## Pomeron in the $\mathcal{N} = 4$ SYM

A. V. Kotikov

Bogoliubov Laboratory of Theoretical Physics, Joint Institute for Nuclear Research, 141980 Dubna, Russia

### Abstract

We review the result for the BFKL Pomeron intercept at  $\mathcal{N} = 4$  Supersymmetric Yang-Mills model in the form of the inverse coupling expansion  $j_0 = 2 - 2\lambda^{-1/2} - \lambda^{-1} + 1/4 \lambda^{-3/2} + 2(3\zeta_3 + 1)\lambda^{-2} + (18\zeta_3 + 361/64)\lambda^{-5/2} + (39\zeta_3 + 447/32)\lambda^{-3} + O(\lambda^{-7/2})$ , which has been calculated in [1]–[5] with the use of the AdS/CFT correspondence.

**Keywords:** Pomeron intercept,  $\mathcal{N} = 4$  Supersymmetric Yang-Mills model

### 1. Introduction

Pomeron is the Regge singularity of the  $t$ -channel partial wave [6] responsible for the approximate equality of total cross-sections for high energy particle-particle and particle-antiparticle interactions valid in accordance with the Pomeranchuk theorem [7]. In QCD the Pomeron is a colorless object, constructed from reggeized gluons [8].

The investigation of the high energy behavior of scattering amplitudes in the  $\mathcal{N} = 4$  Supersymmetric Yang-Mills (SYM) model [9, 10, 11] is important for our understanding of the Regge processes in QCD. Indeed, this conformal model can be considered as a simplified version of QCD, in which the next-to-leading order (NLO) corrections [12] to the Balitsky-Fadin-Kuraev-Lipatov (BFKL) equation [8] are comparatively simple and numerically small. In the  $\mathcal{N} = 4$  SYM the equations for composite states of several reggeized gluons and for anomalous dimensions (AD) of quasi-partonic operators turn out to be integrable at the leading logarithmic approximation [13, 14]. Further, the eigenvalue of the BFKL kernel for this model has the remarkable property of the maximal transcen-

dentiality [10]. This property gave a possibility to calculate the AD  $\gamma$  of the twist-2 Wilson operators in one [15], two [10, 16], three [17], four [18, 19] and five [20] loops using the QCD results [21] and the asymptotic Bethe ansatz [22] improved with wrapping corrections [19] in an agreement with the BFKL predictions [9, 10].

On the other hand, due to the AdS/CFT-correspondence [23, 24, 25], in  $\mathcal{N} = 4$  SYM some physical quantities can be also computed at large couplings. In particular, for AD of the large spin operators Beisert, Eden and Staudacher constructed the integral equation [26] with the use the asymptotic Bethe-ansatz. This equation reproduced the known results at small coupling constants and is in a full agreement (see [27, 28]) with large coupling predictions [29, 30].

With the use of the BFKL equation in a diffusion approximation [9, 11], strong coupling results for AD [29, 30] and the pomeron-graviton duality [31] the Pomeron intercept was calculated at the leading order in the inverse coupling constant (see the Erratum[1] to the paper [17]). Similar results were obtained also in Ref. [2]. The Pomeron-graviton duality in the  $\mathcal{N} = 4$  SYM gives a possibility to

construct the Pomeron interaction model as a generally covariant effective theory for the reggeized gravitons [32].

Below we review the strong coupling corrections to the Pomeron intercept  $j_0 = 2 - \Delta$  in next orders. These corrections were obtained in Refs. [1, 2, 3, 4, 5]<sup>1</sup> (see also a short review in [33]) with the use of the recent calculations [34]–[37] of string energies.

