ABSTRACT

Application specific simulation is challenging task in various real time high performance embedded devices. In this study specific application is implemented with the help of Xilinx. Xilinx provides SDK and XPS tools, XPS tools used for develop complete hardware platform and SDK provides software platform for application creation and verification. Xilinx XUP-5 board have been used and implemented various specific Applications with hardware platform. In this study the base instruction set with customized instructions, supported with specific hardware resources are analyzed.

Keywords

Xilinx, virtex-5 FPGA board, simulation, hardware and software design, Xilinx Platform Studio.

1. INTRODUCTION

In co-design methodology, the hardware and software components for an embedded system are designed jointly. Each of the hardware and software components designed using appropriate tools (hardware synthesis, code generation and hardware-software co-simulation tools). In ASIP design technology hardware can be design according for specific application. Xilinx SDK provides software environment used for various specific application verification and creation. Kucukcakar, K. [1] proposed a unique architecture and methodology to design ASIPs in the embedded controller domain by customizing an existing processor instruction set and architecture. Jain, M.K., Balakrishnan, M., Kumar, A. [2] proposed survey in ASIP area and identifies some issues which need to be addressed. Hartmann, M., Raghavan, P., Agrawal, P., Dehaene, W. [3] proposed a design method for memristor-based (ReRAM) memory architectures for embedded processors to address the effects caused by longer write latencies. Sharma, A., Sutar, S., Sharma, V.K., Mahapatra, K.K. [4] designed an ASIP using language for instruction-set architecture (LISA) and designed processor has optimized instructions for the image enhancement application in spatial domain. Fathy, A., Isshiki, T., Li, D., Kunieda, H. [5]

presented a complete framework for searching for Application specific special instruction patterns based on tree scan algorithm while tweaking it to fit real applications. J. Qiu, X. Gao, Y. Jiang, X. Xiao [7] proposed a hybrid simulation framework which improves the previous simulation methods by aggressively utilizing the host machine resources. H. M. Hassan, K. Mohammed and A. F. Shalash [8] presented an ASIP design for a discrete Fourier transform (DFT)/discrete cosine transform (DCT)/finite impulse response filters (FIR) engine.

2. EMBEDDED DEVELOPMENT KIT

Xilinx [6] provides Embedded Development Kit (EDK) (see figure 1) tools to design a complete embedded processor system for implementation in a Xilinx FPGA device. Xilinx Platform Studio (XPS) is the development environment used for designing the hardware platform and Software Development Kit (SDK) is an integrated development environment used for C/C++ embedded software application creation and verification. Embedded Development Kit also provides ISE Plan ahead is used to design custom Memory and processor configuration according to specific application. Xilinx EDK provides XPS, SDK and ISE tools for simulation analysis.

2.1 XPS

XPS provides hardware system development environments and provides Specification of the microprocessor, peripherals, and the interconnected components, along with their respective detailed configuration.

2.2 SDK

SDK provides software development environments and also used for developing standalone application.

2.3 ISE Design

ISE design used for verifies the correct functionality of Hardware Description Language (HDL), RTL and schematic design.

