Abstract

Plasmodium falciparum 70 kDa heat shock proteins (PfHsp70s) are expressed at all stages of the pathogenic erythrocytic phase of the malaria parasite lifecycle. There are six PfHsp70s, all of which have orthologues in other plasmodial species, except for PfHsp70-x which is unique to *P. falciparum*. This paper highlights a number of original results obtained by a detailed bioinformatics analysis of the protein. Large scale sequence analysis indicated the presence of an extended transit peptide sequence of PfHsp70-x which potentially directs it to the endoplasmic reticulum (ER). Further analysis showed that PfHsp70-x does not have an ER-retention sequence, suggesting that the protein transits through the ER and is secreted into the parasitophorous vacuole (PV) or beyond into the erythrocyte cytosol. These results are consistent with experimental findings. Next, possible interactions between PfHsp70-x and exported *P. falciparum* Hsp40s or host erythrocyte DnaJs were interrogated by modeling and docking. Docking results indicated that interaction between PfHsp70-x and each of the Hsp40s, regardless of biological feasibility, seems equally likely. This suggests that J domain might not provide the specificity in the formation of unique Hsp70-Hsp40 complexes, but that the specificity might be provided by other domains of Hsp40s. By studying different structural conformations of PfHsp70-x, it was shown that Hsp40s can only bind when PfHsp70-x is in a certain conformation. Additionally, this work highlighted the possible dependence of the substrate binding domain residues on the orientation of the α -helical lid for formation of the substrate binding pocket.

Keywords

Plasmodium; J domain; Hsp70-Hsp40 complex; homology modeling; protein-protein docking

Introduction

Recent efforts at combating malaria have led to the number of annual deaths caused by this disease finally falling below the one million mark (Campbell & Steketee, 2011). Yet, the control of malaria is limited by resistance of the parasite to available drugs; thus there is continuous research to identify new drug targets and validate potential antimalarial compounds. Recently, heat shock proteins (Hsps) have received much attention as potential drug targets (Akide-Ndunge *et al.*, 2009; Banumathy, Singh, Pavithra, & Tatu, 2003; Chiang *et al.*, 2009; Kumar, Musiyenko, & Barik, 2003; Ramya, Surolia, & Surolia, 2006; Shonhai, 2010). There is evidence that despite the high levels of conservation, Hsps from the same family have sufficient structural and functional differences to be selectively targeted (Pesce, Cockburn, Goble, Stephens, & Blatch, 2010). Furthermore, highly conserved Hsps are often essential for cell survival, and therefore likely to evolve relatively slowly, making them less susceptible to variation under selection pressure. It is these features that make Hsps such as the 70 kDa family (Hsp70) attractive drug targets.

The most virulent malaria parasite, *Plasmodium falciparum* (*P. falciparum*), has six Hsp70 (PfHsp70) proteins, three of which are believed to be localised in the cytosol (PfHsp70-1), in the endoplasmic reticulum (PfHsp70-2) and in the mitochondria (PfHsp70-3) of the parasite (Sargeant *et al.*, 2006). In 2012, PfHsp70-x, a second cytosolic protein, was shown to be exported to the host erythrocyte cytosol (Külzer *et al.*, 2012). Phylogenetic analysis of PfHsp70-y and PfHsp70-z, believed to localise in the ER and cytosol, respectively, revealed them to be closely related to Hsp110s of other organisms (Shonhai, Boshoff, & Blatch, 2007). Recently, Muralidharan, Oksman, Pal, Lindquist, and Goldberg (2012) characterised PfHsp70-z (named PfHsp110c), showing its role in suppressing protein aggregation during heat stress. Furthermore, knock-down of the PfHsp70-z gene left the parasite unable to survive at high temperatures, making this protein an attractive drug target. PfHsp70-1 has

been biochemically characterised and is mainly localised in the cytosol and nucleus of the parasite. It has been shown to display chaperone functions, in both *in vitro* and *in vivo* assays (Matambo, Odunuga, Boshoff, & Blatch, 2004; Shonhai, Boshoff, & Blatch, 2005; Shonhai, Botha, de Beer, Boshoff, & Blatch, 2008). PfHsp70-1 is a ubiquitous, highly abundant protein, expressed at all stages of the erythrocytic phase of the parasite's lifecycle (Shonhai *et al.*, 2007). PfHsp70-1 has been considered as a potential drug target, and small molecule inhibitors specific for PfHsp70-1 have recently been identified (Cockburn *et al.*, 2011).

PfHsp70-x, with 74% sequence identity to PfHsp70-1, was first detected in 1989 (Kun & Muller-Hill, 1989), as a clone which reacted positively to sera from malaria immune patients during immunological screening. Yet, the expression of the protein was only confirmed in 2009 (Acharya *et al.*, 2009). The findings suggested that the expression of PfHsp70-x is linked to the pathogenic stages of the parasite's life cycle, as it had never been detected in laboratory strains. Recently, PfHsp70-x was shown to be partly exported to the host erythrocyte, and partly present in the parasitophorous vacuole (PV) (Külzer *et al.*, 2012), the parasite's membrane bound compartment, which is an important passageway to transport parasite encoded proteins into the host erythrocyte (Lingelbach & Joiner, 1998). It was reported that there are 49 PfHsp40s encoded on the *P. falciparum* genome, of which 18 are predicted to be exported into the erythrocyte (Njunge, Ludewig, Boshoff, Pesce, & Blatch, 2013). Two of the PfHsp40s, PfA and PfE, (PFA0660w and PFE0055c respectively) shown to be exported (Külzer *et al.*, 2010), have also been found to occur in a common complex with PfHsp70-x (Külzer *et al.*, 2012). Generally, the function of Hsp70 is largely linked to its ability to bind and release peptide substrates in an ATP-dependent cycle with help of Hsp40s and nucleotide exchange factors (NEFs) (Dragovic, Broadley, Shomura, Bracher, & Hartl, 2006; Harrison, Hayer-hartl, Liberto, Hartl, & Kuriyan, 1997; Hartl & Hayer-Hartl, 2002; Mayer & Bukau, 2005).

Hsp70s are structurally divided into two major domains: the 45 kDa N-terminal ATPase domain, which regulates the 25 kDa C-terminal substrate binding domain (SBD). The SBD is further sub-divided into a β -domain, containing the substrate binding pocket, and an α -helical lid, located closest to the C-terminus of the protein (Strub, Zufall, & Voos, 2003; Wang, Chang, & Wang, 1993). The SBD and the ATPase domain are joined by a flexible linker region, believed to facilitate inter-domain communication which has been found to be essential to Hsp70 function (Han & Christen, 2001).

