parabolic subgroup of Sp_4 so that the standard Levi subgroup M_1 is isomorphic to $GL_1 \times SL_2$ and in the Siegel case, we denote the Siegel parabolic subgroups $P_2 = M_2U_2$, where now $M_2 = GL_2$. We describe the corresponding holomorphic sections f_s in each of these cases more thoroughly in the second and the third section of this paper. In both cases, we form the degenerate Eisenstein series

$$(1) \quad E(f_s)(g) \stackrel{\text{def}}{=} \sum_{\gamma \in P_i(\mathbb{Q}) \backslash Sp_4(\mathbb{Q})} f_s(\gamma \cdot g)$$

which converges absolutely and uniformly in (s, g) on compact sets when $s > 2$ in the Heisenberg case, and $s > 3$ in the Siegel case. This is proved by the restriction to $Sp_4(\mathbb{R})$ and then applying Godement's theorem as in ([2], 11.1 Lemma). In particular, there are no poles for such s .

It continues to a function which is meromorphic in s . Outside of poles, it is an automorphic form. As usual and more convenient for computations, we write $E(s, f)$ instead of $E(f_s)$; in this notation s signals that $f \in I(s)$.

We say that $s_0 \in \mathbb{C}$ is a pole of the degenerate Eisenstein series $E(s, \cdot)$ if there exists $f \in I(s)$ such that $E(s, f)$ has a pole at $s = s_0$ (for some choice of $g \in Sp_4(\mathbb{A})$). The order of pole at s_0 is denoted by l ; it is supremum of all orders $E(s, f)$ at s_0 when f ranges over $I(s)$. It may happen that $l = \infty$ as it can be seen from our main theorems

but if $0 \leq l < \infty$, then the map

$$(2) \quad \text{Ind}_{P_i(\mathbb{A})}^{Sp_4(\mathbb{A})}(\pi(\chi)_i) \xrightarrow{f \mapsto (s-s_0)^l E(s,f)} \mathcal{A}(Sp_4(\mathbb{Q}) \setminus Sp_4(\mathbb{A}))$$

for $i = 1, 2$ is an intertwining operator for the action of $(\mathfrak{sp}(4), K_\infty) \times \prod_{p < \infty} Sp_4(\mathbb{Q}_p)$ in the space of automorphic forms. Here

$$(3) \quad \pi(\chi)_1 = \chi | \det |_{GL_1(\mathbb{A})}^{s_0} \otimes 1_{SL_2(\mathbb{A})} \text{ and } \pi(\chi)_2 = \chi | \det |_{GL_2(\mathbb{A})}^{s_0}.$$

The poles of the Eisenstein series are the same as the poles of its constant term along the minimal parabolic subgroup:

$$(4) \quad E_{const}(s, f)(g) = \int_{U(\mathbb{Q}) \backslash U(\mathbb{A})} E(s, f)(ug) du.$$

Here U denotes the unipotent radical of the (upper triangular) Borel subgroup of Sp_4 . The integral in (4) can be computed by the standard unfolding. To explain this we introduce some more notation. We use ν to denote $|\det|$ on GL_n simultaneously. The rank of the general linear group involved will be obvious from the context. We let $\Lambda_s = \chi \nu^s \otimes \nu^{-1}$ if we are in the Heisenberg case and $\Lambda_s = \chi \nu^{s-1/2} \otimes \chi \nu^{s+1/2}$ if we are in the Siegel case.

In this way, we obtain a character of $T(\mathbb{Q}) \setminus T(\mathbb{A}) \rightarrow \mathbb{C}^\times$. We extended trivially across $U(\mathbb{A})$ and we induce up to the principal series $\text{Ind}_{T(\mathbb{A})U(\mathbb{A})}^{Sp_4(\mathbb{A})}(\Lambda_s)$.

We denote by \overline{U} the lower unipotent triangular matrices in Sp_4 (these matrices form the unipotent radical of the opposite Borel subgroup in Sp_4 .) Let $w \in W$. Then, the global intertwining operator

$$M(\Lambda_s, w) : \text{Ind}_{T(\mathbb{A})U(\mathbb{A})}^{Sp_4(\mathbb{A})}(\Lambda_s) \longrightarrow \text{Ind}_{T(\mathbb{A})U(\mathbb{A})}^{Sp_4(\mathbb{A})}(w(\Lambda_s)),$$

defined by

$$M(\Lambda_s, w)f = \int_{U(\mathbb{A}) \cap w \overline{U}(\mathbb{A}) w^{-1}} f(\tilde{w}^{-1}ug) du$$

does not depend on the choice of the representative for w in $Sp_4(\mathbb{Q})$.

The global intertwining operator factors into product of local intertwining operators

$$M(\Lambda_s, w)f = \otimes_{p < \infty} A(\Lambda_{s,p}, \tilde{w})f_p.$$

There is a precise way of normalization of Haar measures used in the definition of intertwining operators [22], [23]. Summary can be found in ([17], Section 2) or ([18], Section 2). The same is with the normalization factor which we explain next. The normalization factor for $A(\Lambda_{s,p}, \tilde{w})$ is defined by

$$r(\Lambda_{s,p}, w) = \prod_{\alpha \in \Sigma^+, w(\alpha) < 0} \frac{L(1, \Lambda_{s,p} \circ \alpha^\vee) \epsilon(1, \Lambda_{s,p} \circ \alpha^\vee, \psi_v)}{L(0, \Lambda_{s,p} \circ \alpha^\vee)},$$

where α^\vee denotes the coroot corresponding to the root α , and ψ_v is an non-degenerate additive character of \mathbb{Q}_p . We define the normalized intertwining operator by the following formula:

$$\mathcal{N}(\Lambda_{s,p}, \tilde{w}) = r(\Lambda_{s,p}, w) A(\Lambda_{s,p}, \tilde{w}).$$

Properties of normalized intertwining operators can be found in [22], [23]. Again, the summary can be found in ([18], Theorem 2-5).

Let us write β for the simple root such that $\Delta - \{\beta\}$ determines P_i . Now, the constant term has the following expression ([17], Lemma 2.1):

$$\begin{aligned} E_{const}(s, f)(g) &= \sum_{w \in W, w(\Delta \setminus \{\beta\}) > 0} M(\Lambda_s, w) f(g) \\ &= \sum_{w \in W, w(\Delta \setminus \{\beta\}) > 0} \int_{U(\mathbb{A}) \cap w \bar{U}(\mathbb{A}) w^{-1}} f(\tilde{w}^{-1} u g) du, \end{aligned}$$

where, by induction in stages, we identify

$$(5) \quad f \in \text{Ind}_{P_i(\mathbb{A})}^{Sp_4(\mathbb{A})}(\pi(\chi)_i) \subset \text{Ind}_{T(\mathbb{A})U(\mathbb{A})}^{Sp_4(\mathbb{A})}(\Lambda_s)$$

where $\pi(\chi)_i$, $i = 1, 2$ is defined in (3). This formula can be more refined up to its final form that we use. Let S be the finite set of all places including ∞ such that for $p \notin S$ we have that χ_p , μ_p , ψ_p , and f_p are unramified. Then we have the following expression:

$$(6) \quad E_{const}(s, f)(g) = \sum_{w \in W, w(\Delta \setminus \{\beta\}) > 0} r(\Lambda_s, w)^{-1} (\otimes_{p \in S} \mathcal{N}(\Lambda_{s,p}, \tilde{w}) f_p) \otimes (\otimes_{p \notin S} f_{w,p}),$$

where we let

$$(7) \quad r(\Lambda_s, w)^{-1} \stackrel{def}{=} \prod_{\alpha \in \Sigma^+, w(\alpha) < 0} \frac{L(0, \Lambda_s \circ \alpha^\vee)}{L(1, \Lambda_s \circ \alpha^\vee) \epsilon(1, \Lambda_s \circ \alpha^\vee)},$$

and we use a well-known property of normalization

$$(8) \quad \mathcal{N}(\Lambda_{s,p}, \tilde{w}) f_p = f_{w,p},$$

for unramified f_p and $f_{w,p}$.

We note that, in the situation as above, taking the constant term is an isomorphism between different spaces of automorphic forms (well known fact, e.g. [6], Lemma 2-9.)

We use standard notation [21] (see also [19]) for the representation theory of classical groups (in local or global settings). In more detail,

if χ is a character of $GL(1)$ and π is a representation of SL_2 , then $\chi \rtimes \pi$ denotes the representation unitarily induced from P_1 to Sp_4 . If π is a representation of $GL(2)$, then $\pi \rtimes 1$ denotes the representation unitarily induced from P_1 to Sp_4 . Also, if χ and μ are characters of $GL(1)$, then $\chi \times \mu \rtimes 1$ is the associated principal series of Sp_4 . Similar notation is used for $GL(2)$ and SL_2 . We denote by $L(\)$ the Langlands quotient whenever in parenthesis is an induced representation having a Langlands quotient.

We use repeatedly the following simple fact (and similarly for $GL(2)$):

Lemma 2.1. *Let $p \leq \infty$. The complex number $s = s_0 \in \mathbb{C}$ is a pole of $\mathcal{N}(s, \mu_p, w)$ (a normalized intertwining operator) if and only if $Re(s_0) < 0$ and $\text{Ind}_{P(\mathbb{Q}_p)}^{SL_2(\mathbb{Q}_p)}(|\cdot|_p^{s_0} \mu_p)$ is reducible.*

Proof. Indeed, the assumption $Re(s_0) < 0$ is clear since we know that $\mathcal{N}(s, \mu_p, w)$ is holomorphic and non-trivial for $Re(s) \geq 0$. Assume $Re(s_0) < 0$. Then, if $\text{Ind}_{P(\mathbb{Q}_p)}^{SL_2(\mathbb{Q}_p)}(|\cdot|_p^{s_0} \mu_p)$ is irreducible, then the functional equation

$$\mathcal{N}(s, \mu_p, w) \mathcal{N}(-s, \mu_p^{-1}, w^{-1}) = \mathcal{N}(-s, \mu_p^{-1}, w^{-1}) \mathcal{N}(s, \mu_p, w) = id,$$

combined with holomorphy and non-triviality of $\mathcal{N}(-s_0, \mu_p^{-1}, w^{-1})$ imply that $\mathcal{N}(s, \mu_p, w)$ is holomorphic at $s = s_0$. Conversely, still assuming $Re(s_0) < 0$, if $\mathcal{N}(s, \mu_p, w)$ is holomorphic for $s = s_0$, then the functional equation, combined with holomorphy and non-triviality of $\mathcal{N}(-s_0, \mu_p^{-1}, w^{-1})$, imply

$$\text{Ind}_{P(\mathbb{Q}_p)}^{SL_2(\mathbb{Q}_p)}(|\cdot|_p^{-s_0} \mu_p) \simeq \text{Ind}_{P(\mathbb{Q}_p)}^{SL_2(\mathbb{Q}_p)}(|\cdot|_p^{s_0} \mu_p).$$

Then the argument with the Langlands quotient implies that $\text{Ind}_{P(\mathbb{Q}_p)}^{SL_2(\mathbb{Q}_p)}(|\cdot|_p^{s_0} \mu_p)$ is irreducible. \square

3. THE HEISENBERG PARABOLIC

The standard Levi subgroup of the Heisenberg parabolic subgroup P_1 is isomorphic to $GL_1 \times SL_2$, thus we study the global induced representation

$$\text{Ind}_{GL_1(\mathbb{A}) \times SL_2(\mathbb{A})}(\chi \nu^s \otimes 1),$$

where χ denotes a Grossencharacter of \mathbb{Q} and 1 is a trivial character of $SL_2(\mathbb{A})$. This space consists of all C^∞ and right K -finite functions

$f : Sp_4(\mathbb{A}) \longrightarrow \mathbb{C}$ which satisfy

$$f \left(\begin{pmatrix} a & 0 & 0 \\ 0 & d & 0 \\ 0 & 0 & a^{-1} \end{pmatrix} \begin{pmatrix} 1 & b_1 & b_2 \\ 0 & I_2 & b_3 \\ 0 & 0 & 1 \end{pmatrix} g \right) = \chi(a) \nu(a)^s \delta_{P_1}^{1/2} \left(\begin{pmatrix} a & 0 & 0 \\ 0 & d & 0 \\ 0 & 0 & a^{-1} \end{pmatrix} \right) f(g),$$

where $a \in GL_1(\mathbb{A})$, $d \in SL_2(\mathbb{A})$, $\begin{pmatrix} 1 & b_1 & b_2 \\ 0 & I_2 & b_3 \\ 0 & 0 & 1 \end{pmatrix} \in U_1(\mathbb{A})$, $g \in Sp_4(\mathbb{A})$.

