

# Hybrid Numerical Solvers for Massively Parallel Eigenvalue Computation and Their Benchmark with Electronic Structure Calculations

HIROTO IMACHI<sup>1,a)</sup> TAKEO HOSHI<sup>1</sup>

Received: xx xx, xxxx, Accepted: xx xx, xxxx

**Abstract:**

Optimally hybrid numerical solvers were constructed for massively parallel generalized eigenvalue problem (GEP). The strong scaling benchmark was carried out on the K computer and other supercomputers for electronic structure calculation problems in the matrix sizes of  $M = 10^4 - 10^6$  with upto  $10^5$  cores. The procedure of GEP is decomposed into the two subprocedures of the reducer to the standard eigenvalue problem (SEP) and the solver of SEP. A hybrid solver is constructed, when a routine is chosen for each subprocedure from the three parallel solver libraries of ScaLAPACK, ELPA and EigenExa. The hybrid solvers with the two newer libraries, ELPA and EigenExa, give better benchmark results than the conventional ScaLAPACK library. The detailed analysis on the results implies that the reducer can be a bottleneck in next-generation (exa-scale) supercomputers, which indicates the guidance for future research. The code was developed as a middleware and a mini-application and will appear online.

**Keywords:** Massively parallel numerical library, Generalized eigenvalue problem, Electronic structure calculation, ELPA, EigenExa, The K computer, mini-application

## 1. Introduction

Numerical linear algebraic solvers for large matrices have strong needs among various applications with the current and next-generation supercomputers. Nowadays ScaLAPACK[1], [2]<sup>\*1</sup> is the *de facto* standard solver library for parallel computations but several routines give severe bottlenecks in the computational speed with current massively parallel architectures. Novel solver libraries were proposed so as to overcome the bottlenecks. Since the performance of numerical routines varies significantly with problems and architectures, the best performance is achieved, when one constructs an optimal ‘hybrid’ among the libraries.

The concept of hybrid solver is illustrated in Fig. 1. It is a numerical middleware and has a unique data interface to real applications. One can choose the optimal workflow for each problem without any programming effort.

The present paper focuses on dense-matrix solvers for generalized eigenvalue problems (GEPs) in the form of

$$A\mathbf{y}_k = \lambda_k B\mathbf{y}_k \quad (1)$$

with the given  $M \times M$  real-symmetric matrices of  $A$  and  $B$ . The matrix  $B$  is positive definite. The eigenvalues  $\{\lambda_k\}$  and the eigenvectors  $\{\mathbf{y}_k\}$  will be calculated. The computational cost is  $O(M^3)$  or is proportional to  $M^3$ . The present hybrid solvers are constructed among ScaLAPACK and the two newer libraries of ELPA [3], [4], [5]<sup>\*2</sup>, and EigenExa [6], [7], [8], [9]. The ELPA and EigenExa libraries are written in Fortran and appeared in 2000’s for efficient massively parallel computations.

The present paper is organized as follows; Section 2 explains the background from the electronic structure calculation. Section 3 describes the mathematical foundation. Sections 4 and 5 are devoted to the benchmark results and discussions, respectively. The summary and future outlook will appear in Sec. 6.

## 2. Background

### 2.1 Large-scale electronic structure calculations

The GEP of Eq. (1) gives the mathematical foundation of electronic structure calculations or quantum mechanical calculations of materials, in which an electron is treated as a quantum me-

**Fig. 1** Concept of hybrid solver; Structure of the program code (a) without and (b) with hybrid solver or numerical middleware.

**Fig. 2** (a) The upper panel is a  $\pi$ -type electronic wavefunction in an amorphous-like conjugated polymer (poly-((9,9) dioctyl fluorine)). The lower panel shows the atomic structure ( $R \equiv C_8H_{17}$ ) [10]. (b) Strong scaling plot by ELSESES for one-hundred-million-atoms calculations on the K computer. [10], [11] The calculated materials are a nano-composite carbon solid (the upper line) and the amorphous-like conjugated polymer (the lower line). The number of used processor nodes are from  $P = 4,096$  to  $82,944$  (full nodes of the K computer).

chanical ‘wave’. The input matrix  $A$  or  $B$  of Eq. (1) is called Hamiltonian or the overlap matrices, respectively. An eigenvalue of  $\{\lambda_k\}$  is the energy of one electron and an eigenvector of  $\{y_k\}$  specifies the wavefunction or the shape of an electronic ‘wave’. Fig. 2(a) shows an example of the wavefunction. The number of the required eigenvalues is, at least, on the order of the number of the electrons or the atoms in calculated materials. See the ELPA paper [3] for a review, because ELPA was developed under tight collaboration with electronic structure calculation society.

Here, our motivation is explained. The present authors developed a large-scale quantum material simulator called ELSESES<sup>\*3</sup> [12], [13]. The theories are explained in Refs. [13], [14] and the reference therein. The matrices are based on the real-space atomic-orbital representation and the matrix size  $M$  is nearly proportional to the number of atoms  $N$  ( $M \propto N$ ). The simulations mainly use novel ‘order- $N$ ’ linear-algebraic methods in which the computational cost is ‘order- $N$ ’ ( $O(N)$ ) or is proportional to the number of atoms  $N$ . Their mathematical foundation is sparse-matrix (Krylov-subspace) solvers. Efficient massively parallel computation is found in Fig. 2, a strong scaling benchmark on the K computer [10], [11] with one hundred million atoms or one-hundred-nanometer scale materials. The simulated materials are a nano-composite carbon solid with  $N = 103,219,200$  or  $M = 412,876,800$  [10] and an amorphous-like conjugated polymer with  $N = 102,238,848$  or  $M = 230,776,128$  [11].

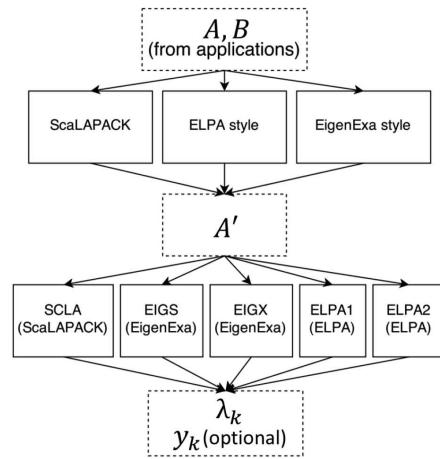

The present dense-matrix solvers are complementary methods to the order- $N$  calculations, because the order- $N$  calculation gives approximate solutions, while the dense-matrix solvers give numerically exact ones with a heavier ( $O(M^3)$ ) computational cost. The use of the two methods will lead us to fruitful researches. The exact solutions are important, for example, when the system has many nearly degenerated eigen pairs and one would like to distinguish them. The exact solutions are important also as reference data for the development of fine approximate solvers.