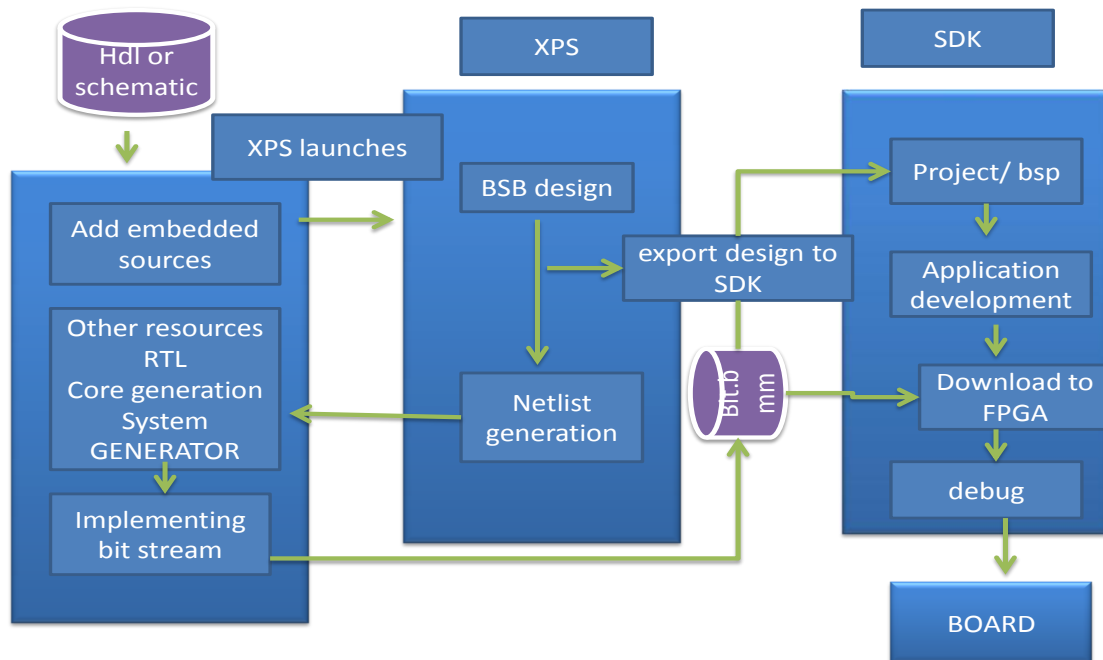

Fig 1: EDK Design flow analysis

3. XILINX PLATFORM STUDIO (XPS)

Xilinx Platform Studio (XPS) provides an interactive development environment that allows specifying all aspects of our hardware platform and XPS also maintains the hardware platform description in a high-level form, known as the Microprocessor Hardware Specification (MHS) file. XPS used to synthesizes the MHS source file into netlists used for the FPGA place and route process. The MHS file [6] is integral to our design process and contains all peripheral

instantiations along with their parameters. The MHS file also defines the configuration of the embedded processor system and includes information on the bus architecture; peripherals, processor, connectivity, and address space etc. One of the supported embedded processor development boards available from Xilinx [6] has been selected for target architecture.

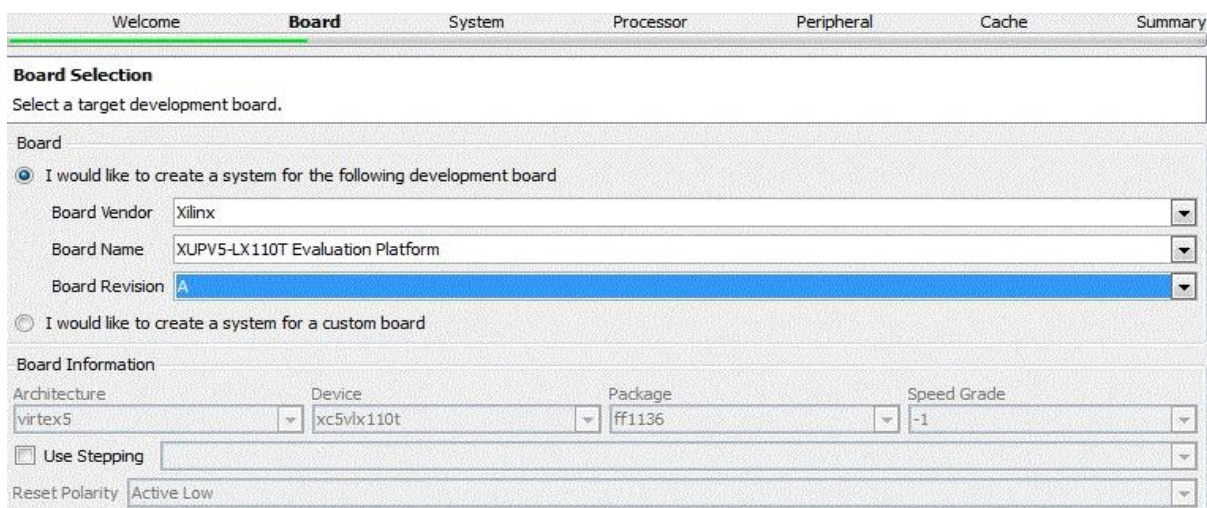

Fig 2: xup-5 fpga board selection

In XPS platform have configured selected XUP-5 FPGA platform (see figure2) for simulation and XUP-5-LX110T board utilizes Xilinx virtex5 XC5VLX110T-FF1136 device. A complete embedded processor system implemented within a Xilinx FPGA device. Hardware platform contains one or

more processors, along with a variety of peripherals and memory blocks. The behavior of each processor or peripheral core can be easily customized (see figure 3,4&5). Hardware platform is ultimately implemented in the FPGA and

Instruction and Data cache sized change according to desire application (see figure 6&7).