At the interface of host - parasite interaction, PfHsp70-x has an important role, yet it is by far the less well-studied of the two cytosolic PfHsp70s, and therefore, it is important to analyse PfHsp70-x in detail. The interest of this paper is to investigate whether PfHsp70-x is a potential drug target by performing a detailed comparative bioinformatics analysis. The study was divided into two parts: 1) *Large scale sequence analysis*: PfHsp70-x was compared with other Hsp70s of *Plasmodium*, Apicomplexa and eukaryotes. To overcome the limitations of handling large data, we proceeded with an unconventional method of using consensus sequences, to simplify the alignments and make it easier to compare different groupings of sequences, as well as identify highly conserved sites. The investigation included sequence features of PfHsp70-x that are predicted to be involved in the interaction with associated proteins and peptide substrates during the ATPase cycle. 2) *Structural analysis*: PfHsp70-x was modeled with J domains of potential *Plasmodium* and human Hsp40 (PfHsp40 and HsHsp40 respectively) co-chaperons. Docking studies were also performed and compared to the homology models. Both aimed at an attempt to better understand the interactions that would aid with targeting the complexes towards anti-malarial drug design. To the authors' knowledge, docking and modeling studies for PfHsp70-x-J-domain complex calculations were not done previously. Further, PfHsp70-x was modeled in three different conformations representing different stages of ATPase cycle to understand the conformational dynamics of

the protein. A number of novel results were obtained, including analysis of the Hsp70-Hsp40 complexes in the dynamics of ATPase cycle, for the first time.

Methodology

Data Retrieval

The sequences of PfHsp70-1, PfHsp70-x, PfHsp70-2 and PfHsp70-3 (accession numbers: PF08_0054, MAL7P1.228, PFI0875w and PF11_0351 respectively) were retrieved from PlasmoDB (The Plasmodium Genome Database Collaborative, 2001). Using PfHsp70-1 and PfHsp70-x, PfHsp70-2 and PfHsp70-3, cytosolic (C-Hsp70), the endoplasmic reticulum (ER-Hsp70) and the mitochondrial (Mt-Hsp70) Hsp70s were searched respectively by NCBI-BLAST (Altschul *et al.*, 1997). An additional 89 sequences were retrieved, making up prokaryotic, eukaryotic, apicomplexan and plasmodial groups, for each type of Hsp70 (see S1). Sequence analyses included 13 eukaryote (non-apicomplexan), 9 apicomplexan (non-plasmodial) and 4 plasmodial (non-*falciparum*) C-Hsp70s; 12 eukaryote (non-apicomplexan), 6 apicomplexan (non-plasmodial), 4 plasmodial (non-*falciparum*) ER-Hsp70s; 15 eukaryote (non-apicomplexan), 8 apicomplexan (non-plasmodial), 3 *Plasmodium* (non-*falciparum*) Mt-Hsp70s as well as 15 prokaryote.

Large Scale Sequence Analysis

Sequence alignments were done using MAFFT (Kato, Misawa, Kuma, & Miyata, 2002) and PROMALS3D (Pei, Kim, & Grishin, 2008). Alignments were performed using representative sequences from eukaryotes, Apicomplexa and *Plasmodium*, for each type of Hsp70. The results of the two alignment programs were compared. In both cases, residues were aligned identically, except highly un-conserved N-terminal and C-terminal regions (see S2). To be able to visualize and analyse the alignment results easily, consensus sequences were calculated. The sets of sequence alignments for Hsp70s from which the consensus sequences are calculated are given in S3A-S3J. The consensus sequences were then re-aligned for each type of Hsp70 with representatives of that Hsp70 type from *P. falciparum*. Alignments were

visualised using BioEdit (Hall, 1999). Identity calculations were performed for all possible sequence pairs in each alignment. The lowest sequence identity pair for each alignment was then recorded (Table 1). All the large scale calculations were done by Python scripting (van Rossum & de Boer, 1991).

Homology Modeling

Homology modeling was performed for **a)** PfHsp70-x in three different conformations using three different templates (PDB IDs: 1YUW, 2KHO and 3D2F), identified using HHpred (Söding, 2005) **b)** The J domains of nine different Hsp40 co-chaperons, which included three Type II PfHsp40s (PF3D7_0113700/PFA0660w, PF3D7_0201800/PFB0090c and PF3D7_0501100.1/PFE0055c, denoted as PfA, PfB and PfE, respectively), two Type I human Hsp40s (HsDnaJA1 and HsDnaJA2), two Type II human Hsp40s (HsDnaJB1 and HsDnaJB4) and two Type III human Hsp40s (HsDnaJC5 and HsDnaJC13). Templates with the following PDB IDs were used for modeling: PfA - 1HDJ, PfB - 2CTR, PfE - 2CTP, HsDnaJA1 - 2O37, HsDnaJA2 - 1HDJ, HsDnaJB1 – 1HDJ, HsDnaJB4 – 1HDJ, HsDnaJC5 – 2CTW and HsDnaJC13 – 2CTW.

Alignments of template sequences to target sequences were done using PROMALS3D (Pei *et al.*, 2008). The alignment results for PfHsp70-x modeling were compared to the results of the large scale alignment, to make sure that they are accurate and if necessary, hand adjustments were made. Modeling was performed using MODELLER 9v7 (Sali & Blundell, 1993), with slow refinement. For each protein, 100 models were built. The best three models were selected by DOPE Z score calculations. These models were further evaluated using MetaMQAPII (Pawlowski, Gajda, Matlak, & Bujnicki, 2008). Final evaluations were performed using MetaMQAPII, Verify3D (Bowie, Luthy, & Eisenberg, 1991) and ProSA (Sippl, 1993; Wiederstein & Sippl, 2007). Model quality assessment results are presented in S4.

Calculation of Protein Complexes

Hsp70-x-Hsp40 protein complexes were calculated by two different approaches; homology modeling and docking. For homology modeling, a hybrid modeling approach was used (Tastan Bishop & Kroon, 2011). Due to the low sequence identity between auxilin and the different Hsp40s being studied, a set of hybrid templates were created for modeling the Hsp70-Hsp40 complexes. First, each Hsp40 J domain was modeled separately as monomers, as described above. Each J domain was then superimposed with auxilin of template structure (PDB ID 2QWO) to replace auxillin, using PyMOL (Schrödinger, LLC). These hybrid structures were used as templates for modeling PfHsp70-x and each J protein complexes, as described above. The resulting models underwent residue repacking and were then put through 100 cycles of energy minimisation, both done using PyRosetta (Chaudhury, Lyskov, & Gray, 2010).