So, for the case of the Heisenberg maximal parabolic, a simple root β such that $\Delta \setminus \{\beta\}$ determines Heisenberg parabolic is $\beta = e_1 - e_2$; i.e., in the expression for the constant term (6) we have a summation over $w \in W; w(2e_2) > 0$. We easily check that these elements are $\{1, c_1, s, sc_1\}$. We note that using s and c_2 (as the Weyl reflections with respect to the simple roots of Sp_4 we can express c_1 and sc_1 as sc_2s and c_2s , respectively, so that c_1 is of length three, and sc_1 is of length two. Now we easily see that the expression for the (global) normalizing factors (obtained as the product of the local ones) for the intertwining operators attached to these Weyl group elements are

$$(9) \quad r(\Lambda_s, c_1)^{-1} = \frac{L(s-1, \chi)}{L(s+2, \chi) \varepsilon(s+2, \chi) \varepsilon(s, \chi) \varepsilon(s+1, \chi)},$$

$$(10) \quad r(\Lambda_s, s)^{-1} = \frac{L(s+1, \chi)}{L(s+2, \chi) \varepsilon(s+2, \chi)},$$

$$(11) \quad r(\Lambda_s, sc_1)^{-1} = \frac{L(s, \chi)}{L(s+2, \chi) \varepsilon(s+1, \chi) \varepsilon(s+2, \chi)}.$$

We want to address the holomorphicity of these expressions. We immediately see the following:

Lemma 3.1. (1) *Assume $s \geq 0$. Then, the denominators of all three of the above expressions are non-zero and holomorphic. Thus, the poles cannot come from the zeroes of the denominators. As for the numerators, they are all holomorphic if $\chi \neq 1$, and if $\chi = 1$ we have the following:*

- (a) $r(\Lambda_s, c_1)^{-1}$ has a pole of the first order for $s = 1$ and $s = 2$,
- (b) $r(\Lambda_s, s)^{-1}$ has a pole of the first order for $s = 0$,
- (c) $r(\Lambda_s, sc_1)^{-1}$ has a pole of the first order for $s = 0$ and $s = 1$.

- (2) *Assume $s < 0$. We analyze the zeroes of the denominators. The denominators (for all three expressions) might have zeroes in the critical strip, i.e., $0 < s+2 < 1$, i.e., $-2 < s < -1$. The*

numerators do not have poles if $\chi \neq 1$ and do have poles for $r(\Lambda_s, s)^{-1}$ for $s = -1$ and $\chi = 1$.

Now we analyze local intertwining operators appearing in (6).

3.1. Local intertwining operators appearing in (6). We recall that for every p , the trivial representation of $SL_2(\mathbb{Q}_p)$ is embedded in the principal series representation $\nu_p^{-1} \rtimes 1$.

Lemma 3.2. *The local intertwining operator $\mathcal{N}(\Lambda_{s,p}, \tilde{c}_1)$ acting on $\chi_p \nu^s \rtimes 1_p$ (where 1_p is the trivial representation of $SL_2(\mathbb{Q}_p)$) is holomorphic for every $p < \infty$ and for every $s \in \mathbb{R}$, except for $s = -2$, where it has a pole of the first order (for every $p < \infty$).*

Proof. According to the decomposition $c_1 = sc_2s$ we have the following decomposition of the local intertwining operator $\mathcal{N}(\Lambda_{s,p}, \tilde{c}_1)$:

$$(12) \quad \begin{aligned} \chi_p \nu^s \times \nu_p^{-1} \rtimes 1 &\rightarrow \nu_p^{-1} \times \chi_p \nu_p^s \rtimes 1 \rightarrow \nu_p^{-1} \times \chi_p^{-1} \nu_p^{-s} \rtimes 1 \\ &\rightarrow \chi_p^{-1} \nu_p^{-s} \times \nu_p^{-1} \rtimes 1. \end{aligned}$$

Then, the first (normalized) intertwining operator appearing in the above relation is induced from the GL_2 -case and is holomorphic unless $\chi_p = 1$ and $s = -2$. The second intertwining operator is induced from the intertwining operator $\chi_p \nu_p^s \rtimes 1 \rightarrow \chi_p^{-1} \nu_p^{-s} \rtimes 1$. This intertwining operator is holomorphic if $s > 0$, (from the Langlands' condition), and for $s \leq 0$, this operator is holomorphic unless the induced representation $\chi_p \nu_p^s \rtimes 1$ is reducible, and this happens if $\chi_p^2 = 1$, $\chi_p \neq 1$ and $s = 0$ and if $\chi_p = 1$ and $s = -1$. If we examine the first case more closely, we see that then the unnormalized intertwining operator is holomorphic since the Plancherel measure does not have a zero for $s = 0$ in that case, and the normalizing factor is holomorphic, too, so that we actually have holomorphicity. On the other hand, if $\chi_p = 1$ and $s = -1$ the pole of the normalized intertwining operator occurs for the unique quotient of the representation $\nu_p^{-1} \rtimes 1$ and this is the Steinberg representation of $SL_2(\mathbb{Q}_p)$. The third intertwining operator is holomorphic unless $\chi_p = 1$ and $s = 0$.

Now we examine the case $\chi_p = 1$ and $s = 0$. Note that in this case

$$(13) \quad \mathcal{N}(\Lambda_{s,p}, \tilde{c}_1) : \nu_p^0 \times \nu_p^{-1} \rtimes 1 \rightarrow \nu_p^0 \times \nu_p^{-1} \rtimes 1.$$

It is known that this induced representation is of length four ([21], Proposition 5.4 (ii)) and that $\nu_p^0 \rtimes 1$ is in irreducible tempered representation of $SL_2(\mathbb{Q}_p)$. Then, $\nu_p^0 \rtimes 1_{SL_2(\mathbb{Q}_p)} = L(\nu^1; \nu_p^0 \rtimes 1) \oplus L(\nu^{1/2} St_{GL_2(\mathbb{Q}_p)}; 1)$. The (normalized) spherical vector belongs to (and generates) representation $L(\nu^1; \nu_p^0 \rtimes 1)$, and according to (8), $\mathcal{N}(\Lambda_{s,p}, \tilde{c}_1)$ acts on it as the

identity. Analogously, for $s = 0$ $\mathcal{N}(\tilde{c}_1(\Lambda_{s,p}), \tilde{c}_1)$ acts as the identity on the spherical vector. We know that $\mathcal{N}(\tilde{c}_1(\Lambda_{s,p}), \tilde{c}_1)\mathcal{N}(\Lambda_{s,p}, \tilde{c}_1) = Id$. Assume that $\mathcal{N}(\tilde{c}_1(\Lambda_{s,p}), \tilde{c}_1)$ has a pole of order n_2 for $s = 0$, and that $\mathcal{N}(\Lambda_{s,p}, \tilde{c}_1)$ has a pole of order n_1 for $s = 0$ on $L(\nu^{1/2}St_{GL_2(\mathbb{Q}_p)})$ (which is a subrepresentation of $\nu_p^0 \times \nu_p^{-1} \rtimes 1$ and appears there with the multiplicity one). Let $N_1 = \lim_{s \rightarrow 0} s^{n_1} \mathcal{N}(\Lambda_{s,p}, \tilde{c}_1)$ and $N_2 = \lim_{s \rightarrow 0} s^{n_2} \mathcal{N}(\tilde{c}_1(\Lambda_{s,p}), \tilde{c}_1)$. This means that N_1 is a holomorphic isomorphism on $L(\nu^{1/2}St_{GL_2(\mathbb{Q}_p)})$, and so is N_2 . But if $n_1 > 0$ or $n_2 > 0$ the composition $N_2 N_1|_{L(\nu^{1/2}St_{GL_2(\mathbb{Q}_p)})} = 0$, which is thus impossible. This means that $\mathcal{N}(\Lambda_{s,p}, \tilde{c}_1)$ is holomorphic on $\nu_p^0 \rtimes 1_{SL_2(\mathbb{Q}_p)}$ and the dual of the commuting algebra theorem ([1]) says that on $L(\nu^{1/2}St_{GL_2(\mathbb{Q}_p)}; 1)$ it acts as $-Id$.

We now examine the case $\chi_p = 1$ and $s = -1$. In this case, both intertwining operators corresponding to s (in the decomposition above corresponding to the decomposition $c_1 = s c_2 S$) are holomorphic isomorphisms, and the second operator has a pole on the representation $\nu^{-1} \rtimes St_{SL_2(\mathbb{Q}_p)}$ (which is an irreducible quotient of $\nu^{-1} \times \nu^{-1} \rtimes 1$) but it is holomorphic on $\nu_p^{-1} \rtimes 1_{SL_2(\mathbb{Q}_p)}$ (irreducible by Proposition 5.4 (ii) of [21]). The image $\mathcal{N}(\Lambda_{s,p}, \tilde{c}_1)(\nu^{-1} \rtimes 1_{SL_2(\mathbb{Q}_p)})$ is thus irreducible subspace $\nu^1 \rtimes 1_{SL_2(\mathbb{Q}_p)} = L(\nu^1, \nu^1; 1)$.

We discuss the case $\chi_p = 1$ and $s = -2$. In this case the last two operators corresponding to s and c_2 are holomorphic isomorphisms, the pole occurs in the first operator, induced from the GL_2 -case $\nu^{-2} \times \nu^{-1} \rightarrow \nu^{-1} \times \nu^{-2}$. Note that the representation $\nu^{-2} \times \nu^{-1} \rtimes 1$ is of length four ([21] Proposition 5.4 (i)) and we have (in the appropriate Grothendieck group) $\nu^{-2} \rtimes 1_{SL_2(\mathbb{Q}_p)} = L(\nu^{3/2}St_{GL_2(\mathbb{Q}_p)}; 1) + L(\nu^2, \nu^1; 1)$, from the Langlands classification it follows that $L(\nu^2, \nu^1; 1)$ is the unique subrepresentation of $\nu^{-2} \rtimes 1_{SL_2(\mathbb{Q}_p)}$. On the other hand, the aforementioned pole is happening on the quotient $\nu^{-3/2}St_{GL_2(\mathbb{Q}_p)} \rtimes 1$. We know that $\mathcal{N}(\Lambda_{s,p}, \tilde{c}_1)$ is holomorphic on $L(\nu^2, \nu^1; 1)$ (this is the trivial character), and it has a pole on $L(\nu^{3/2}St_{GL_2(\mathbb{Q}_p)}; 1)$. \square

Lemma 3.3. *Assume that $s \in \mathbb{R}$. Intertwining operator $\mathcal{N}(\Lambda_{s,\infty}, \tilde{c}_1)$ acting on the representation $\nu_\infty^s \rtimes 1_{SL_2(\mathbb{R})}$ has poles precisely if $s < -1$ is an even integer and $\chi_\infty = 1$ and if $s < -1$ is an odd integer and $\chi_\infty = \text{sgn}$.*

Proof. As in (12), we see that we might have a pole if χ_∞ is trivial or sgn .

- The first operator in the decomposition has a pole if $s < -1$ is an integer, even if $\chi_\infty = 1$ and odd if $\chi_\infty = \text{sgn}$.
- The second operator has a pole if $s < 0$ is an integer, even if $\chi_\infty = \text{sgn}$ and odd if $\chi_\infty = 1$.

- The third operator has a pole if $s < 1$ is an integer, even if $\chi_\infty = 1$ and odd if $\chi_\infty = \text{sgn}$.

Note that if $s \leq -1$, the Langlands quotient $L(\chi_\infty \nu^{-s}, \nu^1; 1)$ is the unique irreducible subrepresentation of $\chi_\infty \nu^s \rtimes 1_{SL_2(\mathbb{R})}$. If, in addition, $\chi_\infty = 1$ we know that $\mathcal{N}(\Lambda_{s,\infty}, \tilde{c}_1)$ is holomorphic and non-zero on $L(\nu^{-s}, \nu^1; 1)$ because this is the spherical subquotient of the principal series. So we firstly resolve the case of $\chi_\infty = 1$.

