Reconstruction of the solution and the source of hyperbolic equations from boundary measurements: mixed formulations

Nicolae Cîndea* Arnaud Münch[†]

March 26, 2022

Abstract

We introduce a direct method allowing to solve numerically inverse type problems for linear hyperbolic equations. We first consider the reconstruction of the full solution of the wave equation posed in $\Omega \times (0,T)$ - Ω a bounded subset of \mathbb{R}^N - from a partial boundary observation. We employ a least-squares technique and minimize the L^2 -norm of the distance from the observation to any solution. Taking the hyperbolic equation as the main constraint of the problem, the optimality conditions are reduced to a mixed formulation involving both the state to reconstruct and a Lagrange multiplier. Under usual geometric optic conditions, we show the well-posedness of this mixed formulation (in particular the inf-sup condition) and then introduce a numerical approximation based on space-time finite elements discretization. We prove the strong convergence of the approximation and then discuss several examples for N = 1 and N = 2. The problem of the reconstruction of both the state and the source term is also addressed.

1 Introduction

Let Ω be a bounded domain of \mathbb{R}^N $(N \ge 1)$ whose boundary $\partial\Omega$ is of class C^2 and let T > 0. We define $Q_T := \Omega \times (0,T)$, $\Sigma_T := \partial\Omega \times (0,T)$ and denote by $\nu = \nu(x)$ the outward unit normal to Ω at any point $x \in \partial\Omega$. We are concerned with inverse type problems for the following linear hyperbolic equation

$$\begin{cases} y_{tt} - \nabla \cdot (c(x)\nabla y) + d(x,t)y = f, & (x,t) \in Q_T \\ y = 0, & (x,t) \in \Sigma_T \\ (y(\cdot,0), y_t(\cdot,0)) = (y_0, y_1), & x \in \Omega. \end{cases}$$
(1)

We assume that $c \in C^1(\overline{\Omega}, \mathbb{R})$ with $c(x) \ge c_0 > 0$ in $\overline{\Omega}, d \in L^{\infty}(Q_T), (y_0, y_1) \in \mathbf{V} := H_0^1(\Omega) \times L^2(\Omega)$ and $f \in L^2(Q_T)$.

For any $(y_0, y_1) \in \mathbf{V}$ and any $f \in L^2(Q_T)$, there exists exactly one solution y to (1), with $y \in C^0([0,T]; H^1_0(\Omega)) \cap C^1([0,T]; L^2(\Omega))$ (see [21, 22]). In the sequel, for simplicity, we shall use the following notation:

$$L y := y_{tt} - \nabla \cdot (c(x)\nabla y) + d(x,t)y.$$

1 INTRODUCTION

Let now Γ be any non empty open subset of $\partial\Omega$ and let $\Gamma_T := \Gamma \times (0,T) \subset \Sigma_T$. A typical inverse problem for (1) is the following one : from an *observation* or *measurement* of the normal derivative $y_{\nu,obs}$ in $L^2(\Gamma_T)$ on the sub-domain Γ_T , we want to recover a solution y of the boundary value problem (1) such that its normal derivative coincides with the observation on Γ_T .

We denote by $\partial_{\nu} y = \nabla y \cdot \nu$ the normal derivative of y on $\partial\Omega$. Introducing the operator $P: Z \to L^2(Q_T) \times L^2(\Gamma_T)$ defined by $P y := (Ly, c(x)\partial_{\nu}y_{|\Gamma_T})$ and the Hilbert space Z defined by (3)-(5), the problem is reformulated as :

find
$$y \in Z$$
 solution of $P y = (f, c(x)y_{\nu,obs}).$ (IP)

From the unique continuation property for (1), if the set Γ_T satisfies some geometric conditions and if $y_{\nu,obs}$ is a restriction to Γ_T of a normal derivative of a solution of (1), then the problem is well-posed in the sense that the state y corresponding to the pair $(y_{\nu,obs}, f)$ is unique.

In view of the unavoidable uncertainties on the data $y_{\nu,obs}$ (coming from measurements, numerical approximations, etc), the problem (IP) needs to be relaxed. In this respect, the most natural (and widely used in practice) approach consists in introducing the following extremal problem (of least-squares type)

$$\begin{cases} \text{minimize over } \boldsymbol{V} \quad J(y_0, y_1) := \frac{1}{2} \| c(x) (\partial_{\nu} y - y_{\nu, obs}) \|_{L^2(\Gamma_T)}^2 \\ \text{where } y \quad \text{solves} \quad (1), \end{cases}$$
(LS)

since y is uniquely and fully determined from f and the data (y_0, y_1) . Here the constraint $c(x)(\partial_{\nu}y - y_{\nu,obs}) = 0$ in $L^2(\Gamma_T)$ is relaxed; however, if $y_{\nu,obs}$ is a restriction to Γ_T of the normal derivative of a solution of (1), then problems (LS) and (IP) coincide. A minimizing sequence for J in V is easily defined in term of the solution of an auxiliary adjoint problem. Apart from a possible low decrease of the sequence near extrema, the main drawback, when one wants to prove the convergence of a discrete approximation is that, it is not in general possible to minimize over a discrete subspace of $\{y; Ly - f = 0\}$ subject to the equality $(\ln L^2(Q_T)) Ly - f = 0$. Therefore, a classical trick consists first in discretizing the functional J and the system (1); this raises the issue of uniform coercivity property (typically here some uniform discrete observability inequality for the adjoint solution) of the discrete functional with respect to the approximation parameter. As far as we know, this delicate issue has received answers only for specific and somehow academic situations (uniform Cartesian approximation of Ω , constant coefficients in (1), etc). We refer to [13, 18, 20, 24] and the references therein.

More recently, a different method to solve inverse type problems like (IP) has emerged and use the so called Luenberger type observers: roughly, this method consists in defining, from the observation on Γ_T , an auxiliary boundary value problem whose solution possesses the same asymptotic behavior in time than the solution of (1): the use of the reversibility of the hyperbolic equation then allows to reconstruct the initial data (y_0, y_1) . We refer to [9, 25] and the references therein. However, for the same reasons, from a numerically point of view, these methods require to prove uniform discrete observability properties.

In a series of works, Klibanov and co-workers use different approaches to solve inverse problems (we refer to [19] and the references therein): they advocate in particular the quasi-reversibility method which reads as follows : for any $\varepsilon > 0$, find $y_{\varepsilon} \in \mathcal{A}$ the solution of

$$\langle Py_{\varepsilon}, P\overline{y} \rangle_{L^{2}(Q_{T}) \times L^{2}(\Gamma_{T})} + \varepsilon \langle y_{\varepsilon}, \overline{y} \rangle_{\mathcal{A}} = \langle (f, c(x)y_{\nu, obs}), P\overline{y} \rangle_{L^{2}(Q_{T}) \times L^{2}(\Gamma_{T})}, \quad \forall \ \overline{y} \in \mathcal{A}, \qquad (QR_{\varepsilon})$$

where \mathcal{A} denotes a Hilbert space subset of $L^2(Q_T)$ so that $Py \in L^2(Q_T) \times L^2(\Gamma_T)$ for all $y \in \mathcal{A}$ and $\varepsilon > 0$ is a Tikhonov like parameter which ensures the well-posedness. We refer for instance to [14] where the lateral Cauchy problem for the wave equation with non constant diffusion is addressed within this method. Remark that (QR_{ε}) can be viewed as a least-squares problem since the solution

1 INTRODUCTION

 y_{ε} minimizes over \mathcal{A} the functional $y \to \|Py - (f, c(x)y_{\nu,obs})\|_{L^2(Q_T) \times L^2(\Gamma_T)}^2 + \varepsilon \|y\|_{\mathcal{A}}^2$. Eventually, if $y_{\nu,obs}$ is the normal derivative of a restriction to Γ_T of a solution of (1), the corresponding y_{ε} converges in $L^2(Q_T)$ toward to the solution of (IP) as $\varepsilon \to 0$. There, unlike in Problem (LS), the unknown is the state variable y itself (as it is natural for elliptic equations) so that any standard numerical methods based on a conformal approximation of the space \mathcal{A} together with appropriate observability inequalities allow to obtain a convergent approximation of the solution. In particular, there is no need to prove discrete observability inequalities. We refer to the book [2]. We also mention [5, 6] where a similar technique has been used recently to solve the inverse obstacle problem associated to the Laplace equation, which consists in finding an interior obstacle from boundary Cauchy data.

In the spirit of the works [6, 14, 19], we explore the direct resolution of the optimality conditions associated to the extremal problem (*LS*), without Tikhonov parameter while keeping y as the unknown of the problem. This strategy, which avoids any iterative process, has been successfully applied in the close context of the exact controllability of (1) in [13] and [8, 11]. The idea is to take into account the state constraint Ly - f = 0 with a Lagrange multiplier. This allows to derive explicitly the optimality system associated to (*LS*) in term of an elliptic mixed formulation and therefore reformulate the original problem. Well-posedness of such new formulation is related to a unique continuation property for the hyperbolic equation (1).

From the observation $y_{\nu,obs}$, we also address the simultaneous reconstruction problem of the source term f and the solution y:

find
$$(y, f) \in Z \times L^2(Q_T)$$
 solution of $P y = (f, c(x)y_{\nu, obs}),$ (IP_f)

where (y, f) solves (1). Without additional assumption on $f \in L^2(Q_T)$, the pair (y, f) solution of (IP_f) is not unique: consider for instance a source term f supported in a set which is near $\Omega \times \{T\}$: from the finite propagation of the solution, the source f will not affect the solution y on Γ_T . On the other hand, a result of Yamamoto and Zhang in [27] asserts that the uniqueness holds true if the source takes the form $f(x,t) = \sigma(t)\mu(x)$, where the smooth time part σ is given and the spatial part μ is a $H^{-1}(\Omega)$ function.

We adapt in this work the arguments of [12] where the observation is distributed in Q_T . The outline is as follow. In Section 2, we consider the least-squares problem (\mathcal{P}) and reconstruct the solution of the hyperbolic equation from a partial observation localized on a subset Γ_T of Σ_T . For that, in Section 2.1, we associate to (\mathcal{P}) the equivalent mixed formulation (6) which relies on the optimality conditions of the problem. Assuming that Γ_T satisfies the classical geometric optic condition (Hypothesis 1, see (\mathcal{H})), we then show the well-posedness of this mixed formulation, in particular, we check the Babuska-Brezzi inf-sup condition (see Theorem 2.1). Interestingly, we also derive in Section 2.2 an equivalent dual extremal problem, which reduces the determination of the state y to the minimization of a strongly elliptic functional with respect to the Lagrange multiplier. In Section 3, we use the uniqueness result [27, Theorem 2.1] of Yamamoto and Zhang and apply the same procedure to recover from a partial observation both the state and the spatial part μ of the source term assumed in $H^{-1}(\Omega)$. Section 4 is devoted to the numerical approximation, through a conformal space-time finite element discretization. The strong convergence of the approximation $\{y_h, \mu_h\}$ is proved as the discretization parameter h tends to zero. In particular, we discuss the discrete inf-sup property of the mixed formulation. We present numerical experiments in Section 5 for $\Omega = (0,1)$ and $\Omega \subset \mathbb{R}^2$, an check the robustness and convergence of the approximations in agreement with the theoretical part. Section 6 concludes with some perspectives: in particular, we highlight that the parabolic case can be treated in a similar way.

2 Recovering the solution from a partial observation: a mixed re-formulation of the problem

In this section, assuming that the initial data $(y_0, y_1) \in \mathbf{V}$ are unknown, we address the inverse problem (*IP*). Without loss of generality, in view of the linearity of the system (1), we assume that the source term f is zero.

We consider the non empty vector space Z defined by

$$Z := \{ y : y \in C([0,T], H_0^1(\Omega)) \cap C^1([0,T], L^2(\Omega)), Ly \in L^2(Q_T) \}$$
(3)

and then first recall that $\partial_{\nu} y \in L^2(\Sigma_T)$ for any $y \in Z$: precisely (see [21, Theorem 4.1, Ch 1]), there exists a constant $C_T > 0$ such that the following holds :

$$\|c(x)\partial_{\nu}y\|_{L^{2}(\Gamma_{T})}^{2} \leq C_{T}\left(\|(y(\cdot,0),y_{t}(\cdot,0))\|_{\boldsymbol{V}}^{2} + \|Ly\|_{L^{2}(Q_{T})}^{2}\right), \quad \forall y \in Z.$$

$$\tag{4}$$

We then introduce the following hypothesis :

Hypothesis 1 There exists a constant $C_{obs} = C(\omega, T, \|c\|_{C^1(\overline{\Omega})}, \|d\|_{L^{\infty}(Q_T)})$ such that the following estimate holds :

$$\|y(\cdot,0), y_t(\cdot,0)\|_{\boldsymbol{V}}^2 \le C_{obs} \left(\|c(x)\partial_{\nu}y\|_{L^2(\Gamma_T)}^2 + \|Ly\|_{L^2(Q_T)}^2 \right), \quad \forall y \in Z.$$
(\mathcal{H})

Condition (\mathcal{H}) is a generalized observability inequality for the solution of the hyperbolic equation (1). For constant coefficients, this estimate is known to hold if the triplet (Γ, T, Ω) satisfies a geometric optic condition. We refer to [1] for the case of constant velocity c. In particular, T must be large enough. In the one-dimensional case, for non constant velocity c and potential d, we refer to [11] and the references therein.