For molecular docking studies, the HADDOCK web server was used (de Vries, van Dijk, & Bonvin, 2010). Each J domain model was submitted, along with PfHsp70-x, to the program. Residues actively involved in binding were set as those forming the HPD motif of each J protein and residues R201, N204, T207, I246 and V419 of PfHsp70-x. No passive residues were set for each docking run. The best docked structures were ranked by HADDOCK score, the weighted sum of the van der Waals energy, electrostatic energy, desolvation energy, the energy from restraint violations and the buried surface area.

Identification of Important Residues

Important residues were identified from large scale sequence analysis, as well as biochemical data from literature. The Protein Interactions Calculator (PIC) webserver (Tina, Bhadra, & Srinivasan, 2007) was used to identify residue interactions in each protein complex. Default settings were used when submitting models to the PIC server.

Further, SBD residues in contact with α -helical lid of PfHsp70-x, modeled after template 1YUW, were also identified as follows: The SBD and α -helical lid of this PfHsp70-x model were saved to a PDB file as two separate molecules, using PyMOL. Thereafter, a python script was run, which gave each molecule a different chain identifier. This PDB file was then submitted to the PIC webserver as mentioned above in order to identify interactions between the two sub-domains. These contact residues of the SBD were then compared to those in *E. coli* DnaK, that Zhu *et al.* (1996) identified as interacting with the substrate during peptide binding.

Results and Discussion

PfHsp70-x is Atypical of Cytosolic Hsp70s

The initial part of the study was focused on large scale sequence analysis. The use of consensus sequences derived from large scale sequence alignments was found to be very useful for comparing the conservation of sequence features in different groups of related proteins. It also made it easy to identify sequence features of a protein that were distinct from features of other proteins that are supposedly related. PfHsp70-x and PfHsp70-1 were aligned with three consensus sequences of plasmodial, apicomplexan, and eukaryotic C-Hsp70s. Also included in this alignment was a consensus sequence of bacterial and archael DnaKs (Figure 1).

An initial notable feature in this alignment is that PfHsp70-x contains an extended N-terminal region that is 18 residues longer than any other C-Hsp70. An extended N-terminus is indicative of a transit peptide, which targets proteins to specific organelles (Patron & Waller, 2007). This is unusual, as C-Hsp70s usually do not have an N-terminal transit peptide sequence (Renner & Waters, 2007). It can also be seen that the *Plasmodium* consensus sequence contains a highly conserved, extended N-terminal region (Figure 1). This sequence differs to that of the PfHsp70-x. The signal peptide sequence responsible for targeting proteins to the ER has been described by von Heijne (1990) as having the following characteristics. Firstly, a positively-charged N-terminal region of up to five residues in length, followed by a hydrophobic patch of up to 15 residues in length, ending off with a more polar set of residues. PfHsp70-x contains two positively-charged residues (Lys2 and Lys4) within the first five residues of its sequence. This is followed by an unusual stretch of polar residues (Cys6, Ser7, Tyr8, His10 and Tyr11) before a stretch of eight hydrophobic residues. This region ends with 12 of the next 15 residues being polar. An alignment of

PfHsp70-x with the transit peptides described by Renner & Waters (2007), as well as two known ER-Hsp70s (human Grp78 and PfHsp70-2) (see S5), indicates that this region of PfHsp70-x has a similar distribution of amino acids to the transit peptides of these ER-Hsp70s. This indicates that the extended N-terminus of PfHsp70-x potentially directs it to the ER. Recent experimental data has confirmed that the first 24 residues of PfHsp70-x play a role as an ER-type signal sequence allowing secretion into the PV (Külzer *et al.*, 2012). The subsequent eight residues are for secretion into host cell cytosol. Although it is indicated as a unique sequence in the paper, the large scale sequence analysis showed that 3 residues (Asn28, Glu31, Ser32) of this octameric export signal is conserved among *Plasmodium* species and further residue Ala25 conserved between *P. falciparum* and *P. knowlesi* (S2-S3). Furthermore, the fact that PfHsp70-x does not have an ER-retention sequence (e.g. the SDEL found at the C-terminus of PfHsp70-2/PfBiP), is consistent with findings that suggest it transits through the ER and is secreted into the PV or beyond into the erythrocyte cytosol.

In Figure 1, the residues highlighted in dark blue indicate those found only in PfHsp70-x at their given positions. PfHsp70-x contains 123 (18%) of these residues. PfHsp70-1, by comparison, only contains 14 (2%) (highlighted in red). PfHsp70-x also contains 32 (5%) residues that are conserved in eukaryotic, but not found in other plasmodial sequences (highlighted in yellow). PfHsp70-1 contains 2 (0.3%) of such residues. The C-terminal region of the C-Hsp70s has an unconserved, glycine-rich region, often containing at least one GGMP motif. A GGMP repeat is rare in non-parasitic Hsp70s (Matambo *et al.*, 2004; Wiser, Jennings, Lockyer, van Belkum, & van Doorn, 1995) and occurred at most once in the eukaryotic C-Hsp70s considered in this research. In the apicomplexan C-Hsp70s considered, there were several repeats of this motif, most prominent in plasmodial sequences. In PfHsp70-x, however, this region is not glycine-rich and does not contain any GGMP motifs. There is a stretch of 24 residues in the C-terminal region that share no resemblance to any of

the other cytosolic proteins. Another interesting feature of PfHsp70-x is the carboxy-terminal EEVN motif, which differs to the EEVD motif, characteristic of cytosolic eukaryotic Hsp70s (Shonhai *et al.*, 2007).

Although PfHsp70-x appears to be cytosolic-like, these differences as described above indicate that it may have functions that differ to other C-Hsp70s. Thus, the analysis was extended to include all ER and Mt sequences (see S6). An indication of the level of conservation between the sequences aligned is given in Table 1, which reports the lowest sequence identity pair for each alignment. Across all alignments, each sequence was at least 50% identical to every other that was studied. The N-terminal extension of PfHsp70-x is approximately the same length as the transit peptides found in the ER-Hsp70 sequences analysed. PfHsp70-x was found to be more similar to C-Hsp70s than both ER-Hsp70s and Mt-Hsp70s. Based on the alignment, it seems that PfHsp70-x is likely to be cytosolic in origin, but is not under the same evolutionary constraints as other C-Hsp70s.

