# WEAK SOLUTIONS OF THE HAMILTON-JACOBI EQUATION FOR TIME PERIODIC LAGRANGIANS

# GONZALO CONTRERAS, RENATO ITURRIAGA, AND HÉCTOR SÁNCHEZ-MORGADO

Abstract. In this work we prove the existence of Fathi's weak KAM solutions for periodic Lagrangians and give a construction of all of them.

#### 0. Introduction and statement of results

Let M be a closed connected manifold, TM its tangent bundle. Let  $L : TM \times$  $\mathbb{R} \to \mathbb{R}$  be a  $C^{\infty}$  Lagrangian. We will assume for the Lagrangian the hypothesis of Mather's seminal paper  $[9]$ . The Lagrangian  $L$  should be:

- (1) Convex. The Lagrangian L restricted to  $T_xM$ , in linear coordinates should have positive definite Hessian.
- (2) Superlinear. For some Riemannian metric we have

$$
\lim_{|v| \to \infty} \frac{L(x, v, t)}{|v|} = \infty,
$$

uniformly on  $x$  and  $t$ .

(3) Periodic. The Lagrangian should be periodic in time, i.e.

$$
L(x, v, t+1) = L(x, v, t),
$$

for all  $x, v, t$ .

(4) Complete. The Euler Lagrange flow associated to the Lagrangian should be complete.

Let  $\mathcal{M}(L)$  be the set of probabilities on the Borel  $\sigma$ -algebra of  $TM \times \mathbb{S}^1$  that have compact support and are invariant under the Euler-Lagrange flow  $\phi_t$ .

The *action* of  $\mu \in \mathcal{M}(L)$  is defined by

$$
A_L(\mu) = \int L \, d\mu.
$$

Mather defined the function  $\alpha: H^1(M, \mathbb{R}) \to \mathbb{R}$  as

(1) 
$$
\alpha([\omega]) = -\min\left\{ \int (L - \omega) d\mu : \ \mu \in \mathcal{M}(L) \right\}.
$$

All authors were partially supported by CONACYT-México grant  $# 28489-E$ .

Keywords: Hamilton-Jacobi equation, weak KAM theory, action potential, periodic Lagrangians, Aubry-Mather theory, Mañé's critical level, lagrangian graphs.

AMS 2000 Math. Subject Classification: 70H20, 37J50, 70H08, 49L99, 37J05.

For any k in R define the  $(L + k)$ -action of an absolutely continuous curve  $\gamma$ :  $[a, b] \to M$  as

$$
A_{L+k}(\gamma) = \int_a^b (L+k)(\gamma(\tau), \dot{\gamma}(\tau), \tau) d\tau
$$

For t in  $\mathbb R$  we denote by [t] the corresponding point in  $\mathbb S^1$ . For any pair of points  $(x,[s]),(y,[t])$  on  $M\times\mathbb{S}^1$  and n a non negative integer, define  $\mathcal{C}((x,[s]),(y,[t]);n)$  as the set of absolutely continuous curves  $\gamma : [a, b] \to M$  with  $\gamma(a) = x$  and  $\gamma(b) = y$ such that  $[a] = [s]$  and  $[b] = [t]$ , and the integer part of  $b - a$  is n.

Let  $\Phi_k^n$  be the real function defined on  $M \times \mathbb{S}^1 \times M \times \mathbb{S}^1$  as

$$
\Phi_k^n((x,[s]),(y,[t])) = \min_{\gamma \in \mathcal{C}((x,[s]),(y,[t]);n)} \{A_{L+k}(\gamma)\}.
$$

so that  $\Phi_k^n = \Phi_0^n + kn$ .

Then the *action functional* is defined by

$$
\Phi_k = \inf_n \Phi_k^n,
$$

and the Extended Peierls barrier by

$$
h_k = \liminf_{n \to \infty} \Phi_k^n.
$$

Thus  $\Phi_k \leq h_k$ .

A curve  $\gamma : [a, b] \to M$  will be called *closed* if  $\gamma(a) = \gamma(b)$  and  $b - a$  is an integer. In analogy to the autonomous case [\[8\]](#page-12-1), [\[2\]](#page-12-2), there is a critical value  $c(L)$  given by the following proposition:

### 1. Proposition.

(1) If  $k < c(L)$ , then  $\Phi_k((x,[s]),(y,[t])) = -\infty$ , for all  $(x,[s]),(y,[t])$  on  $M \times \mathbb{S}^1$ (2)

$$
c(L) = \min\{k : \int_{\gamma} L + k \ge 0 \text{ for all closed curves } \gamma\}
$$

- (3) If  $k \ge c(L)$ , then  $\Phi_k((x,[s]),(y,[t])) > -\infty$  for all  $(x,[s]),(y,[t])$  on  $M \times \mathbb{S}^1$ .
- (4) In terms of Mather's  $\alpha$  function we have

(2) 
$$
c(L) = -\min \Biggl\{ \int L d\mu : \mu \text{ is an invariant probability} \Biggr\}
$$

$$
= \alpha(0)
$$

$$
(3) \quad
$$

<span id="page-1-0"></span>Invariant probabilities realizing the infimum above are called minimizing measures.

From now on, set  $c = c(L)$ .

In contrast with the autonomous case, the action potential  $\Phi_c$  may fail to be continuous and to satisfy the triangle inequality. However, for the extended Peierls barrier we shall prove the following:

### <span id="page-2-0"></span>2. Proposition.

\n- (1) If 
$$
k < c
$$
,  $h_k \equiv -\infty$ .
\n- (2) If  $k > c$ ,  $h_k \equiv \infty$ .
\n- (3)  $h_c$  is finite.
\n- (4)  $h_c((x,[s]),(z,[\tau])) \leq h_c((x,[s]),(y,[t])) + \Phi_c((y,[t]),(z,[\tau])).$
\n- (5)  $h_c$  is Lipschitz.
\n

Let  $H(x, p, t)$  be the Hamiltonian associated to the Lagrangian;

$$
H: T^*M \times \mathbb{R} \to \mathbb{R}
$$

(4) 
$$
H(x, p, t) = \max_{v \in T_x M} pv - L(x, v, t)
$$

In [\[4\]](#page-12-3) the critical value or  $\alpha(0)$  for the autonomous case is characterized as

$$
c(L) = \inf_{f \in C^{\infty}(M,\mathbb{R})} \sup_{x \in M} H(x, d_x f)
$$
  
=  $\inf \{ k \in \mathbb{R} : \text{ there exists } f \in C^{\infty}(M,\mathbb{R}) \text{ such that } H(df) < k \},$ 

This can be restated in physical terms, by saying that  $c(L)$  is either the infimum of the values of  $k \in \mathbb{R}$  for which there is an exact Lagrangian graph with energy less than k, or the infimum of the values of  $k \in \mathbb{R}$  for which there exist smooth solutions of the Hamilton-Jacobi inequality  $H(df) < k$ .

