Abstract

The present study reexamines the recent work of Pradhan et al. (Indian J. Phys. 88: 757, 2014) and obtained general exact solutions of the Einstein’s field equations with variable gravitational and cosmological “constants” for a spatially homogeneous and anisotropic Bianchi type-I space-time. To study the transit behaviour of Universe, we consider a law of variation of scale factor $a(t) = \left(t^k e^t\right)^{\frac{1}{n}}$ which yields a time dependent deceleration parameter $q = -1 + \frac{nk}{(k+t)^2}$, comprising a class of models that depicts a transition of the universe from the early decelerated phase to the recent accelerating phase. We find that the time dependent deceleration parameter is reasonable for the present day Universe and give an appropriate description of the evolution of the universe. For $n = 0.27k$, we obtain $q_0 = -0.73$ which is similar to observed value of deceleration parameter at present epoch. It is also observed that for $n \geq 2$ and $k = 1$, we obtain a class of transit models of the universe from early decelerating to present accelerating phase. For $k = 0$, the universe has non-singular origin. In these models, we arrive at the decision that, from the structure of the field equations, the behaviour of cosmological and gravitational constants and are related. Taking into consideration the observational data, we conclude that the cosmological constant behaves as a positive decreasing function of time whereas gravitational constant is increasing and tend to a constant value at late time. $H(z)/(1+z)$ data (32 points) and model prediction as a function of redshift for different k and n are successfully presented by using recent data (Farooq and Ratra, Astrophys. J. 66: L7, 2013). Some physical and geometric properties of the models are also discussed.

1 Introduction

In Einsteinian field equations, the cosmological constant (Λ) and the gravitational constant (G) are two essential parameters. Accelerated expansion of the universe is due to dark energy as discovered by type Ia supernovae (SN Ia) observations as reported by Riess et al.

¹Corresponding author, Email: pradhan@iucaa.ernet.in; pradhan.anirudh@gmail.com

[1] and Perlmutter et al. [2]. The Wilkinson Microwave Anisotropy Probe (WMAP) [3, 4], combined with more accurate SN Ia data [5] indicates that the Universe is almost spatially flat and the dark energy accounting to approximately to 70% of the total content of the Universe. Little is known about the nature of dark energy. Observations strongly favour a small and positive value of the effective cosmological constant at the present epoch. Among many possible alternatives, the simplest and theoretically appealing possibility of dark energy is the energy density stored on the vacuum state of all existing fields in the universe i. e., $\rho_v = \frac{\Lambda}{8\pi G}$. The variable cosmological constant [6–8] is one of the phenomenological ways to explain the dark energy problem, compatible with observations. The problem in this approach is to determine the right dependence of Λ upon scale factor R or cosmic time t . Motivated by dimensional grounds with quantum cosmology, the variation of cosmological term as $\Lambda \propto R^{-2}$ is considered by Chen and Wu [9]. However, several ansätze have been proposed in which the Λ -term decays with time [10–13]. Several authors [13–18] have recently studied the time dependent cosmological constant in different contexts. Recently, Arkhipova et al. [19] have studied growth rate in dynamical dark energy models by using a compilation of baryonic acoustic oscillation (BAO), growth rate and the distance prior from the cosmic microwave background (CMB) to constrain model parameter of the scalar field model. When combining these constraints with the constraints coming from a distance-redshift relationship (BAO data and the distance prior from CMB) the degeneracy is broken and one obtains $\Omega_m = 0.30 \pm 0.04$ and $\alpha < 1.30$ with the best fit value of $\alpha = 0.00$. Pavlov et al. [20] compile a list of 14 independent measurements of large-scale structure growth rate between redshift $0.067 \leq z \leq 0.8$ and use this to place constraints on model parameters of constant and time-evolving general-relativistic dark energy cosmologies. Chen et al. [21] have recently pointed out that the recent observations still can not distinguish whether dark energy is a time-independent or a time-varying dynamical component through a joint analysis of the strong gravitational lensing data with the more restrictive updated Hubble parameter measurements and the type Ia supernova data from SCP Union2. Farooq, Mania and Ratra [22] have recently constrained two non-flat time evolving dark energy cosmological models by using Hubble parameter data, Type Ia supernova apparent magnitude measurements, and baryonic acoustic oscillation peak length scale observations. These data require the average magnitude of the curvature density parameter $|\Omega_{k0}|$ is less or equivalent to 0.15 at 1σ confidence.

Recent observations do not support the stability of fundamental constants and “Equivalence Principle” of general relativity. Dirac [23, 24] was the first to introduce the time variation of the gravitational constant G in his large number hypothesis and after that it has been used in various modifications of general theory of relativity. The applications to observable tests, use of the recent techniques developed for handling the observational tests for G -varying cosmologies are discussed by Canuto et al. [25, 26]. Theories of gravity in which the G varies with time and cosmological models based on them have been extensively studied in literature [29–31]. The variation of gravitational constant inferred from the Hubble diagram of Type Ia Supernovae [28]. For the case of the gravity theory we can have varying- G , varying- c , or varying- Λ models [32–34]. In these models either G or c is described by a scalar field and the equation of motion determine the dynamics of both the space-time metric and the varying constant. In the context of cosmological models, according to cosmological principle these varying constants are only time-dependent. Several authors [35–40] have recently investigated and discussed the time dependent Λ and G in different contexts.