PfHsp70-x Displays Similar Interactions with Human and Parasitic Hsp40s

Hsp70-Hsp40 protein complexes have been investigated as potential drug targets in various diseases including malaria (Shonhai, 2010). There has been recent evidence which indicates that PfHsp70-x localises with PfA and PfE in structures called J dots, found within the host cytosol (Külzer *et al.*, 2012). Additionally, PfB is predicted to be exported from the parasite (Botha, Pesce, & Blatch, 2007). In this paper, the interaction of PfHsp70-x with these three Type II *P. falciparum* Hsp40 co-chaperones, as well as two of each Type I, Type II and Type III host Hsp40s, was investigated at a structural level using protein complexes, calculated through homology modeling and structural optimisation. The two host Type II Hsp40s (HsDnaJB1 and HsDnaJB4) and Type III Hsp40s (HsDnaJC5 and HsDnaJC13) have both been found to be expressed within the erythrocyte (Pasini *et al.*, 2006; van Gestel *et al.*, 2010). HsDnaJA1 and HsDnaJA2 form a type of negative control, since there is no record of

these proteins being expressed in the erythrocyte cytosol. Although, the absence of these proteins from the erythrocyte cytosol does not necessarily mean they are incapable of interacting with PfHsp70-x. Due to the low sequence identity between the auxilin J domain of the template structure, 2QWO, a set of hybrid templates were made to model each complex as explained in the methodology section. The structures were then optimised using PyRosetta, before interactions were analysed. Figure 2 shows the modeled interaction interface between PfHsp70-x and a J domain, and how the interactions of the nine sets of J domain proteins differed in the way they potentially interact with PfHsp70-x. A number of consistent interactions were observed (see S7). L411 of PfHsp70-x formed hydrophobic interactions with P12, part of the HPD motif (refer to Figure 2C, S7B and S8), in all the J domains studied. Residues L200 and R201 of PfHsp70-x formed hydrogen bonds, mainly with D13 in most proteins and residues A418 and V419 of PfHsp70-x commonly formed hydrogen bonds with K29 of the J domain. A more detailed account of these interactions are tabulated in the supplementary data S7A and S7B. These findings are mostly consistent with Jiang *et al.* (2007), however, they had reported that L200 should interact with H11 of the J domain, which was only seen in HsDnaJC5 and HsDnaJC13. This shift could be due to the variation in residues around the HPD motif of the J domain of auxilin, when compared to *P. falciparum* and human Hsp40s. An ionic interaction was predicted to occur between K420 of PfHsp70-x and acidic residues of the J domains. This was most consistently found to occur with the residue corresponding with E25 of the *P. falciparum* Hsp40s and the immediately adjacent acidic residue of the Type I human Hsp40s, HsDnaJA1 and HSDnaJA2. This interaction did not occur for either Type III host DnaJ. Ionic interactions were also predicted between K189 and R201 of PfHsp70-x and D13 of the J domain. These predicted interactions have not been previously reported. The data suggest that PfHsp70-x is capable of interacting

with all three exported Hsp40s and the set of interactions with the human Hsp40s suggests that these may also interact with PfHsp70-x in a similar manner.

The structures solved by Jiang *et al.* (2007) were determined by cross-linking the residues equivalent to R201 of PfHsp70-x and the aspartic acid of the J domain HPD motif. This was done because work by Suh *et al.* (1998) revealed that these residues are likely to interact during J domain binding. It was mentioned, however, that it was possible that the J domain could freely rotate around this covalent bond when the structure was solved and that a non-functional orientation was calculated. As such, further analysis was conducted by docking each J domain to the ATPase domain of PfHsp70-x. The active residues given to guide the docking were those previously determined to be important to J domain binding. The results presented in Figure 3 indicate the top docking result obtained for each J protein. These reveal a number of orientations that fit the criteria of binding to R201, N204 and T207 (Suh *et al.*, 1998), as well as I246 (Jiang, Prasad, Lafer, & Sousa, 2005) of PfHsp70-x. Remarkably, in all orientations, the residue D13 of the HPD motif is positioned to interact with R201, N204 and T207 and each orientation rotates around this interaction (see S9C). All docked models had good hydrophobic and electrostatic interaction energies, determined by HADDOCK when compared to other complexes that were returned. In spite of these different orientations, the local contact areas on PfHsp70-x were fairly consistent. J domain residues which appeared to be most consistently involved in binding included those of the HPD motif, as well as R4, A7, M8, K14 and F28, indicated in Figures 3B and 3C, with all conserved interactions in the supplementary data S7C and S7D. Residues A7, M8 and F28 were common in hydrophobic interactions, mostly with I246 of PfHsp70-x. D13 formed hydrogen bonds with R201, N204 and T207 of PfHsp70-x and ionic interactions with K185 and R201. K14 was also involved in a large number of interactions, forming hydrogen bonds and ionic interactions with D216, E243, D244, E248, K20 and D421 of PfHsp70-x. H11 and P12 were

found to form hydrogen bonds with F247 and R201, respectively and R4 was found to form both hydrogen bonds and ionic interactions with the adjacent residues, E243 and D244. In addition to the HPD motif, R4 has been found to be a highly conserved (R or K) and functionally important residue in many Hsp40 proteins of prokaryotic, mammalian and parasitic origin (Berjanskii *et al.*, 2000; Genevoux, Schwager, Georgopoulos, & Kelley, 2002; Hennessy, Boshoff, & Blatch, 2005; Nicoll *et al.*, 2007).

The six host Hsp40s had a 3-6 residue truncation within their J domains when compared to auxillin and the three Type II PfHsp40s considered in this study. Residues in this small loop region did display some interactions with PfHsp70-x (Figure 2B, Figure 3B). The docked models suggest this region to be more involved in the J domain-PfHsp70-x interaction than the hybrid models do. As this region does vary quite greatly in size and composition across the different J domains studied it is possible that it contributes to the specificity of this interaction. The correct interaction orientation needs to be determined, however, before this can be further investigated. This does also make it difficult to adequately compare the different groupings of Hsp40s used in this study. Although HsDnaJA1 and HsDnaJA2 were least likely to interact with PfHsp70-x (based on type and localisation), the results indicated that these were just as capable as any other Hsp40s tested. The docking results indicated that the two Type III Hsp40s tested (HsDnaJC5 and HsDnaJC13) may not bind as well as the other Hsp40s, since these displayed the fewest interactions after the HPD motif. However, without knowledge of which interactions are important to this binding process, it is difficult to comment on the significance of this difference.