The second interpretation has a natural generalization. We will prove in section [2](#page-6-0) the following

3. **Theorem.** The critical value,  $c(L)$  or  $\alpha(0)$  is characterized as the infimum of k such that there exists a subsolution  $f: M \times \mathbb{S}^1 \to \mathbb{R}$  of the Hamilton Jacobi equation,

$$
d_t f + H(x, d_x f, t) \leq k.
$$

We can recover the previous interpretation by using the autonomous Hamiltonian  $\mathbb{H}(x, p, t, e) = H(x, p, t) + e$  on  $T^{*}(M \times \mathbb{S}^{1})$ . Then  $df = (d_x f, d_t f)$  is an exact Lagrangian graph and  $c(L) = \inf_u \sup_{(x,t)} \mathbb{H}(d_{(x,t)}u)$ . The results in [\[4\]](#page-12-3) can not be directly applied to this case because the Hamiltonian H does not come from a Lagrangian.

The other values of Mather's alpha function can be similarly characterized by recalling that  $\alpha([\omega]) = c(L - \omega)$  and that the Hamiltonian of  $L - \omega$  is  $(x, p, t) \mapsto$  $H(x, p + \omega, t).$ 

In corollary [14](#page-7-0) we observe that differentiable solutions may only exist when  $k =$  $c(L).$ 

4. **Definition.** Following Fathi [\[6\]](#page-12-4) we say that  $u : M \times \mathbb{S}^1 \to \mathbb{R}$  is a forward weak KAM solution if

(1) u is  $L + c$  dominated, i.e.

$$
u(y, [t]) - u(x, [s]) \le \Phi_c((x, [s]), (y, [t])).
$$

We use the notation  $u \prec L + c$ .

(2) For every  $(x,[s]) \in M \times \mathbb{R}$  there exists a curve  $\gamma : (s,\infty) \to M$  such that  $u(\gamma(t), [t]) - u(x, [s]) = A_{L+c}(\gamma|_{[s,t]})$ , in that case we say that  $\gamma$  realizes u.

Similarly  $u : M \times \mathbb{S}^1 \to \mathbb{R}$  is a backward weak KAM solution if it is dominated and for every  $(x,[s]) \in M \times \mathbb{S}^1$  there exists a curve  $\gamma : (-\infty, s) \to M$  such that  $u(x,[s]) - u(\gamma(t),[t]) = A_{L+c}(\gamma|_{[t,s]}))$ 

Let  $S^-$  (resp.  $S^+$ ) be the set of *backward* (resp. *forward*) weak KAM solutions.

A point  $(x, v, [s]) \in TM \times \mathbb{S}^1$  is a positive (resp. negative) semistatic point if the solution  $\gamma = \gamma_{(x,v,s)}$  of the Euler-Lagrange equation with initial conditions  $(x, v, [s])$ , satisfies for all t

$$
A_{L+c}(\gamma|_{[s,t]}) = \Phi_c((x,[s]),(\gamma(t),[t])),
$$

(resp.  $A_{L+c}(\gamma|_{[t,s]}) = \Phi_c((\gamma(t), [t]), (x, [s]))$  for all t).

A point  $(x, v, [s]) \in TM \times \mathbb{S}^1$  is a *static* point if it is positive semistatic and

 $A_{L+c}(\gamma|_{[s,t]}) = -\Phi_c((\gamma(t), [t]),(x,[s])).$ 

It turns out that if a point is static then its whole orbit under the Euler-Lagrange flow is static.

We denote by  $\Sigma^+$  the set of positive semistatic points.

For a forward weak KAM solution u we define its forward basin as

$$
\Gamma_0^+(u) = \{ (x, v, [s]) \in \Sigma^+ :
$$
  

$$
u(\gamma_{(x,v,s)}(t), [t]) - u(x, [s]) = \Phi_c((x, [s]), (\gamma_{(x,v,s)}(t), [t])) \,\forall t > s \};
$$

and define its *cut locus* by  $\pi(\Gamma_0^+(u) \setminus \Gamma^+(u))$ , where  $\pi: TM \times \mathbb{S}^1 \to M \times \mathbb{S}^1$  is the proyection,

$$
\Gamma^+(u) = \bigcup_{t>0} \phi_t(\Gamma_0^+(u)),
$$

and  $\phi_t$  is the Euler-Lagrange flow. It is easy to see that the sets  $\Sigma^+$  and  $\Gamma_0^+(u)$  are positively invariant and so  $\Gamma^+(u) \subset \Gamma^+_0(u)$ . Similarly, define the backward basins  $\Gamma_0^-(u)$ ,  $\Gamma^-(u)$  for  $u \in \mathcal{S}^-$ .

The relevance of weak KAM solutions is that they have several properties, including those given by the following theorem.

<span id="page-3-0"></span>5. **Theorem.** If  $u : M \times \mathbb{S}^1 \to \mathbb{R}$  is a weak KAM solution then

(1) u is Lipschitz and satisfies the Hamilton Jacobi equation

$$
H(x, d_x u, t) + d_t u = c
$$

#### WEAK SOLUTIONS 5

at any point of differentiability. Moreover,  $d_x u$  and  $\dot{\gamma}$  are Legendre conjugate.