The matrices of  $A$  and  $B$  in the present benchmark appear on ‘ELSESES Matrix Library’. [15] The Library is the collection of the matrix data generated by ELSESES for material simulations. The benchmark was carried out with the data files of ‘NCCS430080’, ‘VCNT22500’ ‘VCNT90000’ and ‘VCNT1008000’ for the matrix sizes of  $M=22,500$ ,  $M=90,000$ ,  $M=430,080$ ,  $M=1,008,000$ , respectively. A large matrix data ( $> 0.5GB$ ) is uploaded as a set

<sup>\*3</sup> ELSESES = Extra-Large-Scale Electronic Structure calculation

of split files for user’s convenience.

The physical origin of the matrices is explained briefly. The files in the present benchmark are carbon materials within modeled tight-binding-form theories based on *ab initio* calculations. The matrix of ‘NCCS430080’ appears in our material research on a nano-composite carbon solid (NCCS) [16]. An sp-orbital form [17] is used and the system contains  $N = M/4 = 107,520$  atoms. The other files are generated for thermally vibrated single-wall carbon nanotubes (VCNTs) within a supercell. An spd-orbital form [18] is used and each system contains  $N = M/9$  atoms. The VCNT systems were prepared, so as to generate matrices systematically in different size with similar eigenvalue distributions. We used these matrices for the investigation on  $\pi$ -electron materials with the present dense-matrix solver and the order- $N$  solver.<sup>\*4</sup>

**Fig. 3** Workflow of the hybrid GEP solver.

### 3. The hybrid solvers

A hybrid solver is constructed, when a routine is chosen for each subprocedure from ScaLAPACK, EigenExa and ELPA. The code was developed as a general middleware that can be connected not only to ELSESES but also to any real application software, as in Fig. 1. A mini-application was also developed and used in the present benchmark. In the benchmark, ScaLAPACK was used as a built-in library on each machine. EigenExa in the version 2.2a<sup>\*5</sup> and ELPA in the version 2014.06.001 were used. ELPA and EigenExa call some ScaLAPACK routines.

#### 3.1 Mathematical formulation

The GEP of Eq. (1) can be written in a matrix form of

$$AY = BY\Lambda, \quad (2)$$

where the matrix  $\Lambda \equiv \text{diag}(\lambda_1, \lambda_2, \dots)$  is diagonal and the matrix  $Y \equiv (y_1 y_2 \dots)$  satisfies  $Y^T B Y = I$ . In the solvers, the GEP of Eq. (1) is reduced to a standard eigenvalue problem (SEP) of

<sup>\*4</sup> The present matrices are sparse, which does not lose the generality of the benchmark, since the cost of the dense matrix solver is not dependent on the number of non-zero elements of the matrix.

<sup>\*5</sup> The present EigenExa package does not include the GEP solver. The GEP solver routine for EigenExa in the present paper is that of the version 2.2b of KMATH\_EIGEN\_GEV [19] that shares the SEP solver routine with the EigenExa package.

$$A'Z = Z\Lambda, \quad (3)$$

where the reduced matrix  $A'$  is real symmetric [20] and the matrix of  $Z \equiv (z_1 z_2 \dots)$  contain eigenvectors of  $A'$ . The reduction procedure can be achieved, when the Cholesky factorization of  $B$  gives the Cholesky factor  $U$  as an upper triangle matrix:

$$B = U^T U. \quad (4)$$

The reduced matrix  $A'$  is defined by

$$A' = U^{-T} A U^{-1}. \quad (5)$$

The eigenvectors of the GEP, written as  $Y \equiv (y_1 y_2 \dots)$ , are calculated from those of the SEP by

$$Y = U^{-1} Z. \quad (6)$$

This procedure is usually called backward transformation.

The GEP solver is decomposed into the two subprocedures of (a) the solver of the SEP in Eq. (3) and (b) the reduction from the GEP to the SEP ( $(A, B) \Rightarrow A'$ ) and the backward transformation ( $Z \Rightarrow Y$ ). The subprocedures (a) and (b) are called ‘SEP solver’ and ‘reducer’, respectively, and require  $O(M^3)$  operations.

Figure 3 summarizes the workflows of the possible hybrid solvers. A hybrid solver is constructed, when one choose the routines for (a) the SEP solver and (b) the reducer, respectively.

For (a) the SEP solver, five routines are found in the base libraries; One routine is a ScaLAPACK routine (routine name in the code : ‘pdsyevd’) that uses the conventional tridiagonalization algorithm. [21] The ELPA or EigenExa library contains a SEP solver routine based on the tridiagonalization algorithm. The routine in ELPA is called ‘ELPA1’ (routine name in the code : ‘solve\_evp\_real’) in this paper, as in the original paper [3], and the one in EigenExa called ‘Eigen\_s’ or ‘EIGS’ (routine name in the code : ‘eigen\_s’). ELPA and EigenExa also contain the novel SEP solvers based on the narrow-band reduction algorithms without the conventional tridiagonalization procedure. The solvers are called ‘ELPA2’ (routine name in the code : ‘solve\_evp\_real\_2stage’) for the ELPA routine and ‘Eigen\_sx’ or ‘EIGX’ (routine name in the code : ‘eigen\_sx’) for the EigenExa routine in this paper. See the papers [4], [8] for details.

For (b) the reducer, three routines are found in the base libraries and are called ScaLAPACK style, ELPA style, and EigenExa style reducers in this paper. In the ScaLAPACK style, the Cholesky factorization, Eq. (4) is carried out and then the reduced matrix  $A'$ , defined in Eq. (5), is generated by a recursive algorithm (routine name ‘pdsygst’) without explicit calculation of  $U^{-1}$  nor  $U^{-T}$ . Details of the recursive algorithm are explained, for example in Ref. [22]. In the ELPA style, the Cholesky factorization (routine name: ‘cholesky\_real’) is carried out, as in the ScaLAPACK style, and the reduced matrix  $A'$  is generated by the explicit calculation of the inverse (triangular) matrix  $R \equiv U^{-1}$  (routine names : ‘invert\_trm\_real’) and the explicit successive matrix multiplication of  $A' = (R^T A) R$  (routine names: ‘mult\_at\_b\_real’) [3] <sup>\*6</sup>. In the EigenExa style, the Cholesky factorization is not used.

