#### Abstract

This paper is devoted to solving a multidimensional backward stochastic differential equation with a general time interval, where the generator is uniformly continuous in $(y, z)$ non-uniformly with respect to $t$. By establishing some results on deterministic backward differential equations with general time intervals, and by virtue of Girsanov's theorem and convolution technique, we establish a new existence and uniqueness result for solutions of this kind of backward stochastic differential equations, which extends the results of Hamadène (2003) and Fan, Jiang, and Tian (2011) to the general time interval case.

Keywords: Backward stochastic differential equation, general time interval, existence and uniqueness, uniformly continuous generator

2010 MSC: 60H10

## 1. Introduction

In this paper, we are concerned with the following multidimensional backward stochastic differential equation (BSDE for short in the remaining):

$$
\begin{equation*}
y_{t}=\xi+\int_{t}^{T} g\left(s, y_{s}, z_{s}\right) \mathrm{d} s-\int_{t}^{T} z_{s} \mathrm{~d} B_{s}, \quad t \in[0, T] \tag{1}
\end{equation*}
$$

where $T$ satisfies $0 \leq T \leq+\infty$ called the terminal time; $\xi$ is a $k$-dimensional random vector called the terminal condition; the random function $g(\omega, t, y, z): \Omega \times[0, T] \times \mathbf{R}^{k} \times \mathbf{R}^{k \times d} \mapsto \mathbf{R}^{k}$ is progressively measurable for each $(y, z)$, called the generator of $\operatorname{BSDE}(1)$; and $B$ is a $d$-dimensional Brownian motion. The solution $\left(y_{t}, z_{t}\right)_{t \in[0, T]}$ is a pair of adapted processes. The triple $(\xi, T, g)$ is called the parameters of $\operatorname{BSDE}(1)$. We also denote by $\operatorname{BSDE}(\xi, T, g)$ the $\operatorname{BSDE}$ with the parameters $(\xi, T, g)$.

The nonlinear BSDEs were initially introduced by Pardoux and Peng (1990). They proved an existence and uniqueness result for solutions of multidimensional BSDEs under the assumptions that the generator $g$ is Lipschitz continuous in $(y, z)$ uniformly with respect to $t$, where the terminal time $T$ is a finite constant. Since then, BSDEs have attracted more and more interesting and many applications on BSDEs have been found in mathematical finance, stochastic control, partial differential equations and so on (See El Karoui, Peng, and Quenez (1997) for details).

[^0]Many works including Mao (1995), Lepeltier and San Martin (1997), Kobylanski (2000), Bahlali (2001), Hamadène (2003), Briand, Lepeltier, and San Martin (2007), Wang and Huang (2009) and Fan, Jiang, and Davison (2010), see also the references therein, have weakened the Lipschitz condition on the generator $g$. In particular, by virtue of some results on deterministic backward differential equations (DBDEs for short in the remaining), Hamadène (2003) proved the existence for solutions of multidimensional BSDEs when the generator $g$ is uniformly continuous in $(y, z)$. Furthermore, by establishing an estimate for a linear-growth function, Fan, Jiang, and Davison (2010) obtained the uniqueness result under the same assumptions as those in Hamadène (2003). It should be pointed out that all these works mentioned above only deal the BSDEs with finite time intervals.

Chen and Wang (2000) first extended the terminal time to the general case and proved the existence and uniqueness for solutions of BSDEs under the assumptions that the generator $g$ is Lipschitz continuous in $(y, z)$ non-uniformly with respect to $t$, which improves the result of Pardoux and Peng (1990) to the infinite time interval case. Furthermore, Fan and Jiang (2010) and Fan, Jiang, and Tian (2011) relaxed the Lipschitz condition of Chen and Wang (2000) and obtained two existence and uniqueness results for solutions of BSDEs with general time intervals, which generalizes the results of Mao (1995) and Lepeltier and San Martin (1997) respectively. Recently, Hua, Jiang, and Shi (2013) extended further the result in Fan and Jiang (2010) to the reflected BSDEs case. However, up to now, the question of the existence and uniqueness for solutions of multidimensional BSDEs with general time intervals and uniformly continuous generators in $(y, z)$ has not been studied.

In this paper, by establishing some results on solutions of DBDEs with general time intervals and by virtue of Girsanov's theorem and convolution technique, we put forward and prove a general existence and uniqueness result for solutions of multidimensional BSDEs with general time intervals and uniformly continuous generators in $(y, z)$ (see Theorem 7 in Section 3), which extends the results of Hamadène (2003) and Fan, Jiang, and Davison (2010) to the general time interval case. It should be mentioned that the uniform continuous assumptions for the generator are not necessarily uniform with respect to $t$ in this result.

We would like to mention that some new troubles arise naturally when we change the terminal time of the BSDE and the DBDE from the finite case to the general case. For example, in the case of $T=+\infty$, the integration of a constant over $[0, T]$ is not finite any more, $\int_{0}^{T} u(t) \mathrm{d} t \leq C \sup _{t \in[0, T]} u(t)$ may not hold any longer, and $\int_{0}^{T} v^{2}(s) \mathrm{d} s<+\infty$ can not imply $\int_{0}^{T} v(s) \mathrm{d} s<+\infty$. All these troubles are well overcome in this paper. Furthermore, although the whole idea of the proof for the existence and uniqueness of Theorem 7 originates from Hamadène (2003) and Fan, Jiang, and Davison (2010) respectively, some different arguments from those employed in Hamadène (2003) is used to prove the existence part of Theorem 7. More specifically, in the Step 1 of the proof for the existence part of Theorem 7, the proof of Lemma 12 is completely different from that of the corresponding result in Hamadène (2003), and we do not use the iteration technique used in Hamadène (2003) for solutions of $\operatorname{BSDE}\left(\xi, T, g^{n}\right)$ (see (14) in Section 4). In addition, the Step 3 of our proof for the existence part is also very different from that in Hamadène (2003). As a result, the proof procedure is simplified at certain degree.

This paper is organized as follows. Section 2 introduces some usual notations and establishes some
results on the solutions of DBDEs with general time intervals. Section 3 is devoted to stating the existence and uniqueness result on BSDEs - Theorem 7. Section 4 gives the detailed proof of Theorem 7, and Appendix provides the proof of the results on DBDEs studied in Section 2.

## 2. Notations and some results on DBDEs

First of all, let $(\Omega, \mathcal{F}, \mathbf{P})$ be a probability space carrying a standard $d$-dimensional Brownian motion $\left(B_{t}\right)_{t \geq 0}$ and let $\left(\mathcal{F}_{t}\right)_{t \geq 0}$ be the natural $\sigma$-algebra filtration generated by $\left(B_{t}\right)_{t \geq 0}$. We assume that $\mathcal{F}_{T}=\mathcal{F}$ and $\left(\mathcal{F}_{t}\right)_{t>0}$ is right-continuous and complete. In this paper, the Euclidean norm of a vector $y \in \mathbf{R}^{k}$ will be defined by $|y|$, and for a $k \times d$ matrix $z$, we define $|z|=\sqrt{\operatorname{Tr}\left(z z^{*}\right)}$, where and hereafter $z^{*}$ represents the transpose of $z$. Let $\langle x, y\rangle$ represent the inner product of $x, y \in \mathbf{R}^{k}$.

Let $L^{2}\left(\Omega, \mathcal{F}_{T}, \mathbf{P} ; \mathbf{R}^{k}\right)$ be the set of $\mathbf{R}^{k}$-valued and $\mathcal{F}_{T}$-measurable random variables $\xi$ such that $\|\xi\|_{L^{2}}^{2}:=\mathbf{E}\left[|\xi|^{2}\right]<+\infty$ and let $\mathcal{S}^{2}\left(0, T ; \mathbf{R}^{k}\right)$ denote the set of $\mathbf{R}^{k}$-valued, adapted and continuous processes $\left(Y_{t}\right)_{t \in[0, T]}$ such that

$$
\|Y\|_{\mathcal{S}^{2}}:=\left(\mathbf{E}\left[\sup _{t \in[0, T]}\left|Y_{t}\right|^{2}\right]\right)^{1 / 2}<+\infty
$$

Moreover, let $\mathrm{M}^{2}\left(0, T ; \mathbf{R}^{k \times d}\right)$ denote the set of (equivalent classes of) $\left(\mathcal{F}_{t}\right)$-progressively measurable $\mathbf{R}^{k \times d_{\text {-valued }}}$ processes $\left(Z_{t}\right)_{t \in[0, T]}$ such that

$$
\|Z\|_{\mathrm{M}^{2}}:=\left(\mathbf{E}\left[\int_{0}^{T}\left|Z_{t}\right|^{2} \mathrm{~d} t\right]\right)^{1 / 2}<+\infty
$$

Obviously, $\mathcal{S}^{2}\left(0, T ; \mathbf{R}^{k}\right)$ is a Banach space and $\mathrm{M}^{2}\left(0, T ; \mathbf{R}^{k \times d}\right)$ is a Hilbert space.
Finally, let $\mathbf{S}$ be the set of all non-decreasing continuous functions $\rho(\cdot): \mathbf{R}^{+} \mapsto \mathbf{R}^{+}$with $\rho(0)=0$ and $\rho(x)>0$ for all $x>0$, where and hereafter $\mathbf{R}^{+}:=[0,+\infty)$.

As mentioned above, we will deal only with the multidimensional BSDE which is an equation of type (1), where the terminal condition $\xi$ is $\mathcal{F}_{T}$-measurable, the terminal time $T$ satisfies $0 \leq T \leq+\infty$, and the generator $g$ is $\left(\mathcal{F}_{t}\right)$-progressively measurable for each $(y, z)$. In this paper, we use the following definition.

Definition 1. A pair of processes $\left(y_{t}, z_{t}\right)_{t \in[0, T]}$ taking values in $\mathbf{R}^{k} \times \mathbf{R}^{k \times d}$ is called a solution of BSDE (1), if $\left(y_{t}, z_{t}\right)_{t \in[0, T]}$ belongs to the space $\mathcal{S}^{2}\left(0, T ; \mathbf{R}^{k}\right) \times \mathrm{M}^{2}\left(0, T ; \mathbf{R}^{k \times d}\right)$ and $\mathrm{d} \mathbf{P}-$ a.s., BSDE (1) holds true for each $t \in[0, T]$.

The following Lemma 2 comes from Lepeltier and San Martin (1997), which will be used later.
Lemma 2. Let $p \in \mathbf{N}, f(\cdot): \mathbf{R}^{p} \mapsto \mathbf{R}$ be a continuous and linear-growth function, i.e., there exists a positive constant $K$ such that $|f(x)| \leq K(1+|x|)$ for all $x \in \mathbf{R}^{p}$. Then $f_{n}(x)=\inf _{y \in \mathbf{R}^{p}}\{f(y)+n|x-y|\}$, $x \in \mathbf{R}^{p}$, is well defined for $n \geq K$ and satisfies
(i) Linear growth: for each $x \in \mathbf{R}^{p},\left|f_{n}(x)\right| \leq K(1+|x|)$;
(ii) Monotonicity in $n$ : for each $x \in \mathbf{R}^{p}, f_{n}(x)$ increases in $n$;
(iii) Lipschitz continuous: for each $x_{1}, x_{2} \in \mathbf{R}^{p}$, we have $\left|f_{n}\left(x_{1}\right)-f_{n}\left(x_{2}\right)\right| \leq n\left|x_{1}-x_{2}\right|$;
(iv) Strong convergence: if $x_{n} \rightarrow x$, then $f_{n}\left(x_{n}\right) \rightarrow f(x)$ as $n \rightarrow+\infty$.

In the following, we will establish some propositions on DBDEs with general time intervals, which will play important roles in the proof of our main result. It is very likely that these results have already appeared somewhere, but we have not seen it, so we provide their proofs in Appendix for the convenience of readers.