Then, within this hypothesis, for any $\eta > 0$, we define on Z the bilinear form

$$\langle y, \overline{y} \rangle_{Z} := \iint_{\Gamma_{T}} c^{2}(x) \,\partial_{\nu} y \,\partial_{\nu} \overline{y} \,d\sigma dt + \eta \iint_{Q_{T}} Ly \,L\overline{y} \,dx dt \quad \forall y, \overline{y} \in Z \tag{5}$$

and we denote the corresponding semi-norm $\|y\|_Z := \sqrt{\langle y, y \rangle_Z}$. We have the following result :

LEMMA 2.1 Under the hypothesis (\mathcal{H}), the space Z is a Hilbert space with the scalar product $\langle \cdot, \cdot \rangle_Z$ defined by (5).

PROOF-The two main properties we need to verify are that the semi-norm associated to this inner product $\|\cdot\|_Z$ is indeed a norm, and that Z is closed with respect to this norm. The first property is a direct consequence of the inequality (\mathcal{H}) .

To check the second property, let us consider a convergent sequence $\{z_k\}_{k\geq 1} \subset Z$ such that $z_k \to z$ in the norm $\|\cdot\|_Z$. We have to see that $z \in Z$. As a consequence of (\mathcal{H}) , there exist $(z_0, z_1) \in \mathbf{V}$ and $f \in L^2(Q_T)$ such that $(z_k(\cdot, 0), z_{k,t}(\cdot, 0)) \to (z_0, z_1)$ in \mathbf{V} and $Lz_k \to f$ in $L^2(Q_T)$. Therefore, z_k can be considered as a sequence of solutions of the hyperbolic equation with convergent initial data and second hand term $Lz_k \to f$.

By the continuous dependence of the solutions of the wave equation on the data, $z_k \to z$ in $C([0,T]; H_0^1(\Omega)) \cap C^1([0,T]; L^2(\Omega))$, where z is the solution of the hyperbolic equation with initial data $(z_0, z_1) \in \mathbf{V}$ and second hand term $Lz = f \in L^2(Q_T)$. Therefore, in view of (4), $z \in Z$. \Box

We consider the following extremal problem :

$$\begin{cases} \inf J(y) := \frac{1}{2} \|c(x)(\partial_{\nu}y - y_{\nu,obs})\|_{L^{2}(\Gamma_{T})}^{2}, \\ \text{subject to} \quad y \in W \end{cases}$$

$$(\mathcal{P})$$

where W is the closed subspace of Z defined by

$$W := \{ y \in Z; Ly = 0 \text{ in } L^2(Q_T) \}$$

and endowed with the norm of Z.

The extremal problem (\mathcal{P}) is well posed : the functional J is continuous over W, is strictly convex and is such that $J(y) \to +\infty$ as $||y||_W \to \infty$. Note also that the solution of (\mathcal{P}) in W does not depend on η .

We recall that from the definition of Z, Ly belongs to $L^2(Q_T)$. Furthermore, the uniqueness of the solution is lost if the hypothesis (\mathcal{H}) is not fulfilled, for instance if T is not large enough. Eventually, from (\mathcal{H}) , the solution y in Z of (\mathcal{P}) satisfies $(y(\cdot, 0), y_t(\cdot, 0)) \in \mathbf{V}$, so that Problem (\mathcal{P}) is equivalent to the minimization of J with respect to $(y_0, y_1) \in \mathbf{V}$ as in problem (IP), Section 1.

2.1 Direct approach

In order to solve (\mathcal{P}) , we have to deal with the constraint equality which appears in the space W. Proceeding as in [13], we introduce a Lagrange multiplier $\lambda \in L^2(Q_T)$ and the following mixed formulation: find $(y, \lambda) \in Z \times L^2(Q_T)$ solution of

$$\begin{cases} a(y,\overline{y}) + b(\overline{y},\lambda) = l(\overline{y}), & \forall \overline{y} \in Z \\ b(y,\overline{\lambda}) = 0, & \forall \overline{\lambda} \in L^2(Q_T), \end{cases}$$
(6)

where

$$a: Z \times Z \to \mathbb{R}, \quad a(y, \overline{y}) := \iint_{\Gamma_T} c^2(x) \,\partial_\nu y \,\partial_\nu \overline{y} \,d\sigma dt, \tag{7}$$

$$b: Z \times L^2(Q_T) \to \mathbb{R}, \quad b(y,\lambda) := \iint_{Q_T} \lambda \, Ly \, dx dt,$$
(8)

$$l: Z \to \mathbb{R}, \quad l(y) := \iint_{\Gamma_T} c^2(x) \, y_{\nu,obs} \, \partial_{\nu} y \, d\sigma dt.$$
 (9)

System (6) is nothing else than the optimality system corresponding to the extremal problem (\mathcal{P}) . Precisely, the following result holds:

THEOREM 2.1 Under the hypothesis (\mathcal{H}) ,

- (i) The mixed formulation (6) is well-posed.
- (ii) The unique solution $(y, \lambda) \in Z \times L^2(Q_T)$ to (6) is the unique saddle-point of the Lagrangian $\mathcal{L}: Z \times L^2(Q_T) \to \mathbb{R}$ defined by

$$\mathcal{L}(y,\lambda) := \frac{1}{2}a(y,y) + b(y,\lambda) - l(y).$$

(iii) We have the estimate

$$\|y\|_{Z} = \left(\|c(x)\,\partial_{\nu}y\|_{L^{2}(\Gamma_{T})}^{2} + \eta\|Ly\|_{L^{2}(Q_{T})}^{2}\right)^{\frac{1}{2}} \le \|c(x)\,y_{\nu,obs}\|_{L^{2}(\Gamma_{T})},$$

$$\|\lambda\|_{L^{2}(Q_{T})} \le 2\sqrt{C_{\Omega,T} + \eta}\|c(x)\,y_{\nu,obs}\|_{L^{2}(\Gamma_{T})}.$$
 (10)

PROOF- The proof is based on classical results for saddle point problems (see [4], chapter 4).

We easily obtain the continuity of the bilinear form a over $Z \times Z$, the continuity of bilinear b over $Z \times L^2(Q_T)$ and the continuity of the linear form l over Z. In particular, we get

$$\|l\|_{Z'} \le \|c(x) y_{\nu,obs}\|_{L^2(\Gamma_T)}, \qquad \|a\|_{(Z \times Z)'} \le 1, \quad \|b\|_{(Z \times L^2(Q_T))'} \le \eta^{-1/2}.$$
(11)

Moreover, the kernel $\mathcal{N}(b) = \{y \in Z; b(y, \lambda) = 0 \quad \forall \lambda \in L^2(Q_T)\}$ coincides with W: we easily get

$$a(y,y) = \|y\|_Z^2, \quad \forall y \in \mathcal{N}(b) = W.$$

Therefore, in view of [4, Theorem 4.2.2], it remains to check the inf-sup constant property : $\exists \delta > 0$ such that

$$\inf_{\lambda \in L^2(Q_T)} \sup_{y \in Z} \frac{b(y, \lambda)}{\|y\|_Z \|\lambda\|_{L^2(Q_T)}} \ge \delta.$$

We proceed as follows. For any fixed $\lambda \in L^2(Q_T)$, we define $y_0 \in Z$ as the unique solution of

$$Ly_0 = \lambda \text{ in } Q_T, \quad (y_0(\cdot, 0), y_{0,t}(\cdot, 0)) = (0, 0) \text{ in } \Omega, \quad y_0 = 0 \text{ on } \Sigma_T.$$
(12)

We get $b(y_0, \lambda) = \|\lambda\|_{L^2(Q_T)}^2$ and

$$\|y_0\|_Z^2 = \|c(x)\,\partial_\nu y_0\|_{L^2(\Gamma_T)}^2 + \eta \|\lambda\|_{L^2(Q_T)}^2.$$

Using (4), the estimate $\|c(x)\partial_{\nu}y_0\|_{L^2(\Gamma_T)} \leq \sqrt{C_{\Omega,T}} \|\lambda\|_{L^2(Q_T)}$ implies that

$$\sup_{y \in Z} \frac{b(y, \lambda)}{\|y\|_Z \|\lambda\|_{L^2(Q_T)}} \ge \frac{b(y_0, \lambda)}{\|y_0\|_Z \|\lambda\|_{L^2(Q_T)}} \ge \frac{1}{\sqrt{C_{\Omega, T} + \eta}} > 0$$

leading to the result with $\delta = (C_{\Omega,T} + \eta)^{-1/2}$.

The third point is the consequence of classical estimates (see [4], Theorem 4.2.3.) :

$$\|y\|_{Z} \le \frac{1}{\alpha_{0}} \|l\|_{Z'}, \quad \|\lambda\|_{L^{2}(Q_{T})} \le \frac{1}{\delta} \left(1 + \frac{\|a\|}{\alpha_{0}}\right) \|l\|_{Z'}$$

where

$$\alpha_0 := \inf_{y \in \mathcal{N}(b)} \frac{a(y, y)}{\|y\|_Z^2}.$$
(13)

Estimates (11) and the equality $\alpha_0 = 1$ lead to the results. Eventually, from (11), we obtain that

$$\|\lambda\|_{L^2(Q_T)} \le \frac{2}{\delta} \|c(x) y_{\nu,obs}\|_{L^2(\Gamma_T)}$$

and that $\delta \geq (C_{\Omega,T} + \eta)^{-1/2}$ to get (10).

In practice, it is very convenient to "augment" the Lagrangian (see [17]) and consider instead the Lagrangian \mathcal{L}_r defined for any r > 0 by

$$\mathcal{L}_{r}(y,\lambda) := \frac{1}{2}a_{r}(y,y) + b(y,\lambda) - l(y),$$
$$a_{r}(y,y) := a(y,y) + r \|Ly\|_{L^{2}(Q_{T})}^{2}.$$

Since $a_r(y, y) = a(y, y)$ on W, the Lagrangian \mathcal{L} and \mathcal{L}_r share the same saddle-point. The positive real r is an augmentation parameter.

Remark 1 Assuming additional hypotheses on the regularity of the solution λ , precisely $L\lambda \in L^2(0,T,H^{-1}(\Omega))$ and $(\lambda,\lambda_t)_{|t=0,T} \in L^2(\Omega) \times H^{-1}(\Omega)$, we easily check, by writing the optimality conditions for \mathcal{L} , that the multiplier λ satisfies the following relations :

$$\begin{cases} L\lambda = 0 & \text{in } Q_T, \\ \lambda = c(x) \left(\partial_{\nu} y - y_{\nu,obs}\right) & \text{on } \Gamma_T, \\ \lambda = 0 & \text{on } \Sigma_T \setminus \Gamma_T, \\ \lambda = \lambda_t = 0 & \text{on } \Omega \times \{0, T\}. \end{cases}$$
(14)

Therefore, λ (defined in the weak sense) is a exact null controlled solution of the hyperbolic equation (1) through the boundary control $(\partial_{\nu}y - y_{\nu,obs}) \mathbf{1}_{\Gamma_T} \in L^2(\Gamma_T)$.

• If $y_{\nu,obs}$ is the normal derivative of a solution of (1) restricted to Γ_T , then the unique multiplier λ must vanish almost everywhere. In that case, we have

$$\sup_{\lambda \in L^2(Q_T)} \inf_{y \in Z} \mathcal{L}_r(y, \lambda) = \inf_{y \in Z} \mathcal{L}_r(y, 0) = \inf_{y \in Z} J_r(y)$$

with

$$J_{r}(y) := \frac{1}{2} \|c(x)(\partial_{\nu}y - y_{\nu,obs})\|_{L^{2}(\Gamma_{T})}^{2} + \frac{r}{2} \|Ly\|_{L^{2}(Q_{T})}^{2}.$$
(15)

The corresponding variational formulation is then : find $y \in Z$ such that

$$a_r(y,\overline{y}) = \iint_{\Gamma_T} c^2(x) \partial_\nu y \, \partial_\nu \overline{y} \, d\sigma dt + r \iint_{Q_T} Ly \, L\overline{y} \, dx dt = l(\overline{y}), \quad \forall \overline{y} \in Z.$$

• In the general case, the mixed formulation can be rewritten as follows: find $(y, \lambda) \in Z \times L^2(Q_T)$ solution of

$$\begin{cases} \langle P_r y, P_r \overline{y} \rangle_{L^2(Q_T) \times L^2(\Gamma_T)} + \langle L \overline{y}, \lambda \rangle_{L^2(Q_T)} = \langle (0, c(x) y_{\nu, obs}), P_r \overline{y} \rangle_{L^2(Q_T) \times L^2(\Gamma_T)}, & \forall \overline{y} \in Z, \\ \langle L y, \overline{\lambda} \rangle_{L^2(Q_T)} = 0, & \forall \overline{\lambda} \in L^2(Q_T) \end{cases}$$

with $P_r: Z \times L^2(Q_T) \times L^2(Q_T)$ defined by $P_r y := (\sqrt{rL} y, c(x) \partial_{\nu} y_{|\Gamma_T})$. This formulation may be seen as a generalization of the quasi-reversibility formulation (QR_{ε}) , where the variable λ is adjusted automatically (while the choice of the parameter ε in (QR_{ε}) is in general a delicate issue).

System (14) can be used to define a equivalent saddle-point formulation, very suitable at the numerical level. Precisely, we define - in view of (14) - the space Λ by

$$\begin{split} \Lambda &:= \{\lambda : \lambda \in C([0,T];L^2(\Omega)) \cap C^1([0,T];H^{-1}(\Omega)), \\ L\lambda \in L^2([0,T];H^{-1}(\Omega)), \lambda(\cdot,0) = \lambda_t(\cdot,0) = 0, \lambda_{|\Gamma_T|} \in L^2(\Gamma_T)\}. \end{split}$$

Similarly to Lemma 2.1, we can prove that Λ is a Hilbert space endowed with the following inner product

$$\langle \lambda, \ \overline{\lambda} \rangle_{\Lambda} := \int_0^T \langle L\lambda(t), L\overline{\lambda}(t) \rangle_{H^{-1}(\Omega)} dt + \iint_{\Gamma_T} c^2(x) \lambda \overline{\lambda} d\sigma dt, \qquad \forall \ \lambda, \ \overline{\lambda} \in \Lambda$$

using notably, that the elements of the non-empty vector space Λ satisfy the inequality

$$\|\lambda\|_{L^2(Q_T)} \le C_{\Omega,T} \sqrt{\langle\lambda,\lambda\rangle_{\Lambda}} \tag{16}$$

for some positive constant $C_{\Omega,T}$ which depend on $\|c\|_{C^1(\overline{\Omega})}$ and $\|d\|_{L^{\infty}(Q_T)}$. In what follows we denote $\|\lambda\|_{\Lambda} := \sqrt{\langle \lambda, \lambda \rangle_{\Lambda}}$.