<sup>\*6</sup> The benchmark was carried out in an ELPA style reduction algorithm. The ScaLAPACK routine of ‘pdtrmm’ is used for the multiplication of the triangular matrix  $R$  from right, while a sample code in the ELPA package uses the ELPA routine (‘mult\_at\_b\_real’). We ignore the difference, since the elapse time of the above procedure is not dominant.

Instead, the SEP for the matrix  $B$

$$B W = W D, \quad (7)$$

is solved by the SEP solver (Eigen\_sx), with the diagonal matrix of  $D \equiv \text{diag}(d_1, d_2, \dots)$  and the unitary matrix of  $W \equiv (w_1 w_2 \dots)$ . A reduced SEP in the form of Eq. (3) is obtained by

$$A' = (D^{-1/2} W^T) A (W D^{-1/2}) \quad (8)$$

$$Y = W D^{-1/2} Z, \quad (9)$$

because of  $Z = D^{1/2} W^T Y$  and  $W^{-T} = W$ . Equation (9) is solved by the SEP solver (Eigen\_sx).

Though the SEP solver of Eq. (3) requires a larger operation cost than the Cholesky factorization (See Fig.1 of Ref. [23], for example), the elapse time can not be estimated only from the operation costs among the modern supercomputers.

**Table 1** List of the workflows in the benchmark. The routine names for the SEP solver and the reducer are shown for each workflow. Abbreviations are shown within parentheses.

Workflow	SEP solver	Reducer
A	ScaLAPACK (SCLA)	ScaLAPACK (SCLA)
B	Eigen_sx (EIGX)	ScaLAPACK (SCLA)
C	ScaLAPACK (SCLA)	ELPA
D	ELPA2	ELPA
E	ELPA1	ELPA
F	Eigen_s (EIGS)	ELPA
G	Eigen_sx (EIGX)	ELPA
H	Eigen_sx (EIGX)	Eigen_sx (EIGX)

The benchmark of the hybrid GEP solvers was carried out for the eight workflows listed in Table 1. In general, a potential issue is the possible overhead of the data conversion process between libraries. This issue will be discussed in Sec. 5.2.

## 4. Benchmark result

Strong scaling benchmarks are investigated for the hybrid solvers. The elapse times were measured for (i) the full eigenpair calculation ( $T_{\text{full}}$ ) and (ii) the ‘eigenvalue-only’ calculation ( $T_{\text{evo}}$ ). In the latter case, the elapse time is ignored for the calculation of the eigenvectors. The two types of calculations are important among electronic structure calculations. [3] The present benchmark ignores small elapse times of the initial procedure for distributed data and the comments on them will appear in Sec. 5.1.

The benchmark was carried out on three supercomputers; the K computer at Riken, Fujitsu FX10 and SGI Altix ICE 8400EX. The K computer has a single SPARC 64 VIII fx processor (2.0GHz, 8-core) on node. The FX10 is Oakleaf-FX of the University of Tokyo. Fujitsu FX10 is the successor of the K computer and has a single SPARC64 IX fx processor (1.848 GHz, 16-core) on each node. <sup>\*7</sup> We also used SGI Altix ICE 8400EX of Institute for Solid State Physics of the University of Tokyo. It is a cluster of Intel Xeon X5570 (2.93GHz, 8-core). The byte-per-flop value (B/F) is B/F=0.5, 0.36 or 0.68, for the K computer, FX10 or SGI Altix, respectively. The numbers of used processor nodes  $P$  are set to be square numbers ( $P = q^2$ ) except in Sec. 4.3, since the

<sup>\*7</sup> Additional options of the K computer and FX10 are explained; We did not specify a MPI process shape on the Tofu interconnect. We used the rank directory feature to alleviate I/O contention.

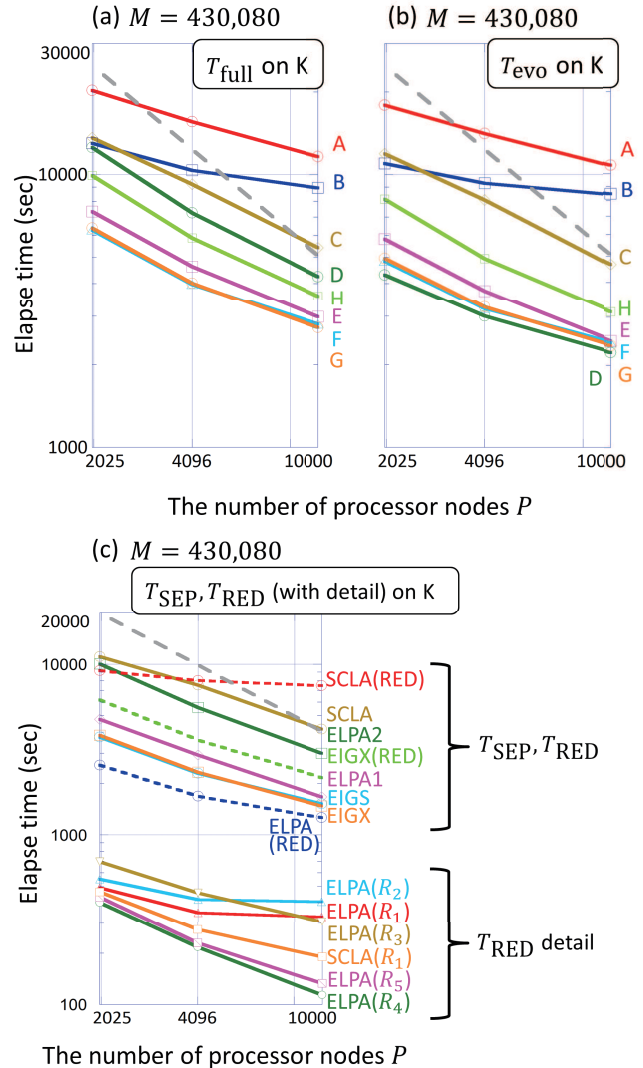

**Table 2** Selected results of the benchmark. The elapse time for the full (eigenpair) calculation ( $T_{full}$ ) and that for the eigenvalue-only calculation ( $T_{evo}$ ) with the workflows. The recorded time is the best data among ones with different numbers of the used nodes. The number of used nodes ( $P$ ) for the best data is shown within parentheses. The best data among the workflows are labelled by ‘[B]’. The saturated data are labelled by ‘[S]’. The workflow  $D'$  on Altix is that without the SSE optimized routine of the ‘ELPA2’ SEP solver. See the text for details.