Recently, Yadav and Sharma [39] and Yadav [40] have discussed about transit universe in Bianchi type-V space-time with variable G and Λ .

It is important to mention here that CMB anisotropy data are sometimes viewed as supporting a very small breaking of spatially isotropy. Recently, Ade et al. [41] have investigated Planck 2013 results. According to their findings, deviations from isotropy have been found and demonstrated to be robust against component separation algorithm, mask choice and frequency dependence. In particular, they investigated that the quadrupole-octopole alignment is also connected to a low observed variance of the CMB signal. While we consider a Bianchi model here, another possible source of this anisotropy is a very small cosmological magnetic field [42, 43]. Chen et al. [42] have discussed the constraints that can be placed on the strength of such a primordial magnetic field using CMB anisotropy data from WMAP experiments. Kahniashvili, Lavrelashvili and Ratra [43] have indicated CMB temperature anisotropy from broken spatial isotropy due to homogeneous cosmological magnetic field. The analysis of WMAP data sets shows that the universe could have a preferred direction. The ILC-WMAP data maps show seven axes well aligned with one another and the direction Virgo. For this reason Bianchi models are important in the study of anisotropies.

It is well established that anisotropic Bianchi type-I universe plays significant role in understanding the phenomenal formation of galaxies in early universe. Theoretical reasoning and recent observations of cosmic microwave background radiation (CMBR) subscribe to the existence of anisotropic phase that approaches an isotropic one. Recently, Yadav et al. [44, 45] have obtained Bianchi type-I cosmological models with viscosity and cosmological term in general relativity by considering scale factor as $a(t) = \sqrt{te^t}$ and $a(t) = \sqrt{t^n e^t}$ respectively. Pradhan et al. [55] have also investigated accelerating Bianchi type-I universe with time varying G and Λ -term in general relativity by taking $a(t) = \sinh^{\frac{1}{n}}(\alpha T)$. Recently, Pradhan et al. [46] have studied Bianchi type-I transit cosmological models with time dependent gravitational and cosmological constants by considering scale factor as $a(t) = \sqrt{t^n e^t}$. Motivated by the above discussions, in this paper, we propose to study homogeneous and anisotropic Bianchi type-I transit cosmological models with time dependent gravitational and cosmological “constants” by assuming $a(t) = (t^k e^t)^{\frac{1}{n}}$ which generalize our previous studies and provide better results.

2 The metric and basic equations

We consider the space-time metric of the spatially homogeneous and anisotropic Bianchi-I of the form

$$ds^2 = dt^2 - A^2(t)dx^2 - B^2(t)dy^2 - C^2(t)dz^2. \quad (1)$$

where $A(t)$, $B(t)$ and $C(t)$ are the metric functions of cosmic time t .

Einstein field equations with time-dependent G and Λ are given by

$$R_{ij} - \frac{1}{2}g_{ij}R = 8\pi G T_{ij} + \Lambda g_{ij}, \quad (2)$$

where the symbols have their usual meaning.

For a perfect fluid, the stress-energy-momentum tensor T_{ij} is given by

$$T_{ij} = (\rho + p)u_i u_j - p g_{ij}, \quad (3)$$

where ρ is the matter density, p is the thermodynamics pressure and u^i is the fluid four-velocity vector of the fluid satisfying the condition

$$u^i u_i = 1. \quad (4)$$

In the field Eqs. (2), Λ accounts for vacuum energy with its energy density ρ_v and pressure p_v satisfying the equation of state

$$p_v = -\rho_v = -\frac{\Lambda}{8\pi G} \quad (5)$$

The critical density and the density parameters for matter and cosmological constant are, respectively, defined as

$$\rho_c = \frac{3H^2}{8\pi G}, \quad (6)$$

$$\Omega_M = \frac{\rho}{\rho_c} = \frac{8\pi G \rho}{3H^2}, \quad (7)$$

$$\Omega_\Lambda = \frac{\rho_v}{\rho_c} = \frac{\Lambda}{3H^2}. \quad (8)$$

We observe that the density parameters Ω_M and Ω_Λ are singular when $H = 0$.