The interactions observed by docking differ substantially from those present in the hybrid models. The latter of which mostly agreed with findings by Jiang *et al.* (2007). The docking results are similar only in the point of contact between the HPD motif and PfHsp70-x. Although, the residue D13 is just buried deeper within the ATPase domain interface, which

allows interactions with N204 and T207. It is possible that this orientation was hindered by the mutation and cross-linking performed by Jiang *et al.* (2007), which may further explain the weaker J domain stimulation of BvHsc70 reported for their complex. The present work suggests an interaction interface which agrees more closely with work performed by Suh *et al.* (1998). Overall, an interaction between PfHsp70-x and each of these Hsp40s seems equally likely.

Hsp40s can only bind when PfHsp70-x is in a Certain Conformation

To get an idea of which J domain binding orientations were most accurate, the docked structures were superimposed with different conformations of PfHsp70-x, modeled based on templates 1YUW and 2KHO (Figure 4). J domain binding is supposed to regulate the interaction of the SBD and the ATPase domain of Hsp70s (Jiang *et al.*, 2007). All complex models were bound in orientations which clashed with this interaction (Figure 4B; S10A). If this is a competitive interaction, it is possible that the J domain displaces the SBD when interacting with the ATPase domain. Only three of the complex models did not interfere with the SBD of PfHsp70-x in its ADP-bound state (Figure 4C; S10B). These were models of PfHsp70-x complexed with HsDnaJA2, PfB and PfE. All three of these binding orientations involve interactions with the correct PfHsp70-x residues and do not clash with the ADP-bound form of PfHsp70-x.

Substrate Binding is Dependent on the Orientation of the α -Helical Lid, Relative to the Substrate Binding Domain

Residues involved in the formation of a substrate binding pocket were identified within PfHsp70-x, based on research done by Zhu *et al.* (1996) and Mayer *et al.* (2000). These residues are identical to those found in PfHsp70-1 and all *Plasmodium* and Apicomplexa C-Hsp70s used in this study. The only residue which differed between PfHsp70-x and the eukaryotic consensus sequence was L434, which was more commonly conserved as

isoleucine. When these residues were mapped to the 3D structures of PfHsp70-x, it was revealed that the conformation of these residues changed with the structural conformation of the protein (Figure 5). The substrate binding pocket formed only when the α -helical lid of the SBD was in contact with the β sub-domain. When the lid was orientated away from the β sub-domain, the substrate binding pocket residues disassembled and the pocket closed. Another interesting effect was that the substrate-binding pocket was found to form independent of whether the SBD and ATPase domain were in contact with each other or if they were separated. As shown in (Figure 5C), even in the absence of a peptide substrate, the α -helical lid itself is bound by the SBD. This phenomenon was also found to occur in template 1YUW, used to model PfHsp70-x in this conformation. This further indicates that the orientation of the lid is important to the formation of the substrate binding pocket. The PIC webserver (Tina *et al.*, 2007), was used once again, this time to identify which residues in the SBD made contact with the α -helical lid. When compared to residues which have been found to interact with the peptide substrate during substrate binding (Zhu *et al.* 1996), the substrate contact residues of PfHsp70-x include L434, T436, V440, T442, F549, T460, Q466, G468 and I471. The residues found to interact with the α -helical lid, did include some of these residues (V440, T460 and Q466), as well as adjacent residues A437, Q457, P467 and L470. While there is some overlap, it would seem that the lid is not bound as a peptide substrate would be, indicating that it may be merely present in the substrate binding pocket which forms, rather than bound by it. There has been much work done regarding the mechanism of substrate binding in Hsp70/DnaK and the α -helical lid has been found to be important in stabilising substrate binding (Moro, Fernández-Sáiz, & Muga, 2004). It has been shown by Pellecchia *et al.* (2000) that the removal of the α -helical lid from DnaK does not abolish substrate binding or ATP-induced release of substrate. However, research by Mayer *et al.* (2000) revealed that without the α -helical lid, DnaK is unable to refold denatured

protein substrates. It has additionally been shown that the lid of DnaK will open to varying degrees to accommodate different types of substrate and will often not enclose the peptide (Schlecht, Erbse, Bukau, & Mayer, 2011). This indicates that the lid does not stabilise substrate binding by closing over the peptide substrate. The present findings for PfHsp70-x may further contribute to the understanding of the Hsp70 substrate-binding mechanism. These indicate that the residues of the SBD form a substrate binding pocket, based on the position of the alpha-helical lid, relative to the SBD. This would suggest that the role of the α -helical lid in substrate binding is an interaction with the β subdomain of the SBD, rather than the substrate itself.

Conclusion

PfHsp70-x has been found to be a highly unusual protein, when compared at an amino acid sequence level to other cytosolic Hsp70s even from the *Plasmodium* genus. Although the fact that PfHsp70-x is exported into the host erythrocyte suggests a possible interaction with exported *P. falciparum* Hsp40s or host erythrocyte DnaJs, analysis conducted in this study was unable to provide any significant differences in the way these Hsp40s may interact with PfHsp70-x. This was largely due to inconclusive findings regarding the nature of the PfHsp70-x interaction with the J domains of these proteins. The loop region right after HPD motif varies quite greatly in size and composition across the different J domains studied and it is possible that it contributes to the specificity of the interactions. However, it is also possible that the domains of Hsp40s other than J domain play a role in the formation of specific Hsp70-x-Hsp40 complexes as indicated by Kampinga and Craig (2010). Homology models of the complexes were informative to a certain extent, as the template used for modeling was a crystal structure in which complex formation was formed by cross-linking. Docking results highlighted that J domain can rotate around HPD motif and present equally likely different orientations for docking. Further, by studying different structural conformations of PfHsp70-x, it was shown that Hsp40s can only bind when PfHsp70-x is in a certain conformation. Additionally, this work highlighted the possible dependence of the SBD residues on the orientation of the α -helical lid for formation of the substrate binding pocket. Since the α -helical lid is a very variable region across Hsp70s, it may present a preferable target for drug design. Overall, the unique substitutions found across the sequence of PfHsp70-x, often in regions highly conserved in other Hsp70s, may make this protein a potential target for drug design.