Size $M$ /Machine	WF	$T_{full}$ (sec)	$T_{evo}$ (sec)

	$F$	48.5 ( $P = 256$ )	37.3 ( $P = 256$ )
	$G$	57.2 ( $P = 256$ )	39.6 ( $P = 256$ )
$H$	71.2 ( $P = 256$ )	64.1 ( $P = 256$ )	

ELPA paper [3] reported that the choice of a (near-)square number for  $P$  can give better performance.

When the non-traditional SEP solver algorithm of ELPA is used on Altix, one can choose an optimized low-level routine

using SSE instructions (‘REAL\_ELPA\_KERNEL\_SSE’) and a generic routine (‘REAL\_ELPA\_KERNEL\_GENERIC’). [3] The optimized code can run only on the Intel-based architectures compatible to SSE instructions and was prepared so as to accelerate the backtransformation subroutine. Among the results on Altix, the ‘ELPA2’ solver and the workflow  $D$  on Altix are those with the optimized routine, while the ‘ELPA2’ solver and the workflow  $D'$  are those with the generic routine.

**Fig. 4** Results with  $M=430,800$  on the K computer. The elapse times are plotted with the workflows for the (a) full ( $T_{full}$ ) and (b) eigenvalue-only ( $T_{evo}$ ) calculations. (c) The decomposed times for the SEP solver ( $T_{SEP}$ ) and for the reducer ( $T_{RED}$ ) are plotted. The routines for the reducers is labeled by ‘(RED)’. Detailed decomposed times for subprocedures of the ELPA style reducer and the Cholesky decomposition in the ScalLAPACK style reducer are also plotted in (c). The ideal speedup in parallelism is drawn as a dashed gray line.

#### 4.1 Result with the matrix size of $M = 430,080$

The benchmark with the matrix size of  $M = 430,080$  was carried out for up to  $P = 10,000$  nodes on the K computer. The elapse times for  $P=10,000$  nodes is shown in Table 2. The elapse time for all the cases are shown in Fig. 4 for the (a) full ( $T_{full}$ ) or (b) eigenvalue-only ( $T_{evo}$ ) calculations. The decomposed times are also shown in Fig. 4 (c) for the SEP solver ( $T_{SEP}$ ) and the reducer

$$(T_{\text{RED}}) (T_{\text{full}} = T_{\text{SEP}} + T_{\text{RED}}).$$

**Table 3** Decomposition of the elapse time (sec) of the SEP solvers with  $M=430,080$  and  $P = 10,000$ . See the text for the subroutine names of ‘TRD/BAND’, ‘D&C’ and ‘BACK’.

SEP solver	TRD/BAND	D&C	BACK	Total ( $T_{\text{SEP}}$ )
SCLA	3,055	465	633	4,152
ELPA2	966	141	1,892	2,999
ELPA1	1,129	138	400	1,667
EIGS	1,058	196	265	1,521
EIGX	828	390	255	1,473

Table 3 shows the decomposed time of the SEP solvers for  $P=10,000$ . A SEP solver routine is decomposed into three sub-routines of (i) the tridiagonalization or narrow-band reduction (‘TRD/BAND’), (ii) the divide and conquer algorithms for the tridiagonal or narrow-band matrices (‘D&C’) so as to compute the eigenvalues, and (iii) the backtransformation of eigenvectors (‘BACK’) so as to compute the eigenvectors of the GEP.

One can observe several features on the results; (I) In the full calculation benchmark (Fig. 4(a)), the best data, the smallest elapse time, appears in the workflow *G* for  $P=10,000$ . The workflow *G* is the hybrid solver that uses the ‘Eigen<sub>sx</sub>’ SEP solver in EigenExa and the ELPA style reducer, since these routines are the best among the SEP solvers and the reducers, respectively, as shown in Fig. 4(c) and Table 3. In Table 2, the speed ( $T_{\text{full}}^{-1}$ ) of the workflow *G* is approximately four times faster than that of the conventional workflow *A* (11,634 sec) / (2,734 sec)  $\approx 4.3$ . (II) Fig. 4 (c) shows that the ELPA style reducer gives significantly smaller elapse times than those of ScaLAPACK and those of EigenExa. The elapse time for  $P=10,000$  is  $T_{\text{RED}} = 1,261$  sec with the ELPA style reducer and is  $T_{\text{RED}} = 2,157$  sec with the EigenExa reducer. The elapse time with the EigenExa reducer is governed by that of the SEP solver for Eq. (7) ( $T_{\text{SEP}} = 1,473$  sec in Table 3). (III) In the eigenvalue-only calculation (Fig. 4(b)), the best data, the smallest elapse time, appears in the workflow *D* for  $P=10,000$ . The workflow *D* is the solver that uses the ‘ELPA2’ SEP solver and the ELPA style reducer and the eigenvector calculation consumes a large elapse time of  $T_{\text{vec}}$ ;  $T_{\text{vec}} \equiv T_{\text{full}} - T_{\text{evo}} = (4,242 \text{ sec}) - (2,227 \text{ sec}) = (2,015 \text{ sec})$  in Table 2. The time  $T_{\text{vec}}$  is contributed mainly by the backward transformation subroutine ( $T_{\text{BACK}} = 1,892$  sec) in Table 3, because the backward transformation subroutine in ELPA2 uses a characteristic two-step algorithm (See Sec. 4.3 of Ref. [3]).

#### 4.2 Benchmark with the matrix sizes of $M=90,000, 22,500$

The benchmark with the smaller matrix sizes of  $M = 90,000$  and  $22,500$  are also investigated. The maximum number of used processor nodes is  $P_{\text{max}} = 4,096, 1,039$  and  $256$ , on the K computer, FX10, and Altix, respectively. <sup>\*8</sup> Figures 5 and 6 show the data with  $M=90,000$  and with  $M=22,500$ , respectively. The decomposed times are shown in Fig. 7. Table 2 shows the best data for each workflow among the different numbers of used nodes.