In a comoving system of coordinates, the field Eqs. (2) for the metric (1) with (3) read as

$$\frac{\ddot{A}}{A} + \frac{\ddot{B}}{B} + \frac{\dot{A}\dot{B}}{AB} = -8\pi G p + \Lambda, \quad (9)$$

$$\frac{\ddot{A}}{A} + \frac{\ddot{C}}{C} + \frac{\dot{A}\dot{C}}{AC} = -8\pi G p + \Lambda, \quad (10)$$

$$\frac{\ddot{B}}{B} + \frac{\ddot{C}}{C} + \frac{\dot{B}\dot{C}}{BC} = -8\pi G p + \Lambda, \quad (11)$$

$$\frac{\dot{A}\dot{B}}{AB} + \frac{\dot{B}\dot{C}}{BC} + \frac{\dot{C}\dot{A}}{CA} = 8\pi G \rho + \Lambda. \quad (12)$$

The covariant divergence of Eq. (2) yields

$$\dot{\rho} + 3(\rho + p)H + \rho \frac{\dot{G}}{G} + \frac{\dot{\Lambda}}{8\pi G} = 0. \quad (13)$$

Spatial volume for the model given by Eq. (1) reads as

$$V = ABC \quad (14)$$

We define average scale factor a of anisotropic model as

$$a = (ABC)^{\frac{1}{3}} = V^{\frac{1}{3}}. \quad (15)$$

So that generalized mean Hubble parameter H is given by

$$H = \frac{1}{3}(H_x + H_y + H_z), \quad (16)$$

where $H_x = \frac{\dot{A}}{A}$, $H_y = \frac{\dot{B}}{B}$, $H_z = \frac{\dot{C}}{C}$ are the directional Hubble parameters in direction of x, y and z respectively and a dot denotes differentiation with respect to cosmic time t.

From Eqs. (15) and (16), we obtain an important relation

$$H = \frac{\dot{a}}{a} = \frac{1}{3} \left(\frac{\dot{A}}{A} + \frac{\dot{B}}{B} + \frac{\dot{C}}{C} \right). \quad (17)$$

Expressions for the dynamical scalars such as the expansion scalar (θ), anisotropy parameter (A_m) and the shear scalar (σ) are defined as usual:

$$\theta = u^i_{;i} = \left(\frac{\dot{A}}{A} + \frac{\dot{B}}{B} + \frac{\dot{C}}{C} \right), \quad (18)$$

$$A_m = \frac{1}{3} \sum_{i=1}^3 \left(\frac{H_i - H}{H} \right)^2, \quad (19)$$

$$\sigma^2 = \frac{1}{2} \sigma_{ij} \sigma^{ij} = \frac{1}{2} \left[\left(\frac{\dot{A}}{A} \right)^2 + \left(\frac{\dot{B}}{B} \right)^2 + \left(\frac{\dot{C}}{C} \right)^2 \right] - \frac{\theta^2}{6}. \quad (20)$$

We define deceleration parameter (DP) q as

$$q = -\frac{a\ddot{a}}{\dot{a}^2} = -\left(\frac{\dot{H} + H^2}{H^2} \right). \quad (21)$$

3 Solution of field equations

The field Eqs. (9)–(12) are a system of four equations with seven unknown parameters A , B , C , G , p , ρ and Λ . Hence, three additional constraints relating these parameters are required to obtain explicit solution of the system.

So first, we assume a power-law form of the gravitational constant (G) with scale factor a as proposed by Chawla et al. [38]

$$G \propto a^m, \quad (22)$$

where m is a constant. For the sake of mathematical simplicity, Eq. (22) may be written as

$$G = G_0 a^m, \quad (23)$$

where G_0 is a positive constant.

Secondly, we assume equation of state for perfect fluid as

$$p = \gamma\rho, \quad (24)$$

where γ ($0 \leq \gamma \leq 1$) is constant.

Following the technique [44, 61–63], we get three equations from field Eqs. (9)–(11)

$$\frac{A}{B} = d_1 \exp\left(k_1 \int a^{-3} dt\right), \quad (25)$$

$$\frac{B}{C} = d_2 \exp\left(k_2 \int a^{-3} dt\right), \quad (26)$$

$$\frac{C}{A} = d_3 \exp\left(k_3 \int a^{-3} dt\right), \quad (27)$$

where d_1, d_2, d_3 and k_1, k_2, k_3 are constants of integration. Finally, using $a = (ABC)^{\frac{1}{3}}$, we write the metric functions from Eqs. (25)–(27) in explicit form as

$$A(t) = l_1 a \exp\left(m_1 \int a^{-3} dt\right), \quad (28)$$

$$B(t) = l_2 a \exp\left(m_2 \int a^{-3} dt\right), \quad (29)$$

$$C(t) = l_3 a \exp\left(m_3 \int a^{-3} dt\right), \quad (30)$$

where constants m_1, m_2, m_3 and l_1, l_2, l_3 satisfy the following two relations:

$$m_1 + m_2 + m_3 = 0, \quad l_1 l_2 l_3 = 1. \quad (31)$$

in the particular case

$$l_1 = \sqrt[3]{d_1 d_2}, \quad l_2 = \sqrt[3]{d_1^{-1} d_3}, \quad l_3 = \sqrt[3]{(d_2 d_3)^{-1}}, \quad (32)$$

and

$$m_1 = \frac{k_1 + k_2}{3}, \quad m_2 = \frac{k_3 - k_1}{3}, \quad m_3 = \frac{-(k_2 + k_3)}{3}. \quad (33)$$

Now, the metric functions can be determined as functions of cosmic time t if the average scale factor is known. Hence, we consider the *ansatz* for the scale factor, where increase in term of time evolution is

$$a = (t^k e^t)^{\frac{1}{n}} \quad (34)$$

In our earlier studies it is found that *ansatz* generalizes [52–55]. The choice of scale factor attracts a time-dependent deceleration parameter (see Eq. (47)) which brings that dark energy era, the solution gives inflation and radiation/matter dominance era with subsequent transition from deceleration to acceleration. Now for a Universe which was decelerating in past and accelerating at the present time, the deceleration parameter must show signature flipping [51]. This theme motivates to choose such scale factor (34) that yields a time dependent deceleration parameter given by Eq. (47).