Then, for every parameter $\alpha \in (0, 1)$, we consider the following mixed formulation:

$$\begin{cases}
 a_{r,\alpha}(y,\overline{y}) + b_{\alpha}(\overline{y},\lambda) = l_{1,\alpha}(\overline{y}), & \forall \ \overline{y} \in Z \\
 b_{\alpha}(y,\overline{\lambda}) - c_{\alpha}(\lambda,\overline{\lambda}) = l_{2,\alpha}(\overline{\lambda}), & \forall \ \overline{\lambda} \in \Lambda,
\end{cases}$$
(17)

where

$$a_{r,\alpha}: Z \times Z \to \mathbb{R}, \quad a_{r,\alpha}(y,\overline{y}) = (1-\alpha) \iint_{\Gamma_T} c^2(x) \partial_\nu y \, \partial_\nu \overline{y} \, d\sigma dt + r \iint_{Q_T} Ly \, L\overline{y} dx dt \tag{18}$$

$$b_{\alpha}: Z \times \Lambda \to \mathbb{R}, \quad b_{\alpha}(y,\lambda) = \iint_{Q_T} Ly\lambda dx dt - \alpha \iint_{\Gamma_T} c^2(x)\partial_{\nu}y\lambda d\sigma dt$$
 (19)

$$c_{\alpha}: \Lambda \times \Lambda \to \mathbb{R}, \quad c_{\alpha}(\lambda, \overline{\lambda}) = \alpha \int_{0}^{T} \langle L\lambda(t), L\overline{\lambda}(t) \rangle_{H^{-1}(\Omega)} dt + \alpha \iint_{\Gamma_{T}} c^{2}(x)\lambda\overline{\lambda}d\sigma dt$$
(20)

$$l_{1,\alpha}: Y \to \mathbb{R}, \quad l_{1,\alpha}(y) = (1-\alpha) \iint_{\Gamma_T} c^2(x) \partial_{\nu} y y_{\nu,obs} d\sigma dt$$
(21)

$$l_{2,\alpha}: \Lambda \to \mathbb{R}, \quad l_{2,\alpha}(\lambda) = -\alpha \iint_{\Gamma_T} c^2(x) y_{\nu,obs} \lambda d\sigma dt.$$
 (22)

From the symmetry of $a_{r,\alpha}$ and c_{α} , we easily check that this formulation corresponds to the saddle point problem :

$$\begin{cases}
\sup_{\lambda \in \Lambda} \inf_{y \in Z} \mathcal{L}_{r,\alpha}(y,\lambda), \\
\mathcal{L}_{r,\alpha}(y,\lambda) := \mathcal{L}_{r}(y,\lambda) - \frac{\alpha}{2} \|L\lambda\|_{L^{2}(H^{-1}(\Omega))}^{2} - \frac{\alpha}{2} \|c(x)\left(\lambda - (\partial_{\nu}y - y_{\nu,obs})\right)\|_{L^{2}(\Gamma_{T})}^{2}.
\end{cases}$$
(23)

Precisely, the following holds true.

PROPOSITION 2.1 Under the hypothesis (\mathcal{H}) , for every $\alpha \in (0,1)$ the stabilized mixed formulation (17) is well-posed. Moreover, the unique pair $(y, \lambda) \in Z \times \Lambda$ satisfies

$$\theta \|y\|_Z^2 + \alpha \|\lambda\|_{\Lambda}^2 \le \frac{(1-\alpha)^2 + \alpha\theta}{\theta} \|y_{\nu,obs}\|_{L^2(\Gamma_T)}^2$$

$$\tag{24}$$

with $\theta := \min(1 - \alpha, r/\eta)$.

PROOF- We easily get the continuity of the bilinear form $a_{r,\alpha}, b_{\alpha}$ and c_{α} :

$$\begin{aligned} |a_{r,\alpha}(y,\overline{y})| &\leq \max\left(1-\alpha,\frac{r}{\eta}\right) \|y\|_{Z} \|\overline{y}\|_{Z}, \quad \forall y, \ \overline{y} \in Z, \\ |b_{\alpha}(y,\alpha)| &\leq \frac{C_{\Omega,T}+\alpha}{\eta} \|y\|_{Z} \|\lambda\|_{\Lambda}, \quad \forall y \in Z, \quad \forall \lambda \in \Lambda, \\ c_{\alpha}(\lambda,\overline{\lambda}) &\leq \alpha \|\lambda\|_{\Lambda} \|\overline{\lambda}\|_{\Lambda}, \quad \forall \lambda, \overline{\lambda} \in \Lambda \end{aligned}$$

and of the linear form $l_{1,\alpha}$ and $l_{2,\alpha}$: $\|l_{1,\alpha}\|_{Z'} \leq (1-\alpha)\|y_{\nu,obs}\|_{L^2(\Gamma_T)}$ and $\|l_{2,\alpha}\|_{\Lambda'} \leq \alpha\|y_{\nu,obs}\|_{L^2(\Gamma_T)}$.

Moreover, with $\alpha \in (0, 1)$, we also obtain the coercivity of $a_{r,\alpha}$ and of c_{α} : precisely, we check that $a_{r,\alpha}(y, y) \ge \theta \|y\|_Z^2$ for all $y \in Z$, while $c_{\alpha}(\lambda, \lambda) \ge \alpha \|\lambda\|_{\Lambda}^2$ for all $\lambda \in \Lambda$.

The result [4, Prop 4.3.1] then implies the well-posedness of the mixed formulation (17) and the estimate (24). $\hfill \Box$

The α -term in $\mathcal{L}_{r,\alpha}$ is a stabilization term: it ensures a coercivity property of $\mathcal{L}_{r,\alpha}$ with respect to the variable λ and automatically the well-posedness. In particular, there is no need to prove any inf-sup property for the application b_{α} .

PROPOSITION 2.2 If the solution $(y, \lambda) \in Z \times L^2(Q_T)$ of (6) verifies $\lambda \in \Lambda$, then the solutions of (6) and (17) coincide.

PROOF- The hypothesis of regularity and the relation (14) imply that the solution $(y, \lambda) \in Z \times L^2(Q_T)$ of (6) is also a solution of (17). The result then follows from the uniqueness of the two formulations.

Remark 2 Remark that the following unique continuation type property for (1)

$$\left(Ly=0 \text{ in } Q_T, \ \partial_{\nu}y=0 \text{ on } \Sigma_T\right) \Longrightarrow y=0 \text{ in } Q_T,$$

which is weaker than (\mathcal{H}) , suffices to prove that the bilinear form $\langle \cdot, \cdot \rangle_Z$ in (5) is a scalar product and therefore the well-posedness of (6). We shall use specifically the observability inequality (\mathcal{H}) in the numerical Section 4 to get an estimate of $||y - y_h||_{L^2(Q_T)}$ from estimate of $||L(y - y_h)||_{L^2(Q_T)}$ and $||\partial_{\nu}(y - y_h)||_{L^2(\Sigma_T)}$.

2.2 Dual formulation of the extremal problem (6) and remarks

As discussed at length in [13] for which we refer to detail, we may also associate to the extremal problem (\mathcal{P}) an equivalent problem involving only the variable λ . Again, this is particularly interesting at the numerical level. This requires a strictly positive augmentation parameter r.

For any r > 0, let us define the linear operator \mathcal{P}_r from $L^2(Q_T)$ into $L^2(Q_T)$ by

$$\mathcal{P}_r \lambda := Ly, \quad \forall \lambda \in L^2(Q_T)$$

where $y \in Z$ is the unique solution to

$$a_r(y,\overline{y}) = b(\overline{y},\lambda), \quad \forall \overline{y} \in Z.$$
 (25)

The assumption r > 0 is necessary here in order to guarantee the well-posedness of (25). Precisely, for any r > 0, the form a_r defines a norm equivalent to the norm on Z.

We then have the following two results, proved in [13, Section 2.2] in the very close context of the exact controllability for (1) (see also Remark 3 below).

LEMMA 2.2 For any r > 0, the operator \mathcal{P}_r is a strongly elliptic, symmetric isomorphism from $L^2(Q_T)$ into $L^2(Q_T)$.

PROPOSITION 2.3 For any r > 0, let $y_0 \in Z$ be the unique solution of

$$a_r(y_0, \overline{y}) = l(\overline{y}), \quad \forall \overline{y} \in Z$$

and let $J_r^{\star\star}: L^2(Q_T) \to \mathbb{R}$ be the functional defined by

$$J_r^{\star\star}(\lambda) = \frac{1}{2} \iint_{Q_T} \mathcal{P}_r \lambda \,\lambda dx \,dt - b(y_0, \lambda).$$

The following equality holds :

$$\sup_{\lambda \in L^2(Q_T)} \inf_{y \in Z} \mathcal{L}_r(y, \lambda) = -\inf_{\lambda \in L^2(Q_T)} J_r^{\star\star}(\lambda) + \mathcal{L}_r(y_0, 0).$$

This proposition reduces the search of y, solution of problem (\mathcal{P}), to the minimization of $J_r^{\star\star}$. The well-posedness is a consequence of the ellipticity of the operator \mathcal{P}_r stated in Lemma 2.2.

Remark 3 We emphasize that the mixed formulation (6) has a structure very close to the one we get when we address - using the same approach - the null controllability of (1): more precisely, the control of minimal $L^2(\Gamma_T)$ -norm which drives to rest the initial data $(y_0, y_1) \in L^2(\Omega) \times H^{-1}(\Omega)$ is given by $v = \partial_{\nu} \varphi \mathbf{1}_{\Gamma_T}$ where $(\varphi, \lambda) \in \Phi \times L^2(Q_T)$ solves the mixed formulation

$$\begin{cases} a(\varphi,\overline{\varphi}) + b(\overline{\varphi},\lambda) &= \hat{l}(\overline{\varphi}), \qquad \forall \overline{\varphi} \in \Phi \\ b(\varphi,\overline{\lambda}) &= 0, \qquad \forall \overline{\lambda} \in L^2(Q_T) \end{cases}$$

where $\Phi := Z$, a and b are given by (7) and (8) respectively, while \hat{l} is given by

$$\hat{l}: \Phi \to \mathbb{R}, \quad l(\varphi) = -\int_{\Omega} \varphi_t(x,0) y_0(x) dx + \langle \varphi(\cdot,0), y_1 \rangle_{H^1_0(\Omega), H^{-1}(\Omega)},$$

and depends on the initial data (y_0, y_1) to be controlled. We refer to [13] for the one dimensional case.

Remark 4 Reversing the order of "priority" between the constraint $\partial_{\nu}y - y_{\nu,obs} = 0$ in $L^2(\Gamma_T)$ and Ly - f = 0 in $L^2(Q_T)$, a possibility could be to minimize the functional $y \mapsto ||Ly - f||^2_{L^2(Q_T)}$ over $y \in Z$ subject to the constraint $\partial_{\nu}y - y_{\nu,obs} = 0$ in $L^2(\Gamma_T)$ via the introduction of a Lagrange multiplier in $L^2(\Gamma_T)$. However, the fact that the following inf-sup property: there exists $\delta > 0$ such that

$$\inf_{\lambda \in L^2(\Gamma_T)} \sup_{y \in Z} \frac{\iint_{\Gamma_T} \lambda y \, d\sigma dt}{\|\lambda\|_{L^2(\Gamma_T)} \|y\|_Z} \ge \delta$$

associated to the corresponding mixed formulation holds true is an open issue. On the other hand, if a ε -term is added as in (QR_{ε}) , this property is satisfied (we refer again to the book [19]).

3 Recovering the source and the solution from a partial observation: a mixed re-formulation of the problem

Given a partial observation $y_{\nu,obs}$ of the solution on the subset Γ_T , we now consider the reconstruction of the full solution as well as the source term f. The situation is different with respect to the previous section, since without additional assumptions on f, the couple (y, f) is not unique. Consider the case of a source f supported in a set which is close to $\Omega \times \{T\}$: from the finite propagation of the solution, the source f will not affect the solution y on Γ_T .

Consequently, we assume that $f(x,t) = \sigma(t)\mu(x)$ with $\sigma \in C^1([0,T])$ such that $\sigma(0) \neq 0$ and $\mu \in H^{-1}(\Omega)$ and then recall the following result of Yamamoto-Zhang (see [27, Theorem 2.1]):

THEOREM 3.1 [27] Let us assume that the triplet (Γ_T, T, Q_T) satisfies the geometric optic condition. Let $y = y(\mu) \in C([0,T]; H_0^1(\Omega)) \cap C^1([0,T]; L^2(\Omega))$ be the weak solution of (1) with c := 1and $(y_0, y_1) = (0, 0)$. Then, there exists a positive constant C such that

$$C^{-1} \|\mu\|_{H^{-1}(\Omega)} \le \|c(x) \,\partial_{\nu} y\|_{L^{2}(\Gamma_{T})} \le C \|\mu\|_{H^{-1}(\Omega)}, \quad \forall \mu \in H^{-1}(\Omega).$$

Therefore, assuming that the initial condition vanishes, this stability result implies the uniqueness of the source.