Proposition 3. Let $0 \leq T \leq+\infty$ and $f(t, y):[0, T] \times \mathbf{R} \mapsto \mathbf{R}$ satisfy the following two assumptions:
(B1) there exists a function $u(\cdot): \mathbf{R}^{+} \mapsto \mathbf{R}^{+}$with $\int_{0}^{T} u(t) \mathrm{d} t<+\infty$ such that for each $y_{1}, y_{2} \in \mathbf{R}$ and $t \in[0, T]$,

$$
\left|f\left(t, y_{1}\right)-f\left(t, y_{2}\right)\right| \leq u(t)\left|y_{1}-y_{2}\right| ;
$$

(B2) $\int_{0}^{T}|f(t, 0)| \mathrm{d} t<+\infty$.
Then for each $\delta \in \mathbf{R}$ the following $D B D E$

$$
\begin{equation*}
y_{t}=\delta+\int_{t}^{T} f\left(s, y_{s}\right) \mathrm{d} s, \quad t \in[0, T] \tag{2}
\end{equation*}
$$

has a unique continuous solution $\left(y_{t}\right)_{t \in[0, T]}$ such that $\sup _{t \in[0, T]}\left|y_{t}\right|<+\infty$.
Proposition 4. Assume $0 \leq T \leq+\infty$, f satisfies (B1) and (B2), $\left(y_{t}\right)_{t \in[0, T]}$ is the unique continuous solution of DBDE (2) such that $\sup _{t \in[0, T]}\left|y_{t}\right|<+\infty, C$ is an arbitrary constant and $y_{t}^{n}$ is defined recursively as follows, for each $n \in \mathbf{N}$ and $\delta \in \mathbf{R}$,

$$
y_{t}^{1}=C ; \quad y_{t}^{n+1}=\delta+\int_{t}^{T} f\left(s, y_{s}^{n}\right) \mathrm{d} s, \quad t \in[0, T]
$$

Then $y_{t}^{n} \rightarrow y_{t}$ as $n \rightarrow+\infty$ for each $t \in[0, T]$.
Proposition 5. Let $0 \leq T \leq+\infty, f$ and $f^{\prime}$ satisfy (B1) - (B2), $\left(y_{t}\right)_{t \in[0, T]}$ and $\left(y_{t}^{\prime}\right)_{t \in[0, T]}$ with $\sup _{t \in[0, T]}\left(\left|y_{t}\right|+\left|y_{t}^{\prime}\right|\right)<+\infty$ satisfy respectively $D B D E$ (2) and the following $D B D E$, for some $\delta^{\prime} \in \mathbf{R}$,

$$
y_{t}^{\prime}=\delta^{\prime}+\int_{t}^{T} f^{\prime}\left(s, y_{s}^{\prime}\right) \mathrm{d} s, \quad t \in[0, T] .
$$

Assume that $f\left(t, y_{t}^{\prime}\right) \geq f^{\prime}\left(t, y_{t}^{\prime}\right)$ for each $t \in[0, T]$. Then, we have
(i) (Comparison theorem) if $\delta \geq \delta^{\prime}$, then $y_{t} \geq y_{t}^{\prime}$ for each $t \in[0, T]$;
(ii) (Strict comparison theorem) if $\delta>\delta^{\prime}$, then $y_{t}>y_{t}^{\prime}$ for each $t \in[0, T]$.

Proposition 6. Let $0 \leq T \leq+\infty, u(\cdot)$ be defined in (B1) and $\varphi(\cdot): \mathbf{R}^{+} \mapsto \mathbf{R}^{+}$be a continuous function such that $\varphi(x) \leq a x+b$ for all $x \in \mathbf{R}^{+}$, where $a$ and $b$ are two given nonnegative constants. Then for each $\delta \in \mathbf{R}^{+}$, the following $D B D E$

$$
\begin{equation*}
y_{t}^{\delta}=\delta+\int_{t}^{T} u(s) \varphi\left(y_{s}^{\delta}\right) \mathrm{d} s, \quad t \in[0, T] \tag{3}
\end{equation*}
$$

has a solution $\left(y_{t}^{\delta}\right)_{t \in[0, T]}$ such that $\sup _{t \in[0, T]}\left|y_{t}^{\delta}\right|<+\infty$. In addition,
(i) if $\delta>0$ and $\varphi(x)>0$ for all $x>0$, then $D B D E$
(3) has a unique solution;
(ii) if $\delta=0$ and $\varphi \in \mathbf{S}$ with $\int_{0^{+}} \varphi^{-1}(x) \mathrm{d} x=+\infty$, then $D B D E$ (3) has a unique solution $y_{t} \equiv 0$.

## 3. Main result

In this section, we will state the main result of this paper. Let us first introduce the following assumptions with respect to the generator $g$ of $\operatorname{BSDE}$ (1), where $0 \leq T \leq+\infty$.
(H1) $g$ is uniformly continuous in $y$ non-uniformly with respect to $t$, i.e., there exists a deterministic function $u(\cdot):[0, T] \mapsto \mathbf{R}^{+}$with $\int_{0}^{T} u(t) \mathrm{d} t<+\infty$ and a linear-growth function $\rho(\cdot) \in \mathbf{S}$ such that $\mathrm{d} \mathbf{P} \times \mathrm{d} t$ - a.e., for each $y_{1}, y_{2} \in \mathbf{R}^{k}$ and $z \in \mathbf{R}^{k \times d}$,

$$
\left|g\left(\omega, t, y_{1}, z\right)-g\left(\omega, t, y_{2}, z\right)\right| \leq u(t) \rho\left(\left|y_{1}-y_{2}\right|\right)
$$

Furthermore, we also assume that $\int_{0^{+}} \rho^{-1}(u) \mathrm{d} u=+\infty$;
(H2) $g$ is uniformly continuous in $z$ non-uniformly with respect to $t$, i.e., there exists a deterministic function $v(\cdot):[0, T] \mapsto \mathbf{R}^{+}$with $\int_{0}^{T}\left(v(t)+v^{2}(t)\right) \mathrm{d} t<+\infty$ and a linear-growth function $\phi(\cdot) \in \mathbf{S}$ such that $\mathrm{d} \mathbf{P} \times \mathrm{d} t-$ a.e., for each $y \in \mathbf{R}^{k}$ and $z_{1}, z_{2} \in \mathbf{R}^{k \times d}$,

$$
\left|g\left(\omega, t, y, z_{1}\right)-g\left(\omega, t, y, z_{2}\right)\right| \leq v(t) \phi\left(\left|z_{1}-z_{2}\right|\right)
$$

(H3) For any $i=1, \cdots, k, g_{i}(\omega, t, y, z)$, the $i$ th component of $g$, depends only on the $i$ th row of $z$;
(H4) $\mathbf{E}\left[\left(\int_{0}^{T}|g(\omega, t, 0,0)| \mathrm{d} t\right)^{2}\right]<+\infty$.
In the sequel, we denote the linear-growth constant for $\rho(\cdot)$ and $\phi(\cdot)$ in (H1) and (H2) by $A>0$, i.e., $\rho(x) \leq A(1+x)$ and $\phi(x) \leq A(1+x)$ for all $x \in \mathbf{R}^{+}$. In the remaining of this paper, we put an $i$ at upper left of $y \in \mathbf{R}^{k}, z \in \mathbf{R}^{k \times d}$ to represent the $i$ th component of $y$ and the $i$ th row of $z$, like ${ }^{i} y$ and ${ }^{i} z$.

The main result of this paper is the following Theorem 7, whose proof will be given in next section.
Theorem 7. Assume that $0 \leq T \leq+\infty$ and $g$ satisfies (H1)-(H4). Then for each $\xi \in L^{2}\left(\Omega, \mathcal{F}_{T}, \mathbf{P} ; \mathbf{R}^{k}\right)$, BSDE (1) has a unique solution.

Remark 8. In the corresponding assumptions in Hamadène (2003) and Fan, Jiang, and Davison (2010) the $u(t), v(t)$ appearing in (H1) and (H2) are bounded by a constant $c>0$, and $T$ is a finite real number. However, in our framework the $u(t), v(t)$ may be unbounded. In addition, Theorem 7 also considers the case of $T=+\infty$. Consequently, Theorem 7 generalizes the corresponding results in Hamadène (2003) and Fan, Jiang, and Davison (2010).

Example 9. Let $0 \leq T \leq+\infty$, and for each $i=1, \cdots, k$ and $(\omega, t, y, z) \in \Omega \times[0, T] \times \mathbf{R}^{k} \times \mathbf{R}^{k \times d}$, define the generator $g=\left(g_{1}, \cdots, g_{k}\right)$ by

$$
g_{i}(\omega, t, y, z)=f_{1}(t)(h(|y|)+1)+f_{2}(t) \sqrt{\left|{ }^{i} z\right|}+\left|B_{t}(\omega)\right|
$$

where

$$
\begin{aligned}
& f_{1}(t)=\frac{1}{\sqrt{t}} \mathbf{1}_{0<t<\delta}+\frac{1}{\sqrt{1+t^{2}}} \mathbf{1}_{\delta \leq t \leq T}, \\
& f_{2}(t)=\frac{1}{\sqrt[4]{t}} \mathbf{1}_{0<t<\delta}+\frac{1}{\sqrt{(1+t)^{2}}} \mathbf{1}_{\delta \leq t \leq T},
\end{aligned}
$$

$$
h(x)=x \ln \frac{1}{x} \mathbf{1}_{0 \leq x \leq \delta}+\left[h^{\prime}(\delta-)(x-\delta)+h(\delta)\right] \mathbf{1}_{x>\delta}
$$

with $\delta$ small enough. Since $h(0)=0$ and $h$ is concave and increasing, we have $h\left(x_{1}+x_{2}\right) \leq h\left(x_{1}\right)+h\left(x_{2}\right)$ for all $x_{1}, x_{2} \in \mathbf{R}^{+}$, which implies that $\left|h\left(x_{1}\right)-h\left(x_{2}\right)\right| \leq h\left(\left|x_{1}-x_{2}\right|\right)$. Thus, note that

$$
\int_{0^{+}} \frac{1}{x \ln \frac{1}{x}} \mathrm{~d} x=+\infty
$$

We know that the generator $g$ satisfies assumptions (H1) - (H4) with $u(t)=f_{1}(t), v(t)=f_{2}(t)$. It then follows from Theorem 7 that for each $\xi \in L^{2}\left(\Omega, \mathcal{F}_{T}, \mathbf{P} ; \mathbf{R}^{k}\right)$, BSDE (1) has a unique solution $\left(y_{t}, z_{t}\right)_{t \in[0, T]}$.

It should be mentioned that the above conclusion can not be obtained by the result of Hamadène (2003), Fan, Jiang, and Davison (2010) and other existing results.

## 4. Proof of the main result

This section will give the proof of our main result - Theorem 7. Before starting the proof, let us first introduce the following Lemma 10, which comes from Theorem 1.2 in Chen and Wang (2000). The following assumption will be used in Lemma 10, where we suppose $0 \leq T \leq+\infty$ :
(A1) There exist two deterministic functions $u(\cdot), v(\cdot):[0, T] \mapsto \mathbf{R}^{+}$with $\int_{0}^{T}\left(u(t)+v^{2}(t)\right) \mathrm{d} t<+\infty$ such that $\mathrm{d} \mathbf{P} \times \mathrm{d} t-$ a.e., for each $y_{1}, y_{2} \in \mathbf{R}^{k}$ and $z_{1}, z_{2} \in \mathbf{R}^{k \times d}$,

$$
\left|g\left(t, y_{1}, z_{1}\right)-g\left(t, y_{2}, z_{2}\right)\right| \leq u(t)\left|y_{1}-y_{2}\right|+v(t)\left|z_{1}-z_{2}\right|
$$

Lemma 10 (Theorem 1.2 in Chen and Wang (2000)). Assume that $0 \leq T \leq+\infty$ and $g$ satisfies (A1) and (H4). Then for each $\xi \in L^{2}\left(\Omega, \mathcal{F}_{T}, \mathbf{P} ; \mathbf{R}^{k}\right)$, BSDE (1) has a unique solution $\left(y_{t}, z_{t}\right)_{t \in[0, T]}$.

### 4.1. Proof of the uniqueness part of Theorem 7

The idea of the proof of this part is partly motivated by Fan, Jiang, and Davison (2010). Let $\left(y_{t}^{1}, z_{t}^{1}\right)_{t \in[0, T]}$ and $\left(y_{t}^{2}, z_{t}^{2}\right)_{t \in[0, T]}$ be two solutions of $\operatorname{BSDE}$ (1). Then we have the following Lemma 11, whose proof is provided at the end of this subsection.