- (2) Graph property:  $\pi : \Gamma^+(u) \to M \times \mathbb{S}^1$  is injective and its inverse is Lipschitz.
- (3) u is differentiable on  $\pi(\Gamma^+(u))$ .

Observe that since a weak KAM solution  $u$  is Lipschitz, by Rademacher's theorem it is differentiable Lebesgue almost everywhere.

Define the Aubry set  $\mathcal A$  as

$$
\mathcal{A} := \{ (x, [t]) \in M \times \mathbb{S}^1 \, | \, h_c((x, [t]), (x, [t])) = 0 \}.
$$

We define an equivalence relation on A by  $(x,[s]) \sim (y,[t])$  if and only if

$$
\Phi_c((x,[s]),(y,[t])) + \Phi_c((y,[t]),(x,[s])) = 0.
$$

The equivalence classes of this relation are called *static classes*.

Let **A** be the set of static classes. For each static class  $\Gamma \in \mathcal{A}$  choose a point  $(p,[s]) \in \Gamma$  and let A be the set of such points.

<span id="page-4-3"></span>6. **Remark.** Observe that by item 4 of proposition [2,](#page-2-0) if  $(p, \lceil \tau \rceil) \in \mathcal{A}$  then

$$
h_c((p,[\tau]),(x,[t])) = \Phi_c((p,[\tau]),(x,[t])).
$$

<span id="page-4-2"></span>7. **Theorem.** The map  $\{f : \mathbb{A} \to \mathbb{R} \mid f \text{ dominated } \} \longrightarrow S^{-1}$ 

$$
f \mapsto u_f(x, [t]) = \min_{(p, [s]) \in \mathbb{A}} f(p, [s]) + h_c((p, [s]), (x, [t])),
$$

and the map  $\{f : \mathbb{A} \to \mathbb{R} \mid f \text{ dominated } \} \longrightarrow S^+$ 

$$
f \mapsto v_f(x, [t]) = \max_{(p, [s]) \in \mathbb{A}} f(p, [s]) - h_c((x, [t]), (p, [s])),
$$

are bijections.

# 1. The Peierls barrier

We will be using the following lemma due to Mather [\[9\]](#page-12-0). We say that an absolutely continuous curve  $\gamma : [a, b] \to M$  is a minimizer if  $A_L(\gamma) \leq A_L(\eta)$  for any absolutely continuous curve  $\eta : [a, b] \to M$  with  $\eta(a) = \gamma(a)$  and  $\eta(b) = \gamma(b)$ . It turns out that a minimizer is a solution of the Euler-Lagrange equation  $\frac{d}{dt}L_v = L_x$ .

<span id="page-4-0"></span>8. Lemma. There is  $A > 0$  such that if  $b-a \geq 1$  and  $\gamma : [a, b] \to M$  is a minimizer, then  $|\dot{\gamma}(t)| \leq A$  for  $t \in [a, b]$ .

The proof of most of Propositions [1](#page-1-0) and [2](#page-2-0) follow standard arguments. We only give the proof of the Lipschitz continuity of  $h_c$ .

<span id="page-4-1"></span>9. **Lemma.** Given  $(z, [\sigma]) \in M \times \mathbb{S}^1$  define

 $u(x, [t]) := h_c((z, [\sigma]; x, [t]), \quad v(x, [t]) := -h_c((x, [t]; z, [\sigma]).$ 

Then  $u \in S^-$  and  $v \in S^+$ .

**Proof:** By item 4 of proposition [2,](#page-2-0)  $h(z, [\sigma]), (x, [t]) \leq h_c((z, [\sigma]), (y, [s]))+\Phi_c((y, [s]), (x, [t]))$ for all  $(y, [s]), (x, [t]) \in M \times \mathbb{S}^1$ . Thus  $u \prec L + c$ .

Given  $(x,[t]) \in M \times \mathbb{S}^1$  choose sequences  $n_k \to +\infty$ ,  $n_k \in \mathbb{Z}$  and  $(x,v_k) \in T_xM$ such that

$$
h_c((z,[\sigma]),(x,[t])) = \lim_k A_{L+c}(\gamma_k|_{[\sigma-n_k,t]}),
$$

where  $\gamma_k(s) = \pi \varphi_{s-t}(x, v_k, t)$  is the solution of the Euler-Lagrange equation such that  $(\gamma_k(t), \dot{\gamma}_k(t)) = (x, v_k)$ . By lemma [8,](#page-4-0) the norm  $||v_k||$  is uniformly bounded. Choose a convergent subsequence  $v_k \to w$ . Let  $\eta(s) := \pi \varphi_{s-t}(x, w, t)$ , then for any fixed  $s < 0$ ,

$$
h_c((z, [\sigma]), (x, [t])) \leq h_c((z, [\sigma]), (\eta(s), [s])) + A_{L+c}(\eta|_{[s,t]})
$$
  
=  $\lim_k h_c((z, [\sigma]), (\gamma_k(s), [s])) + A_{L+c}(\gamma_k|_{[s,t]})$   
 $\leq \lim_k A_{L+c}(\gamma_k|_{[\sigma-n_k, s]}) + A_{L+c}(\gamma_k|_{[s,t]})$   
=  $h_c((z, [\sigma]), (x, [t]))$ .

So that  $u(x, [t]) - u(\eta(s), [s]) = A_{L+c}(\eta|_{[s,t]})$  for all  $s < 0$ .

For autonomous lagrangians, dominated functions are Lipschitz. In contrast, for time periodic lagrangians the action potential is dominated but it is not continuous at  $((x, s), (x, s))$  when  $(x, s)$  is not in the Aubry set. Nevertheless, we have the following:

<span id="page-5-2"></span>10. Lemma. If  $u : M \times \mathbb{S}^1 \to \mathbb{R}$  is a weak KAM solution (i.e.  $u \in \mathcal{S}^+ \cup \mathcal{S}^-$ ) then it is Lipschitz. Moreover the Lipschitz constant does not depend on u.