<sup>\*8</sup> We observed on Altix that the ‘ELPA2’ and ‘ELPA2’ SEP solver required non-blocking communication requests beyond the default limit number of  $N_{\text{MPI\_MAX}} = 16,384$  and the job stopped with an MPI error message. Then we increased the limit number to  $N_{\text{MPI\_MAX}} = 1,048,576$ , the possible maximum of the machine by the environment variable ‘MPIREQUEST\_MAX’ and the calculations were completed.

The results will help general simulation researchers to choose the solver and the number of used nodes, since the elapse times in Table 2 are less than a half hour and such calculations are popular ‘regular class’ jobs among systematic investigations. <sup>\*9</sup>

Here, the results are discussed; (I) Table 2 shows that the smallest elapse time in the full calculation appears among the workflows with the ELPA style reducer (the workflows *D, E, F*, and *G*) and that in the eigenvalue-only calculation appears with the workflow *D*. The above features are consistent to the results in the previous subsection. (II) Unlike the result in the previous subsection, the speed up is sometimes saturated. An example is observed in Fig. 6 (a), in the full calculation with  $M=22,500$  on the K computer, because the elapse time in the workflow *F* gives a minimum as the function of  $P$  at  $P=1,024$ . The decomposition analysis of Fig. 7(b) indicates that the saturation occur both for the SEP solver and the reducer, which implies that the improvement both on the SEP solver and the reducer is desirable. The saturated cases are marked in Table 2 with the label of ‘[S]’. <sup>\*10</sup> (III) Finally, the SSE-optimized routine in the workflow *D* is compared with the generic routine in the workflow *D’* in the case of  $M = 90,000$  on Altix with  $P = 256$ . The SSE-optimized routine is prepared only in the backward transformation process. Since the process with the SSE-optimized routine or the generic one gives the elapse time of  $T_{\text{BACK}} = 929$  sec or  $T_{\text{BACK}} = 1,872$  sec, respectively, the process is accelerated with the SSE-optimized routine by  $1,872 \text{ sec} / 929 \text{ sec} \approx 2.02$ . As shown in Table 2, the full calculation is accelerated with the SSE-optimized routine by  $2,621 \text{ sec} / 1,621 \text{ sec} \approx 1.62$ .

#### 4.3 Benchmark for a million dimensional matrix

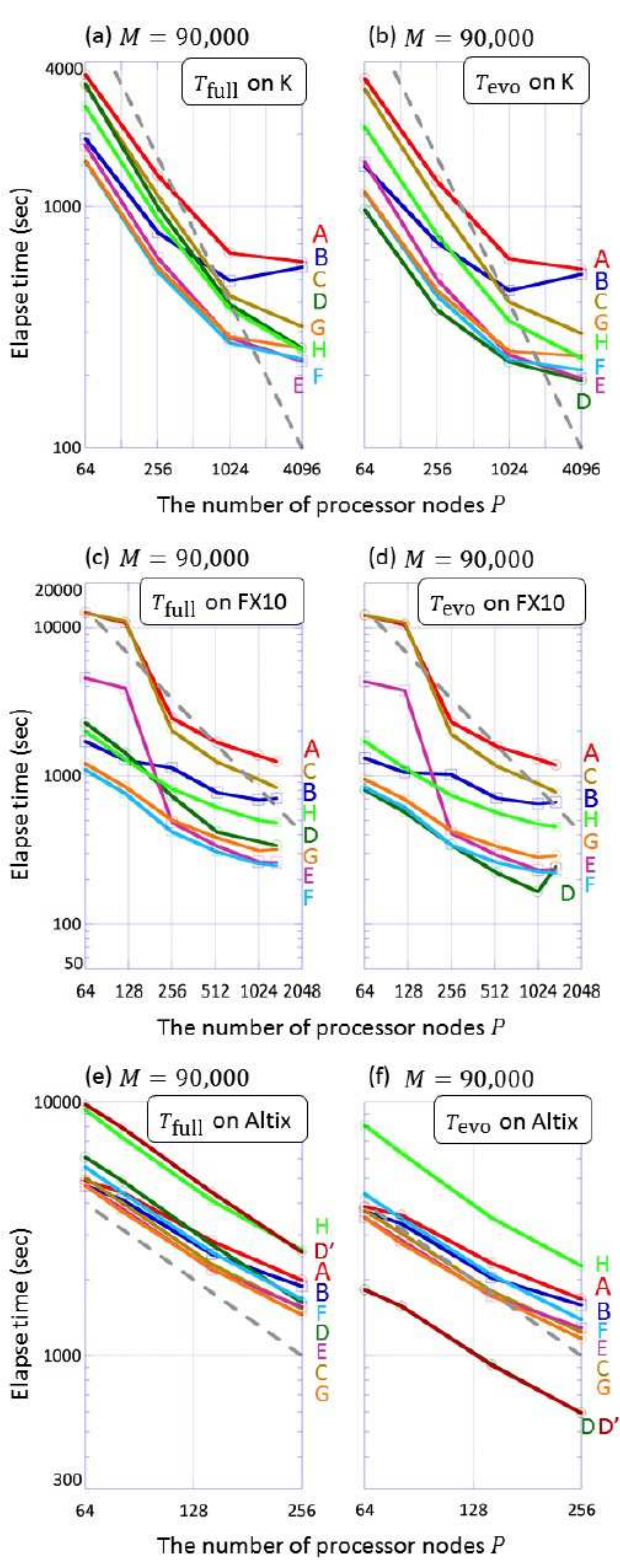

Finally, the benchmark for a million dimensional matrix is discussed. A press release at 2013 [24] reported, as a world record, a benchmark of a million dimensional SEP carried out by EigenExa, in approximately one hour, on the full (82,944) nodes of the K computer. An eigenvalue problem with a million dimensional matrix ( $M=10^6$ ) seems to be the practical limitation of the present supercomputer, owing to the  $O(M^3)$  operation cost.