Using Eq. (34) in Eqs. (28)–(30), we obtain

$$A(t) = l_1 (t^k e^t)^{\frac{1}{n}} \exp[m_1 F(t)], \quad (35)$$

$$B(t) = l_2(t^k e^t)^{\frac{1}{n}} \exp [m_2 F(t)], \quad (36)$$

$$C(t) = l_3(t^k e^t)^{\frac{1}{n}} \exp [m_3 F(t)], \quad (37)$$

where

$$F(t) = \int (t^k e^t)^{-\frac{3}{n}} dt = \sum_{i=1}^{\infty} \frac{(-3)^{i-1} t^{i-\frac{3k}{n}}}{n^{i-2} (ni - 3k)(i-1)!}. \quad (38)$$

From Eqs. (35)–(37), we obtain

$$\begin{aligned} \frac{\dot{A}}{A} &= \frac{1}{n} \left(\frac{k}{t} + 1 \right) + m_1 (t^k e^t)^{-\frac{3}{n}}, \\ \frac{\dot{B}}{B} &= \frac{1}{n} \left(\frac{k}{t} + 1 \right) + m_2 (t^k e^t)^{-\frac{3}{n}}, \\ \frac{\dot{C}}{C} &= \frac{1}{n} \left(\frac{k}{t} + 1 \right) + m_3 (t^k e^t)^{-\frac{3}{n}}, \end{aligned} \quad (39)$$

and

$$\begin{aligned} \frac{\ddot{A}}{A} &= \frac{1}{n^2} \left(\frac{k}{t} + 1 \right)^2 - \frac{k}{nt^2} + m_1^2 (t^k e^t)^{-\frac{6}{n}} - \frac{m_1}{n} (t^k e^t)^{-\frac{3}{n}} \left(\frac{k}{t} + 1 \right), \\ \frac{\ddot{B}}{B} &= \frac{1}{n^2} \left(\frac{k}{t} + 1 \right)^2 - \frac{k}{nt^2} + m_2^2 (t^k e^t)^{-\frac{6}{n}} - \frac{m_2}{n} (t^k e^t)^{-\frac{3}{n}} \left(\frac{k}{t} + 1 \right), \\ \frac{\ddot{C}}{C} &= \frac{1}{n^2} \left(\frac{k}{t} + 1 \right)^2 - \frac{k}{nt^2} + m_3^2 (t^k e^t)^{-\frac{6}{n}} - \frac{m_3}{n} (t^k e^t)^{-\frac{3}{n}} \left(\frac{k}{t} + 1 \right). \end{aligned} \quad (40)$$

Hence the geometry of the universe (1) is reduced to

$$\begin{aligned} ds^2 &= -dt^2 + (t^k e^t)^{\frac{2}{n}} \left[l_1^2 \exp \{2m_1 F(t)\} dx^2 + l_2^2 \exp \{2m_2 F(t)\} dy^2 \right. \\ &\quad \left. + l_3^2 \exp \{2m_3 F(t)\} dz^2 \right]. \end{aligned} \quad (41)$$

4 Results and discussion

Expressions for physical parameters such as spatial volume (V), mean Hubble's parameter (H), expansion scalar (θ), shear scalar (σ) and anisotropy parameter (A_m) for model (41) are given by

$$V = (t^k e^t)^{\frac{3}{n}}, \quad (42)$$

$$H = \frac{1}{n} \left(\frac{k}{t} + 1 \right), \quad (43)$$

$$\theta = \frac{3}{n} \left(\frac{k}{t} + 1 \right), \quad (44)$$

$$A_m = \frac{\beta_1}{3n^2} \left(\frac{k}{t} + 1 \right)^{-2} (t^k e^t)^{-\frac{6}{n}}, \quad (45)$$

$$\sigma^2 = \frac{\beta_1}{2}(t^k e^t)^{-\frac{6}{n}}, \quad (46)$$

where

$$\beta_1 = m_1^2 + m_2^2 + m_3^2.$$

Figure 1: Plots of deceleration parameter q versus time t

Figure 2: Plots of anisotropic parameter A_m versus time t for $m_1 = 0.25$, $m_2 = 0.75$, $m_3 = -1$

From Eq. (21), the deceleration parameter is computed as

$$q = -1 + \frac{nk}{(k+t)^2}. \quad (47)$$

From Eq. (47), we observe that $q > 0$ for $t < \sqrt{nk} - k$ and $q < 0$ for $t > \sqrt{nk} - k$. It is observed that for $n \geq 3$ & $k = 1$, our model is evolving from decelerating phase to accelerating phase. Also, recent observations of SNe Ia expose that the present universe is accelerating and the value of DP lies on some place in the range $-1 < q < 0$. It follows that in our derived model, one can choose the value of DP consistent with the observation. Fig. 1 depicts the variation of deceleration parameter (q) with cosmic time, giving the behaviour of q as in accelerating phase at present epoch for different values of (n, k) which is consistent with recent observations of Type Ia supernovae [1, 2].