Tables

Table 1: Lowest sequence identity pairs from each alignment. For each alignment performed, the sequence identity was calculated for each pair of sequences in the alignment. Listed below are the sequence pairs from each alignment with the lowest sequence identity, as well as the sequence identity for the pair.

| Hsp70 Sequences Aligned | Sequence 1 | Sequence 2 | Sequence Identity (%) |
|--------------------------------|----------------------------------|-------------------------------|------------------------------|
| DnaKs (Prokaryotic) | <i>R. bacterium</i> DnaK | <i>M. tarda</i> DnaK | 51.62 |
| Cytosolic Eukaryotic | <i>A. thaliana</i> Hsp70B | <i>S. cerevisiae</i> Ssa1p | 69.98 |
| Cytosolic Apicomplexan | <i>T. annulata</i> Hsp70 | <i>C. parvum</i> Hsp70 | 70.86 |
| Cytosolic Plasmodial | <i>P. vivax</i> Hsp70 | <i>P. yoelii yoelii</i> Hsp70 | 95.80 |
| ER Eukaryotic | <i>C. elegans</i> Hsp-3 | <i>A. thaliana</i> BiP-2 | 64.55 |
| ER Apicomplexan | <i>E. tenella</i> BiP | <i>B. rodhaini</i> Grp78 | 59.46 |
| ER Plasmodial | <i>P. yoelii yoelii</i> ER-Hsp70 | <i>P. vivax</i> Grp78 | 85.21 |
| Mitochondrial Eukaryotic | <i>E. tenella</i> mtHsp70 | <i>A. echinatio</i> Hsc70-5 | 53.00 |
| Mitochondrial Apicomplexan | <i>T. annulata</i> mtHsp70 | <i>T. gondii</i> mtHsp70 | 64.06 |
| Mitochondrial Plasmodial | <i>P. knowlesi</i> mtHsp70 | <i>P. vivax</i> mtHsp70 | 97.44 |

Figure Legends

Figure 1: Cytosolic Hsp70 sequence alignment. PfHsp70-1 and PfHsp70-x were aligned with consensus sequences of cytosolic Hsp70 representatives of *Plasmodium*, Apicomplexa and eukaryotes, as well as prokaryotic DnaKs. Residues are highlighted as follows: Dark Blue: Unique to PfHsp70-x; Red: Unique to PfHsp70-1; Yellow: Residues present in either PfHsp70-x or PfHsp70-1 and eukaryotes, but not conserved in other *Plasmodium* Hsp70s; Green: Residues conserved in *Plasmodium*; Light Blue: Residues conserved in Apicomplexa; Purple: Residues which are highly conserved in eukaryotes, but not in PfHsp70-1 or PfHsp70-x. Consensus sequence letters in upper case were conserved in all sequences examined, whereas lower case letters indicate residues conserved in most sequences examined. A tilde (~) indicates a lack of consensus.

Figure 2: Comparisons of PfHsp70-x binding to the J domains of different Hsp40s, based on Hybrid modeling. A) Sequence regions of PfHsp70-x which were found to interact with the different J domains. The Hsp40 interacted with is indicated in parentheses. J proteins are denoted as follows: JA1 - HsDnaJA1; JA2 - HsDnaJA2; JB1 – HsDnaJB1; JB4 – HsDnaJB4; JC5 – HsDnaJC5; JC13 – HsDnaJC13. Residues highlighted in red and light blue, respectively, represent interactions found before and after residue repacking and energy minimisation using PyRosetta (refer to methodology). Residues highlighted in green are those which displayed interactions in both structures. B) Sequences are shown for portions of the J domains which displayed interactions with PfHsp70-x. Residues mapped to the structure in C are indicated over their position in the alignment. C) The interactions between PfHsp70-x and J proteins are shown, based on those which are most conserved across the 9 different J proteins. A section of the J domain is shown in cartoon form, with interacting residues displayed as text. Residues of PfHsp70-x are coloured blue, whereas J protein residues are

black and numbered according to their position in alignment 2B. The different types of interactions are displayed alongside.

Figure 3: Comparisons of PfHsp70-x binding to the J domains of different Hsp40s as determined by docking. Each J domain was docked to PfHsp70-x and the interactions between the two proteins were determined using the PIC webserver. A) Sequence regions of PfHsp70-x which were found to interact with the different J domains. Sequences are named as in Fig. 2A. B) Portions of each J domain, highlighting residues predicted to interact with PfHsp70-x. C) The interactions between PfHsp70-x and J proteins are shown, as in Fig. 2C.

Figure 4: Hsp40 binding within the ATPase cycle of Hsp70. A) The ATPase cycle of Hsp70 is shown. The two circled representations of Hsp70 are those found in the PDB. The binding of a J protein occurs between these two states. B and C represent the docked complex of HsDnaJA2 and PfHsp70-x being superimposed with the full length model of PfHsp70-x in an ATP-bound and ADP-bound conformations, respectively. The PfHsp70-x domains are coloured as follows: Grey – ATPase domain; Yellow – β subdomain of the SBD; Pale blue – α helical lid of the SBD. The J domain of HsDnaJA2 is coloured teal.

Figure 5: Formation of the substrate binding is dependent on the orientation of the α -helical lid, relative to the substrate binding domain. A) PfHsp70-x is shown as it is modeled, based on a substrate-bound template, 2KHO (Left) and a template not involved in substrate binding, 3D2F (Right). The domains are coloured in a similar way to those in Figure 4. Residues involved in substrate binding were mapped to the protein and are coloured as follows: Blue – residues that bind substrate peptides; Red – hydrophobic arch residues; Green - residue that forms the hydrophobic pocket. B) Areas on the protein boxed in dashed lines are represented below each structure in surface view. C) The SBD of PfHsp70-x is also shown as modeled after template 1YUW, whose structure was solved in the absence of a peptide substrate. This is shown at two different angles in order to emphasise how the alpha-

helical lid is bound by the substrate binding pocket in the absence of substrate. Residues involved in substrate binding are shown as spheres.

Figure 3: Comparisons of PfHsp70-x binding to the J domains of different Hsp40s as determined by docking.

Figure 4: Hsp40 binding within the ATPase cycle of Hsp70.