Lemma 11. The process $\left(y_{t}^{1}-y_{t}^{2}\right)_{t \in[0, T]}$ is uniformly bounded, i.e., there exists a positive constant $C_{1}>0$ such that

$$
\begin{equation*}
\mathrm{d} \mathbf{P} \times \mathrm{d} t \text { - a.e., } \quad\left|y_{t}^{1}-y_{t}^{2}\right| \leq C_{1} \tag{4}
\end{equation*}
$$

Moreover, for each $n \in \mathbf{N}, i=1,2, \cdots, k$ and $0 \leq r \leq t \leq T$, we have

$$
\begin{equation*}
\mathbf{E}^{n, i}\left[\left|y_{t}^{i} y_{t}^{1} y_{t}^{2}\right| \mid \mathcal{F}_{r}\right] \leq a_{n}+\int_{t}^{T} \mathbf{E}^{n, i}\left[u(s) \rho\left(\left|y_{s}^{1}-y_{s}^{2}\right|\right) \mid \mathcal{F}_{r}\right] \mathrm{d} s \tag{5}
\end{equation*}
$$

where

$$
a_{n}=\phi\left(\frac{2 A}{n+2 A}\right) \int_{0}^{T} v(s) \mathrm{d} s
$$

and $\mathbf{E}^{n, i}\left[X \mid \mathcal{F}_{t}\right]$ represents the conditional expectation of random variable $X$ with respect to $\mathcal{F}_{t}$ under a probability measure $\mathbf{P}^{n, i}$ on $(\Omega, \mathcal{F})$, which depends on $n$ and $i$, and which is absolutely continuous with respect to $\mathbf{P}$.

In the sequel, let $\bar{\rho}(y)=\rho(|y|)$ for each $y \in \mathbf{R}$, and for each $n \in \mathbf{N}$, define $\rho_{n}(\cdot): \mathbf{R} \mapsto \mathbf{R}^{+}$by

$$
\rho_{n}(x)=\sup _{y \in \mathbf{R}}\{\bar{\rho}(y)-n|x-y|\} .
$$

It follows from Lemma 2 that $\rho_{n}$ is well defined for $n \geq A$, Lipschitz continuous, non-increasing in $n$ and converges to $\bar{\rho}$. Then, for each $n \geq A$, by Proposition 3 we can let $f_{t}^{n}$ be the unique solution of the following DBDE

$$
\begin{equation*}
f_{t}^{n}=a_{n}+\int_{t}^{T}\left[u(s) \rho_{n}\left(k \cdot f_{s}^{n}\right)\right] \mathrm{d} s, \quad t \in[0, T] \tag{6}
\end{equation*}
$$

Noticing that $\rho_{n}$ and $a_{n}$ are both decreasing in $n$, we have $0 \leq f_{t}^{n+1} \leq f_{t}^{n}$ for each $n \geq A$ by Proposition 5, which implies that the sequence $\left\{f_{t}^{n}\right\}_{n=1}^{+\infty}$ converges point wisely to a function $f_{t}$. Thus, by sending $n \rightarrow+\infty$ in (6), it follows from Lemma 2 and the Lebesgue dominated convergence theorem that

$$
f_{t}=\int_{t}^{T}\left[u(s) \bar{\rho}\left(k \cdot f_{s}\right)\right] \mathrm{d} s=\int_{t}^{T}\left[u(s) \rho\left(k \cdot f_{s}\right)\right] \mathrm{d} s, \quad t \in[0, T]
$$

Recalling that $\rho(\cdot) \in \mathbf{S}$ and $\int_{0^{+}} \rho^{-1}(u) \mathrm{d} u=+\infty$, Proposition 6 yields that $f_{t} \equiv 0$.
Now, for each $n \geq A, j \in \mathbf{N}$ and $t \in[0, T]$, let $f_{t}^{n, j}$ be the function defined recursively as follows:

$$
\begin{equation*}
f_{t}^{n, 1}=C_{1} ; \quad f_{t}^{n, j+1}=a_{n}+\int_{t}^{T}\left(u(s) \rho_{n}\left(k \cdot f_{s}^{n, j}\right)\right) \mathrm{d} s \tag{7}
\end{equation*}
$$

where $C_{1}$ is defined in (4). Noticing that $\rho_{n}$ is Lipschitz continuous, by Proposition 4 we know that $f_{t}^{n, j}$ converges point wisely to $f_{t}^{n}$ as $j \rightarrow+\infty$ for each $t \in[0, T]$ and $n \geq A$.

On the other hand, it is easy to check by induction that for each $n \geq A, j \geq 1$ and $i=1, \cdots, k$,

$$
\begin{equation*}
\left|{ }^{i} y_{t}^{1}-{ }^{i} y_{t}^{2}\right| \leq f_{t}^{n, j} \leq f_{0}^{n, j}, \quad t \in[0, T] . \tag{8}
\end{equation*}
$$

Indeed, (8) holds true for $j=1$ due to (4). Suppose (8) holds true for $j \geq 1$. Then, for each $t \in[0, T]$,

$$
u(t) \rho\left(\left|y_{t}^{1}-y_{t}^{2}\right|\right) \leq u(t) \rho\left(k \cdot f_{t}^{n, j}\right) \leq u(t) \rho_{n}\left(k \cdot f_{t}^{n, j}\right)
$$

In view of (5) with $r=t$ as well as (7), we can deduce that for each $n \geq A$ and $i=1,2, \cdots, k$,

$$
\left|{ }^{i} y_{t}^{1}-{ }^{i} y_{t}^{2}\right| \leq f_{t}^{n, j+1} \leq f_{0}^{n, j+1}, \quad t \in[0, T]
$$

which is the desired result.
Finally, by sending first $j \rightarrow+\infty$ and then $n \rightarrow+\infty$ in (8), we obtain that $\sup _{t \in[0, T]}\left|{ }^{i} y_{t}^{1}-{ }^{i} y_{t}^{2}\right|=0$ for each $i=1,2, \cdots, k$. That is, the solution of $\operatorname{BSDE}(1)$ is unique. The proof of the uniqueness part is then completed.

Proof of Lemma 11. Using Itô's formula to $\left|y_{t}^{1}-y_{t}^{2}\right|^{2}$ we arrive, for each $t \in[0, T]$, at

$$
\begin{align*}
\left|y_{t}^{1}-y_{t}^{2}\right|^{2}+\int_{t}^{T}\left|z_{s}^{1}-z_{s}^{2}\right|^{2} \mathrm{~d} s= & 2 \int_{t}^{T}\left\langle y_{s}^{1}-y_{s}^{2}, g\left(s, y_{s}^{1}, z_{s}^{1}\right)-g\left(s, y_{s}^{2}, z_{s}^{2}\right)\right\rangle \mathrm{d} s \\
& -2 \int_{t}^{T}\left\langle y_{s}^{1}-y_{s}^{2},\left(z_{s}^{1}-z_{s}^{2}\right) \mathrm{d} B_{s}\right\rangle . \tag{9}
\end{align*}
$$

The inner product term including $g$ can be enlarged by (H1) - (H2) and the basic inequality $2 a b \leq$ $2 a^{2}+b^{2} / 2$ as follows:

$$
2\left\langle y_{s}^{1}-y_{s}^{2}, g\left(s, y_{s}^{1}, z_{s}^{1}\right)-g\left(s, y_{s}^{2}, z_{s}^{2}\right)\right\rangle \leq 2\left|y_{s}^{1}-y_{s}^{2}\right|\left|g\left(s, y_{s}^{1}, z_{s}^{1}\right)-g\left(s, y_{s}^{2}, z_{s}^{1}\right)+g\left(s, y_{s}^{2}, z_{s}^{1}\right)-g\left(s, y_{s}^{2}, z_{s}^{2}\right)\right|
$$

$$
\begin{aligned}
& \leq 2\left|y_{s}^{1}-y_{s}^{2}\right|\left(A u(s)\left|y_{s}^{1}-y_{s}^{2}\right|+A v(s)\left|z_{s}^{1}-z_{s}^{2}\right|+A u(s)+A v(s)\right) \\
& \leq B(s)\left|y_{s}^{1}-y_{s}^{2}\right|^{2}+\frac{1}{2}\left|z_{s}^{1}-z_{s}^{2}\right|^{2}+A u(s)+A v(s)
\end{aligned}
$$

where $B(s)=2 A u(s)+2 A^{2} v^{2}(s)+A u(s)+A v(s)$. Putting the previous inequality into (9) we can obtain that for each $t \in[0, T]$,

$$
\left|y_{t}^{1}-y_{t}^{2}\right|^{2} \leq \int_{t}^{T} B(s)\left|y_{s}^{1}-y_{s}^{2}\right|^{2} \mathrm{~d} s-2 \int_{t}^{T}\left\langle y_{s}^{1}-y_{s}^{2},\left(z_{s}^{1}-z_{s}^{2}\right) \mathrm{d} B_{s}\right\rangle+C
$$

where $C=\int_{0}^{T} A(u(s)+v(s)) \mathrm{d} s$. Note that both $\left(y_{t}^{1}, z_{t}^{1}\right)_{t \in[0, T]}$ and $\left(y_{t}^{2}, z_{t}^{2}\right)_{t \in[0, T]}$ belong to the process space $\mathcal{S}^{2}\left(0, T ; \mathbf{R}^{k}\right) \times \mathrm{M}^{2}\left(0, T ; \mathbf{R}^{k \times d}\right)$. By the Burkholder-Davis-Gundy (BDG for short in the remaining) inequality and Hölder's inequality we have that there exists a positive constant $K^{\prime}>0$ such that

$$
\begin{aligned}
\mathbf{E}\left[\sup _{t \in[0, T]} \mid \int_{0}^{t}\left\langle y_{s}^{1}-y_{s}^{2},\left(z_{s}^{1}-z_{s}^{2}\right) \mathrm{d} B_{s}\right|\right] & \leq K^{\prime} \mathbf{E}\left[\sqrt{\int_{0}^{T}\left|y_{s}^{1}-y_{s}^{2}\right|^{2}\left|z_{s}^{1}-z_{s}^{2}\right|^{2} \mathrm{~d} s}\right] \\
& \leq K^{\prime} \sqrt{\mathbf{E}\left[\sup _{t \in[0, T]}\left|y_{t}^{1}-y_{t}^{2}\right|^{2}\right]} \sqrt{\mathbf{E}\left[\int_{0}^{T}\left|z_{s}^{1}-z_{s}^{2}\right|^{2} \mathrm{~d} s\right]}<+\infty
\end{aligned}
$$

which implies that $\left(\int_{0}^{t}\left\langle y_{s}^{1}-y_{s}^{2},\left(z_{s}^{1}-z_{s}^{2}\right) \mathrm{d} B_{s}\right\rangle\right)_{t \in[0, T]}$ is an $\left(\mathcal{F}_{t}, \mathbf{P}\right)$-martingale. Then we have for each $0 \leq r \leq t \leq T$,

$$
\mathbf{E}\left[\left|y_{t}^{1}-y_{t}^{2}\right|^{2} \mid \mathcal{F}_{r}\right] \leq \int_{t}^{T} B(s) \mathbf{E}\left[\left|y_{s}^{1}-y_{s}^{2}\right|^{2} \mid \mathcal{F}_{r}\right] \mathrm{d} s+C
$$

By Lemma 4 in Fan, Jiang, and Tian (2011) we have

$$
\mathbf{E}\left[\left|y_{t}^{1}-y_{t}^{2}\right|^{2} \mid \mathcal{F}_{r}\right] \leq C \mathrm{e}^{\int_{0}^{T} B(s) \mathrm{d} s}:=\left(C_{1}\right)^{2},
$$

which yields (4) after taking $r=t$.
In the sequel, by (H3) we have for each $t \in[0, T]$,

$$
{ }^{i} y_{t}^{1}-{ }^{i} y_{t}^{2}=\int_{t}^{T}\left(g_{i}\left(s, y_{s}^{1},{ }^{i} z_{s}^{1}\right)-g_{i}\left(s, y_{s}^{2},{ }^{i} z_{s}^{2}\right)\right) \mathrm{d} s-\int_{t}^{T}\left({ }^{i} z_{s}^{1}-{ }^{i} z_{s}^{2}\right) \mathrm{d} B_{s}
$$