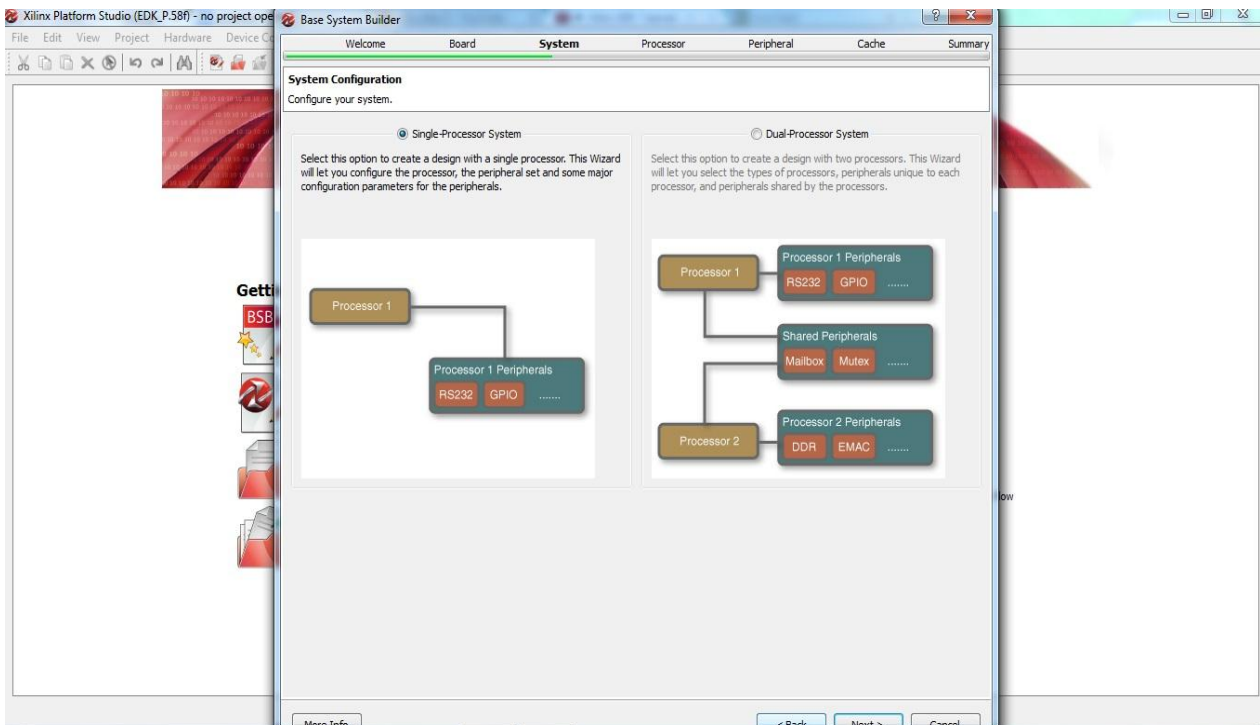

Fig 3: Processor configuration

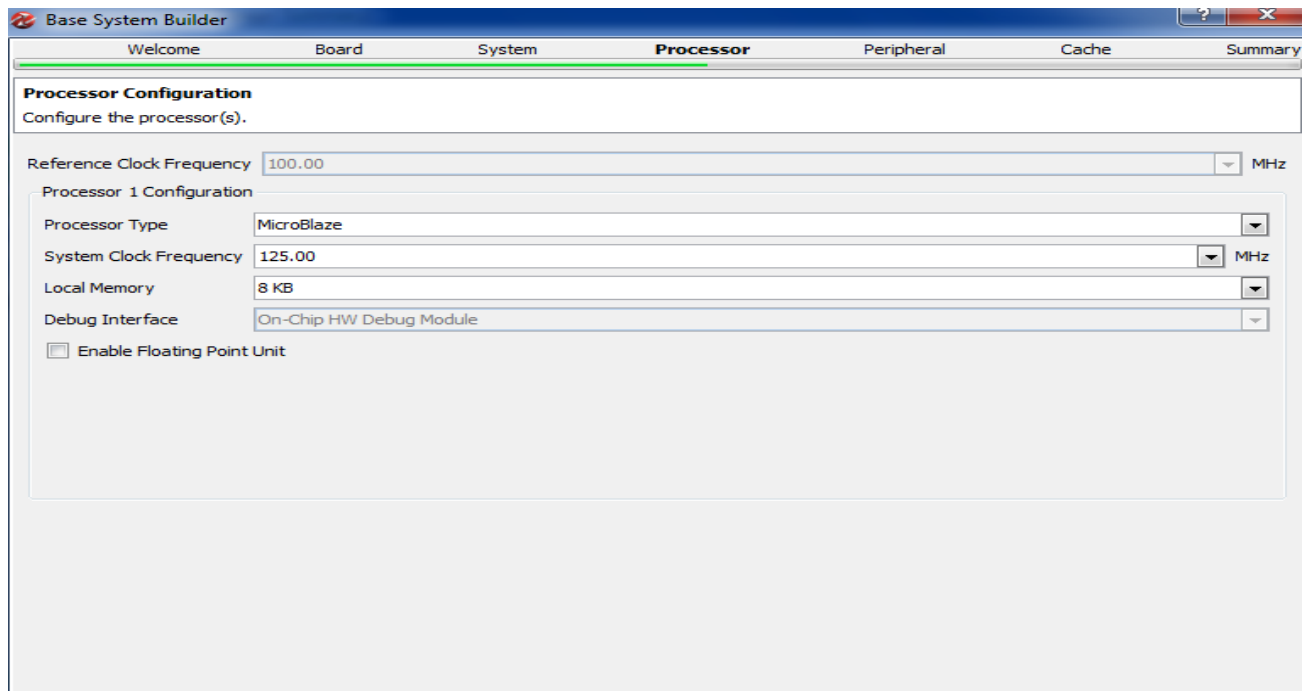

Fig 4: Micro blaze processor configuration

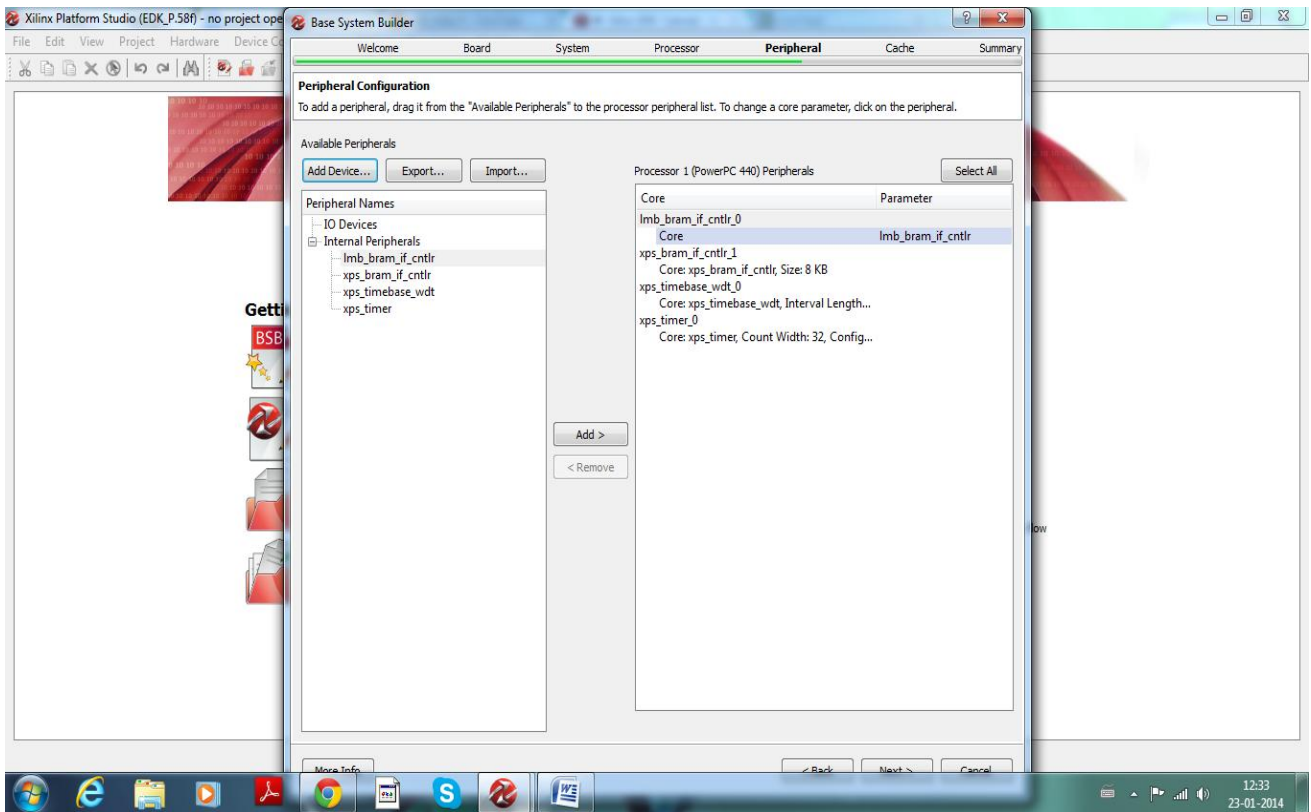

Fig 5: Peripheral design

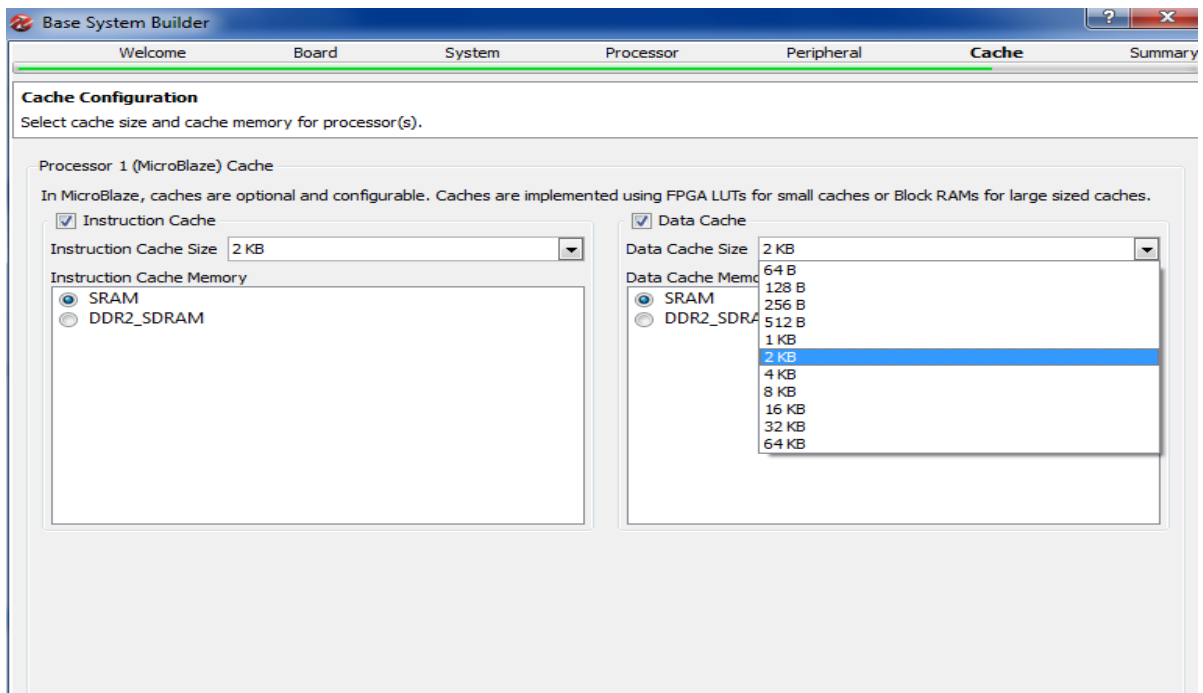

Fig 6: I- Cache configuration

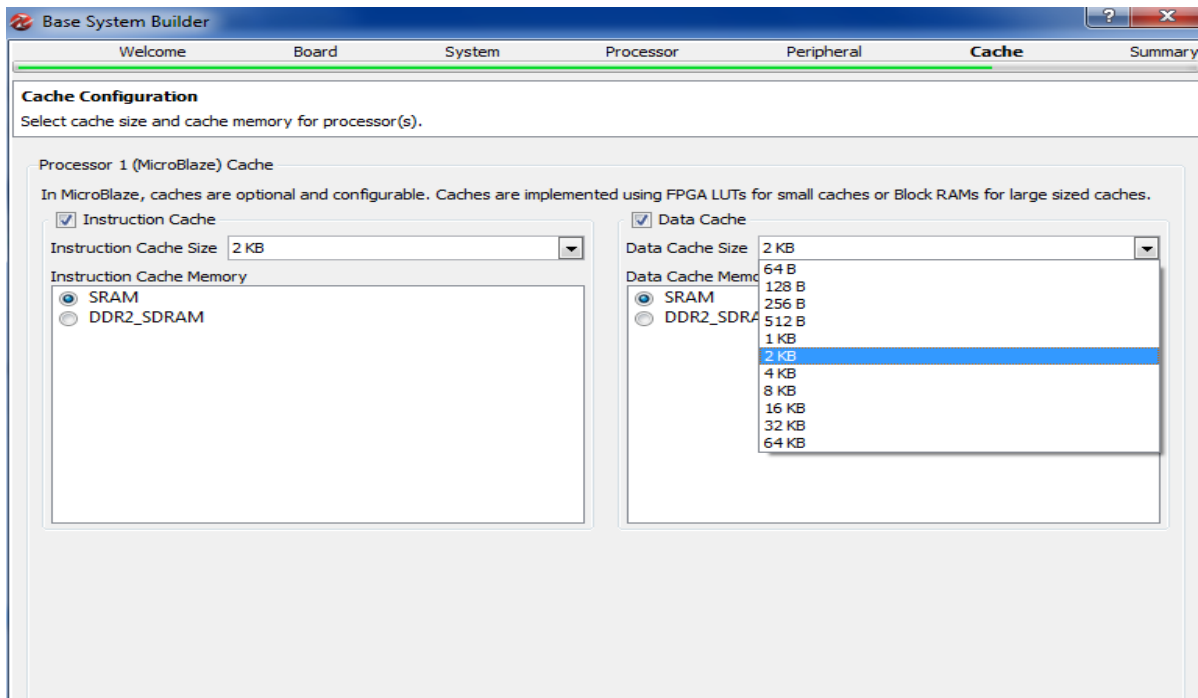

Fig 7: D-Cache configuration

XPS (see figure 8) used the Base System Builder, and it generated a bit stream for the FPGA. Hardware platform is exported to the Software Development Kit (SDK) platform. The hardware platform contains the XML-based hardware description file, the bit stream file, and the BMM file. XPS System Assembly View allows for view and configures the

system block elements. XPS under implement flow; it generated net list implements, the design using the Xilinx backend, synthesis and route to create the final Netlist. The architectural