We then consider the following extremal problem :

$$\begin{cases} \inf J(y,\mu) := \frac{1}{2} \|c(x)(\partial_{\nu}y - y_{\nu,obs})\|_{L^{2}(\Gamma_{T})}^{2}, \\ \text{subject to} \quad (y,\mu) \in W \end{cases}$$
 $(\mathcal{P}_{y,\mu})$

where W is the space defined by

$$W := \left\{ (y,\mu); \ y \in C([0,T]; H_0^1(\Omega)) \cap C^1([0,T]; L^2(\Omega)), \ \mu \in H^{-1}(\Omega), \\ Ly - \sigma\mu = 0 \text{ in } Q_T, \ y(\cdot,0) = y_t(\cdot,0) = 0 \right\}.$$
(26)

Note that, from Theorem 3.1, $\partial_{\nu} y \in L^2(\Gamma_T)$ for any $(y,\mu) \in W$. We easily check that W is a Hilbert space endowed with the norm $||(y,\mu)||_W := ||c(x)\partial_{\nu}y||_{L^2(\Gamma_T)}$. The extremal problem $(\mathcal{P}_{y,\mu})$ is well posed : the functional J is continuous over W, is strictly convex and is such that $J(y,\mu) \to +\infty$ as $||(y,\mu)||_W \to \infty$. Moreover, in view of Theorem 3.1, the solution μ is uniformly bounded in H^{-1} -norm.

As in the previous section, in order to avoid the resolution of the extremal problem $(\mathcal{P}_{y,\mu})$ by an iterative process, we introduce a mixed formulation taking the equation $Ly - \sigma\mu = 0$ as a constraint equality in $L^2(Q_T)$. In this respect, we define the following non empty vector space:

$$Y := \left\{ (y,\mu); \ y \in C([0,T]; H_0^1(\Omega)) \cap C^1([0,T]; L^2(\Omega)), \ \mu \in H^{-1}(\Omega), \\ Ly - \sigma\mu \in L^2(Q_T), \ y(\cdot,0) = y_t(\cdot,0) = 0 \right\}.$$

Then, as in Section 2, we introduce the following hypothesis:

Hypothesis 2 There exists a positive constant $C_{obs} = C(\Gamma_T, T, \|c\|_{C^1(\overline{\Omega})}, \|d\|_{L^{\infty}(\Omega)})$ such that the following estimate holds:

$$\|\mu\|_{H^{-1}(\Omega)}^{2} \leq C_{obs} \bigg(\|c(x)\partial_{\nu}y\|_{L^{2}(\Gamma_{T})}^{2} + \|Ly - \sigma\mu\|_{L^{2}(Q_{T})}^{2} \bigg), \quad \forall (y,\mu) \in Y.$$
 (\$\mathcal{H}_{2}\$)

Again, in the case where the velocity c is constant, this inequality is a consequence of Theorem 3.1: it suffices to decompose any y with $(y, \mu) \in Y$ as $y = y_1 + y_2$ where y_1 and y_2 solve

$$Ly_1 = \sigma \mu$$
 in Q_T , $y_1 = 0$ on Σ_T , $(y_1(\cdot, 0), y_{1,t}(\cdot, 0)) = (0, 0)$,

and

$$Ly_2 = Ly - \sigma\mu$$
 in Q_T , $y_2 = 0$ on Σ_T , $(y_2(\cdot, 0), y_{2,t}(\cdot, 0)) = (0, 0)$

respectively and then, applying Theorem 3.1 for y_1 and [21, Theorem 4.1] for y_2 , to write

$$C^{-1} \|\mu\|_{H^{-1}(\Omega)} \leq \|c(x)\partial_{\nu}y_{1}\|_{L^{2}(\Gamma_{T})} \leq \|c(x)\partial_{\nu}y\|_{L^{2}(\Gamma_{T})} + \|c(x)\partial_{\nu}y_{2}\|_{L^{2}(\Gamma_{T})}$$
$$\leq \|c(x)\partial_{\nu}y\|_{L^{2}(\Gamma_{T})} + C(\Omega,T)\|Ly - \sigma\mu\|_{L^{1}(0,T;L^{2}(\Omega))}$$

for some $C(\Omega, T) > 0$.

Then, within this hypothesis, for any $\eta > 0$ as in Section 2, we define on Y the bilinear form

$$\langle (y,\mu), (\overline{y},\overline{\mu}) \rangle_Y := \iint_{\Gamma_T} c^2(x) \,\partial_\nu y \,\partial_\nu \overline{y} \,d\sigma dt + \eta \iint_{Q_T} (Ly - \sigma\mu) \,(L\overline{y} - \sigma\overline{\mu}) \,dx dt, \tag{27}$$

for every (y,μ) , $(\overline{y},\overline{\mu}) \in Y$. We note the corresponding semi-norm $||(y,\mu)||_Y := \sqrt{\langle (y,\mu), (y,\mu) \rangle_Y}$. Again, in view of (4), $\partial_\nu y \in L^2(\Gamma_T)$ for any $(y,\mu) \in Y$. We have the following result:

LEMMA 3.1 Under the hypotheses (\mathcal{H}_2) , the space Y is a Hilbert space with the scalar product $\langle \cdot, \cdot \rangle_Y$ defined by (27).

PROOF- From the inequality (\mathcal{H}_2) , the semi-norm $\|\cdot\|_Y$ is indeed a norm. Let us check that Y is closed with respect to this norm. Let us consider a sequence $\{(y_k, \mu_k)\}_{k\geq 1} \in Y$ such that $(y_k, \mu_k) \to (y, \mu)$ for the norm Y. Then, there exists $f \in L^2(\Omega)$ such that $Ly_k - \sigma \mu_k \to f$ in $L^2(Q_T)$ and $g \in L^2(\Gamma_T)$ such that $\partial_\nu y_k \to g \in L^2(\Gamma_T)$. Then, (\mathcal{H}_2) implies that $\mu_k \to \mu$ in $H^{-1}(\Omega)$. Consequently, $Ly_k = (Ly_k - \sigma \mu_k) + \sigma \mu_k$ converges to $f + \sigma \mu$ in $L^2(0, T; H^{-1}(\Omega))$. Consequently, y_k can be considered as a sequence of solutions of the hyperbolic equation with zero initial data and second hand term converging in $L^2(0, T, H^{-1}(\Omega))$. Therefore, by the continuous dependence of the solution, $y_k \to y$ in $C([0,T]; L^2(\Omega)) \cap C^1([0,T]; H^{-1}(\Omega))$ where y is the solution of $Ly = f + \sigma \mu \in L^2(Q_T)$ with $(y(\cdot, 0), y_t(\cdot, 0)) = (0, 0) \in \mathbf{V}$. But, again, from Theorem 3.1, this implies that $\partial_\nu y \in L^2(\Gamma_T)$ (and therefore $g = \partial_\nu y$ on Γ_T) and y enjoys the regularity $C([0,T]; H_0^1(\Omega)) \cap C^1([0,T]; L^2(\Omega))$ as the sum of two solutions (as for y_1 and y_2 above) in this space. Therefore, $(y, \mu) \in Y$.

Proceeding as in Section 2.1, we introduce a Lagrange multiplier $\lambda \in L^2(Q_T)$ and the following mixed formulation: find $((y, \mu), \lambda) \in Y \times L^2(Q_T)$ solution of

$$\begin{cases} a((y,\mu),(\overline{y},\overline{\mu})) + b((\overline{y},\overline{\mu}),\lambda) = l(\overline{y},\overline{\mu}), & \forall (\overline{y},\overline{\mu}) \in Y \\ b((y,\mu),\overline{\lambda}) = 0, & \forall \overline{\lambda} \in L^2(Q_T), \end{cases}$$
(28)

where

$$a: Y \times Y \to \mathbb{R}, \quad a((y,\mu),(\overline{y},\overline{\mu})) := \iint_{\Gamma_T} c^2(x) \partial_\nu y \partial_\nu \overline{y} \, d\sigma dt,$$
$$b: Y \times L^2(Q_T) \to \mathbb{R}, \quad b((y,\mu),\lambda) := \iint_{Q_T} \lambda(Ly - \sigma\mu) dx \, dt$$
$$l: Y \to \mathbb{R}, \quad l(y,\mu) := \iint_{\Gamma_T} c^2(x) \, \partial_\nu y \, y_{\nu,obs} \, d\sigma dt.$$

THEOREM 3.2 Under the hypothesis (\mathcal{H}_2) , the following holds :

- (i) The mixed formulation (28) is well-posed.
- (ii) The unique solution $((y,\mu),\lambda) \in Y \times L^2(Q_T)$ is the saddle-point of the Lagrangian \mathcal{L} : $Y \times L^2(Q_T) \to \mathbb{R}$ defined by

$$\mathcal{L}((y,\mu),\lambda) := \frac{1}{2}a((y,\mu),(y,\mu)) + b((y,\mu),\lambda) - l(y,\mu)$$

Moreover, the pair (y, μ) solves the extremal problem $(\mathcal{P}_{y,\mu})$.

(iii) The following estimates hold :

$$\|(y,\mu)\|_{Y} = \|c(x)\partial_{\nu}y\|_{L^{2}(\Gamma_{T})} \le \|c(x)y_{\nu,obs}\|_{L^{2}(\Gamma_{T})}$$
(29)

and

$$\|\lambda\|_{L^{2}(Q_{T})} \leq 2\sqrt{C_{\Omega,T} + \eta} \|c(x) \, y_{\nu,obs}\|_{L^{2}(\Gamma_{T})}$$
(30)

for some constant $C_{\Omega,T} > 0$.

The proof is very close to the proof of Theorem 2.1. In particular, the inf-sup property can be obtained by taking, for any $\lambda \in L^2(Q_T)$, $\mu_0 = 0$ and y_0 as in (12) leading to $(y_0, \mu_0) \in Y$ so that the inf-sup constant

$$\delta := \inf_{\lambda \in L^2(Q_T)} \sup_{(y,\mu) \in Y} \frac{b((y,\mu),\lambda)}{\|(y,\mu)\|_Y \|\lambda\|_{L^2(Q_T)}}$$

is bounded by above by $(C_{\Omega,T} + \eta)^{-1/2}$.

Then, as a consequence of the estimate (\mathcal{H}_2) , the source term μ is uniformly bounded in the H^{-1} -norm:

COROLLARY 3.1 Assuming (\mathcal{H}_2) , the solution μ of (28) satisfies $\|\mu\|_{H^{-1}(\Omega)} \leq C_{obs} \|c(x) y_{\nu,obs}\|_{L^2(\Gamma_T)}$.

Again, it is very convenient to "augment" the Lagrangian (see [17]) and consider instead the Lagrangian \mathcal{L}_r defined for any r > 0 by

$$\mathcal{L}_r((y,\mu),\lambda) := \frac{1}{2}a_r((y,\mu),(y,\mu)) + b(y,\lambda) - l(y,\mu),$$

$$a_r((y,\mu),(y,\mu)) := a((y,\mu),(y,\mu)) + r \|Ly - \sigma\mu\|_{L^2(Q_T)}^2.$$

Since $a((y,\mu),(y,\mu)) = a_r((y,\mu),(y,\mu))$ in W, the Lagrangian \mathcal{L} and \mathcal{L}_r share the same saddlepoint. The positive number r is an augmentation parameter. Moreover, proceeding as in Section 2.2, we may also associate to the saddle-point problem $\sup_{\lambda \in L^2(Q_T)} \inf_{(y,\mu) \in Y} \mathcal{L}_r((y,\mu),\lambda)$ a dual problem, which again reduces the search of the couple (y,μ) , solution of problem $(\mathcal{P}_{y,\mu})$, to the minimization of a elliptic functional with respect to λ . **PROPOSITION 3.1** For any r > 0, let $(y_0, \mu_0) \in Y$ be the unique solution of

$$a_r((y_0,\mu_0),(\overline{y},\overline{\mu})) = l(\overline{y},\overline{\mu}), \quad \forall (\overline{y},\overline{\mu}) \in Y$$

and let \mathcal{P}_r be the operator from $L^2(Q_T)$ into $L^2(Q_T)$ defined by $\mathcal{P}_r \lambda := Ly - \sigma \mu$ where $(y, \mu) \in Y$ is the unique solution to

$$a_r((y,\mu),(\overline{y},\overline{\mu})) = b((\overline{y},\overline{\mu}),\lambda), \quad \forall (\overline{y},\overline{\mu}) \in Y.$$
(31)

The operator \mathcal{P}_r is strongly elliptic and symmetric. Moreover, the following equality holds

$$\sup_{\lambda \in L^2(Q_T)} \inf_{(y,\mu) \in Y} \mathcal{L}_r((y,\mu),\lambda) = -\inf_{\lambda \in L^2(Q_T)} J_r^{\star\star}(\lambda) + \mathcal{L}_r((y_0,\mu_0),0)$$

where $J_r^{\star\star}: L^2(Q_T) \to \mathbb{R}$ is the functional defined by

$$J_r^{\star\star}(\lambda) = \frac{1}{2} \iint_{Q_T} (\mathcal{P}_r \lambda) \lambda dx \, dt - b((y_0, \mu_0), \lambda).$$

PROOF- From the definition of a_r , we easily get that $\|\mathcal{P}_r\lambda\|_{L^2(Q_T)} \leq r^{-1}\|\lambda\|_{L^2(Q_T)}$ and the continuity of \mathcal{P}_r . Next, consider any $\lambda' \in L^2(Q_T)$ and denote by (y', μ') the corresponding unique solution of (31) so that $\mathcal{P}_r\lambda' := Ly' - \sigma\mu'$. Relation (31) with $(\overline{y}, \overline{\mu}) = (y', \mu')$ then implies that

$$\iint_{Q_T} (\mathcal{P}_r \lambda') \lambda \, dx \, dt = a_r((y,\mu), (y',\mu')) \tag{32}$$

and therefore the symmetry and positivity of \mathcal{P}_r . The last relation with $\lambda' = \lambda$ and the observability estimate (\mathcal{H}_2) imply that \mathcal{P}_r is also positive definite.