Then, (H3) and Tanaka's formula lead to that, for each $t \in[0, T]$,

$$
\begin{equation*}
\left|{ }^{i} y_{t}^{1}-{ }^{i} y_{t}^{2}\right| \leq \int_{t}^{T} \operatorname{sgn}\left({ }^{i} y_{s}^{1}-{ }^{i} y_{s}^{2}\right)\left(g_{i}\left(s, y_{s}^{1},{ }^{i} z_{s}^{1}\right)-g_{i}\left(s, y_{s}^{2},{ }^{i} z_{s}^{2}\right)\right) \mathrm{d} s-\int_{t}^{T} \operatorname{sgn}\left({ }^{i} y_{s}^{1}-{ }^{i} y_{s}^{2}\right)\left({ }^{i} z_{s}^{1}-{ }^{i} z_{s}^{2}\right) \mathrm{d} B_{s} \tag{10}
\end{equation*}
$$

Furthermore, it follows from (H1) and (H2) that

$$
\begin{equation*}
\left|g_{i}\left(s, y_{s}^{1},{ }^{i} z_{s}^{1}\right)-g_{i}\left(s, y_{s}^{2},{ }^{i} z_{s}^{2}\right)\right| \leq u(s) \rho\left(\left|y_{s}^{1}-y_{s}^{2}\right|\right)+v(s) \phi\left(\left.\right|^{i} z_{s}^{1}-{ }^{i} z_{s}^{2} \mid\right) \tag{11}
\end{equation*}
$$

Recalling that $\phi(\cdot)$ is a non-decreasing function from $\mathbf{R}^{+}$to itself with at most linear-growth. From Fan, Jiang, and Davison (2010) we know that for each $n \in \mathbf{N}$ and $x \in \mathbf{R}^{+}$,

$$
\begin{equation*}
\phi(x) \leq(n+2 A) x+\phi\left(\frac{2 A}{n+2 A}\right) \tag{12}
\end{equation*}
$$

Thus, combining (10) - (12) we get that for each $n \in \mathbf{N}$,

$$
\left|{ }^{i} y_{t}^{1}-{ }^{i} y_{t}^{2}\right| \leq \phi\left(\frac{2 A}{n+2 A}\right) \int_{0}^{T} v(s) \mathrm{d} s+\int_{t}^{T}\left(u(s) \rho\left(\left|y_{s}^{1}-y_{s}^{2}\right|\right)+\left.(n+2 A) v(s)\right|^{i} z_{s}^{1}-{ }^{i} z_{s}^{2} \mid\right) \mathrm{d} s
$$

$$
-\int_{t}^{T} \operatorname{sgn}\left({ }^{i} y_{s}^{1}-{ }^{i} y_{s}^{2}\right)\left({ }^{i} z_{s}^{1}-{ }^{i} z_{s}^{2}\right) \mathrm{d} B_{s}, \quad t \in[0, T]
$$

Now for each $t \in[0, T]$, let

$$
e_{t}^{n, i}:=(n+2 A) \frac{\operatorname{sgn}\left({ }^{i} y_{t}^{1}-{ }^{i} y_{t}^{2}\right)\left({ }^{i} z_{t}^{1}-{ }^{i} z_{t}^{2}\right)^{*}}{\left|{ }^{i} z_{t}^{1}-{ }^{i} z_{t}^{2}\right|} \mathbf{1}_{\left|{ }^{i} z_{t}^{1}-{ }^{i} z_{t}^{2}\right| \neq 0}
$$

Then, $\left(e_{t}^{n, i}\right)_{t \in[0, T]}$ is a $\mathbf{R}^{d}$-valued, bounded and $\left(\mathcal{F}_{t}\right)$-adapted process. It follows from Girsanov's theorem that $B_{t}^{n, i}=B_{t}-\int_{0}^{t} e_{s}^{n, i} v(s) \mathrm{d} s, t \in[0, T]$, is a $d$-dimensional Brownian motion under the probability $\mathbf{P}^{n, i}$ on $(\Omega, \mathcal{F})$ defined by

$$
\frac{\mathrm{d} \mathbf{P}^{n, i}}{\mathrm{~d} \mathbf{P}}=\exp \left\{\int_{0}^{T} v(s)\left(e_{s}^{n, i}\right)^{*} \mathrm{~d} B_{s}-\frac{1}{2} \int_{0}^{T} v^{2}(s)\left|e_{s}^{n, i}\right|^{2} \mathrm{~d} s\right\}
$$

Thus, for each $n \in \mathbf{N}$ and $t \in[0, T]$,

$$
\begin{equation*}
\left|{ }^{i} y_{t}^{1}-{ }^{i} y_{t}^{2}\right| \leq \phi\left(\frac{2 A}{n+2 A}\right) \int_{0}^{T} v(s) \mathrm{d} s+\int_{t}^{T} u(s) \rho\left(\left|y_{s}^{1}-y_{s}^{2}\right|\right) \mathrm{d} s-\int_{t}^{T} \operatorname{sgn}\left({ }^{i} y_{s}^{1}-{ }^{i} y_{s}^{2}\right)\left({ }^{i} z_{s}^{1}-{ }^{i} z_{s}^{2}\right) \mathrm{d} B_{s}^{n, i} \tag{13}
\end{equation*}
$$

Moreover, the process $\left(\int_{0}^{t} \operatorname{sgn}\left({ }^{i} y_{s}^{1}-{ }^{i} y_{s}^{2}\right)\left({ }^{i} z_{s}^{1}-{ }^{i} z_{s}^{2}\right) \mathrm{d} B_{s}^{n, i}\right)_{t \in[0, T]}$ is an $\left(\mathcal{F}_{t}, \mathbf{P}^{n, i}\right)$-martingale. In fact, let $\mathbf{E}^{n, i}[X]$ represent the expectation of the random variable $X$ under $\mathbf{P}^{n, i}$. By the BDG inequality and Hölder's inequality we know that there exists a positive constant $K^{\prime \prime}>0$ such that for each $n \in \mathbf{N}$,

$$
\begin{aligned}
& \mathbf{E}^{n, i}\left[\sup _{t \in[0, T]}\left|\int_{0}^{t} \operatorname{sgn}\left({ }^{i} y_{s}^{1}-{ }^{i} y_{s}^{2}\right)\left({ }^{i} z_{s}^{1}-{ }^{i} z_{s}^{2}\right) \mathrm{d} B_{s}^{n, i}\right|\right] \\
& \leq K^{\prime \prime} \mathbf{E}^{n, i}\left[\sqrt{\int_{0}^{T}\left|{ }^{i} z_{s}^{1}-{ }^{i} z_{s}^{2}\right|^{2} \mathrm{~d} s}\right] \leq K^{\prime \prime} \sqrt{\mathbf{E}\left[\left(\frac{\mathrm{d} \mathbf{P}^{n, i}}{\mathrm{~d} \mathbf{P}}\right)^{2}\right]} \sqrt{\mathbf{E}\left[\int_{0}^{T}\left|{ }^{i} z_{s}^{1}-{ }^{i} z_{s}^{2}\right|^{2} \mathrm{~d} s\right]}<+\infty
\end{aligned}
$$

Thus, for each $n \in \mathbf{N}$ and $0 \leq r \leq t \leq T$, by taking the condition expectation with respect to $\mathcal{F}_{r}$ under $\mathbf{P}^{n, i}$ in both sides of (13), we can get the desired result (5). The proof of Lemma 11 is complete.

### 4.2. Proof of the existence part of Theorem 7

The idea of the proof of this part is enlightened by Hamadène (2003). But some different arguments are used, and then the proof procedure is simplified at certain degree.

Assume that the generator $g$ satisfies (H1) - (H4) and $\xi \in L^{2}\left(\Omega, \mathcal{F}_{T}, \mathbf{P} ; \mathbf{R}^{k}\right)$. Without loss of generality, we assume that $u(t)$ and $v(t)$ in (H1) and (H2) are both strictly positive functions. Otherwise, we can use $u(t)+\mathrm{e}^{-t}$ and $v(t)+\mathrm{e}^{-t}$ instead of them respectively.

We have the following lemma whose proof is placed at the end of this subsection.
Lemma 12. Let g satisfy (H1) - (H3), and assume that $u(t)>0$ and $v(t)>0$ for each $t \in[0, T]$. Then there exists a generator sequence $\left\{g^{n}\right\}_{n=1}^{+\infty}$ such that
(i) For each $n \in \mathbf{N}, g^{n}(t, y, z)$ is a mapping from $\Omega \times[0, T] \times \mathbf{R}^{k} \times \mathbf{R}^{k \times d}$ into $\mathbf{R}^{k}$ and is $\left(\mathcal{F}_{t}\right)$-progressively measurable. Moreover, we have $\mathrm{d} \mathbf{P} \times \mathrm{d} t$-a.e., for each $y \in \mathbf{R}^{k}$ and $z \in \mathbf{R}^{k \times d}$,

$$
\left|g^{n}(t, y, z)\right| \leq|g(t, 0,0)|+k A u(t)(1+|y|)+k A v(t)(1+|z|)
$$

(ii) For each $n \in \mathbf{N}, g^{n}(t, y, z)$ satisfies (H3), and $\mathrm{d} \mathbf{P} \times \mathrm{d} t-$ a.e., for each $y_{1}, y_{2} \in \mathbf{R}^{k}$ and $z_{1}$, $z_{2} \in \mathbf{R}^{k \times d}$, we have

$$
\begin{aligned}
& \left|g^{n}\left(t, y_{1}, z_{1}\right)-g^{n}\left(t, y_{2}, z_{2}\right)\right| \leq k u(t) \rho\left(\left|y_{1}-y_{2}\right|\right)+k v(t) \phi\left(\left|z_{1}-z_{2}\right|\right) \\
& \left|g^{n}\left(t, y_{1}, z_{1}\right)-g^{n}\left(t, y_{2}, z_{2}\right)\right| \leq k(n+A)\left(u(t)\left|y_{1}-y_{2}\right|+v(t)\left|z_{1}-z_{2}\right|\right)
\end{aligned}
$$

(iii) For each $n \in \mathbf{N}$, there exists a non-increasing deterministic functions sequence $b_{n}(\cdot):[0, T] \mapsto \mathbf{R}^{+}$ with $\int_{0}^{T} b_{n}(t) \mathrm{d} t \rightarrow 0$ as $n \rightarrow+\infty$ such that $\mathrm{d} \mathbf{P} \times \mathrm{d} t-$ a.e., for each $y \in \mathbf{R}^{k}$ and $z \in \mathbf{R}^{k \times d}$,

$$
\left|g^{n}(t, y, z)-g(t, y, z)\right| \leq k b_{n}(t)
$$

It follows from (i) - (ii) of Lemma 12 and (H4) that for each $n \in \mathbf{N}, g^{n}$ satisfies (A1) and (H4). Then it follows from Lemma 10 that for each $n \in \mathbf{N}$ and $\xi \in L^{2}\left(\Omega, \mathcal{F}_{T}, \mathbf{P} ; \mathbf{R}^{k}\right)$, the following $\operatorname{BSDE}$

$$
\begin{equation*}
y_{t}^{n}=\xi+\int_{t}^{T} g^{n}\left(s, y_{s}^{n}, z_{s}^{n}\right) \mathrm{d} s-\int_{t}^{T} z_{s}^{n} \mathrm{~d} B_{s}, \quad t \in[0, T] \tag{14}
\end{equation*}
$$

has a unique solution $\left(y_{t}^{n}, z_{t}^{n}\right)_{t \in[0, T]}$. The following proof will be split into three steps.
Step 1. In this step we show that $\left\{\left(y_{t}^{n}\right)_{t \in[0, T]}\right\}_{n=1}^{+\infty}$ is a Cauchy sequence in $\mathcal{S}^{2}\left(0, T ; \mathbf{R}^{k}\right)$.
For each $n, m \in \mathbf{N}$, let $\left(y_{t}^{n}, z_{t}^{n}\right)_{t \in[0, T]}$ and $\left(y_{t}^{m}, z_{t}^{m}\right)_{t \in[0, T]}$ be, respectively, solutions of $\operatorname{BSDE}\left(\xi, T, g^{n}\right)$ and $\operatorname{BSDE}\left(\xi, T, g^{m}\right)$. Using Itô's formula to $\left|y_{t}^{n}-y_{t}^{m}\right|^{2}$ we arrive, for each $t \in[0, T]$, at

$$
\begin{align*}
\left|y_{t}^{n}-y_{t}^{m}\right|^{2}+\int_{t}^{T}\left|z_{s}^{n}-z_{s}^{m}\right|^{2} \mathrm{~d} s= & 2 \int_{t}^{T}\left\langle y_{s}^{n}-y_{s}^{m}, g^{n}\left(s, y_{s}^{n}, z_{s}^{n}\right)-g^{m}\left(s, y_{s}^{m}, z_{s}^{m}\right)\right\rangle \mathrm{d} s \\
& -2 \int_{t}^{T}\left\langle y_{s}^{n}-y_{s}^{m},\left(z_{s}^{n}-z_{s}^{m}\right) \mathrm{d} B_{s}\right\rangle . \tag{15}
\end{align*}
$$