We first assume that $s = 0$ (and $\chi_\infty = 1$) (so that the third operator has a pole). Then, the first two operators are holomorphic. We can now repeat the discussion from Lemma 3.2, where we had a similar situation of (13). We again have the decomposition $\nu^0 \rtimes 1_{SL_2(\mathbb{R})} = L(\nu_\infty^{1/2} St_{GL_2(\mathbb{R})}; 1) \oplus L(\nu_\infty^1; \nu_\infty^0 \rtimes 1)$. Indeed, cf. Theorem 2.5 (ii) of ([19]) for the essentially square-integrable representation of $GL_2(\mathbb{R})$ we denoted by $\nu^{1/2} St_{GL_2(\mathbb{R})}$; , on the other hand, the representation $\nu_\infty^0 \rtimes 1$ is irreducible (representation of $SL_2(\mathbb{R})$) (cf. Theorem 2.4.(i) of [19]). For the decomposition of $\nu_\infty^0 \rtimes 1_{SL_2(\mathbb{R})}$ (cf. Theorem 10.7., equation (10.72) of [19]). On the other hand, the length of the representation $\nu_\infty^0 \times \nu_\infty^1 \rtimes 1$ is six ([19], Theorem 10.7), but the representation $L(\nu_\infty^1; \nu_\infty^0 \rtimes 1)$ is again a subrepresentation on this principal series, and appears with the multiplicity one, so we again can conclude that $\mathcal{N}(\Lambda_{s,\infty}, \tilde{c}_1)$ is holomorphic on $\nu_\infty^0 \rtimes 1_{SL_2(\mathbb{R})}$ (and non-zero on each summand).

Now we examine the situation of $s = -1$ and $\chi_\infty = 1$. By [19], equation (9.31) and Lemma 9.5. we see that the representation $\nu_\infty^{-1} \rtimes 1_{SL_2(\mathbb{R})}$ is irreducible. By our previous remark $\mathcal{N}(\Lambda_{s,\infty}, \tilde{c}_1)$ is holomorphic and non-zero on that representation, moreover, the image in $\nu_\infty^1 \times \nu_\infty^{-1} \rtimes 1$ generates an irreducible subrepresentation $\nu_\infty^{-1} \rtimes 1_{SL_2(\mathbb{R})} (\cong \nu_\infty^{-1} \rtimes 1_{SL_2(\mathbb{R})})$.

If $s < -1$ odd and $\chi_\infty = 1$, we see in Lemma 9.4 of [19] the representation $\nu_\infty^s \rtimes 1_{SL_2(\mathbb{R})}$ is irreducible, and the conclusion is clear.

If $s < -1$ is even and $\chi_\infty = 1$, we see that the representation $\nu_\infty^s \rtimes 1_{SL_2(\mathbb{R})}$ is reducible , of length two, (Theorem 11.1 (i) [19]). On the other subquotient (besides $L(\chi_\infty \nu^{-s}, \nu^1; 1)$) of $\nu_\infty^s \rtimes 1_{SL_2(\mathbb{R})}$ the first intertwining operator has a pole, and the third operator does not vanish (on that subquotient). We conclude that $\mathcal{N}(\Lambda_{s,\infty}, \tilde{c}_1)$ has a pole on that other subquotient (we could also argue as in the analogous non-archimedean case; namely it is easy to see that $L(\chi_\infty \nu^{-s}, \nu^1; 1)$ cannot appear as a subrepresentation of $\nu^{-s} \times \nu^{-1} \rtimes 1$).

We examine the case when $s = -1$ and $\chi_\infty = \text{sgn}$. According to Theorem 10.4 (ii) of [19], the representation $\nu_\infty^{-1} \text{sgn} \rtimes 1_{SL_2(\mathbb{R})}$ is irreducible. The pole occurs for the third intertwining operator and it appears on the (induced) quotient of that intertwining operator,

namely on the representation $\delta(1, 2) \rtimes 1$ (here we use the notation of [19] (cf. Theorem 2.5 and Lemma 8.1)). The representation $\delta(1, 2) \rtimes 1$ decomposes as a sum of two tempered representations, so $\mathcal{N}(\Lambda_{s,\infty}, \tilde{c}_1)$ is holomorphic on $\nu_\infty^{-1} sgn \rtimes 1_{SL_2(\mathbb{R})}$. The first and the second operator are holomorphic isomorphisms. Since $\mathcal{N}(\tilde{c}_1(\Lambda_{s,\infty}), \tilde{c}_1)\mathcal{N}(\Lambda_{s,\infty}, \tilde{c}_1) = Id$, and $N(\tilde{c}_1(\Lambda_{s,\infty}), \tilde{c}_1)$ is holomorphic on $\nu_\infty^1 sgn \times \nu^{-1} \rtimes 1$ it follows that $\mathcal{N}(\Lambda_{s,\infty}, \tilde{c}_1)$ is non-zero on $\nu_\infty^{-1} sgn \rtimes 1_{SL_2(\mathbb{R})}$.

If $s < -1$ is odd integer and $\chi_\infty = sgn$, the representation $\nu_\infty^s sgn \rtimes 1_{SL_2(\mathbb{R})}$ is of the length two (Theorem 11.1.(i) of [19]). The first and the third operator have poles, and the second is holomorphic isomorphism. The first operator has a pole on the (induced) quotient $\delta(\nu^{-\frac{p+t}{2}}, p-t) \rtimes 1$ and the third on $\delta(\nu^{\frac{p-t}{2}}, p+t) \rtimes 1$. Note that the latter representation is a subquotient of the former (Theorem 10.3. of [19]). Note that the Langlands quotient $L(\nu^{-s} sgn, \nu^1; 1)$ is a subrepresentation of $\nu_\infty^s sgn \rtimes 1_{SL_2(\mathbb{R})}$ and does not appear in the composition series of these two induced representations, so $\mathcal{N}(\Lambda_{s,\infty}, \tilde{c}_1)$ is holomorphic on it. On the other hand, the ‘‘other’’ subquotient of $\nu_\infty^s sgn \rtimes 1_{SL_2(\mathbb{R})}$ is $L(\delta(\nu^{\frac{p+t}{2}}, p-t); 1)$ and it appears with the multiplicity one in $\nu^s sgn \times \nu^1 \rtimes 1$ as can be seen from Theorem 11.1. (i), (ii) and (iii) of [19], so that there is a pole on the ‘‘other’’ subquotient of $\nu_\infty^s sgn \rtimes 1_{SL_2(\mathbb{R})}$ (of order one).

If $s < -1$ is even integer and $\chi_\infty = sgn$, the representation $\nu_\infty^s sgn \rtimes 1_{SL_2(\mathbb{R})}$ is irreducible by Lema 9.4 of [19]. The first and the third operator are holomorphic isomorphisms, and the second has a pole on the quotient $\nu^{-1} \rtimes (X(-s, +) \oplus X(-s, -))$, (e.g., cf. Lemma 7.2 of [19]). The same lemma guarantees that $\nu^{-1} \rtimes X(-s, \varepsilon)$, $\varepsilon = \pm$, are irreducible (and are not isomorphic with $\nu_\infty^s sgn \rtimes 1_{SL_2(\mathbb{R})}$), so the intertwining operator $\mathcal{N}(\Lambda_{s,\infty}, \tilde{c}_1)$ is holomorphic on $\nu_\infty^s sgn \rtimes 1_{SL_2(\mathbb{R})}$, and similarly as above, we conclude that it is also non-zero there. \square

Now we study the intertwining operators for the other relevant element of the Weyl group—which is similar, but easier than the previous case of c_1 .

Proposition 3.4. *Let $p < \infty$. The intertwining operator $\mathcal{N}(\Lambda_{s,p}, \tilde{s})$, where $s \in \mathbb{R}$, is holomorphic on $\nu_p^s \chi_p \rtimes 1_{SL_2(\mathbb{Q}_p)}$, unless $s = -2$ and $\chi_p = 1$; then it has a pole of the first order. If $p = \infty$ then we have poles precisely if $s < -1$ is even and $\chi_\infty = 1$ and if $s < -1$ is odd and $\chi_\infty = sgn$.*

Proof. Already proved in Lemma 3.2 and Lemma 3.3 \square

Proposition 3.5. *Let $p < \infty$. The intertwining operator $\mathcal{N}(\Lambda_{s,p}, \tilde{s}c_1) = \mathcal{N}(\Lambda_{s,p}, \tilde{c}_2s)$, where $s\mathbb{R}$, is holomorphic on $\chi_p \nu^s \rtimes 1_{SL_2(\mathbb{Q}_p)}$ unless $\chi_p = 1$*

and $s = 2$. If $p = \infty$ then we have poles precisely if $s < 1$ is even and $\chi_\infty = 1$ and if $s < 1$ is odd and $\chi_\infty = \text{sgn}$.

Proof. Already proved in Lemma 3.2 and Lemma 3.3 \square

Now we can explicitly describe the image of the constant term of the degenerate Eisenstein series.

Theorem 3.6. *Assume $s \geq 0$. Then, the poles of the Eisenstein series can come only from the poles of the normalizing factors, and then only if $\chi = 1$ and $s \in \{0, 1, 2\}$ (by well-known general results we know that there are no poles for $s = 0$).*

- (1) *If $\chi = 1$ and $s = 0$ the global Eisenstein series is holomorphic (for any choice of $f = \otimes f_p \in \text{Ind}_{GL_1(\mathbb{A}) \times SL_2(\mathbb{A})}(\chi \nu^s \otimes 1)$). For $p \leq \infty$ we have $\nu_p^0 \rtimes 1_{SL_2(\mathbb{Q}_p)} = L(\nu_p^1; \nu_p^0 \rtimes 1) \oplus L(\nu^{1/2} St_{GL_2(\mathbb{Q}_p)}; 1)$. We choose a finite set of places S' and we choose $f_p \in L(\nu^{1/2} St_{GL_2(\mathbb{Q}_p)}; 1)$, for $p \in S'$, and for some bigger finite set of places $S \supset S'$ we choose $f_p \in L(\nu_p^1; \nu_p^0 \rtimes 1)$ for $p \in S \setminus S'$. For all the places outside of S we choose f_p to be the normalized spherical vector. Then, if S' is even, this choice gives an automorphic realization of the corresponding (irreducible) global representation in the space of automorphic forms.*
- (2) *If $\chi = 1$ and $s = 1$ the global Eisenstein series is holomorphic, and for every $p \leq \infty$, the representation $\nu_p^1 \rtimes 1_{SL_2(\mathbb{Q}_p)}$ is irreducible and (2) gives the embedding of the irreducible global representation $\text{Ind}_{GL_1(\mathbb{A}) \times SL_2(\mathbb{A})}(\chi \nu^1 \otimes 1)$ in the space of automorphic forms.*
- (3) *If $\chi = 1$ and $s = 2$ the global Eisenstein series has a pole of the first order, and, after removing the poles, (2) gives the automorphic realization of the trivial representation in the space of (square-integrable) automorphic forms.*
- (4) *Assume $s = 0$ and $\chi^2 = 1$ but $\chi \neq 1$ then for all $p \leq \infty$, $\chi_p \rtimes 1_{SL_2(\mathbb{Q}_p)} = L(\nu_p^1; T_1) \oplus L(\nu_p^1; T_2)$, where T_1 and T_2 are non-isomorphic tempered representations (the limits of the discrete series if $p = \infty$) such that $\chi_p \rtimes 1 = T_1 \oplus T_2$ in $SL_2(\mathbb{Q}_p)$. Here T_1 is such that $\mathcal{N}(s(\Lambda_{s,p}), \tilde{c}_2)$ acts on $\nu_p^{-1} \rtimes T_1$ as the identity, and on $\nu_p^{-1} \rtimes T_2$ as minus identity (so for the spherical places, the spherical vector belongs to $L(\nu_p^1; T_1)$). Let S be a finite set of places such that for $p \notin S$, f_p is spherical. Let $S' \subset S$ be such that for $p \in S'$ we choose $f_p \in L(\nu_p^1; T_2)$ (and for $p \in S \setminus S'$ $f_p \in L(\nu_p^1; T_1)$). With these choices, the mapping (2) gives an*

automorphic realization of this irreducible global representation if $|S'|$ is even.

- (5) In the rest of the cases (we still assume $s \geq 0$) which are not cover above, the embedding (2) is holomorphic and gives an automorphic realization of the whole representation $Ind_{GL_1(\mathbb{A}) \times SL_2(\mathbb{A})}(\chi \nu^s \otimes 1)$.

Proof. Since $s = 0$, in the expression (6) all the local intertwining operators are holomorphic (by Lemma 3.2, Lemma 3.3, Proposition 3.4 and Proposition 3.5) and the poles can only come from the normalizing factors, and then, only if $\chi = 1$ (cf. Lemma 3.1). We now assume that $\chi = 1$.