design of selected processor and memory (see figure 9 & 11) and their VHDL configuration used for specific application (see figure 10 & 12).

4. SOFTWARE DEVELOPMENT KIT

XPS design is exported to the Software Development Kit (SDK) platform. Various Software applications must link against or run on top of a given software platform, using the specific provided Application Program Interfaces (APIs).

Software Part (sdk) contains one or more source files, along with the necessary header files, used for compilation and generation of a binary output (.elf) file (see figure15).

```
void test_memory_range(struct memory_range_s *range) {
    XStatus status;

    /* This application uses print statements instead of xil_printf/printf
    * to reduce the text size.
    *
    * The default linker script generated for this application does not have
    * heap memory allocated. This implies that this program cannot use any
    * routines that allocate memory on heap (printf is one such function).
    * If you'd like to add such functions, then please generate a linker script
    * that does allocate sufficient heap memory.
    */

    print("Testing memory region: "); print(range->name); print("\n\r");
    print("    Memory Controller: "); print(range->ip); print("\n\r");
    print("        Base Address: 0x"); putnum(range->base); print("\n\r");
    print("            Size: 0x"); putnum(range->size); print(" bytes \n\r");

    status = Xil_TestMem32((u32*)range->base, 1024, 0xAAAA5555, XIL_TESTMEM_ALLMEMTESTS);

Fig 19: Peripheral application simulation analysis with xup-5 FPGA BOARD

Memory testing application (see figure 13) used on specific target hardware (see figure 14). SDK examined the hardware specification file and tested the memory application with xup-5 FPGA board. It generates the .elf file and elf contains the ISA behavior for specific application. After the simulation process (see figure 16) we get efficient ISA result (see figure 15). Peripherals testing another application (see figure 17) is used for simulation. It generates the simulation results (see figure 18). The simulation process is to analyze on xup-5 fpga device with custom hardware environment (see figure19).

5. CONCLUSION

Our main focus in this paper is application specific simulation analysis with specific hardware environment. Hardware resources like processor; memories etc. easily implemented

and analyzed custom instruction set behavior for specific application. Various standard applications analyzed on xup-5 FPGA board with specific hardware environments. The ISA behaviour is also analyzed. After this simulation process application specific results are used for high performance embedded system.