Finally, let us check the strong ellipticity of \mathcal{P}_r , equivalently that the bilinear functional $(\lambda, \lambda') \to \iint_{Q_T} (\mathcal{P}_r \lambda) \lambda' \, dx \, dt$ is $L^2(Q_T)$ -elliptic. Thus we want to show that

$$\iint_{Q_T} (\mathcal{P}_r \lambda) \lambda \, dx \, dt \ge C \|\lambda\|_{L^2(Q_T)}^2, \quad \forall \lambda \in L^2(Q_T)$$
(33)

for some positive constant C. Suppose that (33) does not hold; there exists then a sequence $\{\lambda_n\}_{n\geq 0}$ of $L^2(Q_T)$ such that

$$\|\lambda_n\|_{L^2(Q_T)} = 1, \quad \forall n \ge 0, \qquad \lim_{n \to \infty} \iint_{Q_T} (\mathcal{P}_r \lambda_n) \lambda_n \, dx \, dt = 0$$

Let us denote by (y_n, μ_n) the solution of (31) corresponding to λ_n . From (32), we then obtain that

$$\lim_{n \to \infty} (r \| Ly_n - \sigma \mu_n \|_{L^2(Q_T)}^2 + \| c(x) \, \partial_\nu y_n \|_{L^2(\Gamma_T)}^2) = 0.$$
(34)

From (31) with $(y, \mu) = (y_n, \mu_n)$ and $\lambda = \lambda_n$, we have

$$\iint_{Q_T} [r(Ly_n - \sigma\mu_n) - \lambda_n] (L\overline{y} - \sigma\overline{\mu}) \, dx \, dt + \iint_{\Gamma_T} c^2(x) \partial_\nu y_n \partial_\nu \overline{y} d\sigma \, dt = 0, \quad \forall (\overline{y}, \overline{\mu}) \in Y.$$
(35)

We define the sequence $\{\overline{y}_n\}_{n\geq 0}$ as follows :

$$\begin{cases} L\overline{y}_n = r \left(Ly_n - \sigma \mu_n \right) - \lambda_n, & \text{in } Q_T, \\ \overline{y}_n = 0, & \text{on } \Sigma_T, \\ \overline{y}_n(\cdot, 0) = \overline{y}_{n,t}(\cdot, 0) = 0, & \text{in } \Omega, \end{cases}$$

so that, for all n, \overline{y}_n is the solution of a hyperbolic equation with zero initial data and source term $r(Ly_n - \sigma \mu_n) - \lambda_n$ in $L^2(Q_T)$. Using again [21, Theorem 4.1], we get $\|\partial_{\nu} \overline{y}_n\|_{L^2(\Gamma_T)} \leq$

 $\sqrt{C_{\Omega,T}} \| r(Ly_n - \sigma \mu_n) - \lambda_n \|_{L^2(Q_T)}$, so that $(\overline{y}_n, 0) \in Y$. Then, using (35) with $(\overline{y}, \overline{\mu}) = (\overline{y}_n, 0) \in Y$ we get

$$\|r(Ly_n - \sigma\mu_n) - \lambda_n\|_{L^2(Q_T)} \le \sqrt{C_{\Omega,T}} \|c(x)\partial_\nu y_n\|_{L^2(\Gamma_T)}.$$

Then, from (34), we conclude that $\lim_{n\to+\infty} \|\lambda_n\|_{L^2(Q_T)} = 0$ leading to a contradiction and to the strong ellipticity of the operator \mathcal{P}_r . The rest of the proof is standard.

To end this section, it is worth to mention that a result similar to Theorem 3.1 is given in [26, Theorem 1] with a control of μ in $L^2(\Omega)$. However, this requires an observation of $\partial_{\nu} y$ in $H^1(0,T; L^2(\Gamma))$ (equivalently of $\partial_t \partial_{\nu} y$ in $L^2(\Gamma_T)$) which may be too strong in real life applications.

4 Numerical Analysis of the mixed formulations

4.1 Numerical approximation of the mixed formulation (6)

We now proceed to the numerical analysis of the mixed formulation (6), assuming r > 0. We follow [13], to which we refer for the details.

Let Z_h and Λ_h be two finite dimensional spaces parametrized by the variable h such that $Z_h \subset Z, \Lambda_h \subset L^2(Q_T)$ for every h > 0. Then, we can introduce the following approximated problems: find $(y_h, \lambda_h) \in Z_h \times \Lambda_h$ solution of

$$\begin{cases}
 a_r(y_h, \overline{y}_h) + b(\overline{y}_h, \lambda_h) = l(\overline{y}_h), & \forall \overline{y}_h \in Z_h \\
 b(y_h, \overline{\lambda}_h) = 0, & \forall \overline{\lambda}_h \in \Lambda_h.
\end{cases}$$
(36)

The well-posedness of this mixed formulation is again a consequence of two properties. The first one is the coercivity of the bilinear form a_r on the subset $\mathcal{N}_h(b) = \{y_h \in Z_h; b(y_h, \lambda_h) = 0 \ \forall \lambda_h \in \Lambda_h\}$. Actually, from the relation $a_r(y, y) \ge (r/\eta) \|y\|_Z^2$ for all $y \in Z$, the form a_r is coercive on the full space Z, and so a fortiori on $\mathcal{N}_h(b) \subset Z_h \subset Z$.

The second property is a discrete inf-sup condition: precisely, for any h,

$$\delta_h := \inf_{\lambda_h \in \Lambda_h} \sup_{y_h \in Z_h} \frac{b(y_h, \lambda_h)}{\|\lambda_h\|_{L^2(Q_T)} \|y_h\|_Z} > 0.$$
(37)

Let us assume that this condition holds, so that for any fixed h > 0, there exists a unique couple (y_h, λ_h) solution of (36). We then have the following estimate.

PROPOSITION 4.1 Let h > 0. Let (y, λ) and (y_h, λ_h) be the solution of (6) and of (36) respectively. Let δ_h be the discrete inf-sup constant defined by (37). Then,

$$\|y - y_h\|_Z \le 2\left(1 + \frac{1}{\sqrt{\eta}\delta_h}\right) d(y, Z_h) + \frac{1}{\sqrt{\eta}} d(\lambda, \Lambda_h),$$
(38)

$$\|\lambda - \lambda_h\|_{L^2(Q_T)} \le \left(2 + \frac{1}{\sqrt{\eta}\delta_h}\right) \frac{1}{\delta_h} d(y, Z_h) + \frac{3}{\sqrt{\eta}\delta_h} d(\lambda, \Lambda_h)$$
(39)

where $d(\lambda, \Lambda_h) := \inf_{\lambda_h \in \Lambda_h} \|\lambda - \lambda_h\|_{L^2(Q_T)}$ and

$$d(y, Z_h) := \inf_{y_h \in Z_h} \|y - y_h\|_Z$$

=
$$\inf_{y_h \in Z_h} \left(\|\partial_\nu y - \partial_\nu y_h\|_{L^2(\Gamma_T)}^2 + \eta \|L(y - y_h)\|_{L^2(Q_T)}^2 \right)^{1/2}.$$
 (40)

PROOF- From the classical theory of approximation of saddle point problems (see [4, Theorem 5.2.2]) we have that

$$\begin{aligned} \|y - y_h\|_Z &\leq \left(\frac{2\|a_r\|_{(Z \times Z)'}}{\alpha_0} + \frac{2\|a_r\|_{(Z \times Z)'}^{\frac{1}{2}}\|b\|_{(Z \times L^2(Q_T))'}}{\alpha_0^{\frac{1}{2}}\delta_h}\right) d(y, Z_h) \\ &+ \frac{\|b\|_{(Z \times L^2(Q_T))'}}{\alpha_0} d(\lambda, \Lambda_h) \end{aligned}$$

and

$$\begin{aligned} \|\lambda - \lambda_h\|_{L^2(Q_T)} &\leq \left(\frac{2\|a_r\|_{(Z \times Z)'}^{\frac{3}{2}}}{\alpha_0^{\frac{1}{2}}\delta_h} + \frac{\|a_r\|_{(Z \times Z)'}\|b\|_{(Z \times L^2(Q_T))'}}{\delta_h^2}\right) d(y, Z_h) \\ &+ \frac{3\|a_r\|^{\frac{1}{2}}\|b\|_{(Z \times L^2(Q_T))'}}{\alpha_0^{\frac{1}{2}}\delta_h} d(\lambda, \Lambda_h). \end{aligned}$$

Since, $||a_r||_{(Z \times Z)'} = \alpha_0 = 1$; $||b||_{(Z \times L^2(Q_T))'} = \frac{1}{\sqrt{\eta}}$, the result follows.

Remark 5 For r = 0, the discrete mixed formulation (36) is not well-posed over $Z_h \times \Lambda_h$ because the form $a_{r=0}$ is not coercive over the discrete kernel of b: the equality $b(y_h, \lambda_h) = 0$ for all $\lambda_h \in \Lambda_h$ does not imply in general that Ly_h vanishes. Therefore, the term $r \|Ly_h\|_{L^2(Q_T)}^2$, which appears in the Lagrangian \mathcal{L}_r , may be understood as a stabilization term: for any h > 0, it ensures the uniform coercivity of the form a_r and vanishes at the limit in h. We also emphasize that this term is not a regularization term as it does not add any regularity on the solution y_h .

Let $n_h = \dim(Z_h), m_h = \dim(\Lambda_h)$ the dimension of the space Z_h and Λ_h respectively. Let the real matrices $A_{r,h} \in \mathbb{R}^{n_h, n_h}, B_h \in \mathbb{R}^{m_h, n_h}, J_h \in \mathbb{R}^{m_h, m_h}$ and $L_h \in \mathbb{R}^{n_h}$ be defined by

$$\begin{cases} a_r(y_h, \overline{y_h}) = \langle A_{r,h} \{ y_h \}, \{ \overline{y_h} \} \rangle_{\mathbb{R}^{n_h}, \mathbb{R}^{n_h}} & \forall y_h, \overline{y_h} \in Z_h, \\ b(y_h, \lambda_h) = \langle B_h \{ y_h \}, \{ \lambda_h \} \rangle_{\mathbb{R}^{m_h}, \mathbb{R}^{m_h}} & \forall y_h \in Z_h, \lambda_h \in \Lambda_h, \\ \iint_{Q_T} \lambda_h \overline{\lambda_h} \, dx \, dt = \langle J_h \{ \lambda_h \}, \{ \overline{\lambda_h} \} \rangle_{\mathbb{R}^{m_h}, \mathbb{R}^{m_h}} & \forall \lambda_h, \overline{\lambda_h} \in \Lambda_h, \\ l(y_h) = \langle L_h, \{ y_h \} \rangle_{\mathbb{R}^{n_h}} & \forall y_h \in Z_h, \end{cases}$$

$$(41)$$

where $\{y_h\} \in \mathbb{R}^{n_h}$ denotes the vector associated to y_h and $\langle \cdot, \cdot \rangle_{\mathbb{R}^{n_h}, \mathbb{R}^{n_h}}$ the usual scalar product over \mathbb{R}^{n_h} . With these notations, the problem (36) reads as follows: find $\{y_h\} \in \mathbb{R}^{n_h}$ and $\{\lambda_h\} \in \mathbb{R}^{m_h}$ such that

$$\begin{pmatrix} A_{r,h} & B_h^T \\ B_h & 0 \end{pmatrix}_{\mathbb{R}^{n_h+m_h,n_h+m_h}} \begin{pmatrix} \{y_h\} \\ \{\lambda_h\} \end{pmatrix}_{\mathbb{R}^{n_h+m_h}} = \begin{pmatrix} L_h \\ 0 \end{pmatrix}_{\mathbb{R}^{n_h+m_h}}.$$
(42)

The matrix $A_{r,h}$ as well as the mass matrix J_h are symmetric and positive definite for any h > 0and any r > 0. On the other hand, the full matrix of order $m_h + n_h$ in (42) is symmetric but not necessarily positive definite.

We recall (see [4, Theorem 3.2.1]) that the inf-sup property (37) is equivalent to the injective character of the matrice B_h^T of size $n_h \times m_h$, that is $Ker(B_h^T) = 0$. If a necessary condition is given by $m_h \leq n_h$, this property strongly depends on the structure of the spaces Z_h and Λ_h . We will discuss numerically this property in Remark 6 for a specific choice of approximation.

4.1.1 C¹-finite elements and order of convergence for N = 1

The finite dimensional and conformal space Z_h must be chosen such that Ly_h belongs to $L^2(Q_T)$ for any $y_h \in Z_h$. This is guaranteed, for instance, as soon as y_h possesses second-order derivatives

in $L^2(Q_T)$. As in [13], we consider a conformal approximation based on functions continuously differentiable with respect to both variables x and t.