From above Eq. (47), present value of deceleration parameter can be estimated as

$$q_0 = -1 + \frac{k}{nH_0^2 t_0^2}, \quad (48)$$

where where H_0 is present value of Hubble's parameter and t_0 is the age of universe at present epoch. Recent observations show that the deceleration parameter of the universe is in the range $-1 \leq q \leq 0$ i.e $q_0 \approx -0.77$. For $n = 0.27k$, we obtain $q_0 = -0.73$ which is similar to the observed value of DP at present epoch [52]. Therefore, we restrict the values of n and k such that the condition $n = 0.27k$ is satisfied for graphical representations of the physical parameters. As a representative case, we have considered four values of (n, k) as (0.25,

0.9259259260), (0.50, 0.1851851852), (0.75, 2.777777778) and (3, 11.11111111) respectively for graphic presentation of Figs. 1–8.

From Eqs. (42) and (44) we observe that the spatial volume is zero at $t = 0$ and the expansion scalar is infinite, which show that the universe starts evolving with zero volume at $t = 0$ which is big bang scenario. From Eqs. (35)–(37), we observe that the spatial scale factors are zero at the initial epoch $t = 0$ and hence the model has a point type singularity [53]. We observe that proper volume increases with time.

From Eq. (45), we observe that at late time when $t \rightarrow \infty$, $A_m \rightarrow 0$. Thus, our model has transition from initial anisotropy to isotropy at present epoch which is in good harmony with current observations. Fig. 2 depicts the variation of anisotropic parameter (A_m) with cosmic time t . From the figure, we observe that A_m decreases with time and tends to zero as $t \rightarrow \infty$. Thus, the observed isotropy of the universe can be achieved in our model at present epoch.

It is important to note here that $\lim_{t \rightarrow 0} \left(\frac{\rho}{\theta^2} \right)$ spread out to be constant. Therefore, the model of the universe goes up homogeneity and matter is dynamically negligible near the origin. This is in good agreement with the result already given by Collins [54].

Using Eq. (34) into (23), the gravitational constant is obtained as

$$G = G_0(t^k e^t)^{\frac{m}{n}}. \quad (49)$$

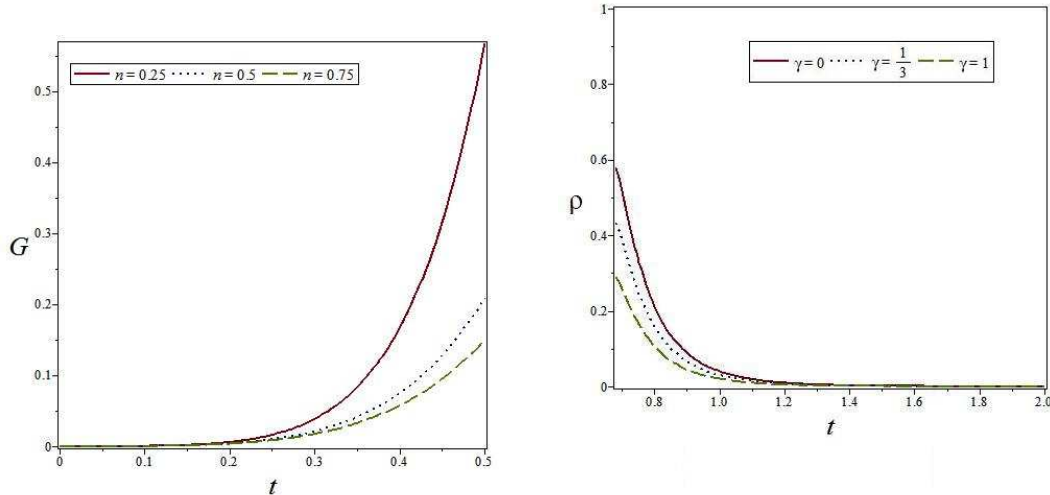

Figure 3: Plots of gravitational constant G versus time t for $G_0 = m = 1$

Figure 4: Plots of energy density ρ versus time t for $m = 1$, $m_1 = 0.25$, $m_2 = 0.75$, $m_3 = -1$, $n = 0.5$

From Eq. (49), we observe that $G \rightarrow 0$ as $t \rightarrow 0$ whereas for $t \rightarrow \infty$, $G \rightarrow \infty$ which shows that G is an increasing function of time. This nature of variation of G with cosmic time is shown in Fig. 3 for three values of $n = 0.25, 0.50$ and 0.75 . Abdel-Rahaman [55] has investigated cosmological models in which G increases in a constantly expanding universe.