## 2. BFKL equation at small coupling constant

The eigenvalue of the BFKL equation in  $\mathcal{N} = 4$  SYM model has the following perturbative expansion [9, 10] (see also Ref. [11])

$$\begin{aligned} j - 1 = \omega &= \frac{\lambda}{4\pi^2} \left[ \chi(\gamma_{\text{BFKL}}) + \delta(\gamma_{\text{BFKL}}) \frac{\lambda}{16\pi^2} \right], \\ \lambda &= g^2 N_c, \end{aligned} \quad (1)$$

where  $\lambda$  is the t'Hooft coupling constant. The quantities  $\chi$  and  $\delta$  are functions of the BFKL anomalous dimension

$$\gamma_{\text{BFKL}} = \frac{1}{2} + i\nu \quad (2)$$

and are presented below [9, 10]

$$\chi(\gamma) = 2\Psi(1) - \Psi(\gamma) - \Psi(1 - \gamma), \quad (3)$$

$$\begin{aligned} \delta(\gamma) &= \Psi''(\gamma) + \Psi''(1 - \gamma) + 6\zeta_3 - 2\zeta_2\chi(\gamma) \\ &\quad - 2\Phi(\gamma) - 2\Phi(1 - \gamma). \end{aligned} \quad (4)$$

Here  $\Psi(z)$  and  $\Psi'(z)$ ,  $\Psi''(z)$  are the Euler  $\Psi$ -function and its derivatives. The function  $\Phi(\gamma)$  is defined as follows

$$\Phi(\gamma) = 2 \sum_{k=0}^{\infty} \frac{1}{k + \gamma} \beta'(k + 1), \quad (5)$$

where

$$\beta'(z) = \frac{1}{4} \left[ \Psi'\left(\frac{z+1}{2}\right) - \Psi'\left(\frac{z}{2}\right) \right]. \quad (6)$$

Due to the symmetry of  $\omega$  to the substitution  $\gamma_{\text{BFKL}} \rightarrow 1 - \gamma_{\text{BFKL}}$  expression (1) is an even function of  $\nu$

$$\omega = \omega_0 + \sum_{m=1}^{\infty} (-1)^m D_m \nu^{2m}, \quad (7)$$

<sup>1</sup>The coefficients  $\sim \lambda^{-1}$  and  $\sim \lambda^{-3/2}$  contain an opposite sign in the original version of Ref. [3].

where

$$\omega_0 = 4 \ln 2 \frac{\lambda}{4\pi^2} \left[ 1 - \bar{c}_1 \frac{\lambda}{16\pi^2} \right] + O(\lambda^3), \quad (8)$$

$$\begin{aligned} D_m &= 2 \left( 2^{2m+1} - 1 \right) \zeta_{2m+1} \frac{\lambda}{4\pi^2} \\ &\quad + \frac{\delta^{(2m)}(1/2)}{(2m)!} \frac{\lambda^2}{64\pi^4} + O(\lambda^3). \end{aligned} \quad (9)$$

According to Ref. [10] we have

$$\begin{aligned} \bar{c}_1 &= 2\zeta_2 + \frac{1}{2 \ln 2} \left( 11\zeta_3 - 32 \text{Li}_3\left(\frac{\pi}{2}\right) - 14\pi\zeta_2 \right) \\ &\approx 7.5812, \end{aligned} \quad (10)$$

where (see [38])

$$\text{Li}_3(x) = - \int_0^x \ln^2 \left| 2 \sin\left(\frac{y}{2}\right) \right| dy. \quad (11)$$

Due to the Möbius invariance and hermiticity of the BFKL hamiltonian in  $\mathcal{N} = 4$  SYM, the expansion (7) is valid also at large coupling constants. In the framework of the AdS/CFT correspondence the BFKL Pomeron is equivalent to the reggeized graviton [31]. In particular, in the strong coupling regime  $\lambda \rightarrow \infty$

$$j_0 = 2 - \Delta, \quad (12)$$

where the leading contribution  $\Delta = 2/\sqrt{\lambda}$  was calculated in Refs. [1, 2]. Below we show the several terms in the strong coupling expansion of the Pomeron intercept, following studies in [3, 4, 5].