First assume $s = 0$. We note that then $s(\Lambda_s) = c_2 s(\Lambda_s)$. We also claim that the intertwining operators $\mathcal{N}(\Lambda_{s,p}, \widetilde{c_2 s})$ and $\mathcal{N}(\Lambda_{s,p}, \widetilde{s})$ have the same effect on $\nu^0 \rtimes 1_{SL_2(\mathbb{Q}_p)}$ (for every p). Indeed, $\mathcal{N}(\Lambda_{s,p}, \widetilde{c_2 s}) = \mathcal{N}(s(\Lambda_{s,p}), \widetilde{c_2}) \mathcal{N}(\Lambda_{s,p}, \widetilde{s})$. Here the operator $\mathcal{N}(s(\Lambda_{s,p}), \widetilde{c_2})$ is induced from the $SL_2(\mathbb{Q}_p)$ operator $\nu_p^0 \rtimes 1 \rightarrow \nu_p^0 \rtimes 1$, which is holomorphic isomorphism (actually, an identity) on an irreducible representation $\nu_p^0 \rtimes 1 \rightarrow \nu_p^0 \rtimes 1$ (for all $p \leq \infty$).

We also have that $c_1(\Lambda_s) = \Lambda_s$ for $s = 0$. Note that for every $p \leq \infty$, by Lemma 3.2 and Lemma 3.3, $\nu_p^0 \rtimes 1_{SL_2(\mathbb{Q}_p)} = L(\nu_p^{1/2} St_{GL_2(\mathbb{Q}_p)}; 1) \oplus L(\nu_p^1; \nu_p^0 \rtimes 1)$. and on $L(\nu_p^1; \nu_p^0 \rtimes 1)$ $\mathcal{N}(\Lambda_{s,p}, \widetilde{c_1})$ acts as the identity, and on $L(\nu_p^{1/2} St_{GL_2(\mathbb{Q}_p)}; 1)$ as minus identity.

We conclude that (6) for $s = 0$ becomes

$$(14) \quad E_{const}(f, s) = f_s + r(\Lambda_s, c_1)^{-1} (\otimes_{p \in S} \mathcal{N}(\Lambda_{s,p}, \widetilde{c_1}) f_{p,s} \otimes (\otimes_{p \notin S} f_{c_1(s),p})) + \\ (r(\Lambda_s, s)^{-1} + r(\Lambda_s, c_2 s)^{-1}) \otimes_{p \in S} \mathcal{N}(\Lambda_{s,p}, \widetilde{s}) f_{p,s} \otimes (\otimes_{p \notin S} f_{s(s),p}).$$

Here we denote by s a real number (in this case equal to 0) and an element of the Weyl group. Since we are dealing with the trivial global character over \mathbb{Q} , all the global ε factors are trivial, and we get that $r(\Lambda_s, s)^{-1} + r(\Lambda_s, c_2 s)^{-1} = \frac{1}{L(s+2,1)}(L(-s, 1) + L(s, 1))$, so this expression is holomorphic and non-zero. We conclude that $E_{const}(f, s)$ is holomorphic for $s = 0$ for any choice of $f_s = \otimes f_{s,p}$ belonging to the global induced representation $Ind_{GL_1(\mathbb{A}) \times SL_2(\mathbb{A})}(\chi \nu^s \otimes 1)$, but this is well-known from the general results of Langlands. But we can now describe the image of Eisenstein series in the space of automorphic forms.

First we analyze the first row in (14). Let $S' \subset S$ be a finite set of primes such that for them we choose $f_p \in L(\nu_p^{1/2} St_{GL_2(\mathbb{Q}_p)}; 1)$ and for rest of the places $S \setminus S'$ we chose $f_p \in L(\nu_p^1; \nu_p^0 \rtimes 1)$. For $p \notin S$ we choose f_p to be the normalized spherical vector. Then,

we have $\lim_{s \rightarrow 0} r(\Lambda_s, c_1)^{-1} = 1$, and $\mathcal{N}(\Lambda_{s,p}, \widetilde{c}_1) f_{p,s} = -f_{p,s}$, $p \in S'$, $\mathcal{N}(\Lambda_{s,p}, \widetilde{c}_1) f_{p,s} = f_{p,s}$, $p \notin S'$. Thus, the first line of (14) becomes $f_0 + (-1)^{|S'|} f_0$. We conclude that this is non-zero if $|S'|$ is even and this means that the global representation (a subrepresentation of $Ind_{GL_1(\mathbb{A}) \times SL_2(\mathbb{A})}(\chi \nu^s \otimes 1)$) with the local components consisting of $L(\nu_p^{1/2} St_{GL_2(\mathbb{Q}_p)}; 1)$ on an even number of places and $L(\nu_p^1; \nu_p^0 \rtimes 1)$ on the rest of the places, is automorphic.

Now we analyze the second line. For $p \in S$, the image $\mathcal{N}(\Lambda_{s,p}, \widetilde{s}) f_{p,s}$ is non-zero if $f_{p,s}$ is not in the kernel of this operator (and the kernel is $\nu^{-1/2} St_{GL_2(\mathbb{Q}_p)} \rtimes 1$). Thus, if we pick $f_{p,s}$ from $L(\nu_p^1; \nu_p^0 \rtimes 1)$ for every $p \in S$, we'll get a non-zero contribution. This now means that the projection of the constant term to part of the sum spanned by the images of the intertwining operators with respect to the Weyl group elements s and $c_2 s$ gives an automorphic realization of the global representation whose every local component is $L(\nu_p^1; \nu_p^0 \rtimes 1)$ -so we get only global representations which form a subset of the ones we obtained by analyzing the first line.

Now we analyze the case $s = 1$. Then, note that for each $p \leq \infty$ the representation $\nu_p^1 \rtimes 1_{SL_2(\mathbb{Q}_p)}$ is irreducible (as was noted in Lemma 3.2 and Lemma 3.3), and thus spherical. In that case $c_2 s(\Lambda_s) = s c_2 s(\Lambda_s) = c_1(\Lambda_s)$. Moreover, $\mathcal{N}(\Lambda_{s,p}, \widetilde{s c_2 s}) = \mathcal{N}(c_2 s(\Lambda_{s,p}), \widetilde{s}) \mathcal{N}(\Lambda_{s,p}, \widetilde{c_2 s})$. Note that $\mathcal{N}(c_2 s(\Lambda_{s,p}), \widetilde{s})$ is for $s = 1$ identity operator induced from the GL_2 operator $\nu_p^{-1} \times \nu_p^{-1} \rightarrow \nu_p^{-1} \times \nu_p^{-1}$. Then, we just sum $r(\Lambda_s, s c_2 s)^{-1} + r(\Lambda_s, c_2 s)^{-1}$. Again we get that the poles cancel, and we obtain a non-zero holomorphic function for $s = 1$. Thus, the expression

$$(r(\Lambda_s, s c_2 s)^{-1} + r(\Lambda_s, c_2 s)^{-1}) \otimes_{p \in S} \mathcal{N}(\Lambda_{s,p}, \widetilde{c_2 s}) f_{p,s} \otimes (\otimes_{p \notin S} f_{c_2 s(s), p})$$

gives a non-zero contribution to the constant term of Eisenstein series and this cannot cancel the identity contribution. This means that we have obtained an automorphic realization (through Eisenstein series) of the global (irreducible representation) $Ind_{GL_1(\mathbb{A}) \times SL_2(\mathbb{A})}(\nu^1 \otimes 1)$.

For $s = 2$ we have

$$\lim_{s \rightarrow 2} (s - 2) E_{const}(f, s) = \left(\lim_{s \rightarrow 2} (s - 2) r(\Lambda_s, s c_2 s)^{-1} \right) \otimes_{p \in S} \mathcal{N}(\Lambda_{s,p}, \widetilde{s c_2 s}) f_{p,s} \\ \otimes (\otimes_{p \notin S} f_{s c_2 s(s), p}).$$

We know that $\mathcal{N}(\Lambda_{s,p}, \widetilde{s c_2 s})$ is holomorphic (and non-zero) on $\nu_p^2 \rtimes 1_{SL_2(\mathbb{Q}_p)}$, for every $p \leq \infty$. Note that, because of the Langlands classification, $L(\nu_p^2, \nu_p^1; 1)$ is the unique quotient of $\nu_p^2 \rtimes 1_{SL_2(\mathbb{Q}_p)}$. On the other hand $\mathcal{N}(\Lambda_{s,p}, \widetilde{s c_2 s})(\nu_p^2 \rtimes 1_{SL_2(\mathbb{Q}_p)}) \subset \nu_p^{-2} \times \nu_p^{-1} \rtimes 1$ and this representation has a unique irreducible subrepresentation; namely $L(\nu_p^2, \nu_p^1; 1)$.

This ensures that $\mathcal{N}(\Lambda_{s,p}, \widetilde{sc_2s})(\nu_p^2 \rtimes 1_{SL_2(\mathbb{Q}_p)}) = L(\nu_p^2, \nu_p^1; 1)$, for every $p \leq \infty$. Note that $L(\nu_p^2, \nu_p^1; 1)$ is actually a trivial representation, thus this (normalized) Eisenstein series gives a realization of the trivial representation as the irreducible subrepresentation in the space of square-integrable automorphic forms (since the constant term along the minimal parabolic has exponent $(-2, -1)$).

If $\chi \neq 1$, or $\chi = 1$ but $s \notin \{0, 1, 2\}$ we have the following situation. Let $w \in W$, $w(2e_2) > 0$. Then $w(\Lambda_s) \neq \Lambda_s$, unless $\chi^2 = 1$ and $s = 0$; then $sc_2s(\Lambda_s) = \Lambda_s$. So if $\chi^2 \neq 1$ or $s \neq 0$, (and we are not in the situations already covered) nothing will cancel the identity contribution; this gives the automorphic realization of the whole representation $Ind_{GL_1(\mathbb{A}) \times SL_2(\mathbb{A})}(\chi\nu^s \otimes 1)$.

Now assume $s = 0$ and $\chi^2 = 1$ but $\chi \neq 1$. Then, for every $p \leq \infty$ such that $\chi_p \neq 1$, the representation $\chi_p \rtimes 1$ (of $SL_2(\mathbb{Q}_p)$) is reducible, and sum of two irreducible tempered representations, say T_1 and T_2 (the limits of the discrete series if $p = \infty$). Note that $\Lambda_s = sc_2s(\Lambda_s)$ and $s(\Lambda_s) = c_2s(\Lambda_s)$. Assume that on T_1 the normalized intertwining operator $\chi_p \rtimes 1 \rightarrow \chi_p \rtimes 1$ acts as the identity and on T_2 as -identity. We also have that $\chi_p \rtimes 1_{SL_2(\mathbb{Q}_p)} = L(\nu_p^1; T_1) \oplus L(\nu_p^1; T_2)$ for all p ([21], Proposition 5.4 and [19] Lema 9.6). We conclude that $\mathcal{N}(\Lambda_{s,p}, \tilde{s})$ acts on $\chi_p \rtimes 1_{SL_2(\mathbb{Q}_p)}$ as an holomorphic isomorphism, and then $\mathcal{N}(s(\Lambda_{s,p}), \tilde{c}_2)$ acts on $\nu^{-1} \rtimes T_1$ as identity, and on $\nu^{-1} \rtimes T_2$ as minus identity. Now again $\mathcal{N}(c_2s(\Lambda_{s,p}), \tilde{s})$ is a holomorphic isomorphism. Let S be a finite set of places such that for $p \notin S$, f_p is the normalized spherical vector. For a subset $S' \subset S$ such that for every $p \in S'$ $\chi_p \neq 1$, we choose f_p to belong to $L(\nu_p^1; T_2)$ (and f_p belongs to $L(\nu_p^1; T_1)$ for $p \in S \setminus S'$). We then have

$$(15) \quad E_{const}(f, s) = f_s + r(\Lambda_s, sc_2s)^{-1}(-1)^{|S'|} f_s + \\ (r(\Lambda_s, s)^{-1} + (-1)^{|S'|} r(\Lambda_s, c_2s)^{-1}) \otimes_{p \in S} \mathcal{N}(\Lambda_{s,p}, \tilde{s}) f_{p,s} \otimes (\otimes_{p \notin S} f_{s(p)}).$$

We use the functional equation ([20], p.279,) $L(1-s, \chi^{-1}) = \varepsilon(s, \chi)L(s, \chi)$. Now, according to that the expression for $r(\Lambda_s, sc_2s)^{-1}$ becomes

$$r(\Lambda_s, sc_2s)^{-1} = \frac{L(-s+2, \chi)\varepsilon(-s+2, \chi)}{L(s+2, \chi)\varepsilon(s+2, \chi)\varepsilon(s, \chi)\varepsilon(s+1, \chi)}.$$