We introduce a triangulation \mathcal{T}_h such that $\overline{Q_T} = \bigcup_{K \in \mathcal{T}_h} K$ and we assume that $\{\mathcal{T}_h\}_{h>0}$ is a regular family. We note $h := \max\{\operatorname{diam}(K), K \in \mathcal{T}_h\}$ where $\operatorname{diam}(K)$ denotes the diameter of K. Then, we introduce the space Z_h as follows :

$$Z_h := \{ z_h \in C^1(\overline{Q_T}) : z_h |_K \in \mathbb{P}(K) \quad \forall K \in \mathcal{T}_h, \ z_h = 0 \text{ on } \Sigma_T \},$$
(43)

where $\mathbb{P}(K)$ denotes an appropriate space of functions in x and t. In this work, we consider two choices, in the one-dimensional setting (for which $\Omega \subset \mathbb{R}$ and $Q_T \subset \mathbb{R}^2$):

- (i) The Bogner-Fox-Schmit (BFS for short) C^1 -element defined for rectangles. It involves 16 degrees of freedom, namely the values of $y_h, y_{h,x}, y_{h,t}, y_{h,xt}$ on the four vertices of each rectangle K. Therefore $\mathbb{P}(K) = \mathbb{P}_{3,x} \otimes \mathbb{P}_{3,t}$ where $\mathbb{P}_{r,\xi}$ is by definition the space of polynomial functions of order r in the variable ξ . We refer to [10, ch. II, sec. 9, p. 94].
- (ii) The reduced *Hsieh-Clough-Tocher* (HCT for short) C^1 -element defined for triangles. This is a so-called composite finite element and involves 9 degrees of freedom, namely, the values of $y_h, y_{h,x}, y_{h,t}$ on the three vertices of each triangle K. We refer to [10, ch. VII, sec. 46, p. 285] and to [3, 23] where the implementation is discussed.

We also define the finite dimensional space

$$\Lambda_h := \{\lambda_h \in C^0(\overline{Q_T}), \lambda_h |_K \in \mathbb{Q}(K) \quad \forall K \in \mathcal{T}_h\}$$

where $\mathbb{Q}(K)$ denotes the space of affine functions both in x and t on the element K.

For any h > 0, we have $Z_h \subset Z$ and $\Lambda_h \subset L^2(Q_T)$.

We then have the following result:

PROPOSITION 4.2 (BFS ELEMENT FOR N = 1 - RATE OF CONVERGENCE FOR THE NORM Z) Let h > 0, let $k \leq 2$ be a nonnegative integer. Let (y, λ) and (y_h, λ_h) be the solution of (6) and (36) respectively. If the solution (y, λ) belongs to $H^{k+2}(Q_T) \times H^k(Q_T)$, then there exist two positives constants

$$K_i = K_i(\|y\|_{H^{k+2}(Q_T)}, \|c\|_{C^1(\overline{Q_T})}, \|d\|_{L^{\infty}(Q_T)}), \qquad i \in \{1, 2\},$$

independent of h, such that

$$\|y - y_h\|_Z \le K_1 \left(1 + \frac{1}{\sqrt{\eta}\delta_h} + \frac{1}{\sqrt{\eta}}\right) h^k,\tag{44}$$

$$\|\lambda - \lambda_h\|_{L^2(Q_T)} \le K_2 \left(\left(1 + \frac{1}{\sqrt{\eta}\delta_h} \right) \frac{1}{\delta_h} + \frac{1}{\sqrt{\eta}\delta_h} \right) h^k.$$
(45)

PROOF - From [10, ch. III, sec. 17], for any $\lambda \in H^k(Q_T)$, $k \leq 2$, there exists $C_1 = C_1(\|\lambda\|_{H^k(Q_T)})$ such that

$$\|\lambda - \Pi_{\Lambda_h, \mathcal{T}_h}(\lambda)\|_{L^2(Q_T)} \le C_1 h^k, \quad \forall h > 0$$

$$\tag{46}$$

where $\Pi_{\Lambda_h,\mathcal{T}_h}$ designates the interpolant operator from $L^2(Q_T)$ to Λ_h associated to the regular mesh \mathcal{T}_h . Similarly, for any $y \in H^{k+2}(Q_T)$, there exists $C_2 = C_2(\|y\|_{H^{k+2}(Q_T)})$ such that for every h > 0 we have

$$\|y - \Pi_{Z_h, \mathcal{T}_h}(y)\|_{L^2(Q_T)} \le C_2 h^{k+2}, \quad \|y - \Pi_{Z_h, \mathcal{T}_h}(y)\|_{H^2(Q_T)} \le C_2 h^k.$$
(47)

Then, using that the linear operator $P: H^{3/2}(Q_T) \to L^2(\Sigma_T)$ defined by $Py := \partial_{\nu} y$ is continuous, there exists a positive constant C_P such that

$$\|c(x)(\partial_{\nu}y - \partial_{\nu}(\Pi_{Z_{h},\mathcal{T}_{h}}(y)))\|_{L^{2}(\Gamma_{T})} \leq \|c\|_{L^{\infty}(\Gamma_{T})}C_{P}\|y - \Pi_{Z_{h},\mathcal{T}_{h}}(y)\|_{H^{3/2}(Q_{T})}.$$
(48)

We then observe that

$$\|Ly - L(\Pi_{Z_h, \mathcal{T}_h}(y))\|_{L^2(Q_T)} \le K(\|c\|_{C^1(\overline{Q_T})}, \|d\|_{L^\infty(Q_T)})\|y - \Pi_{Z_h, \mathcal{T}_h}(y)\|_{H^2(Q_T)},$$
(49)

for some positive constant K; (40) then leads to

$$d(y, Z_h) \le \left(\|\partial_{\nu} y - \partial_{\nu} (\Pi_{Z_h, \mathcal{T}_h}(y))\|_{L^2(\Gamma_T)}^2 + \eta \|Ly - L(\Pi_{Z_h, \mathcal{T}_h}(y))\|_{L^2(Q_T)}^2 \right)^2 \\ \le \sqrt{\|c\|_{L^{\infty}(\Gamma_T)}^2 C_p^2 + \eta K^2} C_2 h^k$$
(50)

and then from Proposition 4.1, we get that

$$\|y - y_h\|_Z \le 2\left(1 + \frac{1}{\sqrt{\eta}\delta_h}\right)\sqrt{\|c\|_{L^{\infty}(\Gamma_T)}^2 C_p^2 + \eta K^2}C_2h^k + \frac{1}{\sqrt{\eta}}C_1h^k.$$

Similarly,

$$\|\lambda - \lambda_h\|_{L^2(Q_T)} \le \left(2 + \frac{1}{\sqrt{\eta}\delta_h}\right) \frac{1}{\delta_h} \sqrt{\|c\|_{L^{\infty}(\Gamma_T)}^2 C_p^2 + \eta K^2} C_2 h^k + \frac{3}{\sqrt{\eta}\delta_h} C_1 h^k.$$

From the last two estimates, we obtain the conclusion of the proposition.

It remains now to deduce the convergence of the approximated solution y_h for the $L^2(Q_T)$ norm. This is done using the observability estimate (\mathcal{H}) . Precisely, we write that $(y - y_h)$ solves the hyperbolic equation

$$\begin{cases} L(y - y_h) = -Ly_h & \text{in } Q_T \\ ((y - y_h), (y - y_h)_t)(\cdot, \ 0) \in \mathbf{V} \\ y - y_h = 0 & \text{on } \Sigma_T. \end{cases}$$

The continuous dependence of the solution with respect to the right hand side and the initial data leads

$$\|y - y_h\|_{L^2(Q_T)}^2 \le C_{\Omega,T}(\|((y - y_h)(\cdot, 0), (y - y_h)_t(\cdot, 0))\|_{\mathbf{V}}^2 + \|Ly_h\|_{L^2(Q_T)}^2).$$

Combined with (\mathcal{H}) applied for $y - y_h$, this leads to

$$\|y - y_h\|_{L^2(Q_T)}^2 \le C_{\Omega,T}(1 + C_{obs})(\|y - y_h\|_{L^2(\Gamma_T)}^2 + \|Ly_h\|_{L^2(Q_T)}^2)$$

from which we deduce, in view of the definition of the norm Y, that

$$\|y - y_h\|_{L^2(Q_T)} \le C_{\Omega,T}(1 + C_{obs}) \max(1, \frac{2}{\sqrt{\eta}}) \|y - y_h\|_Z.$$
(51)

Eventually, by coupling (51) and Proposition 4.2, we obtain the following result :

THEOREM 4.1 (BFS ELEMENT FOR N = 1 - RATE OF CONVERGENCE FOR THE NORM $L^2(Q_T)$) Assume that the hypothesis (\mathcal{H}) holds. Let h > 0, let $k \leq 2$ be a positive integer. Let (y, λ) and (y_h, λ_h) be the solution of (6) and (36) respectively. If the solution (y, λ) belongs to $H^{k+2}(Q_T) \times H^k(Q_T)$, then there exists two positives constant $K = K(\|y\|_{H^{k+2}(Q_T)}, \|c\|_{C^1(\overline{Q_T})}, \|d\|_{L^{\infty}(Q_T)}, C_{\Omega,T}, C_{obs})$, independent of h, such that

$$\|y - y_h\|_{L^2(Q_T)} \le K \max(1, \frac{2}{\sqrt{\eta}}) \left(1 + \frac{1}{\sqrt{\eta}\delta_h} + \frac{1}{\sqrt{\eta}}\right) h^k.$$
 (52)

Remark 6 (About the choice of the augmentation parameter r) Estimate (52) is not fully satisfactory as it depends on the constant δ_h . In view of the complexity of both the constraint Ly = 0and of the structure of the space Z_h , the theoretical estimation of the constant δ_h with respect to

h is a difficult issue. However, as discussed at length in [13, Section 2.1], δ_h can be evaluated numerically for any h, as the solution of the following generalized eigenvalue problem (taking $\eta = r$, so that $a_r(y, y)$ is exactly $\|y\|_Z^2$):

$$\delta_h = \inf\left\{\sqrt{\delta} : B_h A_{r,h}^{-1} B_h^T \{\lambda_h\} = \delta J_h \{\lambda_h\}, \quad \forall \{\lambda_h\} \in \mathbb{R}^{m_h} \setminus \{0\}\right\}$$
(53)

where the matrices $A_{r,h}$, B_h and J_h are defined in (41).

The computation of δ_h given by the problem (53) with respect to h and to $r = \eta$ has been performed in [13, Section 4.2] for the following data : T = 2, $Q_T = (0,1) \times (0,T)$, T = 2, $\Gamma_T = \{1\} \times (0,T)$. There, it is observed, that for both the BFS and the HCT finite element on regular meshes (non necessarily uniform), the constant δ_h behaves like

$$\delta_h \approx C_r \frac{h}{\sqrt{r}} \quad as \quad h \to 0^+ \tag{54}$$

with $C_r > 0$, a uniformly bounded constant w.r.t. h. For the BFS finite element, Table 1 reports some numerical values of δ_h while Figure 1 depicts the evolution of $\sqrt{r}\delta_h$ w.r.t h for $r = 1, 10^{-2}, h$ and $r = h^2$.

h	1.41×10^{-1}	7.01×10^{-2}	3.53×10^{-2}	1.76×10^{-2}	8.83×10^{-3}
$r = 10^2$	4.71×10^{-2}	2.53×10^{-2}	$1.23 imes 10^{-2}$	$6.06 imes 10^{-3}$	$3.01 imes 10^{-3}$
r = 1	4.17×10^{-1}	$2.53 imes 10^{-1}$	$1.23 imes 10^{-1}$	$6.05 imes 10^{-3}$	$3.01 imes 10^{-2}$
$r = 10^{-2}$	1.474	1.427	1.178	$5.99 imes 10^{-1}$	$3.01 imes 10^{-1}$
r = h	1.301	1.086	7.65×10^{-1}	$5.37 imes 10^{-1}$	3.79×10^{-1}
$r = h^2$	1.665	1.483	1.485	1.489	1.497

Table 1: δ_h w.r.t. r and h - T = 2. for the BFS element.

Figure 1: BFS finite element - Evolution of $\sqrt{r}\delta_{h,r}$ with respect to h (see Table 1) for r = 1 (\Box), $r = 10^{-2}$ (\circ), r = h (\star) and $r = h^2$ (<).

Reporting this behavior in the estimate (52), the error $\|y-y_h\|_{L^2(Q_T)}$ behaves like (taking $\eta = r$)

$$\|y - y_h\|_{L^2(Q_T)} \le K \max(1, \frac{2}{\sqrt{r}}) \left(1 + \frac{1}{h} + \frac{1}{\sqrt{r}}\right) h^k$$

The right hand side is minimal for r of the order one leading to $||y - y_h||_{L^2(Q_T)} \leq Kh^{k-1}$. This estimate is very likely not optimal but shows the strong convergence of the approximation for regular enough solution. In particular, the estimate (48) of the boundary term by the $H^2(Q_T)$ -norm may result in a loss of precision.

On the other hand, the same argument for the variable λ_h indicates, using (45) that the estimate of $\|\lambda - \lambda_h\|_{L^2(Q_T)}$ is

$$\|\lambda - \lambda_h\|_{L^2(Q_T)} \le K_2 \frac{\sqrt{r}}{h} \left(1 + \frac{1}{h} + \frac{1}{\sqrt{r}}\right) h^k.$$

The optimal value for the augmentation parameter is now $r = h^2$ leading to $\|\lambda - \lambda_h\|_{L^2(Q_T)} \leq K_2 h^{k-1}$. Remark that for $r = h^2$, the discrete-inf sup constant δ_h remains uniformly bounded by below w.r.t. h. As observed in [13, Section 4.] (see also the numerical experiments of the present paper), if the influence of the parameter r > 0 is not really important (for h small enough), the choice $r = h^2$ offers the best rate of convergence.

As discussed and used in [8, Section 4.3], when y_h is approximated with the BFS and HCT finite element, the quantity $h \| Ly_h \|_{L^2(Q_T)}$ is asymptotically equivalent w.r.t. h to $\| Ly_h \|_{L^2(0,T;H^{-1}(\Omega))}$. Therefore, taking $r = h^2$ in the augmented mixed formulation amounts to relax the constraint Ly = 0 in $L^2(Q_T)$ by the weaker one Ly = 0 in $L^2(0, T, H^{-1}(\Omega))$ enough in practice to approximate weak solutions of (1).