It follows from (ii) - (iii) in Lemma 12 and the basic inequality $2 a b \leq 2 a^{2}+b^{2} / 2$ that, with adding and subtracting the term $g^{n}\left(s, y_{s}^{m}, z_{s}^{m}\right)$,

$$
\begin{aligned}
& 2\left\langle y_{s}^{n}-y_{s}^{m}, g^{n}\left(s, y_{s}^{n}, z_{s}^{n}\right)-g^{m}\left(s, y_{s}^{m}, z_{s}^{m}\right)\right\rangle \\
& \leq 2\left|y_{s}^{n}-y_{s}^{m}\right|\left(k A u(s)\left|y_{s}^{n}-y_{s}^{m}\right|+k A v(s)\left|z_{s}^{n}-z_{s}^{m}\right|+k A u(s)+k A v(s)+\tau_{n, m}(s)\right) \\
& \leq\left(D(s)+\tau_{n, m}(s)\right)\left|y_{s}^{n}-y_{s}^{m}\right|^{2}+\frac{1}{2}\left|z_{s}^{n}-z_{s}^{m}\right|^{2}+k A u(s)+k A v(s)+\tau_{n, m}(s)
\end{aligned}
$$

where

$$
\tau_{n, m}(s)=k\left(b_{n}(s)+b_{m}(s)\right), \quad D(s)=2 k A u(s)+2 k^{2} A^{2} v^{2}(s)+k A u(s)+k A v(s) .
$$

Putting the previous inequality into (15) and taking the conditional expectation with respect to $\mathcal{F}_{r}$ yield that, for each $0 \leq r \leq t \leq T$ and $n, m \in \mathbf{N}$.

$$
\mathbf{E}\left[\left|y_{t}^{n}-y_{t}^{m}\right|^{2} \mid \mathcal{F}_{r}\right] \leq \int_{t}^{T}\left(D(s)+\tau_{n, m}(s)\right) \mathbf{E}\left[\left|y_{s}^{n}-y_{s}^{m}\right|^{2} \mid \mathcal{F}_{r}\right] \mathrm{d} s+C_{n, m}
$$

where $C_{n, m}=\int_{0}^{T}\left(k A u(s)+k A v(s)+\tau_{n, m}(s)\right) \mathrm{d} s$. It follows from Lemma 4 in Fan, Jiang, and Tian (2011) that

$$
\mathbf{E}\left[\left|y_{t}^{n}-y_{t}^{m}\right|^{2} \mid \mathcal{F}_{r}\right] \leq C_{n, m} \mathrm{e}^{\int_{0}^{T}\left(D(s)+\tau_{n, m}(s)\right) \mathrm{d} s} \leq C_{1,1} \mathrm{e}^{\int_{0}^{T}\left(D(s)+\tau_{1,1}(s)\right) \mathrm{d} s}:=\left(C_{2}\right)^{2}
$$

After taking $r=t$ in the previous inequality, we have that for each $n, m \in \mathbf{N}, \mathrm{~d} \mathbf{P} \times \mathrm{d} t-$ a.e., $\left|y_{t}^{n}-y_{t}^{m}\right| \leq C_{2}$.

Furthermore, it follows from (ii) in Lemma 12, (H3) and Tanaka's formula that for each $t \in[0, T]$,

$$
\begin{align*}
\left|{ }^{i} y_{t}^{n}-{ }^{i} y_{t}^{m}\right| \leq & \int_{t}^{T} \operatorname{sgn}\left({ }^{i} y_{s}^{n}-{ }^{i} y_{s}^{m}\right)\left(g_{i}^{n}\left(s, y_{s}^{n},{ }^{i} z_{s}^{n}\right)-g_{i}^{m}\left(s, y_{s}^{m},{ }^{i} z_{s}^{m}\right)\right) \mathrm{d} s \\
& -\int_{t}^{T} \operatorname{sgn}\left({ }^{i} y_{s}^{n}-{ }^{i} y_{s}^{m}\right)\left({ }^{i} z_{s}^{n}-{ }^{i} z_{s}^{m}\right) \mathrm{d} B_{s} . \tag{16}
\end{align*}
$$

It follows from (ii) - (iii) in Lemma 12 that, by adding and subtracting the term $g_{i}^{n}\left(s, y_{s}^{m},{ }^{i} z_{s}^{m}\right)$,

$$
\begin{equation*}
\left|g_{i}^{n}\left(s, y_{s}^{n},{ }^{i} z_{s}^{n}\right)-g_{i}^{m}\left(s, y_{s}^{m},{ }^{i} z_{s}^{m}\right)\right| \leq k u(s) \rho\left(\left|y_{s}^{n}-y_{s}^{m}\right|\right)+k v(s) \phi\left(\left.\right|^{i} z_{s}^{n}-{ }^{i} z_{s}^{m} \mid\right)+\tau_{n, m}(s) . \tag{17}
\end{equation*}
$$

Combining (16) - (17) with (12) we get that for each $n, m, q \in \mathbf{N}$ and $t \in[0, T]$,

$$
\begin{align*}
\left|{ }^{i} y_{t}^{n}-{ }^{i} y_{t}^{m}\right| \leq & C_{n, m, q}+k \int_{t}^{T}\left(u(s) \rho\left(\left|y_{s}^{n}-y_{s}^{m}\right|\right)+\left.(q+2 A) v(s)\right|^{i} z_{s}^{n}-{ }^{i} z_{s}^{m} \mid\right) \mathrm{d} s \\
& -\int_{t}^{T} \operatorname{sgn}\left({ }^{i} y_{s}^{n}-{ }^{i} y_{s}^{m}\right)\left({ }^{i} z_{s}^{n}-{ }^{i} z_{s}^{m}\right) \mathrm{d} B_{s} \tag{18}
\end{align*}
$$

where

$$
C_{n, m, q}:=k \phi\left(\frac{2 A}{q+2 A}\right) \int_{0}^{T} v(s) \mathrm{d} s+\int_{0}^{T} \tau_{n, m}(s) \mathrm{d} s
$$

In the sequel, by virtue of Girsanov's theorem, in the same way as in the proof of Lemma 11 we can deduce from (18) that for each $n, m, q \in \mathbf{N}, i=1, \cdots, k$, and $0 \leq r \leq t \leq T$,

$$
\mathbf{E}^{n, m, q, i}\left[\left|y_{t}^{i}-{ }^{i} y_{t}^{m}\right| \mid \mathcal{F}_{r}\right] \leq C_{n, m, q}+k \int_{t}^{T} \mathbf{E}^{n, m, q, i}\left[u(s) \rho\left(\left|y_{s}^{n}-y_{s}^{m}\right|\right) \mid \mathcal{F}_{r}\right] \mathrm{d} s
$$

where $\mathbf{E}^{n, m, q, i}\left[X \mid \mathcal{F}_{t}\right]$ represents the conditional expectation of random variable $X$ with respect to $\mathcal{F}_{t}$ under a probability measure $\mathbf{P}^{n, m, q, i}$ on $(\Omega, \mathcal{F})$, which depends on $n, m, q$ and $i$, and which is absolutely continuous with respect to $\mathbf{P}$.

Finally, note that $C_{n, m, q}$ tends non-increasingly to 0 as $n, m, q \rightarrow+\infty$. The same argument as in the proof of the uniqueness part of Theorem 7 yields that for each $i=1, \cdots, k$,

$$
\lim _{n, m \rightarrow+\infty} \mathbf{E}\left[\sup _{t \in[0, T]}\left|{ }^{i} y_{t}^{n}-{ }^{i} y_{t}^{m}\right|^{2}\right]=0
$$

which means that $\left\{\left(y_{t}^{n}\right)_{t \in[0, T]}\right\}_{n=1}^{+\infty}$ is a Cauchy sequence in $\mathcal{S}^{2}\left(0, T ; \mathbf{R}^{k}\right)$. We denote the limit by $\left(y_{t}\right)_{t \in[0, T]}$.

Step 2. In this step we show that $\left\{\left(z_{t}^{n}\right)_{t \in[0, T]}\right\}_{n=1}^{+\infty}$ is a Cauchy sequence in $\mathrm{M}^{2}\left(0, T ; \mathbf{R}^{k \times d}\right)$.
Using Itô's formula for $\left|y_{t}^{n}\right|^{2}$ defined in $\operatorname{BSDE}$ (14), we can obtain that

$$
\left|y_{t}^{n}\right|^{2}+\int_{t}^{T}\left|z_{s}^{n}\right|^{2} \mathrm{~d} s=|\xi|^{2}+2 \int_{t}^{T}\left\langle y_{s}^{n}, g^{n}\left(s, y_{s}^{n}, z_{s}^{n}\right)\right\rangle \mathrm{d} s-2 \int_{t}^{T}\left\langle y_{s}^{n}, z_{s}^{n} \mathrm{~d} B_{s}\right\rangle
$$

Let $G_{n}(\omega):=\sup _{t \in[0, T]}\left|y_{t}^{n}\right|$. It follows from the convergence of $\left\{\left(y_{t}^{n}\right)_{t \in[0, T]}\right\}_{n=1}^{+\infty}$ in $\mathcal{S}^{2}\left(0, T ; \mathbf{R}^{k}\right)$ that $\sup _{n \in \mathbf{N}} \mathbf{E}\left[G_{n}^{2}(\omega)\right]<+\infty$. In view of (i) in Lemma 12 we have that for each $t \in[0, T]$,

$$
\begin{aligned}
\left|y_{t}^{n}\right|^{2}+\int_{t}^{T}\left|z_{s}^{n}\right|^{2} \mathrm{~d} s \leq & |\xi|^{2}-2 \int_{t}^{T}\left\langle y_{s}^{n}, z_{s}^{n} \mathrm{~d} B_{s}\right\rangle \\
& +2 G_{n}(\omega) \int_{t}^{T}\left(|g(s, 0,0)|+k A u(s)\left(1+\left|y_{s}^{n}\right|\right)+k A v(s)\left(1+\left|z_{s}^{n}\right|\right)\right) \mathrm{d} s
\end{aligned}
$$