Since $L(s, \chi)$ is holomorphic for $s \in \mathbb{C}$ we have $\lim_{s \rightarrow 0} \frac{L(-s+2, \chi)\varepsilon(-s+2, \chi)}{L(s+2, \chi)\varepsilon(s+2, \chi)} = 1$ so that $\lim_{s \rightarrow 0} r(\Lambda_s, sc_2s)^{-1} = \frac{1}{\varepsilon(0, \chi)\varepsilon(1, \chi)}$. Further, we have $L(-s, \chi) = \varepsilon(1+s, \chi)L(1+s, \chi)$. If we multiply these two functional equations and let $s = 0$, we get $\varepsilon(s, \chi)\varepsilon(s+1, \chi) = 1$ (since $L(0, \chi)L(1, \chi) \neq 0$). Then, the factor in the first line of (15) becomes $1 + (-1)^{|S'|}$. We conclude

that if $|S'|$ is odd that the first line of (15) vanishes. The numerical factor in the second line of (15) becomes $\frac{1}{L(s+2, \chi)\varepsilon(s+2, \chi)\varepsilon(s+1, \chi)}(L(-s, \chi) + (-1)^{|S'|}L(s, \chi))$. We conclude that for $|S'|$ odd the second line also vanishes. So, we can get a non-zero contribution only if $|S'|$ is even. \square

Theorem 3.7. *Assume $s < 0$.*

- (1) *If $-1 < s < 0$ the Eisenstein series is holomorphic and (2) gives an embedding of the irreducible representation $\text{Ind}_{GL_1(\mathbb{A}) \times SL_2(\mathbb{A})}(\chi\nu^s \otimes 1)$ in the space of automorphic forms.*
- (2) *If $s = -1$ and $\chi \neq 1$ the result is analogous to the previous case.*
- (3) *If $s = -1$ and $\chi = 1$ the Eisenstein series is identically zero on $\text{Ind}_{GL_1(\mathbb{A}) \times SL_2(\mathbb{A})}(\nu^{-1} \otimes 1)$.*
- (4) *If $-2 < s < -1$ all the (inverses) of the (non-trivial) normalizing factors can have a pole (of the same order) coming from the zero of the L -function in the denominator. After the normalization, we have an embedding of the representation $\text{Ind}_{GL_1(\mathbb{A}) \times SL_2(\mathbb{A})}(\chi\nu^s \otimes 1)$ in the space of automorphic forms.*
- (5) *If $s = -2$ and $\chi = 1$ then, if we pick $f_p \in L(\nu^2, \nu^1; 1)$ (the trivial representation) for all p , then $E_{\text{const}}(f, -2) = f_{-2}$ so (2) gives an embedding of the trivial representation in the space of (square-integrable) automorphic forms. If we pick at exactly one finite place $f_p \in L(\nu_p^{3/2} \text{St}_{GL_2(\mathbb{Q}_p)}; 1)$ (and on the rest of the places the trivial representation), the Eisenstein series are holomorphic on this global representation and the image is, on that one place, an irreducible subrepresentation isomorphic to $L(\nu_p^{3/2} \text{St}_{GL_2(\mathbb{Q}_p)}; 1)$, on the rest of the places the image spans a representation of the length two (in semisimplification $L(\nu^2, \nu^1; 1) + L(\nu_p^{3/2} \text{St}_{GL_2(\mathbb{Q}_p)}; 1)$). Analogously, if we pick at the finite number of place, say $|S|$, a vector from $L(\nu_p^{3/2} \text{St}_{GL_2(\mathbb{Q}_p)}; 1)$, the Eisenstein series have a pole of order $|S| - 1$ (so we can get a pole of any finite order), and after normalization, the local images are irreducible for the ramified choice of subquotient, and of the length equal to two for the choice of the unramified subquotient.*
- (6) *If $s = -2$ and $\chi \neq 1$ we have the following. For each p such that $\chi_p = 1$ the local intertwining operators have a pole if $f_p \in L(\nu_p^{3/2} \text{St}_{GL_2(\mathbb{Q}_p)}; 1)$, and if $\chi_p \neq 1$ there are no poles for the intertwining operators (all isomorphisms) and the image is isomorphic to the representation $\chi_p \nu_p^{-2} \rtimes 1_{SL_2(\mathbb{Q}_p)}$. The discussion about the image is analogous to the previous case when*

$\chi_p = 1$, and we can obtain a pole of order $|S|$ if, for every $p \in S$ $\chi_p = 1$ and $f_p \in L(\nu_p^{3/2} St_{GL_2(\mathbb{Q}_p)}; 1)$.

- (7) Assume $s < -2$. Then unless s is even integer and $\chi_\infty = 1$ or s is odd integer and $\chi_\infty = \text{sgn}$, the Eisenstein series is always holomorphic and (2) gives an embedding of $Ind_{GL_1(\mathbb{A}) \times SL_2(\mathbb{A})}(\chi \nu^s \otimes 1)$ in the space of automorphic forms. If s is even integer and $\chi_\infty = 1$ or s is odd integer and $\chi_\infty = \text{sgn}$, and (in both of these cases) we pick $f_\infty \in L(\delta \nu^{\frac{-s+1}{2}}, -s-1)$ (notation [19] Theorem 11.1(i)), the Eisenstein series have a pole on $\otimes f_p$ of the first order. After the normalization, the image on the non-archimedean place spans an irreducible representation, and on the archimedean place it spans a representation $\chi_\infty \nu^{-s} \rtimes 1_{SL_2(\mathbb{R})}$.

Proof. Assume $-1 < s < 0$. The claim is then obvious.

In the case $s = -1$ if $\chi \neq 1$ the Eisenstein series is holomorphic, the other contributions in the constant term cannot cancel the identity contribution, the global representation is again irreducible (Lemma 9.5. or Theorem 10.4 of [19]), so again (2) gives an embedding in the space of automorphic forms.

On the other hand, if $s = -1$ and $\chi = 1$, the global representation is again irreducible, and intertwining operators holomorphic) but the normalizing factors $r(\Lambda_s, c_1)^{-1}$ and $r(\Lambda_s, c_2 s)^{-1}$ vanish. On the other hand, $\lim_{s \rightarrow -1} r(\Lambda_s, s)^{-1} = -\frac{1}{\varepsilon(1,1)} = -1$ and $\mathcal{N}(\Lambda_{s,p}, \tilde{s}) f_{p,s}$ is the identity. In this way, (6) comes down to

$$E_{const}(f, -1) = 0.$$

Now assume $-2 < s < -1$. Then, the normalized intertwining operators are all holomorphic and the representation $Ind_{GL_1(\mathbb{A}) \times SL_2(\mathbb{A})}(\chi \nu^s \otimes 1)$ is irreducible (obvious, e.g., Theorem 12.1. (ii) [19]). The (inverses of) normalizing factors might have a pole (and the order of the possible pole is equal to the order of the zero of $L(s+2, \chi)$, and this happens for all the (non-trivial) normalizing factors. Note that, for example $sc_2 s(\Lambda_s) \neq s(\Lambda_s)$, so after the possible removing of the pole, the contributions according to the different element of the Weyl group do not cancel, so by (6) we have an embedding of this global representation into the space of automorphic forms.

Assume $s = -2$ and $\chi = 1$. Then all the nontrivial normalizing factors vanish because of the poles in the denominator. On the other hand, if we pick $f_p \in L(\nu^2, \nu^1; 1)$ for all w appearing in the expression for the constant term, $\mathcal{N}(\Lambda_{s,p}, \tilde{w}) f_p$ is holomorphic and non-zero, and if we pick $f_p \in L(\nu^{3/2} St_{GL_2(\mathbb{Q}_p)}; 1)$ we have a pole for each such w , analogously for the archimedean places (Lemma 3.2, Lemma 3.3, Proposition

3.4, Proposition 3.5). We conclude that by picking $f_p \in L(\nu^2, \nu^1; 1,)$ for each $p \leq \infty$, the contributions in the constant term of Eisenstein series (from all the non-trivial elements of the Weyl group appearing there) will be zero, so that we would have $E_{const}(f, -2) = f_{-2}$. This would imply that the global representation consisting of $L(\nu_p^2, \nu_p^1; 1,)$ for every $p \leq \infty$ appears in the space of automorphic forms through (2), moreover the appearance in $\mathcal{A}(Sp_4(\mathbb{Q}) \backslash Sp_4(\mathbb{A}))$ is in the space of square-integrable automorphic forms (this is well-known; $L(\nu_p^2, \nu_p^1; 1)$ is the trivial character). On the other hand, assume we pick $f_p \in L(\nu^{3/2} St_{GL_2(\mathbb{Q}_p)}; 1)$ at exactly one (say, finite) place from S . Then, the contribution $r(\Lambda_s, w)^{-1} \otimes \otimes_{p \in S} \mathcal{N}(\Lambda_{s,p}, \tilde{w}) f_{p,s} \otimes (\otimes_{p \notin S} f_{w(s),p})$ is holomorphic (for each $w \neq 1$). To study the image, we examine what is happening on each place. On that specific place, f_p spans the representation $L(\nu^{3/2} St_{GL_2(\mathbb{Q}_p)}; 1)$ which is a subrepresentation in $Ind_B^{Sp_4(\mathbb{Q}_p)}(w(\nu_p^{-2} \otimes \nu_p^{-1}))$. On the other places (in S and outside of S) it is enough to see what kind of space the spherical vector generates. It generates a subspace of length two in $Ind_B^{Sp_4(\mathbb{Q}_p)}(w(\nu_p^{-2} \otimes \nu_p^{-1}))$ where $w \in \{s, c_2s, sc_2s\}$: it cannot be an irreducible subrepresentation in any of those induced representations (a simple Jacquet module argument); on the other hand it generates a subrepresentation of length two in $Ind_B^{Sp_4(\mathbb{Q}_p)}(sc_2s(\nu_p^{-2} \otimes \nu_p^{-1}))$, and the other representations are isomorphic to it. The generated representation is (in semisimplification) $L(\nu_p^2, \nu_p^1; 1) + L(\nu^{3/2} St_{GL_2(\mathbb{Q}_p)}; 1)$. Analogously, by choosing an arbitrary but finite set of places p where we can pick $f_p \in L(\nu^{3/2} St_{GL_2(\mathbb{Q}_p)}; 1)$ we can make the pole for $s = -2$ of $E_{const}(s, f)$ of the arbitrary high order. After removing the poles the local images are irreducible on the ramified choices and of length two on the unramified choices. Thus, the image of (2) spans (highly) reducible representation. Similarly, if $s = -2$ but $\chi \neq 1$, all the normalizing factors are holomorphic and non-vanishing, and we have a pole for each place p for which $\chi_p = 1$, so the discussion about local images is similar to the discussion for $\chi = 1$ -case, modulo the number of places where we have $\chi_p = 1$. If $\chi_p \neq 1$, the representation $\chi_p \nu_p^{-2} \rtimes 1_{SL_2(\mathbb{Q}_p)}$ is irreducible, (e.g., Lemma 9.4. of [19], equally easy for the non-archimedean case) and all the intertwining operators are holomorphic isomorphisms.

If $s < -2$ all the normalizing factors are holomorphic and non-zero, and all the representations on the finite places are irreducible, and the intertwining operators acting on those representations are holomorphic isomorphisms. Then, the images generated locally are also irreducible. We can only get poles of the intertwining operators at the archimedean

place, when s is odd and $\chi_\infty = \text{sgn}$ or when s is even and $\chi_\infty = 1$ for all of them (attached to s , c_2s , sc_2s) as follows from Lemma 3.3. In all other situation the Eisenstein series are holomorphic and (2) gives the embedding in the space of automorphic forms. In these exceptional cases, we get a pole of the first order if we pick $f_\infty \in L(\delta\nu^{\frac{-s+1}{2}}, -s-1; 1)$ in both of these cases (Theorem 11.1.(i) of [19]). By normalizing the Eisenstein series to eliminate this pole, we again get no cancelations between contributions attached to the different Weyl group elements. In the situation when we pick $f_\infty \in L(\delta\nu^{\frac{-s+1}{2}}, -s-1; 1)$ (and normalize the Eisenstein series), the image will generate an irreducible representation in $\text{Ind}_B^{Sp_4(\mathbb{R})} w(\nu^s \otimes \nu^{-1})$, for $w \in \{s, c_2s\}$, but reducible for $w = sc_2s$; indeed, for $w = sc_2s$ f_∞ generates the whole representation $\chi_\infty \nu_\infty^{-s} \rtimes 1_{SL_2(\mathbb{R})} \hookrightarrow \nu_\infty^{-s} \times \nu^{-1} \rtimes 1$. \square

4. THE SIEGEL CASE

We now study the degenerate Eisenstein series of the representation

$$\text{Ind}_{P_2(\mathbb{A})}^{Sp_4(\mathbb{A})} (\chi \nu^s 1_{GL_2(\mathbb{A})}).$$

Thus $\Lambda_s = \chi \nu^{s-1/2} \otimes \chi \nu^{s+1/2}$, where $s \in \mathbb{R}$.