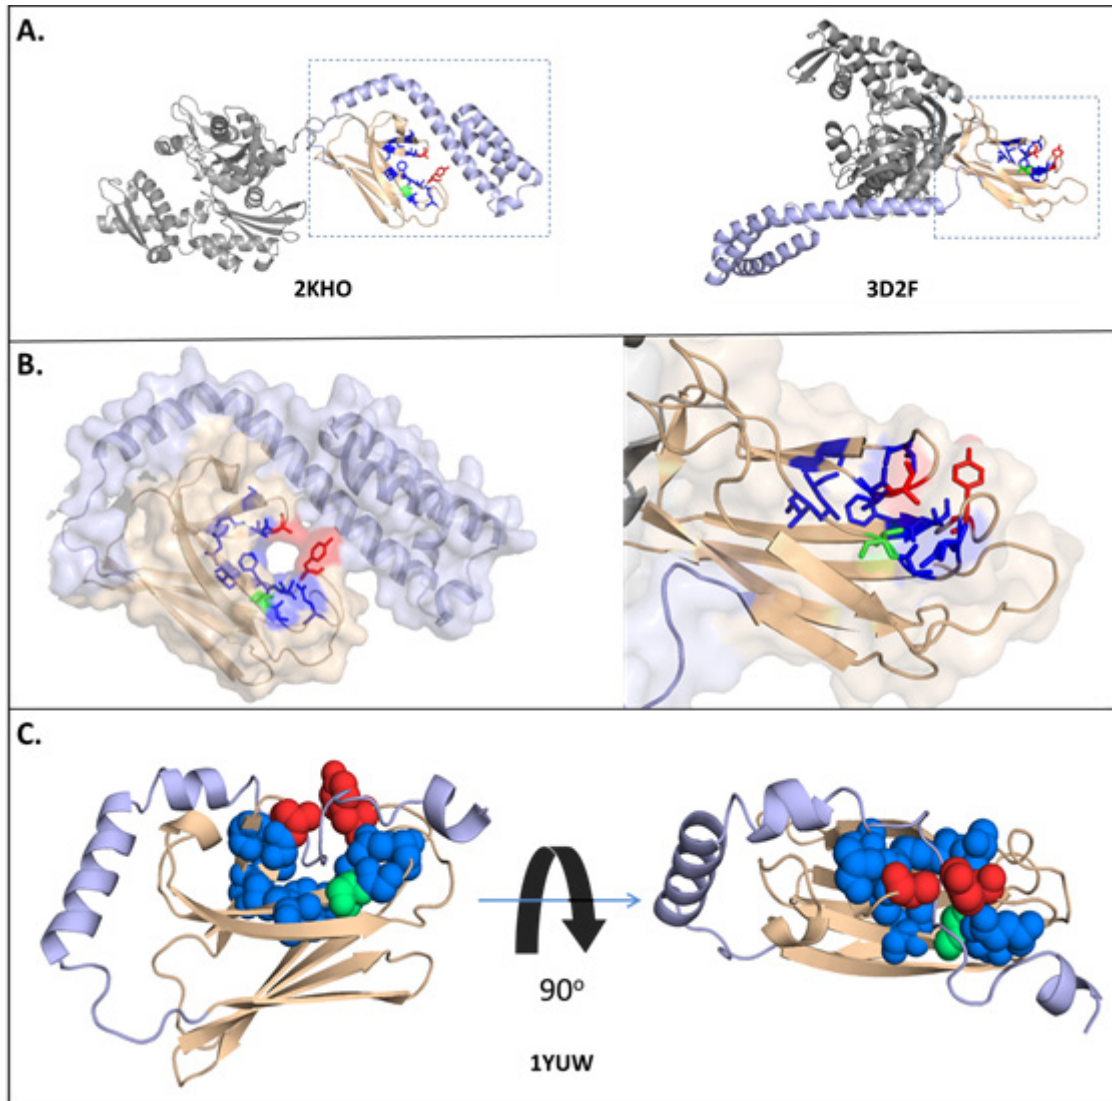

Figure 5: Formation of the substrate binding is dependent on the orientation of the α -helical lid, relative to the substrate binding domain.

Supplementary Data S1:

List of Hsp70 sequences used for alignments. Listed is the name of the Hsp70s used in the alignments performed. Included is the organism the protein comes from, the Genbank, NCBI or Uniprot reference number of the protein, the predicted cellular localization of the protein and the alignment group it was included in when making consensus sequences.

Supplementary Data S2:

Supplementary Data S2A: Comparison of alignments of eukaryote C-Hsp70s as performed by MAFFT and PROMALS3D. C-Hsp70s obtained from a variety of eukaryote sources were aligned using PROMALS3D and MAFFT. PfHsp70-1 and PfHsp70-x were included in this alignment. Each sequence aligned using PROMALS3D was placed directly above the same sequence aligned using MAFFT. Sequences aligned using PROMALS 3D have the suffix `_Pm` added to their names whereas those aligned using MAFFT have the suffix `_Ma`.

Supplementary Data S2B: Comparison of alignments of eukaryote ER-Hsp70s as performed by MAFFT and PROMALS3D. The eukaryotic ER-Hsp70s were aligned with PfHsp70-2 using PROMALS3D and MAFFT and annotated as in Supplementary Data S2A. Since the Alignments done by the two programs were of different lengths, the PROMALS3D sequences were moved forward until the GIDL motif of each sequence was aligned. A tilde (~) indicates that the sequence was moved one space forward.

Supplementary Data S2C: Comparison of alignments of eukaryote Mt-Hsp70s as performed by MAFFT and PROMALS3D. The eukaryotic Mt-Hsp70s were aligned with PfHsp70-3 using PROMALS3D and MAFFT and annotated as in Figure B.1. Sequences were hand-adjusted as in Supplementary Data S2A.

Supplementary Data S3:

Supplementary Data S3A: Alignment of eukaryote C-Hsp70 protein sequences. Sequences aligned include those listed in Supplementary Data S1, whose predicted cellular localization was the cytosol and were in the eukaryotic alignment group. Alignment of these sequences was done using MAFFT. Residues highlighted in black represent those which are conserved at the level of identity, whereas those highlighted in grey represent those that were conserved at the level of similarity. A consensus sequence of these sequences is represented at the top of the alignment. Residues in upper case were conserved in all sequences whereas those in lower case were conserved in most sequences. A tilde (~) represents a variable region where there is no consensus residue.

Supplementary Data S3B: Alignment of apicomplexan C-Hsp70 protein sequences. Sequences aligned include those listed in Supplementary Data S1, whose predicted cellular localization was the cytosol and were in the Apicomplexa alignment group. This figure was otherwise constructed and highlighted as described in Supplementary Data S3A.

Supplementary Data S3C: Alignment of *Plasmodium* C-Hsp70 protein sequences. Sequences aligned include those listed in Supplementary Data S1 whose predicted cellular localization was the cytosol and were in the *Plasmodium* alignment group. This figure was otherwise constructed and highlighted as described in Supplementary Data S3A.

Supplementary Data S3D: Alignment of eukaryote ER-Hsp70 protein sequences. Sequences aligned include those listed in Supplementary Data S1 whose predicted cellular localization was the ER and were in the eukaryotic alignment group. This figure was otherwise constructed and highlighted as described in Supplementary Data S3A.