We calculated a million dimensional GEP at Dec. 2014 on the full (4,800) nodes of Oakleaf-FX. <sup>\*11</sup> Since our computational resource was limited, only one calculation was carried out with the workflow *G*, because it gives the best data among those with  $M = 430,080$  in Table 2. The calculation finished in approximately a half day, as shown in Table 2 ( $T_{\text{full}} = 39,919$  sec and  $T_{\text{evo}} = 35,103$  sec). The elapse time of the reducer ( $T_{\text{RED}} = T_{\text{full}} - T_{\text{SEP}} = 15,179$  sec) is smaller than but comparable to that of the SEP solver ( $T_{\text{SEP}} = 24,740$ ). The benchmark proved that the present code qualifies as a software applicable to massively parallel computation with up to a million dimensional matrix.

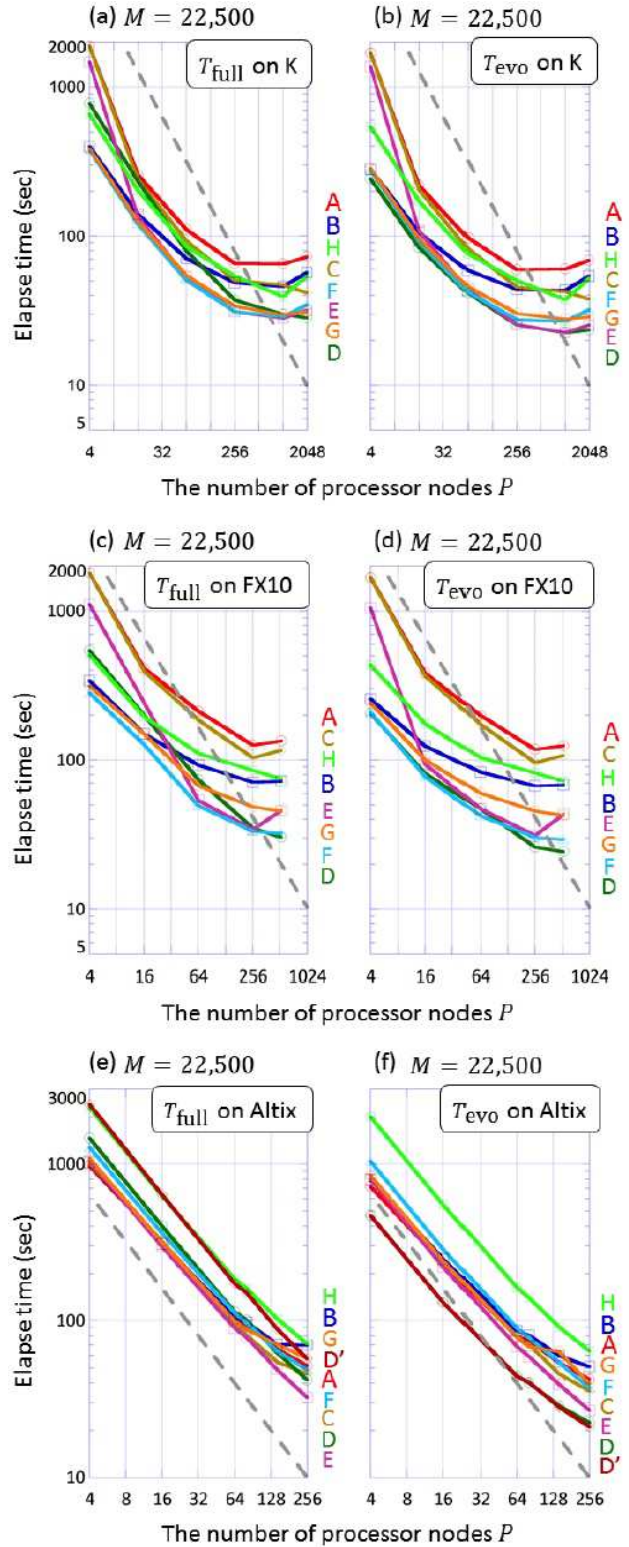

<sup>\*9</sup> One should remember that supercomputers are usually shared by many researchers who run many calculations in similar problem sizes successively and/or simultaneously.

<sup>\*10</sup> No saturation is found on Altix, unlike on the K computer and FX10, partially because the maximum number of used nodes ( $P_{\text{max}} = 256$ ) is smaller.

<sup>\*11</sup> We used FX10 not the K computer, because FX10 is in a newer architecture with a lower B/F value and the result on FX10 is speculated to be closer to that on the next-generation (exa-scale) machine.

**Fig. 5** Benchmark with the matrix size of  $M=90,000$ , (I) on the K computer for the (a) full (eigenpair) and (b) eigenvalue-only calculation, (II) on FX10 for the (c) full and (d) eigenvalue-only calculation, (III) on Altix for the (e) full and (f) eigenvalue-only calculation. The ideal speedup in parallelism is drawn as a dashed gray line.

**Fig. 6** Benchmark with the matrix size of  $M=22,500$ , (I) on the K computer for the (a) full (eigenpair) and (b) eigenvalue-only calculation, (II) on FX10 for the (c) full and (d) eigenvalue-only calculation, (III) on Altix for the (e) full and (f) eigenvalue-only calculation. The ideal speedup in parallelism is drawn as a dashed gray line.