## 3. AdS/CFT correspondence

Due to the energy-momentum conservation, the universal AD of the stress tensor  $T_{\mu\nu}$  should be zero, i.e.,

$$\gamma(j=2) = 0. \quad (13)$$

It is important, that the AD  $\gamma$  contributing to the Dokshitzer-Gribov-Lipatov-Altarelli-Parisi equations [39] does not coincide with  $\gamma_{\text{BFKL}}$  appearing in the BFKL equation. They are related as follows [12, 40]

$$\gamma = \gamma_{\text{BFKL}} + \frac{\omega}{2} = \frac{j}{2} + i\nu, \quad (14)$$

where the additional contribution  $\omega/2$  is responsible in particular for the cancelation of the singular terms  $\sim 1/\nu^3$  obtained from the NLO corrections (1) to the eigenvalue of the BFKL kernel [12]. Using above relations one obtains

$$\nu(j=2) = i. \quad (15)$$

As a result, from eq. (7) for the Pomeron trajectory we derive the following representation for the correction  $\Delta$  (12) to the graviton spin 2

$$\Delta = \sum_{m=1}^{\infty} D_m. \quad (16)$$

According to (12) and (16), we have the following small- $v$  expansion for the eigenvalue of the BFKL kernel

$$j - 2 = \sum_{m=1}^{\infty} D_m ((-v^2)^m - 1), \quad (17)$$

where  $v^2$  is related to  $\gamma$  according to eq. (14)

$$v^2 = -\left(\frac{j}{2} - \gamma\right)^2. \quad (18)$$

On the other hand, due to the ADS/CFT correspondence the string energies  $E$  in dimensionless units are related to the AD  $\gamma$  of the twist-two operators as follows [24, 25]<sup>2</sup>

$$E^2 = (j - 2\gamma)^2 - 4 \quad (19)$$

and therefore we can obtain from (18) the relation between the parameter  $v$  for the principal series of unitary representations of the Möbius group and the string energy  $E$

$$v^2 = -\left(\frac{E^2}{4} + 1\right). \quad (20)$$

This expression for  $v^2$  can be inserted in the r.h.s. of Eq. (17) leading to the following expression for the Regge trajectory of the graviton in the anti-de-Sitter space

$$j - 2 = \sum_{m=1}^{\infty} D_m \left[ \left( \frac{E^2}{4} + 1 \right)^m - 1 \right]. \quad (21)$$

#### 4. Pomeron intercept

We assume, that eq. (21) is valid also at large  $j$  and large  $\lambda$  in the region  $1 \ll j \ll \sqrt{\lambda}$ , where the

---

<sup>2</sup>Note that our expression (19) for the string energy  $E$  differs from a definition, in which  $E$  is equal to the scaling dimension  $\Delta_{sc}$ . But eq. (19) is correct, because it can be presented as  $E^2 = (\Delta_{sc} - 2)^2 - 4$  and coincides with Eqs. (45) and (3.44) from Refs. [24] and [25], respectively.

strong coupling calculations of energies were performed [34, 37]. These energies can be presented in the form<sup>3</sup>

$$\frac{E^2}{4} = \sqrt{\lambda} \frac{S}{2} \left[ h_0(\lambda) + h_1(\lambda) \frac{S}{\sqrt{\lambda}} + h_2(\lambda) \frac{S^2}{\lambda} \right] + O(S^4), \quad (22)$$

where

$$h_i(\lambda) = a_{i0} + \sum_{m=1}^{\infty} \frac{a_{im}}{\lambda^{m/2}}. \quad (23)$$

The contribution  $\sim S$  can be extracted directly from the Basso result [35] taking  $J_{an} = 2$  according to [36]:

$$h_0(\lambda) = \frac{I_3(\sqrt{\lambda})}{I_2(\sqrt{\lambda})} + \frac{2}{\sqrt{\lambda}} = \frac{I_1(\sqrt{\lambda})}{I_2(\sqrt{\lambda})} - \frac{2}{\sqrt{\lambda}}, \quad (24)$$

where  $I_k(\sqrt{\lambda})$  is the modified Bessel functions. It leads to the following values of coefficients  $a_{0m}$

$$\begin{aligned} a_{00} &= 1, \quad a_{01} = -\frac{1}{2}, \quad a_{02} = a_{03} = \frac{15}{8}, \\ a_{04} &= \frac{135}{128}, \quad a_{04} = -\frac{45}{32}. \end{aligned} \quad (25)$$