The terms in (6) which appear in the Siegel case are the following:

$$(16) \quad W' = \{w \in W : w(e_1 - e_2) > 0\} = \{id, c_2, sc_2, c_2sc_2\}.$$

The corresponding normalizing factors are

$$\begin{aligned} r(\Lambda_s, c_2)^{-1} &= \frac{L(s + \frac{1}{2}, \chi)}{L(s + \frac{3}{2}, \chi) \varepsilon(s + \frac{3}{2}, \chi)}, \\ r(\Lambda_s, sc_2)^{-1} &= \frac{L(s + \frac{1}{2}, \chi) L(2s, \chi^2)}{L(s + \frac{3}{2}, \chi) \varepsilon(s + \frac{3}{2}, \chi) L(2s + 1, \chi^2) \varepsilon(2s + 1, \chi^2)}, \\ r(\Lambda_s, c_2sc_2)^{-1} &= \frac{L(2s, \chi^2) L(s - \frac{1}{2}, \chi)}{L(s + \frac{3}{2}, \chi) L(2s + 1, \chi^2) \varepsilon(s + \frac{3}{2}, \chi) \varepsilon(s + \frac{1}{2}, \chi) \varepsilon(2s + 1, \chi^2)}. \end{aligned}$$

We discuss the poles of the (inverses) of the normalizing factors above, which appear only in the following situations.

Proposition 4.1. (1) Assume $s \geq 0$.

(a) $r(\Lambda_s, c_2)^{-1}$ has a pole of the first order for $s = \frac{1}{2}$ if $\chi = 1$.

(b) $r(\Lambda_s, sc_2)^{-1}$ has a pole for $s = \frac{1}{2}$ of the second order if $\chi = 1$ and of the first order if $\chi^2 = 1$, but $\chi \neq 1$.

(c) for $r(\Lambda_s, c_2sc_2)^{-1}$ the same discussion as for $r(\Lambda_s, sc_2)^{-1}$.

(2) Assume $s < 0$.

(a) $r(\Lambda_s, c_2)^{-1}$ may have a pole for some $-\frac{3}{2} < s < -\frac{1}{2}$, where the denominator has a zero.

- (b) $r(\Lambda_s, sc_2)^{-1}$ may have a pole for some $-\frac{3}{2} < s < -\frac{1}{2}$, or some $-\frac{1}{2} < s < 0$ where the denominator has a zero.
- (c) for $r(\Lambda_s, c_2sc_2)^{-1}$ the same discussion as for $r(\Lambda_s, sc_2)^{-1}$.

Now we discuss the local normalized intertwining operators corresponding to the elements of W' (16). The following lemma follows straightforward from the GL_2 and SL_2 cases.

- Lemma 4.2.** (1) Assume $p < \infty$. Then, the operator $\mathcal{N}(\Lambda_{s,p}, \widetilde{c}_2)$ is holomorphic unless $s = -\frac{3}{2}$ and $\chi_p = 1$. Assume $p = \infty$. Then, the operator $\mathcal{N}(\Lambda_{s,\infty}, \widetilde{c}_2)$ is holomorphic unless $s + \frac{1}{2}$ is a negative odd integer and $\chi_\infty = 1$ and $s + \frac{1}{2}$ is a negative even integer and $\chi_\infty = \text{sgn}$.
- (2) In addition to the poles from the case of $\mathcal{N}(\Lambda_{s,p}, \widetilde{c}_2)$, the operator $\mathcal{N}(\Lambda_{s,p}, \widetilde{sc}_2)$ may have additional poles as follows: if $p < \infty$ then the pole might appear if $\chi_p^2 = 1$ and $s = -\frac{1}{2}$. If $p = \infty$, then the pole appears if $2s$ is a negative odd integer, and $\chi_\infty = \text{sgn}^l$, $l \in \{0, 1\}$.
- (3) In addition to the poles from the case of $\mathcal{N}(\Lambda_{s,p}, \widetilde{sc}_2)$, the operator $\mathcal{N}(\Lambda_{s,p}, \widetilde{c_2sc_2})$ may have additional poles as follows: if $p < \infty$ and $s = -\frac{1}{2}$ and $\chi_p = 1$. Assume $p = \infty$. Then we may have a pole if $s - \frac{1}{2}$ a negative odd integer and $\chi_\infty = 1$ and $s - \frac{1}{2}$ is a negative even integer and $\chi_\infty = \text{sgn}$.

Theorem 4.3. Assume $s \geq 0$. Then all the local intertwining operators corresponding to $w \in W'$ are holomorphic.

- (1) If $s \neq \frac{1}{2}$, or $\chi^2 \neq 1$, then the Eisenstein series are holomorphic for every choice of $f = \otimes f_p$, and (2) gives and holomorphic embedding of $\text{Ind}_{P_2(\mathbb{A})}^{Sp_4(\mathbb{A})}(\chi\nu^s 1_{GL_2(\mathbb{A})})$ in the space of automorphic forms.
- (2) If $s = \frac{1}{2}$ and $\chi = 1$, $E_{\text{const}}(s, f)$ has a pole of the first order, and then the image of (2) is the unique spherical subquotient of $\text{Ind}_{P_2(\mathbb{A})}^{Sp_4(\mathbb{A})}(\chi\nu^{\frac{1}{2}} 1_{GL_2(\mathbb{A})})$.
- (3) If $s = \frac{1}{2}$ and $\chi \neq 1$, then for all $p \leq \infty$ such that $\chi_p \neq 1$, let $\chi_p\nu_p^0 \rtimes 1 = T_1 \oplus T_2$ (of course, then T_1 and T_2 depend on p). Then, in the appropriate Grothendieck group we have

$$\nu_p^{1/2} \chi_p 1_{GL_2(\mathbb{Q}_p)} \rtimes 1 = L(\chi_p\nu_p^1; T_1) + L(\chi_p\nu_p^1; T_2) + L(\chi_p\nu_p^{1/2} \text{St}_{GL_2(\mathbb{Q}_p)}; 1).$$

Here T_2 is the representation on which $SL_2(\mathbb{Q}_p)$ operator on $\chi_p\nu_p^0 \rtimes 1$ attains value minus identity. Now, we pick f_p from the subquotient $L(\chi_p\nu_p^1; T_2)$ on the set of places S' . If $|S'|$ is even, then $E_{\text{const}}(\frac{1}{2}, \cdot)$ has a pole of the first order, and (2) gives,

in the space of automorphic forms, a realization of the global representation with $L(\chi_p \nu^1; T_2)$ on the even number of places, and $L(\chi_p \nu^1; T_1)$ on the rest of the places. If $|S'|$ is odd, then $E_{const}(\frac{1}{2}, \cdot)$ is holomorphic and (2) gives an embedding of the whole global representation $\text{Ind}_{P_2(\mathbb{A})}^{Sp_4(\mathbb{A})}(\chi \nu_{GL_2(\mathbb{A})}^{\frac{1}{2}})$ in the space of automorphic forms.

Proof. The claims for $s \neq \frac{1}{2}$ or $\chi^2 \neq 1$ are obvious. Now assume that $\chi^2 = 1$ and $s = \frac{1}{2}$. Since for every $p \leq \infty$ $\chi_p^2 = 1$, we have that $\mathcal{N}(\Lambda_{s,p}, \widetilde{sc}_2)$ and $\mathcal{N}(\Lambda_{s,p}, \widetilde{c_2 sc_2})$ have the same codomain. Assume now $p < \infty$. If $\chi_p = 1$ then $\nu_p^{1/2} 1_{GL_2(\mathbb{Q}_p)} \rtimes 1$ has the unique irreducible quotient, namely $L(\nu_p^1; \nu_p^0 \rtimes 1)$ (which is spherical) (cf. [21] Proposition 5.4.(ii)) and a tempered subrepresentation, say T_2 . Then, the spherical vector generates the whole representation $\nu_p^{1/2} 1_{GL_2(\mathbb{Q}_p)} \rtimes 1$, and since $\mathcal{N}(\Lambda_{s,p}, \widetilde{sc}_2)$ and $\mathcal{N}(\Lambda_{s,p}, \widetilde{c_2 sc_2})$ agree on the spherical vector (and are holomorphic and non-zero on that vector), they agree on the whole representation $\nu_p^{1/2} 1_{GL_2(\mathbb{Q}_p)} \rtimes 1$. The image of this spherical vector by $\mathcal{N}(\Lambda_{s,p}, \widetilde{sc}_2)$ (or by $\mathcal{N}(\Lambda_{s,p}, \widetilde{c_2 sc_2})$) generates in $\nu_p^{-1} \times \nu_p^0 \rtimes 1$ an irreducible subspace (thus isomorphic to $L(\nu_p^1; \nu_p^0 \rtimes 1)$). If $\chi_p \neq 1$, then $\nu_p^{1/2} \chi_p 1_{GL_2(\mathbb{Q}_p)} \rtimes 1$ is of length 3, and in the appropriate Grothendieck group we have

$$\nu_p^{1/2} \chi_p 1_{GL_2(\mathbb{Q}_p)} \rtimes 1 = L(\chi_p \nu^1; T_1) + L(\chi_p \nu^1; T_2) + L(\chi_p \nu_p^{1/2} St_{GL_2(\mathbb{Q}_p)}; 1).$$

Here $\chi_p \nu_p^0 \rtimes 1 = T_1 \oplus T_2$ and $L(\chi_p \nu_p^{1/2} St_{GL_2(\mathbb{Q}_p)}; 1)$ is an irreducible subrepresentation of $\nu_p^{1/2} \chi_p 1_{GL_2(\mathbb{Q}_p)} \rtimes 1$, moreover, we have an epimorphism $\nu_p^{1/2} \chi_p 1_{GL_2(\mathbb{Q}_p)} \rtimes 1 \rightarrow L(\chi_p \nu^1; T_1) \oplus L(\chi_p \nu^1; T_2)$ (with the kernel $L(\chi_p \nu_p^{1/2} St_{GL_2(\mathbb{Q}_p)}; 1)$). Since $\mathcal{N}(\Lambda_{s,p}, \widetilde{sc}_2)$ maps $\nu_p^{1/2} \chi_p 1_{GL_2(\mathbb{Q}_p)} \rtimes 1$ to the representation $\chi_p \nu_p^{-1} \times \nu_p^0 \chi_p \rtimes 1$, which has two unique subrepresentations $L(\chi_p \nu^1; T_1)$ and $L(\chi_p \nu^1; T_2)$, we see that $L(\chi_p \nu_p^{1/2} St_{GL_2(\mathbb{Q}_p)}; 1)$ is in the kernel of the operator $\mathcal{N}(\Lambda_{s,p}, \widetilde{sc}_2)$ (restricted on $\nu_p^{1/2} \chi_p 1_{GL_2(\mathbb{Q}_p)} \rtimes 1$) and it is easy to see that

$$\mathcal{N}(\Lambda_{s,p}, \widetilde{sc}_2)(\nu_p^{1/2} \chi_p 1_{GL_2(\mathbb{Q}_p)} \rtimes 1) = L(\chi_p \nu^1; T_1) \oplus L(\chi_p \nu^1; T_2).$$

On the other hand

$$\mathcal{N}(\Lambda_{s,p}, \widetilde{c_2 sc_2}) = \mathcal{N}(sc_2(\Lambda_{s,p}), \widetilde{c_2}) \mathcal{N}(\Lambda_{s,p}, \widetilde{sc_2}),$$

and $\chi_p \nu_p^{-1} \times \chi_p \nu_p^0 \rtimes 1 = \chi_p \nu_p^{-1} \rtimes T_1 \oplus \chi_p \nu_p^{-1} \rtimes T_2$, and $\mathcal{N}(sc_2(\Lambda_{s,p}), \widetilde{c_2})$ acts on one of these two summands as identity and on the other as minus identity, say on the first one as identity. Assume now $p = \infty$. If $\chi_\infty = 1$ then again as in the non-archimedean case, the operators $\mathcal{N}(\Lambda_{s,p}, \widetilde{sc}_2)$

and $\mathcal{N}(\Lambda_{s,p}, \widetilde{c_2 s c_2})$ have the same action on $\nu_\infty^{1/2} \chi_\infty 1_{GL_2(\mathbb{R})} \rtimes 1$ (which is again generated by the spherical vector), and the image is isomorphic to $L(\nu_\infty^1; \nu_\infty^0 \rtimes 1)$. If $\chi_\infty = \text{sgn}$ we have the same situation as in the non-archimedean case; cf. Theorem 11.2 of [19].