Figure 5: Plots of cosmological constant Λ versus time t for $m_1 = 0.25$, $m_2 = 0.75$, $m_3 = -1$, $n = 0.5$

Figure 6: Plots of density parameter Ω_M versus time t for $m_1 = 0.25$, $m_2 = 0.75$, $m_3 = -1$, $n = 0.5$

Some authors [56, 57] found in their study that G is decreasing function of time whereas an increasing G has also been reported [36, 37, 63]. This alteration in G leaves the form of Einstein's equations formally intact by allowing the variation of G to be accompanied by a change in Λ and enables to solve the cosmological constant problem, inflationary scenario etc. [59].

Using Eqs. (24), (39) and (40) and solving the field Eqs. (9)–(12), we get the expressions for energy density, pressure and cosmological constant for universe (41) as

$$\rho = \frac{1}{8\pi G_0(1+\gamma)} \left[\frac{2k}{nt^2} (t^k e^t)^{-\frac{m}{n}} - \beta_1 (t^k e^t)^{-\frac{(m+6)}{n}} \right], \quad (50)$$

$$p = \frac{\gamma}{8\pi G_0(1+\gamma)} \left[\frac{2k}{nt^2} (t^k e^t)^{-\frac{m}{n}} - \beta_1 (t^k e^t)^{-\frac{(m+6)}{n}} \right], \quad (51)$$

$$\Lambda = \frac{3}{n^2} \left(\frac{k}{t} + 1 \right)^2 + \frac{1}{(1+\gamma)} \left[\beta_2 (t^k e^t)^{-\frac{6}{n}} - \frac{2k}{nt^2} \right], \quad (52)$$

where

$$\beta_2 = m_1^2 + m_2^2 + m_1 m_2 + \gamma(m_1 m_2 + m_2 m_3 + m_3 m_1).$$

We find that the above solutions satisfy Eq. (13) identically and hence represent exact solution of Einstein's field equations (9)–(12).

From above relations (50)–(52), we can obtain the expressions of energy density, pressure and cosmological constant for four types of models: (i) Empty model for $\gamma = 0$, (ii) radiating dominated model for $\gamma = \frac{1}{3}$, (iii) degenerate vacuum or false vacuum or ρ vacuum model [60] for $\gamma = -1$ and (iv) Zeldovich fluid or stiff fluid model [61, 62] for $\gamma = 1$.

Figure 7: Plots of density parameter Ω_Λ versus time t for $m_1 = 0.25$, $m_2 = 0.75$, $m_3 = -1$, $n = 0.5$

Figure 8: Plots of total density parameter Ω versus time t for $m_1 = 0.25$, $m_2 = 0.75$, $m_3 = -1$

From Eq. (50), it is observed that the energy density ρ is a decreasing function of time and $\rho > 0$ under condition $t^{3k-1}e^{\frac{6t}{n}} > \frac{n\beta_1}{2k}$. The energy density versus time is shown in Fig. 4 for $\gamma = 0, \frac{1}{3}$ and 1. It is evident that the energy density remains positive in all the three types of models under appropriate condition. However, it decreases more sharply with the cosmic time in Zeldovich universe, compared to radiating dominated and empty fluid universes.

Fig. 5 shows the plot of the cosmological term Λ versus cosmic time for $\gamma = 0, \frac{1}{3}$ and 1. We observe that Λ is decreasing function of time t and it approaches a small positive value at late time in all the three types of models. We also observe that Λ decreases more aggressively with the cosmic time in empty universe than radiating dominated and stiff fluid universes. From recent cosmological observations [1, 3, 5], it is well established that cosmological constant Λ is small and positive at present epoch. A positive Λ increases the expansion speed with time while a negative Λ tends to decelerate it. Thus, the nature of Λ in our derived models are supported by recent observations.

The vacuum energy density (ρ_ν), critical density (ρ_c) and the density parameters (Ω_M, Ω_Λ) for model (41) read as

$$\rho_\nu = \frac{1}{8\pi G_0} \left[\frac{3}{n^2} \left(\frac{k}{t} + 1 \right)^2 (t^k e^t)^{-\frac{m}{n}} + \frac{\beta_2}{(1+\gamma)} (t^k e^t)^{-\frac{(m+6)}{n}} - \frac{2k}{n(1+\gamma)} t^{-\frac{km}{n}+2} e^{-\frac{mt}{n}} \right], \quad (53)$$

$$\rho_c = \frac{3}{8\pi G_0 n^2} \left(\frac{k}{t} + 1 \right)^2 (t^k e^t)^{-\frac{m}{n}}, \quad (54)$$

$$\Omega_M = \frac{n^2 \left[\frac{2k}{nt^2} - \beta_1 (t^k e^t)^{-\frac{6}{n}} \right]}{3(1+\gamma) \left(\frac{k}{t} + 1 \right)^2}, \quad (55)$$

$$\Omega_\Lambda = 1 + \frac{n^2 \left[\beta_2 (t^k e^t)^{-\frac{6}{n}} - \frac{2k}{nt^2} \right]}{3(1+\gamma) \left(\frac{k}{t} + 1 \right)^2}. \quad (56)$$