**Proof:** Assume that  $u \in S^-$ , the case  $u \in S^+$  is similar. Let  $(x,[t_0]),(y,[s_0]) \in$  $M \times \mathbb{S}^1$  be nearby points with  $|s_0 - t_0| < \frac{1}{4}$  $\frac{1}{4}$ . Let  $\gamma : [0,1] \rightarrow M$  be a length minimizing geodesic joining x to y and let  $\tau(r) = t_0 + r (s_0 - t_0), r \in [0, 1]$ . Fix  $\delta > 1$  and let  $z : [t_0 - \delta, t_0] \to M$  be such that

<span id="page-5-0"></span>(5) 
$$
u(x,[t_0]) = u(z(t),[t]) + \int_t^{t_0} L(z,\dot{z}) + c \, dt \quad \text{for all } t_0 - \delta < t \leq t_0.
$$

For  $r \in [0, 1]$ , let  $\eta(r, t)$ ,  $t \in [t_0 - \delta, \tau(r)]$ , be a locally minimizing solution of (E-L) such that  $\eta(r, t_0 - \delta) = z(t_0 - \delta)$  and  $\eta(r, \tau(r)) = \gamma(r)$ .

Then

$$
u(\gamma(r),[\tau(r)]) \leq u(z(t_0-\delta),[t_0-\delta]) + \int_{t_0-\delta}^{\tau(r)} L(\eta,\frac{\partial \eta}{\partial t},t) + c \, dt.
$$

with equality for  $r = 0$ . Substracting the equality [\(5\)](#page-5-0) at  $r = 0$ , we get that

<span id="page-5-1"></span>(6) 
$$
u(\gamma(r), [\tau(r)]) - u(x, [t_0]) \leq \int_{t_0 - \delta}^{\tau(r)} (L + c) dt - A_{L+c}(z|_{[t_0 - \delta, t_0]}).
$$

 $\Box$ 

### WEAK SOLUTIONS  $\hspace{1.5cm}7$

Observe that this formula holds either for  $s_0 \leq t_0$  or  $t_0 \leq s_0$ . As we shall see below, formula [\(6\)](#page-5-1) implies that  $u(y, s) - u(x, t) \leq K(|s-t| + d(x, y))$  for some fixed  $K > 0$ . Then changing the roles of  $s$  and  $t$  we get that  $u$  is Lipschitz.

Indeed, differentiating the right hand side and integrating by parts, we have

$$
\frac{d}{dr} \int_{t_0-\delta}^{t_0+r(s_0-t_0)} L(\eta, \frac{\partial \eta}{\partial t}, t) + c \ dt =
$$
\n
$$
= \left[ L(\eta, \frac{\partial \eta}{\partial t}, t) \Big|_{(r,\tau(r))} + c \right] (s_0 - t_0) + \int_{t_0-\delta}^{\tau(r)} L_x \frac{\partial \eta}{\partial r} + L_v \frac{\partial^2 \eta}{\partial t \partial r}
$$
\n
$$
= \left[ L(\eta, \frac{\partial \eta}{\partial t}, t) \Big|_{(r,\tau(r))} + c \right] (s_0 - t_0) + \frac{\partial L}{\partial v} (\eta, \frac{\partial \eta}{\partial t}, t) \Big|_{(r,\tau(r))} \cdot \frac{\partial \eta}{\partial r} \Big|_{(r,\tau(r))}
$$

Observe that since  $u$  is dominated the realizing curve  $z$  must be a minimizer. By lemma [8,](#page-4-0)  $\|\dot{z}\|$  is uniformly bounded. By the continuity of the solutions of (E-L) with respect to initial values,  $\parallel$ ∂η  $\frac{\partial \eta}{\partial t}$  is uniformly bounded. Hence there is a uniform constant  $K > 0$  (independent of  $z(t), x, y, [s_0], [t_0], u$ ) such that

$$
\left| L\left(\eta, \frac{\partial \eta}{\partial t}, t\right) + c \right| \le K \quad \text{and} \quad \left\| \frac{\partial L}{\partial v}(\eta, \frac{\partial \eta}{\partial t}, t) \right\| < K.
$$

Since  $\frac{\partial \eta}{\partial \eta}$ ∂r  $\Bigg|_{(r,\tau(r))}$  $=\dot{\gamma}(r)$ , we get that

$$
\frac{d}{dr}\left[\int_{t_0-\delta}^{\tau(r)} [L+c] - A_{L+c}(z)\right] \leq K \left|s_0 - t_0\right| + K \|\dot{\gamma}\|.
$$

The value of the right hand side of [\(6\)](#page-5-1) is 0 at  $r = 0$ . Integrating this inequality,

$$
u(y,[s_0])-u(x,[t_0])\leq K[[s_0-t_0]+d(x,y)].
$$

Interchanging the roles of  $(x,[t_0])$  and  $(y,[s_0])$  we obtain that the function u is Lipschitz.

 $\Box$ 

Combining lemmas [9](#page-4-1) and [10](#page-5-2) we get that the functions  $f, g : M \times \mathbb{S}^1 \to \mathbb{R}$ ,  $f(y,[t]) = h_c((x,[s]),(y,[t]))$  and  $g(x,[s]) = h_c((x,[s]),(y,[t]))$  are Lipschitz. This implies that  $h_c$  is Lipschitz.

# 2. Subsolutions of the Hamilton Jacobi equation

<span id="page-6-0"></span>Following the same ideas as in [\[4\]](#page-12-3), one obtains

<span id="page-6-1"></span>11. Lemma. If k is a real number such that there exists a function f in  $C^1(M \times \mathbb{S}^1)$ subsolution of the Hamilton Jacobi equation

$$
H(x, d_x f) + d_t f \le k
$$

Then  $k \geq c(L)$ .

<span id="page-7-3"></span>12. Lemma. Let  $k \geq c(L)$ . If  $f : M \times \mathbb{S}^1 \to \mathbb{R}$  is differentiable at  $(x, [t]) \in M \times \mathbb{S}^1$ and satisfies

$$
f(y, [t_2]) - f(x, [t_1]) \le \Phi_k(x, [t_1], y, [t_2])
$$

for all y in a neighbourhood of x, then  $H(x, d_x f) + d_t f \leq k$ .