Now assume that $\chi = 1$. Then $E_{const}(1/2, \cdot)$ has a pole of the first order (due to the poles of the global normalizing factors) and (normalized) (6) becomes

$$(17) \quad \lim_{s \rightarrow \frac{1}{2}} (s - \frac{1}{2}) (r(\Lambda_s, s c_2)^{-1} + r(\Lambda_s, c_2 s c_2)^{-1}) \otimes_{p \in S} \mathcal{N}(\Lambda_{s,p}, \widetilde{s c_2}) f_{p,s} \otimes \otimes_{p \notin S} f_{p, s c_2(s)} + \\ \lim_{s \rightarrow \frac{1}{2}} (s - \frac{1}{2}) (r(\Lambda_s, c_2)^{-1} \otimes_{p \in S} \mathcal{N}(\Lambda_{s,p}, \widetilde{s c_2}) f_{p,s} \otimes \otimes_{p \notin S} f_{p, s c_2(s)}).$$

Note that for $\mathcal{N}(\Lambda_{s,p}, \widetilde{c_2})$, the image is again generated by the spherical vector, thus for $\mathcal{N}(\Lambda_{s,p}, \widetilde{c_2})$, all other subquotients of $\nu_p^{1/2} \chi_p 1_{GL_2(\mathbb{Q}_p)} \rtimes 1$, $p \leq \infty$ are in the kernel. Because $\chi = 1$, all the ε factors are trivial, and $\lim_{s \rightarrow \frac{1}{2}} (s - \frac{1}{2}) (r(\Lambda_s, s c_2)^{-1} + r(\Lambda_s, c_2 s c_2)^{-1})$ becomes $\lim_{s \rightarrow \frac{1}{2}} (s - \frac{1}{2}) \frac{L(2s, 1)}{L(2, 1)^2} \lim_{t \rightarrow 0} (L(-t, 1) + L(t, 1))$. In the equation (17) the contribution is zero if we pick a vector f_p which does not belong to the spherical quotient.

Assume $\chi \neq 1$, but $\chi^2 = 1$. Assume that we have picked $S' \subset S$ such that for every $p \in S'$ $\chi_p \neq 1$ and f_p belongs to the subquotient $L(\chi_p \nu^1; T_2)$. We denote $A(s) = \frac{L(2s, \chi^2)}{L(s + \frac{3}{2}, \chi) \varepsilon(s + \frac{3}{2}, \chi) L(2s+1, \chi^2) \varepsilon(2s+1, \chi^2)}$. Then $r(\Lambda_s, s c_2)^{-1} = A(s) L(s + \frac{1}{2}, \chi)$ and $r(\Lambda_s, c_2 s c_2)^{-1} = A(s) \frac{L(s - \frac{1}{2}, \chi)}{\varepsilon(s + \frac{1}{2}, \chi)}$. Then, it is easy to see that the contributions to E_{const} coming from $s c_2$ and $c_2 s c_2$ together give:

$$\frac{A(s) (L(\frac{1}{2} - s, \chi) + L(s - \frac{1}{2}, \chi) (-1)^{|S'|})}{\varepsilon(s + \frac{1}{2}, \chi)} \otimes_{p \in S'} \mathcal{N}(\Lambda_{s,p}, \widetilde{s c_2}) f_{p,s} \otimes \otimes_{p \notin S'} f_{p, s c_2(s)}.$$

If $|S'|$ is odd, since $A(s)$ has a pole for $s = \frac{1}{2}$, the expression

$$A(s) (L(\frac{1}{2} - s, \chi) + L(s - \frac{1}{2}, \chi) (-1)^{|S'|})$$

is then holomorphic and non-zero, and if $|S'|$ is even it has a pole. Note that for $\chi_p \neq 1$, the operator $\mathcal{N}(\Lambda_{s,p}, \widetilde{c_2})$ is a holomorphic isomorphism on $\nu_p^{1/2} \chi_p 1_{GL_2(\mathbb{Q}_p)} \rtimes 1$.

We conclude: if $|S'|$ is even, then $E_{const}(\frac{1}{2}, \cdot)$ has a pole of the first order, and (2) gives, in the space of automorphic forms, a realization of the global representation with $L(\chi_p \nu^1; T_2)$ on the even number of

places, and $L(\chi_p \nu^1; T_1)$ on the rest of the places. Note that if $|S'|$ is odd, then $E_{const}(\frac{1}{2}, \cdot)$ is holomorphic and (2) gives an embedding of the whole global representation $Ind_{P_2(\mathbb{A})}^{Sp_4(\mathbb{A})}(\chi \nu_{GL_2(\mathbb{A})}^{\frac{1}{2}})$ in the space of automorphic forms. \square

Theorem 4.4. *Assume now that $s < 0$. Then we have the following:*

- (1) *Assume $-\frac{1}{2} < s < 0$. Then either the Eisenstein series are holomorphic or they have a possible pole of the first order due to the pole of $r(\Lambda_s, sc_2)^{-1}$ and $r(\Lambda_s, c_2 sc_2)^{-1}$ coming from the zero of $L(2s + 1, \chi^2)$ for given s ; in both cases the intertwining operators are holomorphic isomorphisms so that (2) gives an embedding of the whole global representation $Ind_{P_2(\mathbb{A})}^{Sp_4(\mathbb{A})}(\chi \nu_{GL_2(\mathbb{A})}^s)$ in the space of automorphic forms.*
- (2) *Assume $s = -\frac{1}{2}$. Then, If $\chi_p^2 \neq 1$ then all the local intertwining operators are holomorphic isomorphisms (for all $p \leq \infty$) and the image is isomorphic to $\chi_p \nu_p^{-1/2} 1_{GL_2(\mathbb{Q}_p)} \rtimes 1$. If $\chi_p^2 = 1$ but $\chi_p \neq 1$ all the intertwining operators are homomorphisms. If $\chi_p = 1$ the local intertwining operator $\mathcal{N}(\Lambda_{s,p}, \widetilde{c_2 sc_2})$ where $p \leq \infty$ can have a pole for every p with the choice of f_p from the non-spherical subquotient. This gives us a pole of the Eisenstein series (for χ which allows this possibility, e.g., $\chi = 1$) of every possible order. In this case, the image (by (2) after the normalization) consists of the irreducible tempered representations (on these “problematic” places where $\chi_p = 1$ and a non-spherical (tempered) choice of a subquotient and of the representation generated by the spherical subquotient on the rest of the places (and the spherical subquotient generates the representation $\nu_p^{1/2} 1_{GL_2(\mathbb{Q}_p)} \rtimes 1$).*
- (3) *Assume $-\frac{3}{2} < s < -\frac{1}{2}$. Then either the Eisenstein series are holomorphic or they have a possible pole of the first order due to the pole of $r(\Lambda_s, c_2)^{-1}$, $r(\Lambda_s, sc_2)^{-1}$ and $r(\Lambda_s, c_2 sc_2)^{-1}$ coming from the zero of $L(2s + \frac{3}{2}, \chi)$ for given s ; in both cases the intertwining operators are holomorphic isomorphisms so that (2) gives an embedding of the whole global representation $Ind_{P_2(\mathbb{A})}^{Sp_4(\mathbb{A})}(\chi \nu_{GL_2(\mathbb{A})}^s)$ in the space of automorphic forms.*
- (4) *Assume $s = -\frac{3}{2}$. Then, If $\chi_p^2 \neq 1$ then all the local intertwining operators are holomorphic isomorphisms (for all $p \leq \infty$) and the image is isomorphic to $\chi_p \nu_p^{-3/2} 1_{GL_2(\mathbb{Q}_p)} \rtimes 1$. Assume $p < \infty$. If $\chi_p = 1$ all the nontrivial local intertwining operators have a pole for every p with the choice of f_p from the*

non-spherical subquotient. On the spherical subrepresentation of $\chi_p \nu_p^{-3/2} 1_{GL_2(\mathbb{Q}_p)} \rtimes 1$ (in this case just the trivial representation) all these operators are holomorphic, and the image generated in that way is isomorphic to the representation $\nu_p^{3/2} 1_{GL_2(\mathbb{Q}_p)} \rtimes 1$ (thus reducible). For the choice of f_p which does not belong to the spherical subrepresentation, all these operators have a pole, and, after removing the pole by normalization, the image spans an irreducible subrepresentation $L(\nu_p^2; St_{SL_2(\mathbb{Q}_p)})$. If $\chi_p \neq 1$ all the local intertwining operators are isomorphisms. At the archimedean place, all the choices of f_p different from $L(\nu_\infty^2, \nu_\infty^1; 1)$ if $\chi_\infty = 1$ or $L(\text{sgn}\nu_\infty^2, \text{sgn}\nu_\infty^1; 1)$ if $\chi_\infty = \text{sgn}$ give us poles of the intertwining operators. This gives us a pole of the Eisenstein series (for χ which allows this possibility, e.g., $\chi = 1$) of every possible order.

- (5) Assume $s < -\frac{3}{2}$. Then, if $\chi_\infty^2 \neq 1$ or $s \pm \frac{1}{2}$ is not an integer, the Eisenstein series is holomorphic and (2) gives an embedding of the whole global representation $\text{Ind}_{P_2(\mathbb{A})}^{Sp_4(\mathbb{A})}(\chi \nu_{GL_2(\mathbb{A})}^s)$ in the space of automorphic forms. Assume that $\chi_\infty^2 = 1$ and $s \pm \frac{1}{2}$ is an integer. Then, the Eisenstein series is holomorphic on $\otimes f_p$, if f_∞ belongs to the Langlands quotient $L(\chi_\infty \nu_\infty^{-(s-\frac{1}{2})}, \chi_\infty \nu_\infty^{-(s+\frac{1}{2})}; 1)$ (which is a subrepresentation of $\chi_\infty \nu_\infty^s 1_{GL_2(\mathbb{R})} \rtimes 1$). In this case, (2) gives an embedding of an irreducible global representation $\otimes_{p < \infty} (\chi_p \nu_p^s 1_{GL_2(\mathbb{Q}_p)} \rtimes 1) \otimes L(\chi_\infty \nu_\infty^{-(s-\frac{1}{2})}, \chi_\infty \nu_\infty^{-(s+\frac{1}{2})}; 1)$ in the space of automorphic forms. If f_∞ is not chosen in that way, the Eisenstein series have a pole of the first order coming from the pole of the archimedean intertwining operators (in the constant term). After the normalization, the image of (2) in that case is a realization of a representation which has, on the archimedean place, the unique maximal proper subrepresentation of $\nu_\infty^{-s} 1_{GL_2(\mathbb{R})} \rtimes 1$.