4.2 Numerical approximation of the *stabilized* mixed formulation (17)

We address the numerical approximation of the *stabilized* mixed formulation (17) with $\alpha \in (0, 1)$, assuming again that r > 0. Let h be a real parameter. Let Z_h and $\tilde{\Lambda}_h$ be two closed finite dimensional spaces such that

$$Z_h \subset Z, \quad \overline{\Lambda}_h \subset \Lambda, \qquad \forall h > 0$$

The problem (17) becomes : find $(y_h, \lambda_h) \in Z_h \times \widetilde{\Lambda}_h$ solution of

$$\begin{cases}
 a_{r,\alpha}(y_h, \overline{y}_h) + b_{\alpha}(\lambda_h, \overline{y}_h) = l_{1,\alpha}(\overline{y}_h), & \forall \overline{y}_h \in Z_h \\
 b_{\alpha}(\overline{\lambda}_h, y_h) - c_{\alpha}(\lambda_h, \overline{\lambda}_h) = l_{2,\alpha}(\overline{\lambda}_h), & \forall \overline{\lambda}_h \in \widetilde{\Lambda}_h.
\end{cases}$$
(55)

In view of the properties of the forms $a_{r,\alpha}$, c_{α} , $l_{1,\alpha}$ and $l_{2,\alpha}$, this formulation is well-posed.

Proceeding as in the proof of [4, Theorem 5.5.2], we first check that the following estimate holds.

LEMMA 4.1 Let $(y, \lambda) \in Y \times \Lambda$ be the solution of (17) and $(y_h, \lambda_h) \in Z_h \times \tilde{\Lambda}_h$ be the solution of (55). Then we have,

$$\frac{1}{4}\theta \|y - y_h\|_Z^2 + \frac{1}{4}\alpha \|\lambda - \lambda_h\|_{\Lambda}^2 \leq \left(\frac{\|a_{r,\alpha}\|_{(Z\times Z)'}^2}{\theta} + \frac{\|b_{\alpha}\|_{(Z\times \Lambda)'}^2}{\alpha} + \frac{\theta}{2}\right) \inf_{\overline{y}_h \in Z_h} \|\overline{y}_h - y\|_Z^2 + \left(\frac{\|b_{\alpha}\|_{(Z\times \Lambda)'}^2}{\theta} + \alpha + \frac{\alpha}{2}\right) \inf_{\overline{\lambda}_h \in \widetilde{\lambda}_h} \|\overline{\lambda}_h - \lambda\|_{\Lambda}^2$$
(56)

with $||a_{r,\alpha}||_{(Z\times Z)'} \leq \max(1-\alpha,\eta^{-1}r), ||b_{\alpha}||_{(Z\times\Lambda)'} \leq (C_{\Omega,T}+\alpha)\eta^{-1}$. Parameter θ is defined in Proposition 2.1.

Concerning the space $\widetilde{\Lambda}_h$, since $L\lambda_h$ should belong to $L^2(0,T,H^{-1}(\Omega))$, a natural choice is

$$\Lambda_h = \{ \lambda \in Z_h; \lambda(\cdot, 0) = \lambda_t(\cdot, 0) = 0 \}.$$
(57)

where $Z_h \subset Z$ is defined by (43). Then, using Lemma 4.1 and the estimate (50), we obtain the following result.

PROPOSITION 4.3 (BFS ELEMENT FOR N = 1 - RATE OF CONVERGENCE FOR THE NORM $Z \times \Lambda$) Let h > 0, let $k \leq 2$ be a positive integer and $\alpha \in (0, 1)$. Let (y, λ) and (y_h, λ_h) be the solution of (17) and (55) respectively. If (y, λ) belongs to $H^{k+2}(Q_T) \times H^{k+2}(Q_T)$, then there exists a positive constant $K = K(||y||_{H^{k+2}(Q_T)}, ||c||_{C^1(\overline{Q_T})}, ||d||_{L^{\infty}(Q_T)}, \alpha, r, \eta)$ independent of h, such that

$$\|y - y_h\|_Z + \|\lambda - \lambda_h\|_\Lambda \le Kh^k.$$
(58)

SKETCH OF THE PROOF- The estimate of $||y - \prod_{Z_h, \mathcal{T}_h}(y)||_Z$ for any $y \in Z$ in term of $\mathcal{O}(h^k)$, is detailed in the proof of Proposition 4.2: precisely, we refer to (50). Similarly, we write that, for any $\lambda \in \Lambda$,

$$\inf_{\lambda_{h}\in\tilde{\Lambda}_{h}}\|\lambda-\lambda_{h}\|_{\Lambda} \leq \|\lambda-\Pi_{\tilde{\Lambda}_{h},\mathcal{T}_{h}}(\lambda)\|_{\Lambda} \\
\leq \left(\|L(\lambda-\Pi_{\tilde{\Lambda}_{h},\mathcal{T}_{h}}(\lambda))\|_{L^{2}(H^{-1}(\Omega))}^{2} + \|c(x)(\lambda-\Pi_{\tilde{\Lambda}_{h},\mathcal{T}_{h}}(\lambda))\|_{L^{2}(\Gamma_{T})}^{2}\right)^{1/2} \\
\leq \left(\|L(\lambda)-L(\Pi_{\tilde{\Lambda}_{h},\mathcal{T}_{h}}(\lambda))\|_{L^{2}(Q_{T})}^{2} + \|c\|_{L^{\infty}(\Gamma_{T})}^{2}\|\lambda-\Pi_{\tilde{\Lambda}_{h},\mathcal{T}_{h}}(\lambda)\|_{H^{1/2}(Q_{T})}^{2}\right)^{1/2} \\
\leq K(\|c\|_{C^{1}(\overline{Q_{T}})},\|d\|_{L^{\infty}(Q_{T})})\|\lambda-\Pi_{\tilde{\Lambda}_{h},\mathcal{T}_{h}}(\lambda)\|_{H^{2}(Q_{T})} \tag{59}$$

for which the $\mathcal{O}(h^k)$ estimate follows, in view of the definition of $\widetilde{\Lambda}_h$.

In particular, arguing as in the previous section, using Proposition 4.3, the observability estimate (\mathcal{H}) for the variable y and the estimate (16) for the variable λ , we get the following desired global estimate:

THEOREM 4.2 (BFS ELEMENT FOR N = 1 - RATE OF CONVERGENCE FOR THE $L^2(Q_T)$ NORM) Assume that the hypothesis (\mathcal{H}) holds. Let h > 0, let an integer $k \leq 2$. Let (y, λ) and (y_h, λ_h) be the solution of (17) and (55) respectively. If the solution (y, λ) belongs to $H^{k+2}(Q_T) \times H^{k+2}(Q_T)$, then there exist two positive constants $K_i = K_i(||y||_{H^{k+2}(Q_T)}, ||\lambda||_{H^{k+2}(Q_T)}, ||c||_{C^1(\overline{Q_T})}, ||d||_{L^{\infty}(Q_T)}, \alpha, r, \eta), i = 1, 2$ independent of h such that

$$|y - y_h||_{L^2(Q_T)} \le K_1 \frac{h^k}{\sqrt{\eta}}, \quad ||\lambda - \lambda_h||_{L^2(Q_T)} \le K_2 h^k.$$
 (60)

We emphasize that, within the stabilized formulation, these estimates do not depend of any discrete inf-sup constant. In particular, the positive augmentation parameter r can be chosen arbitrarily.

4.3 Numerical approximation of the mixed formulation (28)

We now consider the numerical analysis of the mixed formulation (28) where both the solution y and the spatial part μ of the source are unknown. We take a strictly positive augmentation parameter r.

Let Y_h and Λ_h be two finite dimensional spaces parametrized by the variable h such that $Y_h \subset Y, \Lambda_h \subset L^2(Q_T)$, and $\dim(Y_h) \geq \dim(\Lambda_h)$ for every h > 0. Then, we can introduce the following approximated problems: find $((y_h, \mu_h), \lambda_h) \in Y_h \times \Lambda_h$ solution of

$$\begin{cases}
 a_r((y_h,\mu_h),(\overline{y}_h,\overline{\mu}_h)) + b((\overline{y}_h,\overline{\mu}_h),\lambda_h) = l(\overline{y}_h), & \forall (\overline{y}_h,\overline{\mu}_h) \in Y_h \\
 b((y_h,\mu_h),\overline{\lambda}_h) = 0, & \forall \overline{\lambda}_h \in \Lambda_h.
\end{cases}$$
(61)

Again, for any r > 0, the coercivity of the form a_r holds true on the whole space Y:

$$a_r((y,\mu),(y,\mu)) \ge \frac{r}{\eta} ||(y,\mu)||_Y^2, \quad \forall (y,\mu) \in Y$$

so a fortiori, uniformly on the subspace Y_h . Therefore, assuming that the discrete inf-sup constant defined by

$$\delta_h := \inf_{\lambda_h \in \Lambda_h} \sup_{(y_h, \mu_h) \in Y_h} \frac{b((y_h, \mu_h), \lambda_h)}{\|\lambda_h\|_{L^2(Q_T)} \|(y_h, \mu_h)\|_Y}$$
(62)

is, for any h > 0, strictly positive, there exists a unique solution (y_h, μ_h) of (61) and the following holds true:

PROPOSITION 4.4 Let h > 0. Let $((y, \mu), \lambda)$ and $((y_h, \mu_h), \lambda_h)$ be the solution of (28) and of (61) respectively. Let δ_h be the discrete inf-sup constant defined by (62). Then,

$$\|(y,\mu) - (y_h,\mu_h)\|_Y \le 2\left(1 + \frac{1}{\sqrt{\eta}\delta_h}\right)d((y,\mu),Y_h) + \frac{1}{\sqrt{\eta}}d(\lambda,\Lambda_h),\tag{63}$$

$$\|\lambda - \lambda_h\|_{L^2(Q_T)} \le \left(2 + \frac{1}{\sqrt{\eta}\delta_h}\right) \frac{1}{\delta_h} d(y, Z_h) + \frac{3}{\sqrt{\eta}\delta_h} d(\lambda, \Lambda_h)$$
(64)

where $d(\lambda, \Lambda_h)$ is as in Proposition 4.1 and

$$d((y,\mu),Y_h) := \inf_{(y_h,\mu_h)\in Y_h} \|(y,\mu) - (y_h,\mu_h)\|_Y$$

=
$$\inf_{y_h\in Y_h} \left(\|c(x)\partial_\nu(y-y_h)\|_{L^2(\Gamma_T)}^2 + \eta \|L(y-y_h) - \sigma(\mu-\mu_h)\|_{L^2(Q_T)}^2 \right)^{1/2}.$$
 (65)

PROOF- The proof is similar to the proof of Proposition 4.1 using again that $||a_r||_{(Y \times Y)'} \leq 1$ and $||b||_{(Y \times \Lambda)'} \leq \frac{1}{\sqrt{\eta}}$.

The finite dimensional problem (61) reads as follows: find $\{y_h, \mu_h\} \in \mathbb{R}^{n_h}$ and $\{\lambda_h\} \in \mathbb{R}^{m_h}$ such that

$$\begin{pmatrix} A_{r,h} & B_h^T \\ B_h & 0 \end{pmatrix}_{\mathbb{R}^{n_h+m_h, n_h+m_h}} \begin{pmatrix} \{y_h, \mu_h\} \\ \{\lambda_h\} \end{pmatrix}_{\mathbb{R}^{n_h+m_h}} = \begin{pmatrix} L_h \\ 0 \end{pmatrix}_{\mathbb{R}^{n_h+m_h}}$$
(66)

with matrices similarly defined as in the previous section.

Since the variable μ is a function of $x \in \Omega$ only, we first introduce a triangulation $\mathcal{T}_{\Delta x}$ such that $\overline{\Omega} = \bigcup_{K \in \mathcal{T}_{\Delta x}} K$ and we assume that $\{\mathcal{T}_{\Delta x}\}_{\Delta x > 0}$ is a regular family. We denote $\Delta x := \max\{\operatorname{diam}(K), K \in \mathcal{T}_{\Delta x}\}$. We then introduce the subspace $M_{\Delta x}$ of $H^{-1}(\Omega)$ defined by

$$M_{\Delta x} = \{ \mu_{\Delta x} \subset C^0(\overline{\Omega}) : \mu_{\Delta x} |_K \in \mathbb{Q}_x(K), \quad \forall K \in \mathcal{T}_{\Delta x} \},$$
(67)

where $\mathbb{Q}_x(K)$ denotes the space of affine functions in the variable x in the element K.

Similarly, we define a subdivision $\mathcal{T}_{\Delta t}$ of [0,T] such that $[0,T] = \bigcup_{Q \in \mathcal{T}_{\Delta t}} Q$ and denote $\Delta t := \max\{\operatorname{diam}(Q), Q \in \mathcal{T}_{\Delta t}\}$. Then, we consider the triangulation defined by $\{\mathcal{T}_h\} := \{\mathcal{T}_{\Delta x}\}_{\Delta x>0} \otimes \{\mathcal{T}_{\Delta t}\}_{\Delta t>0}$ such that

$$\overline{Q_T} = \bigcup_{K \in \mathcal{T}_{\Delta x}, Q \in \mathcal{T}_{\Delta t}} \{ K \times Q \}.$$

Again, we denote by $h := \max\{\operatorname{diam}(K \times Q), K \in \mathcal{T}_{\Delta x}, Q \in \mathcal{T}_{\Delta t}\}$. The triangulation $\{\mathcal{T}_h\}_h$ is a regular family for Q_T as soon as $\{\mathcal{T}_{\Delta x}\}_{\Delta x>0}$ is a regular family for Ω .

As in the previous section, we now go on in the one dimensional case in space.