## 5. Discussions

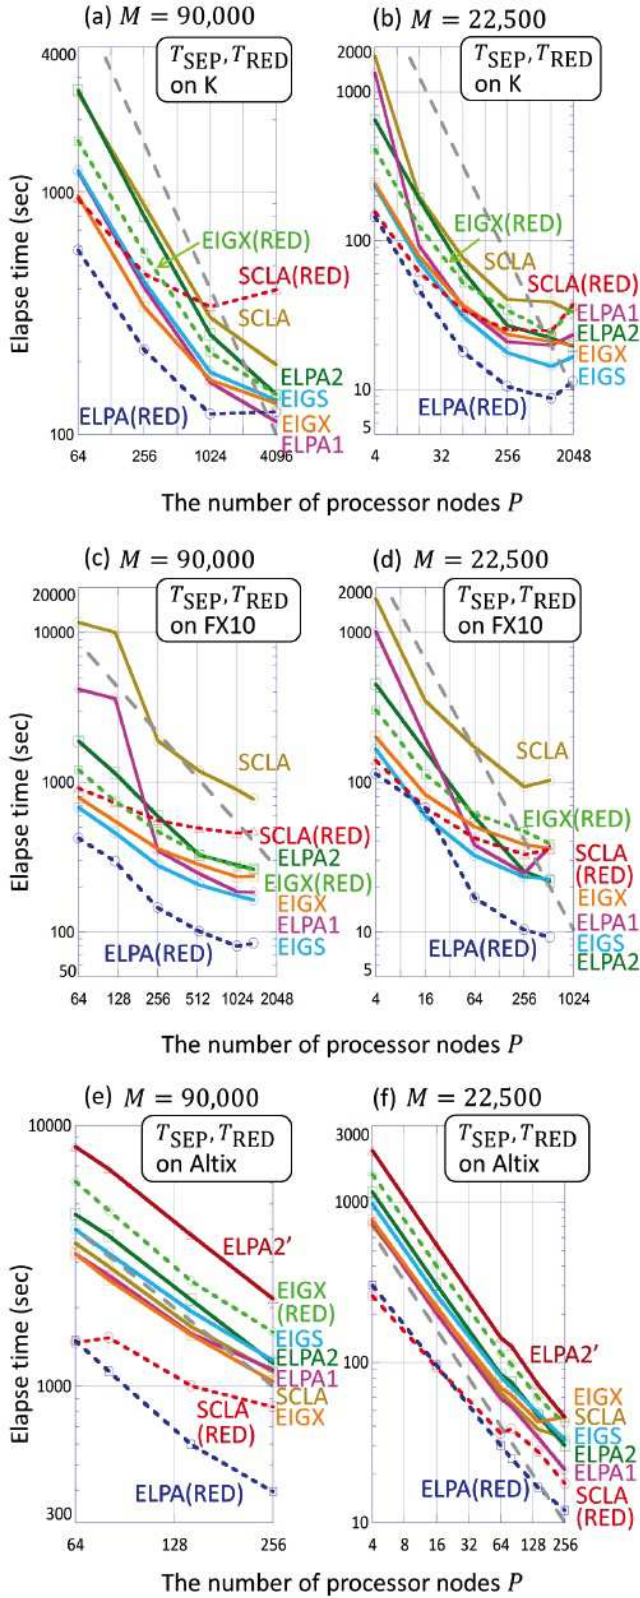

### 5.1 Preparation of initial distributed data

In the benchmark, the initial procedures including file read-

ing are carried out for the preparation of distributed data. Its elapse time is always small and is ignored in the previous section. <sup>\*12</sup> These procedures, however, may consume significant

<sup>\*12</sup> In the case of the workflow G on the K computer with  $M=430,080$

**Fig. 7** Decomposition analysis of the elapse time into those of the SEP solver and the reducer (I) on the K computer with (a)  $M=90,000$  and (b)  $M=22,500$ , (II) on FX10 with (c)  $M=90,000$  and (d)  $M=22,500$ , (III) on Altix with (e)  $M=90,000$  and (f)  $M=22,500$ . The routines for the reducers is labeled by '(RED)'. The 'ELPA2'' SEP solver is that without the SSE optimized routine. The ideal speedup in parallelism is drawn as a dashed gray line.

elapse times, when the present solver is used as a middleware with real applications. The discussions on such cases are beyond the present scope, since they depend on the program structure of the real applications. Here, several comments are added for real application developers; In general, the matrix data cost is, at most,  $O(M^2)$  and the operation cost is  $O(M^3)$  in the dense-matrix solvers and one should consider a balance between them. In the case of  $M = 430,080$ , for example, the required memory size for all the matrix elements is  $8 \text{ B} \times M^2 \approx 1.5 \text{ TB}$ , which can not be stored on a node of the K computer. Therefore, the data should be always distributed. In our real application (ELSES), the initial distributed data is prepared, when only the required elements are generated and stored on each node.

## 5.2 Data conversion overhead

As explained in Sec. 3.1, several workflows require data conversion processes between distributed data formats, since ScaLAPACK and ELPA use block cyclic distribution with a given block size  $n_{\text{block}} (> 1)$  and EigenExa uses cyclic distribution ( $n_{\text{block}} \equiv 1$ ). In the present benchmark, the block size  $n_{\text{block}}$  in ScaLAPACK and ELPA was set to be  $n_{\text{block}} = 128$ , a typical value. Consequently, the workflows B, F, G require data conversion processes. In the present paper, the elapse time of the conversion procedures is included in the reducer part ( $T_{\text{red}}$ ).

Table 4 shows the elapse time for the data conversion. The elapse times are shown in the cases with the maximum numbers of used nodes ( $P = P_{\text{max}}$ ) among the present benchmark. Two data conversion procedures are required. One is the conversion from the block cyclic distribution into the cyclic distribution, shown as '(b  $\rightarrow$  1)' in Table 4 and the other is the inverse process shown as '(1  $\rightarrow$  b)'. The two procedures are carried out, commonly, by the 'pdgcmr2d' routine in ScaLAPACK.

Table 4 indicates that the overhead of the data conversion procedures is always small and is not the origin of the saturation. In general, the conversion requires an  $O(M^2)$  operation cost, while the calculation in a dense-matrix solver requires an  $O(M^3)$  operation cost. The fact implies the general efficiency of hybrid solvers, at least, among dense-matrix solvers.

**Table 4** The elapse times for data conversion; '(b  $\rightarrow$  1)', '(1  $\rightarrow$  b)' and ' $T_{\text{RED}}$ ' are the times in seconds for, the conversion process from block cyclic into cyclic distributions, the inverse process and the whole reducer procedure, respectively. The saturated data of  $T_{\text{RED}}$  are labelled by '[S]'. The 'ratio' is  $((b \rightarrow 1) + (1 \rightarrow b)) / T_{\text{RED}}$ .

Size M	Machine(P)	(b $\rightarrow$ 1)	(1 $\rightarrow$ b)	$T_{\text{RED}}$	ratio[%]
1,008,000	FX10(4,800)	51.4	51.7	8,208	1.26
430,080	K(10,000)	13.4	6.48	1,261	1.58
90,000	K(4,096)	6.89	0.797	124[S]	6.21
	FX10(1,369)	1.89	0.973	84.0[S]	3.41
22,500	Altix(256)	2.01	2.02	394	1.02
	K(2,025)	0.571	0.610	11.3[S]	10.4
	FX10(529)	0.328	0.176	9.20	5.48
	Altix(256)	0.120	0.279	11.9	3.35

is  $T_{\text{ini}} = 123 \text{ sec}$  and is much smaller than that of the total computation ( $T_{\text{tot}} = 2,734 \text{ sec}$ . See Table. 2). It is noteworthy that the present matrices are sparse, as explained in Sec. 2.