The contribution  $\sim S^2$  has been evaluated recently in [5]. It leads to the following values of coefficients  $a_{1m}$  ( $\zeta_3$  and  $\zeta_5$  are the Euler  $\zeta$ -functions)

$$\begin{aligned} a_{10} &= \frac{3}{4}, \quad a_{11} = \frac{3}{2} \left( \frac{1}{8} - \zeta_3 \right), \\ a_{12} &= -\frac{9}{4} \left( \zeta_3 + \frac{3}{8} \right), \\ a_{13} &= \frac{3}{16} \left( \zeta_3 + 20\zeta_5 - \frac{37}{2} \right). \end{aligned} \quad (26)$$

The coefficients  $a_{im}$  for  $m \geq 2$  are currently not known. However, as it was discussed in [5], from an analysis of classical energy, with semi-classical corrections, it is in principle possible to extract the coefficients  $a_{0m}$  and  $a_{1m}$  for all  $m$  values. For  $m = 2$ , we have [5]

$$a_{20} = -\frac{3}{16}, \quad a_{21} = \frac{15}{8} \left( \zeta_3 + \zeta_5 - \frac{17}{60} \right). \quad (27)$$

Comparing the l.h.s. and r.h.s. of (21) at large  $j$  values gives us the coefficients  $D_m$  (see Appendix

---

<sup>3</sup>Here we put  $S = j - 2$ , which in particular is related to the use of the angular momentum  $J_{an} = 2$  in calculations of Refs [34, 37].

Fig. 1. (color-online). The results for  $j_0$  as a function of  $z$  ( $\lambda = 10^2$ ).

$A$  in [4]) and  $\Delta$  in eq. (28) below.

To obtain an unified expression for the position of the Pomeron intercept  $j_0$  for arbitrary values of  $\lambda$ , an interpolation between weak and strong coupling regimes has been used in [4]. Following the method of Refs. [16, 17, 41], it is possible to write a simple algebraic equation for  $j_0 = j_0(\lambda)$  whose solution will interpolate  $j_0$  for the full  $\lambda$  range (see ref. [4]).<sup>4</sup>

On Fig. 1, we plot the Pomeron intercept  $j_0$  as a function of the coupling constant  $\lambda$ . The behavior of the Pomeron intercept  $j_0$  is similar to that found in QCD with some additional assumptions (see ref. [43]). Indeed, for the often-used values  $0.1 \div 0.3$  of OCD strong coupling constant  $\alpha_s$  (i.e., respectively, for the values  $z = 0.5 \div 1$  in Fig. 1) we have the predictions  $j_0 = 0.15 \div 0.3$  for the pomeron intercept  $j_0$  in QCD. It corresponds to the  $j_0$  values commonly used in QCD phenomenology (see, for example, [44]–[48] and the reviews [49] and references therein).

## 5. Conclusion

We have shown the intercept of the BFKL Pomeron in the  $\mathcal{N} = 4$  SYM at weak coupling regime and demonstrated an approach to obtain its values at strong couplings (for details, see refs. [4] and [5]).

<sup>4</sup>We note here the recent paper [42], where the leading BFKL results [8] have been reproduced from integrability. The method presented in [42] could be used to build the numerical pomeron intercept for finite  $\lambda$  values.

At  $\lambda \rightarrow \infty$ , the correction  $\Delta$  for the Pomeron intercept  $j_0 = 2 - \Delta$  has the form

$$\begin{aligned} \Delta = & \frac{2}{\lambda^{1/2}} \left[ 1 + \frac{1}{2\lambda^{1/2}} - \frac{1}{8\lambda} - \left( 1 + 3\zeta_3 \right) \frac{1}{\lambda^{3/2}} \right. \\ & - \left( \frac{361}{128} + 9\zeta_3 \right) \frac{1}{\lambda^2} - \left( \frac{447}{64} + \frac{39}{2}\zeta_3 \right) \frac{1}{\lambda^{5/2}} \\ & \left. + O\left(\frac{1}{\lambda^3}\right) \right]. \end{aligned} \quad (28)$$

Note that the corresponding expansion at strong couplings for the Odderon intercept in the  $\mathcal{N} = 4$  SYM has been obtained recently in [50].