Adding Eqs. (55) and (56), we get

$$\Omega = \Omega_M + \Omega_\Lambda = 1 + \frac{\beta n^2 (t^k e^t)^{-\frac{6}{n}}}{3 \left(\frac{k}{t} + 1 \right)^2}, \quad (57)$$

where $\beta = m_1 m_2 + m_2 m_3 + m_3 m_1$. For $\beta = 0$, we have $\Omega = 1$. We also observe from Eq. (57) that Ω approaches to one for sufficiently large time independent to β . Figs. 6 and 7 plot the variation of density parameters for matter (Ω_M) and cosmological constant (Ω_Λ) versus t respectively. From these figures it is clear that the universe is dominated by matter in early stage of evolution whereas it is dominated by dark energy (cosmological constant Λ) at present epoch. Fig. 8 shows a variation of total energy parameter (Ω) versus cosmic time t . From the Fig. 8, we observe that $\Omega \rightarrow 1$ at late time for arbitrary value of β . This is in good agreement with the observational results [63].

Figure 9: $H(z)/(1+z)$ data (32 points) and model prediction as a function of redshift.

Figure 10: $H(z)/(1+z)$ data (32 points) and model prediction as a function of redshift for different n with fixed $k = 0.5$ and $a_0 = 0.5$.

The updated Hubble parameter measurements:

Recently Farooq and Ratra [64], following Farooq et al. [65], have compiled a list of 28 independent measurements of the Hubble parameter between redshift $0.07 \leq z \leq 2.3$ and used this to place constraints on model parameter of constant and time-evolving dark

Figure 11: $H(z)/(1+z)$ data (32 points) and model prediction as a function of redshift for different k with fixed $n = 0.75$ and $a_0 = 0.5$.

Figure 12: Plots of deceleration parameter q vs time t for transit universe for different sets of k and n .

energy cosmologies. This is the extension of the analysis of Busca et al. [66] to a larger independent set and determined the cosmological deceleration-acceleration transition redshift $z_{da} = 0.74 \pm 0.05$. These $H(z)$ data are well-described by all best-fit models, and provide tight constraints on the model parameter. In the following we plotted $H(z)/(1+z)$ as a function of z , and also plotted the data (Table 1) of Farooq and Ratra [64] in Figs. [9–11]. This was determined from the 6 best-fit transition redshifts measured in three different cosmological models, Λ CDM, XCDM, and ϕ CDM, for two different Hubble constant priors.

The expansion rate, i.e. the Hubble parameter, is defined as:

$$H(z) = \frac{\dot{a}}{a} = -\frac{1}{1+z} \frac{dz}{dt}, \quad (58)$$

where the redshift z of the chronometers is known with a high accuracy based on the spectra of galaxies and the differential measurement of time (dt) at a given redshift interval (dz) automatically provides a direct measurement on $H(z)$.

From $a(t) = (t^k e^t)^{1/n}$ we have

$$H = \frac{1}{n} \left(\frac{k}{t} + 1 \right), \quad (59)$$

and

$$1+z = \frac{a(t_0)}{a(t)} = \frac{a_0}{(t^k e^t)^{1/n}}. \quad (60)$$

Suppose $H(z)$ is theoretical function. H_i is measured at point z_i (experimental data taken from the paper of Farooq and Ratra [64]) differs from $H(z_i)$ by random values having Gaussian distribution with zero mathematical expectation and standard deviation σ_i . The expression

$$\xi_i = \frac{H(z_i) - H_i}{\sigma_{H_i}} \quad (61)$$

possesses Gaussian distribution with zero mathematical expectation and unit standard deviation. The quantities

$$\chi^2 = \sum_i \xi_i^2 \quad (62)$$

have known χ^2 distribution and maximum likelihood is attained by minimizing χ^2 by parameters a_0, k, n .

The minimum was reached at $a_0 = 0.502$, $k = 0.504$ and $n = 0.793$ with the magnitude

$$\min_{a_0, k, n} \sqrt{\frac{1}{N} \sum_{i=1}^N \left(\frac{H(z_i) - H_i}{\sigma_{H_i}} \right)^2} = 0.8 \quad (63)$$

The $H(z)$ data require accelerated cosmological expansion at the current epoch, and are consistent with the decelerated cosmological expansion at earlier times predicted and required in standard dark energy models.