13. Proposition. For any  $k > c(L)$  there exists  $f \in C^{\infty}(M \times \mathbb{S}^1, \mathbb{R})$  such that  $H(x, d_x f, t) + d_t f < k$ .

We give a proof of the following fact

<span id="page-7-0"></span>14. Corollary. If u is a  $C^{1+\text{Lip}}$  global solution of the Hamilton-Jacobi equation  $u_t$  +  $H(x, u_x, t) = k$ , then  $k = c(L)$  and u is a weak KAM solution in  $S^- \cap S^+$ .

**Proof:** By lemma [11,](#page-6-1)  $k \ge c(L)$ . Let  $\mathcal{L}_t(x, v) = L_v(x, v, t)$  be the conjugate moment associated to L and let  $\xi(x, t)$  be the vector field defined by

 $\xi(x,t) = \mathcal{L}_t^{-1}(u_x) \in T_xM$ . Then the vector field  $(\xi,1)$  in  $M \times \mathbb{S}^1$  is Lipschitz. Let  $\rho_t$  be the flow of  $(\xi, 1)$  in  $M \times \mathbb{S}^1$ . From the Hamilton-Jacobi equation we get that

<span id="page-7-1"></span>(7) 
$$
d_{(x,[t])}u \cdot (v,1) = u_x(x,t) \cdot v + u_t \cdot 1 \leq L(x,v,[t]) + k.
$$

and that

<span id="page-7-2"></span>(8) 
$$
d_{(x,[t])}u \cdot (\xi(x,t),1) = L(x,\xi(x,t),t) + k
$$
 for all  $(x,[t]) \in M \times \mathbb{S}^1$ .

Integrating equation [\(7\)](#page-7-1) along absolutely continuous curves  $(\gamma(t), [t])$  in  $M \times \mathbb{S}^1$  from  $(x,[s])$  to  $(y,[t])$ , we get that

$$
u(y, [t]) - u(x, [s]) \leq \inf_{\gamma} \oint_{\gamma} (L + k) = \Phi_k((x, [s]), (y, [t])).
$$

So that  $u \prec L + k$ .

Also, integrating equation [\(8\)](#page-7-2), we get that the orbits of  $\rho_t$  realize u in the sense of the definition of a weak KAM solution. In particular, the orbits of  $\rho$  are global minimizers of the  $(L + k)$ -action, and thus they are solutions of the Euler-Lagrange equation.

It remains to prove that  $k = c(L)$ . Let  $\nu$  be an invariant Borel probability for  $\rho_t$  and let  $\mu$  be its lift to  $TM \times \mathbb{S}^1$  using the vectorfield  $\xi$ . Then  $\mu$  is an invariant probability of the Lagrangian flow and, by equation [\(8\)](#page-7-2),

$$
\int (L+k) \ d\mu = \int du \ d\mu = 0.
$$

This implies that  $k \leq c(L)$ . Thus  $k = c(L)$  and also  $\mu$  is a minimizing measure.  $\Box$ 

#### WEAK SOLUTIONS 9

#### 3. Weak KAM solutions

### Proof of theorem [5:](#page-3-0)

We first prove item 1. By lemma [10](#page-5-2) we have that  $u$  is Lipschitz and hence it is differentiable almost everywhere. Let  $(x, [t])$  be a point of differentiability, then by lemma [12](#page-7-3) we have

$$
H(x, d_x u, t) + u_t \leq c.
$$

Moreover let  $\gamma : [t, \infty) \to M$  be such that

$$
u(\gamma(s), [s]) - u(x, [t]) = A_{L+c}(\gamma|_{[t,s]}),
$$

$$
\lim_{s \to t} \frac{u(\gamma(s), [s]) - u(x, [t])}{s - t} = \lim_{s \to t} \frac{1}{s - t} \int_t^s (L + c)(\gamma(s), \dot{\gamma}(s), [s]) ds,
$$

so

$$
d_x u(x, [t]) \dot{\gamma} + d_t u(x, [t]) = L(x, \dot{\gamma}, t) + c.
$$

Therefore

$$
c = d_x u \dot{\gamma} - L + d_t u \le H(x, d_x u, t) + d_t u \le c.
$$

So u is a solution of the Hamilton Jacobi Equation and  $d_xu$  and  $\dot{\gamma}$  are related by the Legendre transformation of L.

### Proof of the Graph Property:

We need the following lemma due to Mather, a proof of which can be found in [\[9\]](#page-12-0).

<span id="page-8-0"></span>15. Lemma. Given  $A > 0$  there exists  $K > 0 \varepsilon_1 > 0$  and  $\delta > 0$  with the following property: if  $|v_i| < A$ ,  $(p_i, v_i, [t_i]) \in TM \times \mathbb{S}^1$ ,  $i = 1, 2$  satisfy  $d((p_1, [t_1]), (p_2, [t_2])) < \delta$ and  $d((p_1, v_1, [t_1]), (p_2, v_2, [t_2])) \geq K^{-1}d((p_1, [t_1]), (p_2, [t_2]))$  then, if  $a \in \mathbb{R}$  and  $x_i$ :  $\mathbb{R} \to M$ ,  $i = 1, 2$ , are the solutions of  $\tilde{L}$  with  $x_i(t_i) = p_i$ ,  $\dot{x}_i(p_i) = v_i$ , there exist solutions  $\gamma_i : [t_i - \varepsilon, t_i + \varepsilon] \to M$  of L with  $0 < \varepsilon < \varepsilon_1$ , satisfying

$$
\gamma_1(t_1 - \varepsilon) = x_1(t_1 - \varepsilon) , \quad \gamma_1(t_2 + \varepsilon) = x_2(t_2 + \varepsilon) ,
$$
  
\n
$$
\gamma_2(t_2 - \varepsilon) = x_2(t_2 - \varepsilon) , \quad \gamma_2(t_1 + \varepsilon) = x_1(t_1 + \varepsilon) ,
$$
  
\n
$$
S_L(x_1|_{[t_1 - \varepsilon, t_2 + \varepsilon]}) + S_L(x_2|_{[t_2 - \varepsilon, t_1 + \varepsilon]}) > S_L(\gamma_1) + S_L(\gamma_2)
$$