It follows from the BDG inequality that $\left(\int_{0}^{t}\left\langle y_{t}^{n}, z_{t}^{n} \mathrm{~d} B_{s}\right\rangle\right)_{t \in[0, T]}$ is an $\left(\mathcal{F}_{t}, \mathbf{P}\right)$-martingale. By the inequalities $2 a b \leq a^{2}+b^{2}, 2 a b \leq \lambda a^{2}+b^{2} / \lambda\left(\lambda:=2 k^{2} A^{2} \int_{0}^{T} v^{2}(s) \mathrm{d} s\right)$ and Hölder's inequality we deduce that for each $n \in \mathbf{N}$,

$$
\begin{gathered}
\mathbf{E}\left[\int_{0}^{T}\left|z_{s}^{n}\right|^{2} \mathrm{~d} s\right] \leq \mathbf{E}\left[|\xi|^{2}\right]+\left[1+k A+\lambda+2 k A \int_{0}^{T} u(s) \mathrm{d} s\right] \sup _{n \in \mathbf{N}} \mathbf{E}\left[G_{n}^{2}(\omega)\right]+\mathbf{E}\left[\left(\int_{0}^{T}|g(s, 0,0)| \mathrm{d} s\right)^{2}\right] \\
\quad+k A\left(\int_{0}^{T}(u(s)+v(s)) \mathrm{d} s\right)^{2}+\frac{k^{2} A^{2}}{\lambda} \mathbf{E}\left[\left(\int_{0}^{T} v(s)\left|z_{s}^{n}\right| \mathrm{d} s\right)^{2}\right] \leq C_{3}+\frac{1}{2} \mathbf{E}\left[\int_{0}^{T}\left|z_{s}^{n}\right|^{2} \mathrm{~d} s\right]
\end{gathered}
$$

from which it follows that

$$
\begin{equation*}
\sup _{n} \mathbf{E}\left[\int_{0}^{T}\left|z_{s}^{n}\right|^{2} \mathrm{~d} s\right] \leq 2 C_{3}<+\infty \tag{19}
\end{equation*}
$$

where $C_{3}$ is a positive constant and independent of $n$.
On the other hand, by taking expectation in both sides of (15), we have that for each $n, m \in \mathbf{N}$,

$$
\begin{equation*}
\mathbf{E}\left[\int_{0}^{T}\left|z_{s}^{n}-z_{s}^{m}\right|^{2} \mathrm{~d} s\right] \leq 2 \mathbf{E}\left[\int_{0}^{T}\left\langle y_{s}^{n}-y_{s}^{m}, g^{n}\left(s, y_{s}^{n}, z_{s}^{n}\right)-g^{m}\left(s, y_{s}^{m}, z_{s}^{m}\right)\right\rangle \mathrm{d} s\right] . \tag{20}
\end{equation*}
$$

It follows from (i) in Lemma 12 that

$$
\begin{aligned}
& 2\left\langle y_{s}^{n}-y_{s}^{m}, g^{n}\left(s, y_{s}^{n}, z_{s}^{n}\right)-g^{m}\left(s, y_{s}^{m}, z_{s}^{m}\right)\right\rangle \\
& \leq 4 k\left|y_{s}^{n}-y_{s}^{m}\right|\left[|g(s, 0,0)|+A u(s)\left(G_{n}(\omega)+G_{m}(\omega)\right)+A v(s)\left(\left|z_{s}^{n}\right|+\left|z_{s}^{m}\right|\right)+A(u(s)+v(s))\right]
\end{aligned}
$$

Putting the previous inequality into (20) and using Hölder's inequality and (19) yields that

$$
\begin{aligned}
\mathbf{E}\left[\int_{0}^{T}\left|z_{s}^{n}-z_{s}^{m}\right|^{2} \mathrm{~d} s\right] \leq & 16 k \sqrt{\mathbf{E}\left[\sup _{t \in[0, T]}\left|y_{t}^{n}-y_{t}^{m}\right|^{2}\right]} \sqrt{\mathbf{E}\left[\left(\int_{0}^{T}[|g(s, 0,0)|+A(u(s)+v(s))] \mathrm{d} s\right)^{2}\right]} \\
& +32 k A \int_{0}^{T} u(s) \mathrm{d} s \sqrt{\sup _{n \in \mathbf{N}} \mathbf{E}\left[G_{n}^{2}(\omega)\right]} \sqrt{\mathbf{E}\left[\sup _{t \in[0, T]}\left|y_{t}^{n}-y_{t}^{m}\right|^{2}\right]} \\
& +32 k A \sqrt{2 C_{3} \int_{0}^{T} v^{2}(s) \mathrm{d} s} \sqrt{\mathbf{E}\left[\sup _{t \in[0, T]}\left|y_{t}^{n}-y_{t}^{m}\right|^{2}\right]}
\end{aligned}
$$

Since $\sup _{n \in \mathbf{N}} \mathbf{E}\left[G_{n}^{2}(\omega)\right]<+\infty,\left\{\left(y_{t}^{n}\right)_{t \in[0, T]}\right\}_{n=1}^{+\infty}$ converges in $\mathcal{S}^{2}\left(0, T ; \mathbf{R}^{k}\right)$ and

$$
\begin{aligned}
& \mathbf{E}\left[\left(\int_{0}^{T}[|g(s, 0,0)|+A(u(s)+v(s))] \mathrm{d} s\right)^{2}\right] \\
& \leq 2 \mathbf{E}\left[\left(\int_{0}^{T}|g(s, 0,0)| \mathrm{d} s\right)^{2}\right]+2\left(\int_{0}^{T} A(u(s)+v(s)) \mathrm{d} s\right)^{2}<+\infty
\end{aligned}
$$

we can deduce that,

$$
\lim _{n, m \rightarrow+\infty} \mathbf{E}\left[\int_{0}^{T}\left|z_{s}^{n}-z_{s}^{m}\right|^{2} \mathrm{~d} s\right]=0
$$

Therefore, $\left\{\left(z_{t}^{n}\right)_{t \in[0, T]}\right\}_{n=1}^{+\infty}$ is a Cauchy sequence in $\mathrm{M}^{2}\left(0, T ; \mathbf{R}^{k \times d}\right)$. We denote by $\left(z_{t}\right)_{t \in[0, T]}$ the limit.
Step 3. This step will show that the process $\left(y_{t}, z_{t}\right)_{t \in[0, T]}$ is a solution of $\operatorname{BSDE}$ (1).

Now, we have known that for each fixed $t \in[0, T]$, the sequence $\left\{y_{t}^{n}\right\}_{n=1}^{+\infty}$ and $\left\{\int_{t}^{T} z_{s}^{n} \mathrm{~d} B_{s}\right\}_{n=1}^{+\infty}$ converge in $L^{2}\left(\Omega, \mathcal{F}_{T}, \mathbf{P} ; \mathbf{R}^{k}\right)$ toward to $y_{t}$ and $\int_{t}^{T} z_{s} \mathrm{~d} B_{s}$ respectively. Next let us check the limit of $g^{n}\left(s, y_{s}^{n}, z_{s}^{n}\right)$ in BSDE (14). First, for each $t \in[0, T]$, we have

$$
\begin{align*}
& \mathbf{E}\left[\left(\int_{t}^{T}\left|g^{n}\left(s, y_{s}^{n}, z_{s}^{n}\right)-g\left(s, y_{s}, z_{s}\right)\right| \mathrm{d} s\right)^{2}\right] \\
& \leq 2 \mathbf{E}\left[\left(\int_{0}^{T}\left|g^{n}\left(s, y_{s}^{n}, z_{s}^{n}\right)-g\left(s, y_{s}^{n}, z_{s}^{n}\right)\right| \mathrm{d} s\right)^{2}\right]+2 \mathbf{E}\left[\left(\int_{0}^{T}\left|g\left(s, y_{s}^{n}, z_{s}^{n}\right)-g\left(s, y_{s}, z_{s}\right)\right| \mathrm{d} s\right)^{2}\right] \tag{21}
\end{align*}
$$

It follows from (iii) in Lemma 12 that the first term on the right side of (21) converges to 0 as $n \rightarrow+\infty$. Furthermore, by (H1) - (H2) and (12) we have that for each $n, m \in \mathbf{N}$,

$$
\begin{align*}
\mathbf{E}\left[\left(\int_{0}^{T}\left|g\left(s, y_{s}^{n}, z_{s}^{n}\right)-g\left(s, y_{s}, z_{s}\right)\right| \mathrm{d} s\right)^{2}\right] \leq & 2(m+2 A)^{2} \mathbf{E}\left[\left(\int_{0}^{T}\left(u(s)\left|y_{s}^{n}-y_{s}\right|+v(s)\left|z_{s}^{n}-z_{s}\right|\right) \mathrm{d} s\right)^{2}\right] \\
& +2\left(\int_{0}^{T}\left[u(s) \rho\left(\frac{2 A}{m+2 A}\right)+v(s) \phi\left(\frac{2 A}{m+2 A}\right)\right] \mathrm{d} s\right)^{2} \tag{22}
\end{align*}
$$

Note that the second term on the right side of (22) converges to 0 as $m \rightarrow+\infty$. On the other hand, it follows from Hölder's inequality that

$$
\begin{aligned}
& \mathbf{E}\left[\left(\int_{0}^{T}\left(u(s)\left|y_{s}^{n}-y_{s}\right|+v(s)\left|z_{s}^{n}-z_{s}\right|\right) \mathrm{d} s\right)^{2}\right] \\
& \leq 2\left(\int_{0}^{T} u(s) \mathrm{d} s\right)^{2} \mathbf{E}\left[\sup _{t \in[0, T]}\left|y_{t}^{n}-y_{t}\right|^{2}\right]+2 \int_{0}^{T} v^{2}(s) \mathrm{d} s \mathbf{E}\left[\int_{0}^{T}\left|z_{s}^{n}-z_{s}\right|^{2} \mathrm{~d} s\right] .
\end{aligned}
$$

Thus, by virtue of the fact that $\left\{\left(y_{t}^{n}, z_{t}^{n}\right)_{t \in[0, T]}\right\}_{n=1}^{+\infty}$ is a Cauchy sequence in $\mathcal{S}^{2}\left(0, T ; \mathbf{R}^{k}\right) \times \mathrm{M}^{2}\left(0, T ; \mathbf{R}^{k \times d}\right)$, taking $n \rightarrow+\infty$ and then $m \rightarrow+\infty$ in (22) and taking $n \rightarrow+\infty$ in (21) yield that for each $t \in[0, T]$,

$$
\lim _{n \rightarrow+\infty} \mathbf{E}\left[\left|\int_{t}^{T} g^{n}\left(s, y_{s}^{n}, z_{s}^{n}\right) \mathrm{d} s-\int_{t}^{T} g\left(s, y_{s}, z_{s}\right) \mathrm{d} s\right|^{2}\right]=0
$$

Consequently, noticing that $\left(y_{t}\right)_{t \in[0, T]}$ is a continuous process, by passing to the limit in BSDE (14) we deduce that $\mathrm{d} \mathbf{P}-$ a.s.,

$$
y_{t}=\xi+\int_{t}^{T} g\left(s, y_{s}, z_{s}\right) \mathrm{d} s-\int_{t}^{T} z_{s} \mathrm{~d} B_{s}, \quad t \in[0, T]
$$

which means that $\left(y_{t}, z_{t}\right)_{t \in[0, T]} \in \mathcal{S}^{2}\left(0, T ; \mathbf{R}^{k}\right) \times \mathrm{M}^{2}\left(0, T ; \mathbf{R}^{k \times d}\right)$ is a solution of BSDE (1).
Proof of Lemma 12. For each $i=1, \ldots, k$, by (H1) $-(H 3)$ we deduce that $\mathrm{d} \mathbf{P} \times \mathrm{d} t-$ a.e., for each $n \in \mathbf{N}, y, p \in \mathbf{R}^{k}$ and $z, q \in \mathbf{R}^{k \times d}$,

$$
\begin{align*}
& g_{i}\left(t, p,{ }^{i} q\right)+(n+A)\left(u(t)|p-y|+\left.v(t)\right|^{i} q-{ }^{i} z \mid\right) \\
& \geq g_{i}(t, 0,0)-\left(A u(t)(1+|p|)+A v(t)\left(1+\left|{ }^{i} q\right|\right)\right)+A u(t)(|p|-|y|)+A v(t)\left(\left.\right|^{i} q\left|-\left|\left.\right|^{i} z\right|\right)\right. \\
& \geq g_{i}(t, 0,0)-A u(t)(1+|y|)-A v(t)\left(1+\left|{ }^{i} z\right|\right) \tag{23}
\end{align*}
$$