Supplementary Data S3E: Alignment of apicomplexan ER-Hsp70 protein sequences. Sequences aligned include those listed in Supplementary Data S1 whose predicted cellular localization was the ER and were in the Apicomplexa alignment group. This figure was otherwise constructed and highlighted as described in Supplementary Data S3A.

Supplementary Data S3F: Alignment of *Plasmodium* ER-Hsp70 protein sequences. Sequences aligned include those listed in Supplementary Data S1 whose predicted cellular localization was the ER and were in the *Plasmodium* alignment group. This figure was otherwise constructed and highlighted as described in Supplementary Data S3A.

Supplementary Data S3G: Alignment of eukaryote Mt-Hsp70 protein sequences. Sequences aligned include those listed in Supplementary Data S1 whose predicted cellular localization was the mitochondria and were in the eukaryotic alignment group. This figure was otherwise constructed and highlighted as described in Supplementary Data S3A.

Supplementary Data S3H: Alignment of apicomplexan Mt-Hsp70 protein sequences. Sequences aligned include those listed in Supplementary Data S1 whose predicted cellular localization was the mitochondria and were in the Apicomplexa alignment group. This figure was otherwise constructed and highlighted as described in Supplementary Data S3A.

Supplementary Data S3I: Alignment of *Plasmodium* Mt-Hsp70 protein sequences. Sequences aligned include those listed in Supplementary Data S1 whose predicted cellular localization was the mitochondria and were in the *Plasmodium* alignment group. This figure was otherwise constructed and highlighted as described in Supplementary Data S3A.

Supplementary Data S3J: Alignment of prokaryote DnaK protein sequences. Sequences aligned include those listed in Supplementary Data S1 that were in the prokaryote alignment group. This figure was otherwise constructed and highlighted as described in Supplementary Data S3A.

Supplementary Data S4:

Comparison of top models produced using original and modified templates. Models were all produced using the same modeling procedure, with exception to the template used. Five different model quality assessment scores are reported for each set of models. DOPE Z score was calculated using MODELLER and the GDT_TS scores are values predicted by MetaMQAPII.

Supplementary Data S5:

Alignment of N-terminal sequence of PfHsp70-x with other ER-transit peptides. PfHsp70-x was aligned with the sequences of five different ER-Hsp70 sequences from *Chlamydomonas reinhardtii* (CrHsp70-4 and CrHsp70-5), *Ostreococcus lucimarinus* (OlHsp70-3), humans (HsGrp78) and *P. falciparum* (PfHsp70-2). Residues are coloured according to their physicochemical properties.

Supplementary Data S6:

Localization Alignment of Hsp70s. The sequences of PfHsp70-1 and PfHsp70-x were aligned with the consensus sequences of cytosolic, ER- and Mt-Hsp70s of representative sequences of eukaryotic, apicomplexan and plasmodial species. The Residues are highlighted as follows: Dark Blue - Residues previously identified as being “unique” to PfHsp70-x, as indicated in Figure 1; Light Blue - Residues conserved specifically in C-Hsp70s. Green - Residues conserved specifically in ER-Hsp70s. Red - Residues conserved specifically in Mt-Hsp70s. Pink - PfHsp70-x residues not found in any of the cytosolic groups, but were highly conserved in ER-Hsp70s and/or Mt-Hsp70s. Yellow boxed line - gap regions common to more than one of the Hsp70 groups.

Supplementary Data S7:

Supplementary Data S7A: Conserved interactions between PfHsp70-x and each J protein, based on Hybrid modeling. The different types of interactions are displayed for PfHsp70-x, modeled in complex with each of nine J proteins.

Supplementary Data S7B: Conserved interactions between PfHsp70-x and each J protein, based on Hybrid modeling (Alignment renumbered). The different types of interactions are displayed for PfHsp70-x, modeled in complex with each of nine J proteins. Residues of the J proteins have been renumbered, according to their position in the alignment of Figure 2B, in order to make these interactions comparable.

Supplementary Data S7C: Conserved interactions between PfHsp70-x and each J protein, based on HADDOCK Docking. The different types of interactions are displayed for PfHsp70-x, docked to each of nine J proteins, using the HADDOCK online webserver.

Supplementary Data S7D: Conserved interactions between PfHsp70-x and each J protein, based on HADDOCK Docking (Alignment renumbered). The different types of interactions are displayed for PfHsp70-x, docked to each of nine J proteins, using the HADDOCK online webserver. Residues of the J proteins have been renumbered, according to their position in the alignment of Figure 3B, in order to make these interactions comparable.

Supplementary Data S8:

Interaction interface between PfHsp70-x and a J domain as determined by Hybrid modelling. A) The interaction interface between the ATPase domain of PfHsp70-x (grey) and a J domain (green). The area within the dashed box is shown in B. Some of the residues which showed conserved interactions are mapped to the structure in stick representation.

Supplementary Data S9:

Interaction interface between PfHsp70-x and a J domain as determined by HADDOCK docking. A) Superimposition of the five different Type II J proteins docked in complex with PfHsp70-x, showing the different orientations adopted by the J domain proteins docked. These proteins are coloured as follows: Purple – PfA; Yellow – PfB; Orange – PfE; Red – HsDnaJB1; Green – HsDnaJB4. The ATPase domains of PfHsp70-x in each complex are coloured grey. B) The models are rotated 90° to indicate the interaction interface between the ATPase domain of PfHsp70-x and the J domains. The area within the dashed box is shown in C. Residues which showed conserved interactions are mapped to the structure in stick representation. The aspartic acids of each HPD motif are also shown as yellow sticks.

Supplementary Data S10:

Supplementary Data S10A:

Superimposition of J domain binding orientations to PfHsp70-x in an ATP-bound state. The J domain of each J protein docked to the ATPase domain of PfHsp70-x was superimposed with the full length structure of PfHsp70-x, modeled after template 1YUW. The J domain docked is labelled next to each model. JA1 and JA2 represent HsDnaJA1 and HsDnaJA2, respectively.

Supplementary Data S10B:

Superimposition of J domain binding orientations to PfHsp70-x in an ADP-bound state. The J domain of each J protein docked to the ATPase domain of PfHsp70-x was superimposed with the full length structure of PfHsp70-x, modeled after template 2KHO. The J domain docked is labelled next to each model. JA1 and JA2 represent HsDnaJA1 and HsDnaJA2, respectively.

Supplementary Data S1