### 5.3 Decomposition analysis of the reducer

The decomposition analysis of the ELPA-style reducer is focused on, since the ELPA-style reducer is fastest among the three libraries. Figure 4 (c) shows the case on the K computer with  $M=430,080$ . The elapse times of the subprocedures of the ELPA-style reducer are plotted; ‘ELPA( $R_1$ )’ is the Cholesky factorization of Eq. (4), ‘ELPA( $R_2$ )’ is the explicit calculation of the inversion  $R = U^{-1}$  of the Cholesky factor  $U$ , ‘ELPA( $R_3$ )’ and ‘ELPA( $R_4$ )’ are the successive matrix multiplication of Eq. (5) and ‘ELPA( $R_5$ )’ is the backward transformation of eigenvectors by matrix multiplication of Eq. (6). The elapse times of the Cholesky factorization in the ScaLAPACK style reducer is also plotted as ‘SCLA( $R_1$ )’ as a reference data. The same decomposition analysis is carried out also for other cases, as shown in Fig. 8. One can observe that the Cholesky factorization of the ELPA-style reducer does not scale and sometimes is slower than that of the ScaLAPACK reducer. In particular, the saturation of the ELPA-style reducer is caused by that of the Cholesky factorization in Fig. 8 (a)(b)(c).

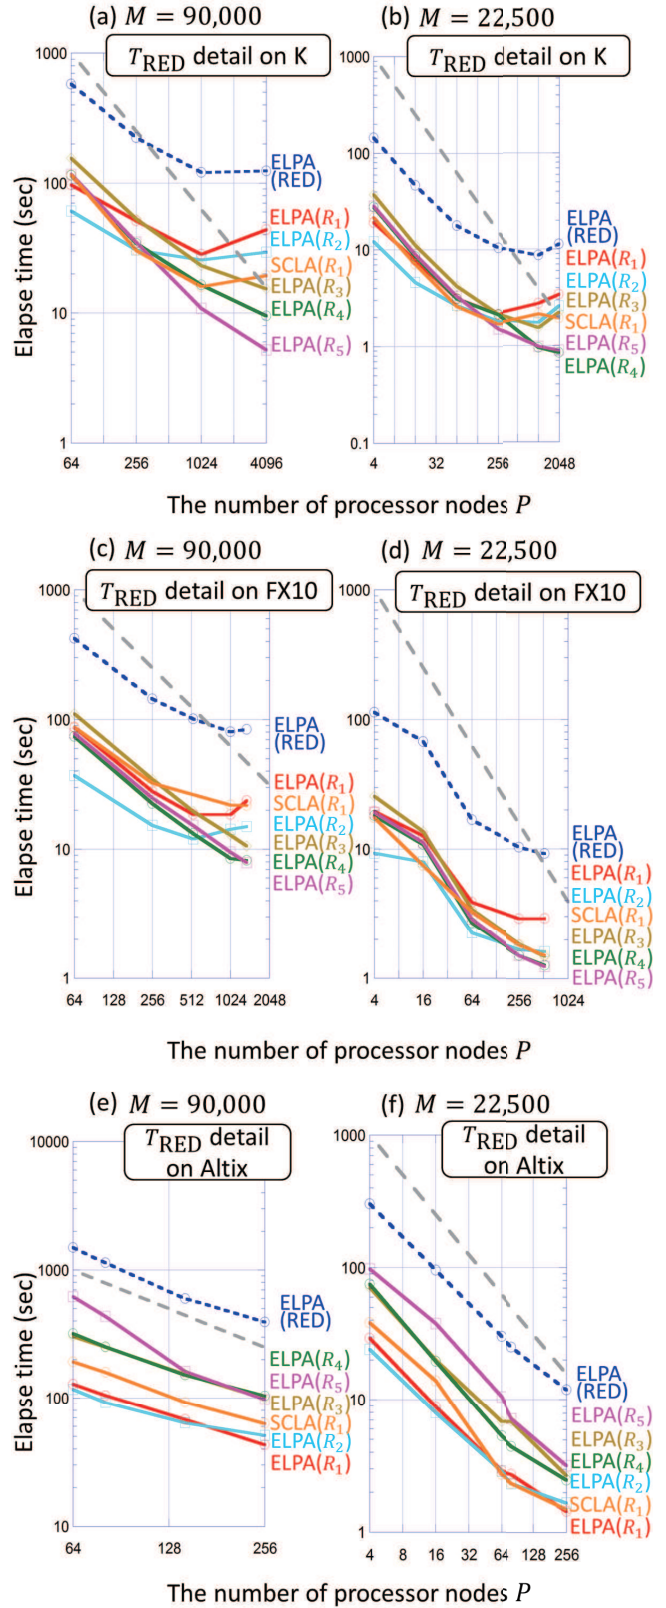

The above observation implies that the reducer can be a serious bottleneck in the next-generation (exa-scale) supercomputers, though not in the present benchmark. One possible strategy is the improvement on the Cholesky factorization for better scalability and another is the development of a reducer without the Cholesky factorization, as in the EigenExa-style reducer.

## 6. Summary and future outlook

In summary, hybrid GEP solvers were constructed between the three parallel dense-matrix solver libraries of ScaLAPACK, ELPA and EigenExa. The benchmark was carried out with up to a million dimensional matrix on the K computer and other supercomputers. The hybrid solvers with ELPA and EigenExa give better benchmark results than the conventional ScaLAPACK library. The code was developed as a middleware and a mini-application and will appear online. Several issues are discussed. In particular, the decomposition analysis of the elapse time reveals a potential bottleneck part on next-generation (exa-scale) supercomputers, which indicates the guidance for future development of the algorithms and the codes.

As a future outlook, the present code for the hybrid solvers is planned to be extended by introducing the solvers with different mathematical foundations. A candidate is the parallel block Jacobi solver [25], [26]. Since the solver is applicable only to standard eigenvalue problems, the hybrid solver enables us to use the solver in generalized eigenvalue problems.

**Acknowledgments** The authors thank to Toshiyuki Imamura and Takeshi Fukaya in RIKEN Advanced Institute of Computational Science (AICS) for fruitful discussions on EigenExa. The authors also thank to Yusaku Yamamoto in The University of Electro-Communications on the parallel block Jacobi solver.