Proof. The case of $-\frac{1}{2} < s < 0$ is obvious. Assume $s = -\frac{1}{2}$. Then, all the inverses of the global normalizing factors are holomorphic. For $p \leq \infty$, all the intertwining operators are holomorphic if $\chi_p^2 \neq 1$. Now assume $p < \infty$. Assume that $\chi_p = 1$. From the discussion in Theorem 4.3, we know that we have

$$L(\nu_p^1; \nu_p^0 \rtimes 1) \hookrightarrow \nu^{-1/2} 1_{GL_2(\mathbb{Q}_p)} \rtimes 1 \rightarrow T_2,$$

where T_2 is a tempered representation, and $L(\nu_p^1; \nu_p^0 \rtimes 1)$ the spherical subquotient. The operator $\mathcal{N}(\Lambda_{s,p}, \widetilde{c}_2)$ is a holomorphic isomorphism on $\nu^{-1/2}1_{GL_2(\mathbb{Q}_p)} \rtimes 1$ (actually, an identity operator). The operator $\mathcal{N}(\Lambda_{s,p}, \widetilde{s})$ acting on $\nu^{-1/2}1_{GL_2(\mathbb{Q}_p)} \rtimes 1$ (i.e., $\mathcal{N}(\Lambda_{s,p}, \widetilde{s\widetilde{c}_2})$ acting on $\nu^{-1/2}1_{GL_2(\mathbb{Q}_p)} \rtimes 1$ because of the previous remark) has a pole on the quotient $\nu^{-1/2}St_{GL_2(\mathbb{Q}_p)} \rtimes 1$, but is holomorphic on $\nu^{-1/2}1_{GL_2(\mathbb{Q}_p)} \rtimes 1$. The operator $\mathcal{N}(\Lambda_{s,p}, \widetilde{c}_2)$ acting on $\nu^0 \times \nu^{-1} \rtimes 1$ has a pole on $\nu^0 \rtimes SL_2(\mathbb{Q}_p) = T_1 \otimes T_2$, where T_1 is the other tempered representation. We conclude that if we pick f_p from $L(\nu_p^1; \nu_p^0 \rtimes 1)$ then all the operators will be holomorphic f_p (belongs to the spherical subquotient, generated by the spherical vector), but if we pick f_p which belongs to the quotient T_2 , the operator $\mathcal{N}(\Lambda_{s,p}, \widetilde{c_2s\widetilde{c}_2})$ has a pole on that f_p . Assume now that $\chi_p^2 = 1$, but $\chi_p \neq 1$. Then, we know by Theorem 4.3 that the length of the representation $\chi_p \nu^{-1/2}1_{GL_2(\mathbb{Q}_p)} \rtimes 1$ is three, and that it has two subrepresentations. Now, the operator $\mathcal{N}(\Lambda_{s,p}, \widetilde{c}_2)$ acts on $\chi_p \nu_p^{-1} \rtimes T_1$ as the identity, and on $\chi_p \nu_p^{-1} \rtimes T_2$ as minus identity. The operator $\mathcal{N}(\Lambda_{s,p}, \widetilde{s})$ acting on $\chi_p \nu_p^{-1} \times \chi_p \nu_p^0 \rtimes 1$ has a pole on $\chi_p \nu^{-1/2}St_{GL_2(\mathbb{Q}_p)} \rtimes 1$, thus it does not have a pole on $\chi_p \nu^{-1/2}1_{GL_2(\mathbb{Q}_p)} \rtimes 1$. The operator $\mathcal{N}(\Lambda_{s,p}, \widetilde{c}_2)$ acts on $\chi_p \nu_p^0 \times \chi_p \nu_p^{-1} \rtimes 1$ as a holomorphic isomorphism. We conclude that all the operators are holomorphic on $\chi_p \nu^{-1/2}1_{GL_2(\mathbb{Q}_p)} \rtimes 1$. Now, assume that $p = \infty$. Then, again $\mathcal{N}(\Lambda_{s,\infty}, \widetilde{c}_2)$ is holomorphic isomorphism, and $\mathcal{N}(\Lambda_{s,\infty}, \widetilde{s\widetilde{c}_2})$ does not have a pole on $\chi_\infty \nu^{-1/2}1_{GL_2(\mathbb{R})} \rtimes 1$. The operator $\mathcal{N}(\Lambda_{s,\infty}, \widetilde{c}_2)$ acting on $\chi_\infty \nu_\infty^0 \times \chi_\infty^{-1} \nu_\infty^{-1} \rtimes 1$ can only have a pole if $\chi_\infty^{-1} \nu_\infty^{-1} \rtimes 1$ is reducible, and that is if $\chi_\infty = 1$. In that case, we have

$$V_1 = L(\nu_\infty^1; 1) \hookrightarrow \nu_\infty \rtimes 1 \rightarrow X(1, +) \oplus X(1, -),$$

where $X(1, \pm)$ are discrete series of $SL_2(\mathbb{R})$ (cf. [19] Theorem 2.4). The operator $\mathcal{N}(\Lambda_{s,p}, \widetilde{c}_2)$ has a pole on the quotient $\nu_\infty^0 \rtimes (X(1, +) \oplus X(1, -))$. This quotient decomposes as a sum of four tempered representations (cf. [19] Theorem 10.7), two of which are quotients of $\nu_\infty^{-1/2}1_{GL_2(\mathbb{R})} \rtimes 1$. So, we conclude that the operator $\mathcal{N}(\Lambda_{s,\infty}, \widetilde{c_2s\widetilde{c}_2})$ is holomorphic on the spherical subrepresentation of $\nu_\infty^{-1/2}1_{GL_2(\mathbb{R})} \rtimes 1$ (this also follows from the general properties of the normalized intertwining operators), but other choices of f_p will give us a pole.

Now assume $s = -\frac{3}{2}$. Assume $p < \infty$ and $\chi_p = 1$ (this is the only case when poles might occur). Then, $\mathcal{N}(\Lambda_{s,p}, \widetilde{c}_2)$ has a pole on the quotient $\nu_p^{-2} \rtimes St_{SL_2(\mathbb{Q}_p)}$, which decomposes (in the appropriate Grothendick group) as $St_{Sp_4(\mathbb{Q}_p)} + L(\nu_p^2; St_{SL_2(\mathbb{Q}_p)})$. On the other hand, we have

$$L(\nu_p^2, \nu_p^1; 1) \hookrightarrow \nu_p^{-3/2}1_{GL_2(\mathbb{Q}_p)} \rtimes 1 \rightarrow L(\nu_p^2; St_{SL_2(\mathbb{Q}_p)}).$$

Note that $\mathcal{N}(\Lambda_{s,p}, \tilde{s})$ acting on $\nu_p^{-2} \times \nu_p^1 \rtimes 1$ is a holomorphic isomorphism, and so is $\mathcal{N}(\Lambda_{s,p}, \tilde{c}_2)$ acting on $\nu_p^1 \times \nu_p^{-2} \rtimes 1$. We conclude that the images of $\mathcal{N}(\Lambda_{s,p}, \tilde{c}_2)$, $\mathcal{N}(\Lambda_{s,p}, \tilde{s}c_2)$ and $\mathcal{N}(\Lambda_{s,p}, \tilde{c}_2 \tilde{s}c_2)$ will be mutually isomorphic on $\nu_p^{-3/2} 1_{GL_2(\mathbb{Q}_p)} \rtimes 1$. We see that on the spherical subrepresentation (in this case just the trivial representation) all these operators are holomorphic, and the image generated in that way is isomorphic to the representation $\nu_p^{3/2} 1_{GL_2(\mathbb{Q}_p)} \rtimes 1$ (thus reducible). If we pick f_p which does not belong to the spherical $L(\nu_p^2, \nu_p^1; 1)$, all these operators have a pole, and, after removing the pole by normalization, the image spans an irreducible subrepresentation $L(\nu_p^2; St_{SL_2(\mathbb{Q}_p)})$. If $\chi_p \neq 1$ all the local intertwining operators are isomorphisms. Now assume $p = \infty$. Then, by Lemma 4.2, we see that the poles may occur if $\chi_\infty = 1$ or $\chi_\infty = sgn$. We first deal with the case $\chi_\infty = 1$. Then, already the operator $\mathcal{N}(\Lambda_{s,\infty}, \tilde{c}_2)$ has a pole on each the subquotients of $\nu_\infty^{-3/2} 1_{GL_2(\mathbb{R})} \rtimes 1$, except on its unique subrepresentation (which is again the trivial representation, as in the non-archimedean case), cf. [19] Theorem 11.1. Note that the action of the other intertwining operators cannot cancel this pole. Assume now that $\chi_\infty = sgn$. Then, $\mathcal{N}(\Lambda_{s,\infty}, \tilde{c}_2)$ acting on $sgn \nu_\infty^{-3/2} 1_{GL_2(\mathbb{R})} \rtimes 1$ is a holomorphic isomorphism. The pole of $\mathcal{N}(\Lambda_{s,\infty}, \tilde{s})$ acting on $sgn \nu_\infty^{-2} \times sgn \nu_\infty^1 \rtimes 1$ happens on the subquotients of $\delta(sgn \nu_{inf}^{1/2}, 3) \rtimes 1$ and $sgn \nu_\infty^{-3/2} 1_{GL_2(\mathbb{R})} \rtimes 1$ and this representation do not have common irreducible subquotients by [19], proof of Theorem 10.1 and (10.64) there. The pole of $\mathcal{N}(\Lambda_{s,\infty}, \tilde{c}_2)$ acting on $sgn \nu_\infty^1 \times sgn \nu_\infty^{-2} \rtimes 1$ happens on the subquotients of $sgn \nu_\infty^1 \rtimes X(2, +) \oplus sgn \nu_\infty^1 \rtimes X(2, -)$. But the representation $sgn \nu_\infty^{-3/2} 1_{GL_2(\mathbb{R})} \rtimes 1$ is of length three and two of its subquotients (so the ones different from $L(sgn \nu_\infty^2, sgn \nu_\infty^1; 1)$) appear in this space where the poles occur. Note that the representation $sgn \nu_\infty^2 \times sgn \nu_\infty^1 \rtimes 1$ is multiplicity free.

From Lemma 4.2 we now that in the case $s < -\frac{3}{2}$ it is enough to see what is happening on the archimedean places (all the local intertwining operators at the non-archimedean places are holomorphic isomorphisms) the following situations:

- (1) $\chi_\infty = 1$, $s + \frac{1}{2}$ is odd integer,
- (2) $\chi_\infty = 1$, $s + \frac{1}{2}$ is even integer,
- (3) $\chi_\infty = sgn$, $s + \frac{1}{2}$ is an odd integer,
- (4) $\chi_\infty = sgn$, $s + \frac{1}{2}$ is an even integer.

Assume the first possibility. Then from Theorem 11.1 of [19], we see that $\mathcal{N}(\Lambda_{s,\infty}, \tilde{c}_2)$ acting on $\nu_\infty^s 1_{GL_2(\mathbb{R})} \rtimes 1$ has a pole of the first order for every choice f_p which does not belong to the Langlands quotient $L(\nu_\infty^{-s+1/2}, \nu_\infty^{-s-1/2}; 1)$ (the representation $sgn \nu_\infty^s 1_{GL_2(\mathbb{R})} \rtimes 1$ is of

the length four). The second intertwining operator has a pole on $\nu_\infty^{s-1/2} \times \nu_\infty^{-(s+1/2)} \rtimes 1$, but it does not add a pole of the higher order on the image of $\mathcal{N}(\Lambda_{s,\infty}, \tilde{c}_2)(\nu_\infty^s 1_{GL_2(\mathbb{R})} \rtimes 1)$ (and is non-zero on the subquotients of $\nu_\infty^s 1_{GL_2(\mathbb{R})} \rtimes 1$). The intertwining operator $\mathcal{N}(\Lambda_{s,\infty}, \tilde{c}_2)$ acting on $\nu_\infty^{-(s+1/2)} \times \nu_\infty^{s-1/2} \rtimes 1$ is a holomorphic isomorphism by Lemma 4.2. In the second possibility, the first intertwining operator $\mathcal{N}(\Lambda_{s,\infty}, \tilde{c}_2)$ acting on $\nu_\infty^s 1_{GL_2(\mathbb{R})} \rtimes 1$ is a holomorphic isomorphism. The second intertwining operator has a pole on $\delta(-1/2, 2s) \rtimes 1$ (again notation from [19], the proof of Theorem 10.1) which is a representation of the length three and does not have a common subquotient with the representation $\nu_\infty^s 1_{GL_2(\mathbb{R})} \rtimes 1$ (cf. Theorem 10.6 of [19]), so it's holomorphic and non-zero on it. The third intertwining operator $\mathcal{N}(\Lambda_{s,\infty}, \tilde{c}_2)$ acts on $\nu_\infty^{-(s+1/2)} \times \nu_\infty^{s-1/2} \rtimes 1$, and pole is obtained on the subquotients of $\nu_\infty^{-(s+1/2)} \rtimes (X(-(s-\frac{1}{2}), +) \oplus X(-(s-\frac{1}{2}), -))$. All the subquotients of $\nu_\infty^s 1_{GL_2(\mathbb{R})} \rtimes 1$, except $L(\nu_\infty^{-(s-\frac{1}{2})}, \nu_\infty^{-(s+\frac{1}{2})}; 1)$ are among those on which the pole occurs.

The situation with the rest of the cases is totally symmetric (i.e., one uses Theorem 10.1, Theorem 10.6 or Theorem 11.1 of [19]), and we conclude that in all of these four cases, at least one of the operators $\mathcal{N}(\Lambda_{s,\infty}, \tilde{c}_2)$, $\mathcal{N}(\Lambda_{s,\infty}, \widetilde{sc}_2)$ and $\mathcal{N}(\Lambda_{s,\infty}, \widehat{c_2 sc_2})$ has a pole of the first order on each of the subquotients of $sgn^\varepsilon \nu_\infty^s 1_{GL_2(\mathbb{R})} \rtimes 1$, except $L(sgn^\varepsilon \nu_\infty^{-(s-\frac{1}{2})}, sgn^\varepsilon \nu_\infty^{-(s+\frac{1}{2})}; 1)$ (here $\varepsilon \in \{0, 1\}$). If one removes the pole, the image spans the unique maximal proper subrepresentation of $\nu_\infty^{-s} 1_{GL_2(\mathbb{R})} \rtimes 1$. \square