We now prove the graph property. Let  $(p_1, v_1, [t_1])$ ,  $(p_2, v_2, [t_2]) \in \Gamma^+(u)$  and suppose that  $K d((v_1, [t_1]), (v_2, [t_2])) > d((p_1, [t_1]), (p_2, [t_2]))$ , where K is from lemma [15](#page-8-0) and the A that we input on lemma [15](#page-8-0) is from lemma [8.](#page-4-0) Let  $y_i^+ = x_i(t_i + \varepsilon)$ ,  $i = 1, 2$ , and  $y_i^- = x_i(t_i - \varepsilon)$  for  $\varepsilon$  small, then

<span id="page-8-1"></span>(9) 
$$
u(y_1^+, [t_1 + \varepsilon]) - u(y_1^-, [t_1 - \varepsilon]) = \Phi_c((y_1^-, [t_1 - \varepsilon]), (y_1^+, [t_1 + \varepsilon]))
$$

<span id="page-8-2"></span>(10) 
$$
u(y_2^+, [t_2 + \varepsilon]) - u(y_2^-, [t_2 - \varepsilon]) = \Phi_c((y_2^-, [t_2 - \varepsilon]), (y_2^+, [t_2 + \varepsilon]))
$$

 $\Box$ 

Then using that  $u \prec L + c$  and lemma [15](#page-8-0), we get that

$$
(11) \quad u(y_2^+, [t_2 + \varepsilon]) - u(y_1^-, [t_1 - \varepsilon]) + u(y_1^+, [t_1 + \varepsilon]) - u(y_2^-, [t_2 - \varepsilon])
$$
  
\n
$$
\leq S_{L+c}(\gamma_1) + S_{L+c}(\gamma_2)
$$
  
\n
$$
< S_{L+c}(x_1|_{[t_1-\varepsilon,t_2+\varepsilon]} + S_{L+c}(x_2|_{[t_2-\varepsilon,t_1+\varepsilon]})
$$
  
\n
$$
= \Phi_c((y_1^-, [t_1 - \varepsilon]), (y_1^+, [t_1 + \varepsilon]) + \Phi_c((y_2^-, [t_2 - \varepsilon]), (y_2^+, [t_2 + \varepsilon]).
$$

Which is a contradiction with the sum of [\(9\)](#page-8-1) and [\(10\)](#page-8-2).

$$
\qquad \qquad \Box
$$

 $\Box$ 

### Proof of item 3:

Let  $(x,[s])$  in  $\pi\Gamma^+(u)$ , let  $(\sigma(\tau), [\alpha(\tau)])$  be a curve on  $M\times\mathbb{S}^1$  with  $\sigma(0)=x,\alpha(0)=0$ s. Let  $\gamma_s$  be the curve such that

$$
u(\gamma_s(t),[t]) - u(\gamma_s(s-\delta),[s-\delta]) = A_{L+c}(\gamma_s|_{[s-\delta,t]}).
$$

Since  $(x,[s])$  is in  $\pi\Gamma^+(u)$  we can make a backwards variation  $(\gamma_{\tau})$  of the solution  $\gamma_s$ . That is,  $\gamma_\tau : [s - \delta, \alpha(\tau)] \to M$  is a solutions of the Euler -Lagrange equation joining the points  $p = \gamma_s(s - \delta)$  and  $\sigma(\tau)$ .

Since  $u$  is dominated we have

$$
u(\sigma(\tau), [\alpha(\tau)]) - u(x, [s]) = u(\sigma(\tau), [\alpha(\tau)]) - u(p, [s - \delta]) - (u(x, [s]) - u(p, [s - \delta]))
$$
  
\n
$$
\leq A_{L+c}(\gamma_{\tau}|_{[s-\delta,\alpha(\tau)]}) - A_{L+c}(\gamma_{s}|_{[s-\delta,s]})
$$
  
\n
$$
= A_{L+c}(\gamma_{\tau}|_{[s-\delta,s]}) - A_{L+c}(\gamma_{s}|_{[s-\delta,s]}) + A_{L+c}(\gamma_{\tau}|_{[s,\alpha(\tau)]})
$$

Dividing by  $\tau - s$  and taking limits as  $\tau$  tends to s and using the fact that  $\gamma_{\tau}$  is a solution of the Euler-Lagrange equation, we obtain

$$
\limsup_{\tau \to s} \frac{u(\sigma(\tau), [\alpha(\tau)]) - u(x, [s])}{\tau - s} \le L_v(\dot{\gamma}_s, s) \cdot \sigma'(0) + L + c(\dot{\gamma}_s, s) \alpha'(0)
$$

Similarly we can make a forward variation to get

$$
\liminf_{\tau \to s} \frac{u(\sigma(\tau), [\alpha(\tau)]) - u(x, [s])}{\tau - s} \ge L_v(\dot{\gamma}_s, s) \cdot \sigma'(0) + L + c(\dot{\gamma}_s, s)\alpha'(0)
$$

# Proof of theorem [7:](#page-4-2)

Let  $u \in \mathcal{S}^-$ , since u is dominated, then

(12) 
$$
u(x, [t]) \leq \min_{(y, [r])} u(y, [r]) + \Phi_c((y, [r]), (x, [t])).
$$

Let  $\gamma : ] - \infty, t] \to M$  be such that for all  $s \leq t$ ,

<span id="page-9-0"></span>
$$
u(x, [t]) - u(\gamma(s), [s]) = A_{L+c}(\gamma|_{[s,t]}).
$$

#### WEAK SOLUTIONS 11

Then  $\gamma(s)$  is semistatic and the minimum in [\(12\)](#page-9-0) is realized at every point  $(\gamma(s), [s])$ with  $s < t$ . Choose a convergent sequence  $(\gamma(s_n), [s_n]) \to (p, [\tau]) \in M \times \mathbb{S}^1$ , with  $s_n \to -\infty$ . Then by lemma [16](#page-10-0) below,  $(p, \lceil \tau \rceil)$  is in the Pierls set. Therefore, using the continuity of  $\Phi_c$  at  $(p, [\tau])$  (see lemma [17](#page-11-0) below) and [\(12\)](#page-9-0), we have that