Thus, for each $n \in \mathbf{N}, i=1, \cdots, k, y \in \mathbf{R}^{k}$ and $z \in \mathbf{R}^{k \times d}$, we can define the following $\left(\mathcal{F}_{t}\right)$-progressively measurable function:

$$
\begin{equation*}
g_{i}^{n}(t, y, z)=\inf _{(p, q) \in \mathbf{R}^{k} \times \mathbf{R}^{k \times d}}\left\{g_{i}\left(t, p,{ }^{i} q\right)+(n+A)\left(u(t)|p-y|+\left.v(t)\right|^{i} q-{ }^{i} z \mid\right)\right\} \tag{24}
\end{equation*}
$$

and it depends only on the $i$ th row of $z$. Obviously, $g_{i}^{n}\left(t, y,{ }^{i} z\right) \leq g_{i}\left(t, y,{ }^{i} z\right)$, and it follows from (23) that

$$
g_{i}^{n}\left(t, y,{ }^{i} z\right) \geq-\left|g_{i}(t, 0,0)\right|-A u(t)(1+|y|)-A v(t)\left(1+\left.\right|^{i} z \mid\right)
$$

Hence, for each $n \in \mathbf{N}, g_{i}^{n}$ is well defined and (i) holds true with setting $g^{n}:=\left(g_{1}^{n}, g_{2}^{n}, \cdots, g_{k}^{n}\right)$.
Furthermore, it follows from (24) that

$$
g_{i}^{n}\left(t, y,{ }^{i} z\right)=\inf _{(\bar{p}, \bar{q}) \in \mathbf{R}^{k} \times \mathbf{R}^{k \times d}}\left\{g_{i}\left(t, y-\bar{p},{ }^{i} z-{ }^{i} \bar{q}\right)+(n+A)\left(u(t)|\bar{p}|+\left.v(t)\right|^{i} \bar{q} \mid\right)\right\} .
$$

Thus, in view of (H1) - (H2) and the following basic inequality

$$
\begin{equation*}
\left|\inf _{x \in D} f_{1}(x)-\inf _{x \in D} f_{2}(x)\right| \leq \sup _{x \in D}\left|f_{1}(x)-f_{2}(x)\right| \tag{25}
\end{equation*}
$$

we have, $\mathrm{d} \mathbf{P} \times \mathrm{d} t$ - a.e., for each $n \in \mathbf{N}, i=1, \cdots, k, y_{1}, y_{2} \in \mathbf{R}^{k}$ and $z_{1}, z_{2} \in \mathbf{R}^{k \times d}$,

$$
\begin{aligned}
\left|g_{i}^{n}\left(t, y_{1},{ }^{i} z_{1}\right)-g_{i}^{n}\left(t, y_{2},{ }^{i} z_{2}\right)\right| & \leq \sup _{(\bar{p}, \bar{q}) \in \mathbf{R}^{k} \times \mathbf{R}^{k \times d}}\left|g_{i}\left(t, y_{1}-\bar{p},{ }^{i} z_{1}-{ }^{i} \bar{q}\right)-g_{i}\left(t, y_{2}-\bar{p},{ }^{i} z_{2}-{ }^{i} \bar{q}\right)\right| \\
& \leq u(t) \rho\left(\left|y_{1}-y_{2}\right|\right)+v(t) \phi\left(\left|{ }^{i} z_{1}-{ }^{i} z_{2}\right|\right),
\end{aligned}
$$

which means that (H1) - (H2) hold true for $g_{i}^{n}$.
In the sequel, it follows from (24) and (25) that, $\mathrm{d} \mathbf{P} \times \mathrm{d} t$ - a.e., for each $n \in \mathbf{N}, i=1, \cdots, k, y_{1}$, $y_{2} \in \mathbf{R}^{k}$ and $z_{1}, z_{2} \in \mathbf{R}^{k \times d}$,

$$
\begin{aligned}
& \left|g_{i}^{n}\left(t, y_{1},{ }^{i} z_{1}\right)-g_{i}^{n}\left(t, y_{2},{ }^{i} z_{2}\right)\right| \\
& \leq \sup _{(p, q) \in \mathbf{R}^{k} \times \mathbf{R}^{k \times d}}\left|(n+A)\left(u(t)\left|p-y_{1}\right|+v(t)\left|{ }^{i} q-{ }^{i} z_{1}\right|\right)-(n+A)\left(u(t)\left|p-y_{2}\right|+\left.v(t)\right|^{i} q-{ }^{i} z_{2} \mid\right)\right| \\
& \leq(n+A)\left(u(t)\left|y_{1}-y_{2}\right|+v(t){ }^{i} z_{1}-{ }^{i} z_{2} \mid\right) .
\end{aligned}
$$

Hence, (A1) is right for $g_{i}^{n}$.
Finally, for each $n \in \mathbf{N}, i=1, \cdots, k, y \in \mathbf{R}^{k}, z \in \mathbf{R}^{k \times d}$ and $t \in[0, T]$, let

$$
\mathbf{H}_{n, i, t}(y, z):=\left\{(p, q) \in \mathbf{R}^{k} \times \mathbf{R}^{k \times d}: u(t)|p-y|+\left.v(t)\right|^{i} q-{ }^{i} z \left\lvert\,>\frac{2 A}{n}(u(t)+v(t))\right.\right\},
$$

then

$$
\mathbf{H}_{n, i, t}^{c}(y, z)=\left\{(p, q) \in \mathbf{R}^{k} \times \mathbf{R}^{k \times d}: u(t)|p-y|+\left.v(t)\right|^{i} q-{ }^{i} z \left\lvert\, \leq \frac{2 A}{n}(u(t)+v(t))\right.\right\}
$$

For each $n \in \mathbf{N}, i=1, \cdots, k, y \in \mathbf{R}^{k}, z \in \mathbf{R}^{k \times d}, t \in[0, T]$ and $(p, q) \in \mathbf{H}_{n, i, t}(y, z)$, it follows from (H1) - (H2) that

$$
\begin{aligned}
g_{i}\left(t, p,{ }^{i} q\right)+(n+A)\left(u(t)|p-y|+\left.v(t)\right|^{i} q-{ }^{i} z \mid\right) & \geq g_{i}\left(t, y,{ }^{i} z\right)+n\left(u(t)|p-y|+\left.v(t)\right|^{i} q-{ }^{i} z \mid\right)-A(u(t)+v(t)) \\
& >g_{i}\left(t, y,{ }^{i} z\right)+A(u(t)+v(t)), \quad \mathrm{d} \mathbf{P}-\text { a.s.. }
\end{aligned}
$$

Then, since $g_{i}^{n}\left(t, y,{ }^{i} z\right) \leq g_{i}\left(t, y,{ }^{i} z\right)$, we have that $\mathrm{d} \mathbf{P} \times \mathrm{d} t-$ a.e., for each $n \in \mathbf{N}, i=1, \cdots, k, y \in \mathbf{R}^{k}$ and $z \in \mathbf{R}^{k \times d}$,

$$
\begin{equation*}
g_{i}^{n}\left(t, y,{ }^{i} z\right)=\inf _{(p, q) \in \mathbf{H}_{n, i, t}^{c}(y, z)}\left\{g_{i}\left(t, p,{ }^{i} q\right)+(n+A)\left(u(t)|p-y|+\left.v(t)\right|^{i} q-{ }^{i} z \mid\right)\right\} \tag{26}
\end{equation*}
$$

In the sequel, (H1) - (H3) and (26) yield that, $\mathrm{d} \mathbf{P} \times \mathrm{d} t-$ a.e., for each $n \in \mathbf{N}, i=1, \cdots, k, y \in \mathbf{R}^{k}$ and $z \in \mathbf{R}^{k \times d}$,

$$
g_{i}^{n}\left(t, y,{ }^{i} z\right) \geq \inf _{(p, q) \in \mathbf{H}_{n, i, t}^{c}(y, z)}\left\{g_{i}\left(t, y,{ }^{i} z\right)-u(t) \rho(|p-y|)-v(t) \phi\left(\left.\right|^{i} q-{ }^{i} z \mid\right)\right\} \geq g_{i}\left(t, y,{ }^{i} z\right)-b_{n}(t)
$$

where

$$
b_{n}(t)=u(t) \rho\left(\frac{2 A}{n} \cdot \frac{u(t)+v(t)}{u(t)}\right)+v(t) \phi\left(\frac{2 A}{n} \cdot \frac{u(t)+v(t)}{v(t)}\right) .
$$

Thus, $\mathrm{d} \mathbf{P} \times \mathrm{d} t-$ a.e., for each $n \in \mathbf{N}, i=1, \cdots, k, y \in \mathbf{R}^{k}$ and $z \in \mathbf{R}^{k \times d}$,

$$
0 \leq g_{i}\left(t, y,{ }^{i} z\right)-g_{i}^{n}\left(t, y,{ }^{i} z\right) \leq b_{n}(t)
$$

It is clear that $b_{n}(t) \downarrow 0$ as $n \rightarrow+\infty$ for each $t \in[0, T]$. Since $\rho(\cdot)$ and $\phi(\cdot)$ are at most linear-growth, we have

$$
b_{n}(t) \leq A u(t)+\frac{2 A^{2}}{n}(u(t)+v(t))+A v(t)+\frac{2 A^{2}}{n}(u(t)+v(t)) \leq\left(A+4 A^{2}\right)(u(t)+v(t))
$$

from which and the Lebesgue dominated convergence theorem it follows that $\int_{0}^{T} b_{n}(t) \mathrm{d} t \rightarrow 0$ as $n \rightarrow+\infty$.
Thus, the sequence $g^{n}:=\left(g_{1}^{n}, g_{2}^{n}, \cdots, g_{k}^{n}\right)$ is just the one we desire. The proof is complete.
Remark 13. Note that if there exists a constant $K>0$ such that the function $\phi(\cdot)$ appearing in (H2) satisfies $\phi(x) \leq K x$ for all $x \in \mathbf{R}^{+}$, then the condition $\int_{0}^{T}\left(v(t)+v^{2}(t)\right) \mathrm{d} t<+\infty$ in Theorem 7 can be weakened to $\int_{0}^{T} v^{2}(t) \mathrm{d} t<+\infty$ as in Lemma 10.

## Appendix: Some proofs of results on DBDEs

For the convenience of readers, we would like to provide here the proofs of those results on deterministic backward stochastic differential equations introduced in Section 2.

Proof of Proposition 3. For each $\beta(\cdot): \mathbf{R}^{+} \mapsto \mathbf{R}^{+}$such that $\int_{0}^{T} \beta(t) \mathrm{d} t<+\infty$, let $\mathcal{H}_{\beta(\cdot)}$ denote the set of the continuous functions $\left(y_{t}\right)_{t \in[0, T]}$ such that

$$
\|y\|_{\beta(\cdot)}:=\left(\sup _{t \in[0, T]}\left[\mathrm{e}^{-\int_{t}^{T} \beta(r) \mathrm{d} r}\left|y_{t}\right|^{2}\right]\right)^{1 / 2}<+\infty
$$

It is easy to verify that $\mathcal{H}_{\beta(\cdot)}$ is a Banach space. Note that for any $y_{t} \in \mathcal{H}_{\beta(\cdot)}$, in view of (B1) and (B2),

$$
\begin{aligned}
\int_{0}^{T}\left|f\left(t, y_{t}\right)\right| \mathrm{d} t & \leq \int_{0}^{T} u(t)\left|y_{t}\right| \mathrm{d} t+\int_{0}^{T}|f(t, 0)| \mathrm{d} t \\
& \leq \int_{0}^{T} u(t) \mathrm{d} t \cdot\left[\mathrm{e}^{\int_{0}^{T} \beta(r) \mathrm{d} r}\|y\|_{\beta(\cdot)}\right]+\int_{0}^{T}|f(t, 0)| \mathrm{d} t<+\infty
\end{aligned}
$$

For any $y_{t} \in \mathcal{H}_{\beta(\cdot)}$, define

$$
Y_{t}:=\delta+\int_{t}^{T} f\left(s, y_{s}\right) \mathrm{d} s, \quad t \in[0, T]
$$

Then we have

$$
\|Y\|_{\beta(\cdot)}=\sqrt{\sup _{t \in[0, T]}\left[\mathrm{e}^{-\int_{t}^{T} \beta(r) \mathrm{d} r}\left|Y_{t}\right|^{2}\right]} \leq \sup _{t \in[0, T]}\left|Y_{t}\right| \leq|\delta|+\int_{0}^{T}\left|f\left(t, y_{t}\right)\right| \mathrm{d} t<+\infty
$$

Thus, we have constructed a mapping $\Phi: \mathcal{H}_{\beta(\cdot)} \mapsto \mathcal{H}_{\beta(\cdot)}$ such that $\Phi\left(y_{t}\right)=Y_{t}$. Next we prove that this mapping is strictly contractive when $\beta(\cdot)$ is chosen appropriately.