Fig. 9 shows the $H(z)/(1+z)$ data (32 points) and model prediction as a function of redshift. Fig. 10 represents $H(z)/(1+z)$ data (32 points) and model prediction as a function of redshift for different n with fixed $k = 0.5$ and $a_0 = 0.5$ whereas Fig. 11 indicates $H(z)/(1+z)$ data (32 points) and model prediction as a function of redshift for different k with fixed $n = 0.75$ and $a_0 = 0.5$

For different values of k and n , we can generate a class of models of the universe in Bianchi type-I space-time with time dependent gravitational and cosmological constants. We observe that for $n \geq 2$ and $k = 1$, we obtain a class of transit models of the universe from early decelerated to present accelerating phase. For $n \leq 1$ and $k = 1$, we obtain accelerating models at present epoch. For examples:

- If we put $n = 2$ in Eq. (34), we obtain $a(t) = \sqrt{(t^k e^t)}$. In this case, we obtain the expressions for different physical and geometric quantities as obtained by Pradhan et al. [67]. Thus, our investigations generalize the recent results of Pradhan et al. [47].
- If we put $n = 2$ and $k = 1$ in Eq. (34), we obtain $a(t) = \sqrt{(te^t)}$. In this case, we obtain the expressions for different physical parameters and geometric quantities by putting $n = 2$ and $k = 1$ in Eqs. (42)–(57). Fig. 12 depicts the variation of deceleration parameter with cosmic time for different values of (n, k) . From Fig. 12, we observe that for $n = 2$ and $k = 1$ the model has a transition from very early decelerated phase to the present accelerating phase. We have already mentioned in Sect. 3 that in such type of universe, the deceleration parameter must show signature interchange [67]. The variation of energy density, cosmological constant and density parameters with cosmic

time t have been examined and found to have similar character like model given by Eq. (41) in previous section.

- If we put $n = 3$ and $k = 1$ in Eq. (34), we obtain $a(t) = (te^t)^{\frac{1}{3}}$. In this case, we obtain the expressions for different physical parameters and geometric quantities as usual. From Fig. 12, we observe that for $n = 3$ and $k = 1$, the model has transition from early decelerated phase to the present accelerating phase. The variation of energy density, cosmological constant and density parameters with cosmic time t have been examined and found the same as in previous case. The present value q_0 of the deceleration parameter obtained from observations are $-1.27 \leq q_0 \leq 2$ [68]. Studies of galaxy from redshift surveys provide a value of $q_0 = 0.1$, with an upper limit of $q_0 < 0.75$ [68]. Recent observations show that the deceleration parameter of the universe is in the range $-1 \leq q \leq 0$ i.e $q_0 \approx -0.77$. First, we set $n = 3$ and $k = 1$ in Eq. (48), we obtain $q_0 = -0.67$. This value is very near to the observed value of deceleration parameter (i.e., $q_0 \approx -0.77$) at present epoch [52]. Secondly, if we choose $n = 3$ and $k = 1$, we observe that all the values of physical and geometric parameters are easily integrable. Hence this case is important from physical aspects.
- If we put $n = 1$ and $k = 1$ in Eq. (34), we obtain $a(t) = te^t$. In this case, we obtain the expressions for different physical parameters and geometric quantities as usual. From Fig. 12, one can see that for $n = 1$ and $k = 1$ the model is accelerating at present epoch. The other physical parameters have the same property as already discussed.
- If we put $k = 0$ in Eq. (34), we obtain $a(t) = e^{t/n}$. In this case the universe has non-singular origin which seems reasonable to envision the dynamics of future universe. In this case, we found that energy density (ρ) is always negative and hence it is an unphysical case. We plan to work out a physically viable non-singular model in forthcoming paper.
- We have also plotted $H(z)/(1+z)$ data (32 points) and model prediction as a function of z for different values of k and n by using the data given by Farooq and Ratra [64].

5 Conclusions

In this paper, we have presented a new class of models of accelerating universe and transit universe with gravitational coupling $G(t)$ and cosmological term $\Lambda(t)$ in the framework of general relativity. The models represent expanding, shearing and non-rotating universe. The parameters H , θ , and σ diverge at the initial singularity. There is a Point Type singularity [53] at $t = 0$ in the models. The rate of expansion slows down and finally tends to zero at $t \rightarrow 0$. The pressure, energy density and cosmological term Λ become negligible whereas the scale factors, gravitational constant G and spatial volume become infinite as $t \rightarrow \infty$. The nature of decaying vacuum energy density $\Lambda(t)$ in our derived models is supported by recent cosmological observations. We observe that our derived models are isotropic at present epoch which is in good agreement with the current observations.

For different choice of n and k , we can generate a class of viable cosmological models of the universe in Bianchi type space-time as well as in FRW universe. For example: if we set $n = 2$

in Eq. (34), we find $a = \sqrt{t^k e^t}$ which is used by Pradhan and Amirhashchi [50] in studying the accelerating dark energy models in Bianchi type-V space-time and Pradhan et al. [69] in studying Bianchi type-I in scalar-tensor theory of gravitation. If we set $k = 1$, $n = 2$ in Eq. (34), we find $a = \sqrt{t e^t}$ which is utilized by Amirhashchi et al. [70] in studying interacting two-fluid scenario for dark energy in FRW universe. If we set $k = 1$, $n = 1$ in Eq. (34), we find $a = t e^t$ which is exercised by Pradhan et al. [71] to study the dark energy model in Bianchi type- VI_0 universe. It is observed that such models are also in good harmony with current observations. The present work generalizes the recent works (Pradhan et al. [18, 47]).