<span id="page-10-1"></span>(13) 
$$
u(x, [t]) = u(p, [\tau]) + \Phi_c((p, [\tau]), (x, [t])) = \min_{(q, [\sigma]) \in \mathcal{A}} u(q, [\sigma]) + \Phi_c((q, [\sigma]), (x, [t])).
$$

We show now that it is enough to choose one point on each static class to achieve the minimum on [\(13\)](#page-10-1). Suppose that  $(p, \lceil \tau \rceil)$  and  $(q, \lceil \sigma \rceil)$  are in the same static class. Then

$$
\Phi_c((q, [\sigma]), (x, [t])) \leq \Phi_c((q, [\sigma]), (p, [\tau])) + \Phi_c((p, [\tau]), (x, [t]))
$$
  
\n
$$
\leq \Phi_c((q, [\sigma]), (p, [\tau])) + \Phi_c((p, [\tau]), (q, [\sigma])) + \Phi_c((q, [\sigma]), (x, [t]))
$$
  
\n
$$
= \Phi_c((q, [\sigma]), (x, [t]))
$$

So that  $\Phi_c((q,[\sigma]),(x,[t])) = \Phi_c((q,[\sigma]),(p,[\tau])) + \Phi_c((p,[\tau]),(x,[t]))$ . Moreover,

$$
u(p, [\tau]) \le u(q, [\sigma])) + \Phi_c((q, [\sigma], p, [\tau]))
$$
  
\n
$$
\le u(p, [\tau]) + \Phi_c((p, [\tau]), (q, [\sigma])) + \Phi_c((q, [\sigma]), (p, [\tau]))
$$
  
\n
$$
= u(p, [\tau]).
$$

So that  $u(q, [\sigma]) + \Phi_c((q, [\sigma]), (p, [\tau])) = u(p, [\tau])$ . Thus  $u(q, [\sigma]) + \Phi_c((q, [\sigma]),(x, [t])) = u(q, [\sigma]) + \Phi_c((q, [\sigma]),(p, [\tau])) + \Phi_c((p, [\tau]),(x, [t]))$  $= u(p, [\tau]) + \Phi_c((p, [\tau]),(x, [t])).$ 

So that  $u = u_f$ , with  $f = u|_{\mathbb{A}}$ .

Observe that by definition, if  $f : \mathbb{A} \to \mathbb{R}$  is dominated, then  $u_f |_{\mathbb{A}} \equiv f$ . This implies that the map  $\{f \text{ dominated}\}\mapsto u_f$  is injective.

Finally, it remains to prove that if  $f : \mathbb{A} \to \mathbb{R}$  then  $u_f \in \mathcal{S}^-$ . This follows from lemma [9](#page-4-1) and lemma [18](#page-12-5) below.

<span id="page-10-0"></span>16. Lemma. If  $\gamma$  :  $]-\infty, t_0] \rightarrow M$  is semistatic and  $s_n \rightarrow -\infty$  is such that  $\lim_{n} (\gamma(s_n), [s_n]) = (p, [\tau])$  exists. Then  $(p, [\tau])$  is in the Aubry set.

**Proof:** Let  $\varepsilon > 0$  be small. Chose  $n_0 > 0$  such that for  $n > n_0$ , we have

$$
|s_n-\tau \mod 1| < \tfrac{\varepsilon}{2} \qquad , \qquad d(\gamma(s_n),p) < \tfrac{\varepsilon}{2}.
$$

Let  $\lambda_n^- : [\tau, s_n + \varepsilon \mod 1] \to M$  be a minimizer with  $\lambda_n^-(\tau) = p$ ,  $\lambda_n^-(s_n + \varepsilon \mod 1) =$  $\gamma(s_n + \varepsilon)$ . By lemma [8,](#page-4-0)  $\|\dot{\gamma}\|$  is uniformly bounded. By the same argument, using the first variation formula, as in proposition [2.](#page-2-0)c,

$$
A_{L+c}(\lambda_n^-) \le K_1 \left[ d(\gamma(s_n), p) + |s_n + \varepsilon - \tau \mod 1| \right] \le 3 \varepsilon K_1.
$$

Let  $\lambda_n^+$ :  $[s_n - \varepsilon \mod 1, \tau] \to M$  be a minimizer with  $\lambda_n^+(s_n - \varepsilon) = \gamma(s_n - \varepsilon)$ ,  $\lambda_n^+(\tau) = p$ . Similarly,

$$
A_{L+c}(\lambda_n^+) \le 3 \varepsilon K_1.
$$

We have that

<span id="page-11-2"></span>
$$
h_c((p, [\tau]), (p, [\tau])) \leq \liminf_{N \to \infty} A_{L+c}(\lambda_N^-) + A_{L+c}(\gamma|_{[s_N + \varepsilon, s_n - \varepsilon]}) + A_{L+c}(\lambda_n^+)
$$
  
(14)  

$$
\leq 6 \varepsilon K_1 + \liminf_{N} A_{L+c}(\gamma|_{[s_N + \varepsilon, s_n - \varepsilon]})
$$
.

Adding the action of  $\gamma$  on the intervals with endpoints  $s_N - \varepsilon < s_N + \varepsilon < s_n - \varepsilon <$  $s_n + \varepsilon$  and using that  $\gamma$  is semistatic on  $[s_N - \varepsilon, s_n + \varepsilon]$ , we have that

<span id="page-11-1"></span>(15)  
\n
$$
A_{L+c}(\gamma|_{[s_N+\varepsilon,s_n-\varepsilon]}) = \Phi_c((\gamma(s_N-\varepsilon),s_N-\varepsilon), (\gamma(s_n+\varepsilon),s_n+\varepsilon)) - A_{L+c}(\gamma|_{[s_N-\varepsilon,s_N+\varepsilon]}) - A_{L+c}(\gamma|_{[s_n-\varepsilon,s_n+\varepsilon]}).
$$