Take $y_{t}^{1}, y_{t}^{2} \in \mathcal{H}_{\beta(\cdot)}$ and assume that $\Phi\left(y_{t}^{1}\right)=Y_{t}^{1}, \Phi\left(y_{t}^{2}\right)=Y_{t}^{2}$. Let us set $\hat{Y}_{t}:=Y_{t}^{1}-Y_{t}^{2}, \hat{y}_{t}:=y_{t}^{1}-y_{t}^{2}$. Then we have

$$
\begin{aligned}
\mathrm{d}\left[\mathrm{e}^{-\int_{s}^{T} \beta(r) \mathrm{d} r}\left|\hat{Y}_{s}\right|^{2}\right] & =\mathrm{e}^{-\int_{s}^{T} \beta(r) \mathrm{d} r}\left(\beta(s)\left|\hat{Y}_{s}\right|^{2} \mathrm{~d} s+2 \hat{Y}_{s} \mathrm{~d} \hat{Y}_{s}\right) \\
& =\mathrm{e}^{-\int_{s}^{T} \beta(r) \mathrm{d} r}\left(\beta(s)\left|\hat{Y}_{s}\right|^{2} \mathrm{~d} s-2 \hat{Y}_{s}\left(f\left(s, y_{s}^{1}\right)-f\left(s, y_{s}^{2}\right)\right) \mathrm{d} s\right)
\end{aligned}
$$

from which it follows that

$$
\mathrm{e}^{-\int_{t}^{T} \beta(r) \mathrm{d} r}\left|\hat{Y}_{t}\right|^{2}=\int_{t}^{T} \mathrm{e}^{-\int_{s}^{T} \beta(r) \mathrm{d} r}\left[2 \hat{Y}_{s}\left(f\left(t, y_{s}^{1}\right)-f\left(t, y_{s}^{2}\right)\right)-\beta(s)\left|\hat{Y}_{s}\right|^{2}\right] \mathrm{d} s
$$

By (B1) and the inequality $2 a b \leq \lambda a^{2}+b^{2} / \lambda(\lambda>0)$ we get that

$$
\begin{aligned}
\mathrm{e}^{-\int_{t}^{T} \beta(r) \mathrm{d} r}\left|\hat{Y}_{t}\right|^{2} & \leq \int_{t}^{T} \mathrm{e}^{-\int_{s}^{T} \beta(r) \mathrm{d} r}\left[2 \sqrt{u(s)}\left|\hat{Y}_{s}\right| \sqrt{u(s)}\left|\hat{y}_{s}\right|-\beta(s)\left|\hat{Y}_{s}\right|^{2}\right] \mathrm{d} s \\
& \leq \int_{t}^{T} \mathrm{e}^{-\int_{s}^{T} \beta(r) \mathrm{d} r}\left[(\lambda u(s)-\beta(s))\left|\hat{Y}_{s}\right|^{2}+\frac{u(s)}{\lambda}\left|\hat{y}_{s}\right|^{2}\right] \mathrm{d} s
\end{aligned}
$$

from which it follows that, with choosing $\lambda>4 \int_{0}^{T} u(s) \mathrm{d} s$ and $\beta(s)=\lambda u(s)$,

$$
\|\hat{Y}\|_{\beta(\cdot)}^{2} \leq \frac{1}{\lambda} \int_{0}^{T} \mathrm{e}^{-\int_{s}^{T} \beta(r) \mathrm{d} r} u(s)\left|\hat{y}_{s}\right|^{2} \mathrm{~d} s \leq \frac{1}{\lambda} \sup _{t \in[0, T]}\left[\mathrm{e}^{-\int_{t}^{T} \beta(r) \mathrm{d} r}\left|\hat{y}_{t}\right|^{2}\right] \int_{0}^{T} u(s) \mathrm{d} s<\frac{1}{4}\|\hat{y}\|_{\beta(\cdot)}^{2}
$$

So $\|\hat{Y}\|_{\beta(\cdot)}<\frac{1}{2}\|\hat{y}\|_{\beta(\cdot)}$, which implies that $\Phi$ is a contractive mapping from $\mathcal{H}_{\beta(\cdot)}$ to $\mathcal{H}_{\beta(\cdot)}$. Then the conclusion follows from the fixed point theorem immediately.

Proposition 4 follows directly from the proof Proposition 3.
Proof of Proposition 5. For each $t \in[0, T]$, let us set

$$
a(t):= \begin{cases}\frac{f\left(t, y_{t}\right)-f\left(t, y_{t}^{\prime}\right)}{y_{t}-y_{t}^{\prime}}, & y_{t} \neq y_{t}^{\prime} \\ 0, & y_{t}=y_{t}^{\prime}\end{cases}
$$

$b(t):=f\left(t, y_{t}^{\prime}\right)-f^{\prime}\left(t, y_{t}^{\prime}\right)$ and $\hat{y}_{t}:=y_{t}-y_{t}^{\prime}$. From (B1) and (B2) we can deduce that $\int_{0}^{T}|a(s)| \mathrm{d} s \leq$ $\int_{0}^{T} u(s) \mathrm{d} s<+\infty$ and $\int_{0}^{T} b(s) \mathrm{d} s<+\infty$. Then we have

$$
\begin{aligned}
\hat{y}_{t} & =\delta-\delta^{\prime}+\int_{t}^{T}\left(f\left(s, y_{s}\right)-f\left(s, y_{s}^{\prime}\right)+f\left(s, y_{s}^{\prime}\right)-f^{\prime}\left(s, y_{s}^{\prime}\right)\right) \mathrm{d} s \\
& =\delta-\delta^{\prime}+\int_{t}^{T} a(s) \hat{y}_{s} \mathrm{~d} s+\int_{t}^{T} b(s) \mathrm{d} s, \quad t \in[0, T]
\end{aligned}
$$

Consequently, in view of the conditions that $\delta \geq \delta^{\prime}$ and $b(t) \geq 0$ for each $t \in[0, T]$,

$$
\hat{y}_{t}=\mathrm{e}^{\int_{t}^{T} a(s) \mathrm{d} s}\left[\delta-\delta^{\prime}+\int_{t}^{T} b(s) \mathrm{e}^{\int_{s}^{T} a(r) \mathrm{d} r} \mathrm{~d} s\right] \geq 0, \quad t \in[0, T]
$$

Furthermore, if $\delta>\delta^{\prime}$, then $\hat{y}_{t}>0$ for each $t \in[0, T]$. The proof is then completed.

Proof of Proposition 6. Let $\varphi_{n}(x):=\inf _{y \in \mathbf{R}}\{\bar{\varphi}(y)+n|x-y|\}$ with $\bar{\varphi}(y)=\varphi(|y|)$ for $y \in \mathbf{R}$, then it follows from Lemma 2 and Proposition 3 that $\varphi_{n}(x)$ is well defined on $\mathbf{R}$ for each $n \geq a$, and for each $n \geq a$, the following two DBDEs

$$
\begin{equation*}
y_{t}^{n, \delta}=\delta+\int_{t}^{T} u(s) \varphi_{n}\left(y_{s}^{n, \delta}\right) \mathrm{d} s, \quad t \in[0, T] \tag{27}
\end{equation*}
$$

and

$$
\bar{y}_{t}^{\delta}=\delta+\int_{t}^{T}\left(a u(s) \bar{y}_{s}^{\delta}+b u(s)\right) \mathrm{d} s, \quad t \in[0, T]
$$

have, respectively, unique solutions $y_{t}^{n, \delta}$ and $\bar{y}_{t}^{\delta}$ with $\sup _{t \in[0, T]}\left|y_{t}^{n, \delta}\right|<+\infty$ and $\sup _{t \in[0, T]}\left|\bar{y}_{t}^{\delta}\right|<+\infty$. Clearly, $y_{t}^{n, \delta} \geq 0$ and $\bar{y}_{t}^{\delta} \geq 0$ for each $t \in[0, T]$ and $n \geq a$. By Proposition 5 and the fact that $\varphi_{n} \leq \varphi_{n+1}$, we have $y^{n, \delta} \leq y^{n+1, \delta} \leq \bar{y}^{\delta}$. Therefore, for each $t \in[0, T]$, the limit of the sequence $\left\{y_{t}^{n, \delta}\right\}_{n=a}^{+\infty}$ must exist, we denote it by $y_{t}^{\delta}$. In view of (i) and (iv) in Lemma 2, using Lebesgue's dominated convergence theorem we can obtain that

$$
\lim _{n \rightarrow+\infty} \int_{0}^{T} u(s) \varphi_{n}\left(y_{s}^{n, \delta}\right) \mathrm{d} s=\int_{0}^{T} u(s) \bar{\varphi}\left(y_{s}^{\delta}\right) \mathrm{d} s=\int_{0}^{T} u(s) \varphi\left(y_{s}^{\delta}\right) \mathrm{d} s
$$

Thus, by passing to the limit in both sides of $\operatorname{DBDE}$ (27) we deduce that

$$
y_{t}^{\delta}=\delta+\int_{t}^{T} u(s) \varphi\left(y_{s}^{\delta}\right) \mathrm{d} s, \quad t \in[0, T]
$$

which means that $y_{t}^{\delta}$ is a solution of DBDE (3).
Let us now suppose that $\delta>0$ and $\varphi(x)>0$ for all $x>0$. For each $z \geq \delta$, set $G(z):=\int_{z}^{1} \varphi^{-1}(x) \mathrm{d} x$. It is easy to see that $-\infty=G(+\infty)<G\left(z_{1}\right)<G\left(z_{2}\right)<G(\delta)$ for each $z_{1}>z_{2}>\delta$. Then the inverse function of $G(z)$ must exist, we denote it by $G^{-1}(u)$ for $u \leq G(\delta)$. Let $y_{t}^{\delta}$ be a solution of $\operatorname{DBDE}$ (3). It is obvious that $y_{t}^{\delta} \geq \delta$ and $\mathrm{d} G\left(y_{t}^{\delta}\right)=u(t) \mathrm{d} t$. Hence, $G\left(y_{T}^{\delta}\right)-G\left(y_{t}^{\delta}\right)=\int_{t}^{T} u(s) \mathrm{d} s$, which implies that $y_{t}^{\delta}=G^{-1}\left(G(\delta)-\int_{t}^{T} u(s) \mathrm{d} s\right)$ for each $t \in[0, T]$. The proof of (i) is then completed.

Finally, we prove that (ii) is also right. Assume that $\delta=0$ and $\varphi \in \mathbf{S}$ with $\int_{0^{+}} \varphi^{-1}(x) \mathrm{d} x=+\infty$. For each $z>0$, set $H(z):=\int_{z}^{1} \varphi^{-1}(x) \mathrm{d} x$. It is clear that $-\infty=H(+\infty)<H\left(z_{1}\right)<H\left(z_{2}\right)<H(0)=+\infty$ for each $z_{1}>z_{2}>0$. Then the inverse function of $H(z)$ must exist, we denote it by $H^{-1}(u)$ for each $u \in \mathbf{R}$. Now let $y_{t}^{0}$ be a continuous solution of DBDE (3). Then $y_{t}^{0} \geq 0$ and $\mathrm{d} H\left(y_{t}^{0}\right)=u(t) \mathrm{d} t$. Hence, for each $0 \leq t \leq t_{1}<T$,

$$
y_{t}^{0}=H^{-1}\left(H\left(y_{t_{1}}^{0}\right)-\int_{t}^{t_{1}} u(s) \mathrm{d} s\right)
$$

Furthermore, noticing that $H\left(y_{t_{1}}^{0}\right) \rightarrow H\left(y_{T}^{0}\right)=H(0)=+\infty$ as $t_{1} \rightarrow T$ and $H^{-1}(+\infty)=0$, we know that $y_{t}^{0}=0$ for each $t \leq T$. Consequently, $\operatorname{DBDE}$ (3) has a unique solution $y_{t} \equiv 0$.