Comparing  $\Phi_c$  with the action of a minimal length geodesic, parameterized by the small interval  $I = [s_N - \varepsilon \mod 1, s_n + \varepsilon \mod 1]$  of length  $\varepsilon \leq \ell(I) \leq 3\varepsilon$ , with

$$
\text{speed} \leq \frac{1}{\varepsilon} d(\gamma(s_N - \varepsilon), \gamma(s_n + \varepsilon)) \leq \frac{1}{\varepsilon} \left[ \varepsilon \, \|\dot{\gamma}\| + d(\gamma(s_N), \gamma(s_n)) + \varepsilon \, \|\dot{\gamma}\| \, \right]
$$
\n
$$
\leq 2 \, \|\dot{\gamma}\| + 1;
$$

we have that

$$
\Phi_c((\gamma(s_N-\varepsilon),s_N-\varepsilon),(\gamma(s_n+\varepsilon),s_n+\varepsilon))\leq \ell(I)\left[\max_{|v|\leq 2\|\dot{\gamma}\|+1}L+c\right]\leq 3\,\varepsilon\,K_2.
$$

The two actions in [\(15\)](#page-11-1) are bounded by  $2(2\varepsilon \cdot K_2)$ . Thus, from (15),

$$
A_{L+c}(\gamma|_{[s_N+\varepsilon,s_n-\varepsilon]}) \le 7 \varepsilon K_2.
$$

From [\(14\)](#page-11-2),

$$
0 \le h_c\big((p,[\tau]),(p,[\tau])\big) \le 6\,\varepsilon\,K_1 + 7\,\varepsilon\,K_2.
$$

Now let  $\varepsilon \to 0$ .

<span id="page-11-0"></span>17. Lemma. If 
$$
\lim_{n} (y_n, [s_n]) = (p, [\tau]) \in A
$$
 then for all  $(x, [t]) \in M \times \mathbb{S}^1$ ,  
 $\lim_{n} \Phi_c((y_n, [s_n]), (x, [t])) = \Phi_c((p, [\tau]), (x, [t])) = h_c((p, [\tau]), (x, [t]))$ .

**Proof:** Recall that by remark [6,](#page-4-3)  $h_c((p, [\tau]),(x,[t])) = \Phi_c((p, [\tau]),(x,[t]))$ . By item 4 of proposition [2,](#page-2-0)

<span id="page-11-3"></span>
$$
\Phi_c((p, [\tau]), (x, [t])) = h_c((p, [\tau]), (x, [t]))
$$
\n
$$
\leq h_c((p, [\tau]), (y_n, [s_n])) + \Phi_c((y_n, [s_n]), (x, [t]))
$$
\n
$$
\leq h_c((p, [\tau]), (y_n, [s_n])) + h_c((y_n, [s_n]), (x, [t]))
$$
\n
$$
(17) \leq h_c((p, [\tau]), (y_n, [s_n])) + h_c((y_n, [s_n]), (p, [\tau])) + \Phi_c((p, [\tau]), (x, [t]))
$$

<span id="page-11-4"></span>Using that  $h_c$  is continuous, taking  $\lim_{n \to \infty}$  on inequalities [\(16\)](#page-11-3) and [\(17\)](#page-11-4), we get that  $\lim_{n} \Phi_c((y_n, [s_n]),(x,[t])) = \Phi_c((p,[\tau]),(x,[t])).$ 

<span id="page-12-5"></span>18. Lemma.

If 
$$
U \subset S^-
$$
, let  $\mathfrak{u}(x, [t]) := \inf_{u \in U} u(x, [t])$  then either  $\mathfrak{u} \equiv -\infty$  or  $\mathfrak{u} \in S^-$ .  
If  $V \subset S^+$ , let  $\mathfrak{v}(x, [t]) := \sup_{v \in V} v(x, [t])$  then either  $\mathfrak{v} \equiv +\infty$  or  $\mathfrak{v} \in S^+$ .

**Proof:** Since  $u \lt L + c$  for all  $u \in \mathcal{U}$ , for all  $(x, [s]), (y, [t]) \in M \times \mathbb{S}^1$ ,

$$
u(y, [t]) \le u(x, [s]) + \Phi_c((x, [s]), (y, [t])), \quad \text{for all } u \in \mathcal{U},
$$
  
\n
$$
\min_{u \in \mathcal{U}} u(y, [t]) = \mathfrak{u}(y, [t]) \le u(x, [s]) + \Phi_c((x, [s]), (y, [t])), \quad \text{for all } u \in \mathcal{U},
$$
  
\n(18) 
$$
\mathfrak{u}(y, [t]) \le \mathfrak{u}(x, [s]) + \Phi_c((x, [s]), (y, [t])).
$$

<span id="page-12-6"></span>Now fix  $(x,[t]) \in M \times \mathbb{S}^1$  and fix a sequence  $u_k \in \mathcal{U}$  such that  $\mathfrak{u}(x,[t]) =$  $\lim_k u_k(x,[t])$ . Let  $(x,v_k,[t]) \in \Gamma^-(u_k)$ . By lemma [8,](#page-4-0)  $||v_k||$  is uniformly bounded. We can assume that  $v_k \to w$ . Let  $\gamma_{v_k}(s) := \pi \varphi_{s-t}(x, v_k, t)$  and  $\gamma_w(s) := \pi \varphi_{s-t}(x, w, t)$ . Then

$$
u_k(x,t) = u_k(\gamma_{v_k}(s), [s]) + A_{L+c}(\gamma_{v_k}|_{[s,t]}), \quad \text{for all } s < t,
$$

Since  $\gamma_{v_k} \stackrel{C^1}{\longrightarrow} \gamma_w$  uniformly on bounded intervals, using that by lemma [10](#page-5-2) all the  $u_k$ 's have the same Lipschitz constant, taking the lim inf on k we get that

<span id="page-12-7"></span>(19) 
$$
\mathfrak{u}(x,t) \ge \mathfrak{u}(\gamma_w(s),[s]) + A_{L+c}(\gamma_w|_{[s,t]}), \qquad \text{for all } s < t,
$$

The domination condition [\(18\)](#page-12-6) implies that [\(19\)](#page-12-7) is an equality.  $\square$