4.3.1 C^1 -finite elements and order of convergence for N = 1

We only discuss the BFS finite element and introduce the space Z_h as follows :

$$Z_h = \{ z_h \subset C^1(\overline{Q_T}) : z_h |_M \in \mathbb{P}(M), \quad \forall M \in \mathcal{T}_h, \ z_h = 0 \text{ on } \Sigma_T, \ z_h = z_{h,t} = 0 \text{ on } \Omega \times \{0\} \},$$
(68)

with $\mathbb{P}(M) := \mathbb{P}_{3,x}(Q) \times \mathbb{P}_{3,t}(K)$, for all $(Q, K) \in (\mathcal{T}_{\Delta x}, T_{\Delta t})$. Finally, we define the space Y_h by

$$Y_h := \{y_h = (z_h, \mu_{\Delta x}) : z_h \in Z_h, \mu_{\Delta x} \in M_{\Delta x}\}$$

so that, for each value of $t \in [0,T]$, the variables $z_h(\cdot,t)$ and $\mu_{\Delta x}$ share the same triangulation with respect to the variable x. We check that $Y_h \subset Y$ for each h > 0. In the sequel, for simplicity, we use the notation μ_h for $\mu_{\Delta x}$.

We then have the following result:

PROPOSITION 4.5 (BFS ELEMENT FOR N = 1 - RATE OF CONVERGENCE FOR THE NORM Y) Let h > 0, let $k, q \leq 2$ be two nonnegative integers. Let $((y, \mu), \lambda)$ and $((y_h, \mu_h), \lambda_h)$ be the solution of (28) and (61) respectively. If the solution $((y, \mu), \lambda)$ belongs to $(H^{k+2}(Q_T) \times H^q(\Omega)) \times H^k(Q_T)$, then there exist two positive constants

$$K_{i} = K_{i}(\|y\|_{H^{k+2}(Q_{T})}, \|\mu\|_{H^{q}(\Omega)}, \|\lambda\|_{H^{k}(Q_{T})}, \|c\|_{C^{1}(\overline{Q_{T}})}, \|d\|_{L^{\infty}(Q_{T})}, \|\sigma\|_{L^{\infty}([0,T])}), \qquad i \in \{1,2\},$$

independent of h, such that

$$\|(y,\mu) - (y_h,\mu_h)\|_Y \le K_1 \left(1 + \frac{1}{\sqrt{\eta}\delta_h} + \frac{1}{\sqrt{\eta}}\right) h^k + K_1 \left(1 + \frac{1}{\sqrt{\eta}\delta_h}\right) (\Delta x)^q,$$
(69)

$$\|\lambda - \lambda_h\|_{L^2(Q_T)} \le K_2 \left(\left(1 + \frac{1}{\sqrt{\eta}\delta_h}\right) \frac{1}{\delta_h} + \frac{1}{\sqrt{\eta}\delta_h} \right) h^k + K_2 \left(\left(1 + \frac{1}{\sqrt{\eta}\delta_h}\right) \frac{1}{\delta_h} \right) (\Delta x)^q.$$
(70)

PROOF - We proceed as in the proof of Proposition 4.2. We write that

$$\begin{split} \|L(y - \Pi_{Y_h, \mathcal{T}_h}(y)) - \sigma(\mu - \Pi_{Z_h, \mathcal{T}_h}(\mu))\|_{L^2(Q_T)} \\ &\leq \|L(y - \Pi_{Z_h, \mathcal{T}_h}(y))\|_{L^2(Q_T)} + \|\sigma\|_{L^{\infty}([0,T])} \|\mu - \Pi_{M_{\Delta x}, \mathcal{T}_{\Delta x}}(\mu)\|_{L^2(\Omega)} \\ &\leq K \|y - \Pi_{Z_h, \mathcal{T}_h}(y)\|_{H^2(Q_T)} + \|\sigma\|_{L^{\infty}([0,T])} \|\mu - \Pi_{M_{\Delta x}, \mathcal{T}_{\Delta x}}(\mu)\|_{L^2(\Omega)} \end{split}$$

where K is from (49).

We use that, if $\mu \in H^q(\Omega)$, $q \leq 2$, there exists a positive constant $C_3 = C_3(\|\mu\|_{H^q(\Omega)})$ such that $\|\mu - \prod_{M_{\Delta x}, \tau_{\Delta x}}(\mu)\|_{L^2(\Omega)} \leq C_3(\Delta x)^q$ for any $\Delta x > 0$. Consequently, from (47), we have the estimate

$$\|L(y - \Pi_{Y_h, \mathcal{T}_h}(y)) - \sigma(\mu - \Pi_{Z_h, \mathcal{T}_h}(\mu))\|_{L^2(Q_T)} \le KC_2h^k + C_3(\Delta x)^q \le (KC_2 + C_3)(h^k + (\Delta x)^q).$$

This leads to the following estimates :

$$d((y,\mu),Y_h) \leq \left((\|c\|_{L^{\infty}(\Gamma_T)}^2 C_P^2 + \eta K^2) C_2^2 h^{2k} + \eta \|\sigma\|_{L^{\infty}([0,T])}^2 C_3^2 (\Delta x)^{2q} \right)^{1/2}$$

$$\leq \sqrt{2} \sqrt{(\|c\|_{L^{\infty}(\Gamma_T)}^2 C_P^2 + \eta K^2)} C_2 h^k + \sqrt{2} \sqrt{\eta} \|\sigma\|_{L^{\infty}([0,T])} C_3 (\Delta x)^q$$

Using (63), we then get

$$\begin{split} \|(y,\mu) - (y_h,\mu_h)\|_Y \\ \leq & 2\sqrt{2} \left(1 + \frac{1}{\sqrt{\eta}\delta_h} \right) \left[\sqrt{(\|c\|_{L^{\infty}(\Gamma_T)}^2 C_P^2 + \eta K^2)} C_2 h^k + \sqrt{\eta} \|\sigma\|_{L^{\infty}([0,T])}) C_3(\Delta x)^q \right] \\ & + \frac{1}{\sqrt{\eta}} C_1 h^k. \end{split}$$

Similarly, using (64), we get

$$\begin{split} \|\lambda - \lambda_h\|_{L^2(Q_T)} \\ \leq & \sqrt{2} \bigg(2 + \frac{1}{\sqrt{\eta}\delta_h} \bigg) \frac{1}{\delta_h} \bigg[\sqrt{(\|c\|_{L^{\infty}(\Gamma_T)}^2 C_P^2 + \eta K^2)} C_2 h^k + \sqrt{\eta} \|\sigma\|_{L^{\infty}([0,T])} C_3 (\Delta x)^q \bigg] \\ & + \frac{3}{\sqrt{\eta}\delta_h} C_1 h^k. \end{split}$$

4 NUMERICAL ANALYSIS OF THE MIXED FORMULATIONS

The proposition then follows from the last two estimates.

It remains now to deduce the convergence of the approximation y_h for a global norm, typically $L^2(Q_T)$. We write that $y - y_h$ solves the problem

$$\begin{cases} L(y - y_h) = \sigma(\mu - \mu_h) + L(y - y_h) - \sigma(\mu - \mu_h) & \text{in } Q_T \\ ((y - y_h), (y - y_h)_t)(\cdot, 0) = (0, 0) & \text{in } \Omega \\ y - y_h = 0 & \text{on } \Sigma_T \end{cases}$$

leading to

$$\|y - y_h\|_{L^2(Q_T)} \le C_{\Omega,T} \bigg(\|\sigma\|_{L^{\infty}(0,T)} \|(\mu - \mu_h)\|_{H^{-1}(\Omega)} + \|L(y - y_h) - \sigma(\mu - \mu_h)\|_{L^2(Q_T)} \bigg).$$

On the other hand, proceeding as before, assuming (\mathcal{H}_2) , we have

$$\|\mu - \mu_h\|_{H^{-1}(\Omega)}^2 \le C_{obs} \left(\|c(x)(\partial_\nu y - \partial_\nu y_h)\|_{L^2(\Gamma_T)}^2 + \|L(y - y_h) - \sigma(\mu - \mu_h)\|_{L^2(Q_T)}^2 \right)$$

leading to

$$\begin{split} \|y - y_h\|_{L^2(Q_T)} &\leq C_{\Omega,T} \bigg(\|\sigma\|_{L^{\infty}([0,T])} \sqrt{C_{obs}} \|c(x)\partial_{\nu}(y - y_h)\|_{L^2(\Gamma_T)} \\ &+ (1 + \|\sigma\|_{L^{\infty}([0,T])} \sqrt{C_{obs}}) \|L(y - y_h) - \sigma(\mu - \mu_h)\|_{L^2(Q_T)} \bigg) \\ &\leq C_{\Omega,T} (1 + \|\sigma\|_{L^{\infty}([0,T])} \sqrt{C_{obs}}) \bigg(\|c(x)\partial_{\nu}(y - y_h)\|_{L^2(\Gamma_T)} \\ &+ \|L(y - y_h) - \sigma(\mu - \mu_h)\|_{L^2(Q_T)} \bigg) \\ &\leq \sqrt{3} C_{\Omega,T} (1 + \|\sigma\|_{L^{\infty}([0,T])} \sqrt{C_{obs}}) \max(1, \frac{1}{\sqrt{\eta}}) \|(y - y_h, \mu - \mu_h)\|_{Y}. \end{split}$$

Therefore, in view of Proposition 4.5, we get the following a priori estimate for the L^2 -norm :

THEOREM 4.3 (BFS ELEMENT FOR N = 1 - RATE OF CONVERGENCE FOR THE $L^2(Q_T)$ -NORM) Let h > 0, let $k, q \leq 2$ be two nonnegative integers. Let $((y, \mu), \lambda)$ and $((y_h, \mu_h), \lambda_h)$ be the solution of (28) and (61) respectively. If $((y, \mu), \lambda)$ belongs to $(H^{k+2}(Q_T) \times H^q(\Omega)) \times H^k(Q_T)$, then there exists a positive constant

$$K = K(\|y\|_{H^{k+2}(Q_T)}, \|\mu\|_{H^k(\Omega)}, \|c\|_{C^1(\overline{Q_T})}, \|d\|_{L^{\infty}(Q_T)}),$$

independent of h, such that

$$\|y - y_h\|_{L^2(Q_T)} \le KC_{\Omega,T}(1 + \|\sigma\|_{L^{\infty}([0,T])}\sqrt{C_{obs}})\max(1, \frac{1}{\sqrt{\eta}})$$
$$\left[\left(1 + \frac{1}{\sqrt{\eta}\delta_h} + \frac{1}{\sqrt{\eta}}\right)h^k + \left(1 + \frac{1}{\sqrt{\eta}\delta_h}\right)(\Delta x)^q\right].$$

Remark 7 We have presented along Section 4 error estimates in the one-dimensional case in the case where the space Z_h (and Λ_h for the present section) is based on the BFS finite element. Similar results may be obtained within the HCT finite element. Precisely, we refer to [10, ch. VII, sec. 48, p. 295] where the following interpolation estimates for the HCT element are developed:

$$||y - \Pi_{Z_h, \mathcal{T}_h}(y)||_{L^2(Q_T)} \le Ch^{k+2}, \quad ||y - \Pi_{Z_h, \mathcal{T}_h}(y)||_{H^2(Q_T)} \le Ch^k, \quad \forall y \in H^2(Q_T)$$

for $k \in \{0, 1\}$ and some constant C > 0.

5 Numerical experiments

We now report and discuss some numerical experiments corresponding to mixed formulations (36), (55) and (61) for N = 1 and N = 2 respectively.

5.1 Reconstruction of the solution - One dimensional case (N = 1)

We take $\Omega = (0,1)$ and $\Gamma = \{1\} \subset \partial\Omega$, T = 2, $c \equiv 1$ and $d \equiv 0$. We check that for these data, the inequality (\mathcal{H}) holds true. Moreover, in order to check the convergence of the numerical approximations, we consider explicit solutions of (1). We first define the following initial condition in $H_0^1(\Omega) \times L^2(\Omega)$ (see [9]):

(EX1) $y_0(x) = 1 - |2x - 1|, \quad y_1(x) = 1_{(1/3, 2/3)}(x), \qquad x \in (0, 1)$

and f = 0. The corresponding solution of (1) is given by

$$y(x,t) = \sum_{k>0} \left(a_k \cos(k\pi t) + \frac{b_k}{k\pi} \sin(k\pi t) \right) \sqrt{2} \sin(k\pi x)$$
(71)

with

$$a_k = \frac{4\sqrt{2}}{\pi^2 k^2} \sin(\pi k/2), \quad b_k = \frac{1}{\pi k} (\cos(\pi k/3) - \cos(2\pi k/3)), \quad k > 0.$$

In particular $\|y\|_{L^2(Q_T)} = \sqrt{\sum_{k>0} (a_k^2 + \frac{b_k^2}{(k\pi)^2})} \approx 0.58663$. The corresponding normal derivative $\partial_{\nu} y|_{\Gamma_T} = y_x(1,t)$ is depicted in Figure 2. This example is rather stiff: the normal derivative is in $L^2(0,T)$ but is discontinuous (in view of the regularity of the initial condition). We compute $\|\partial_{\nu} y\|_{L^2(\Gamma_T)} = \sqrt{2\sum_{k>0}((k\pi)^2 a_k^2 + b_k^2)} \approx 8.33298$.

We recall that the direct method amounts to solve, for any h, the linear system (42). We use exact integration methods developed in [16] for the evaluation of the coefficients of the matrices. Moreover, the linear system (42) is solved using the LU decomposition method.

We first consider the BFS finite element with uniform triangulation (each element K of the triangulation \mathcal{T}_h is a rectangle of lengths Δx and Δt so that $h = \sqrt{(\Delta x)^2 + (\Delta t)^2}$). Table 2 collects some numerical values with respect to h for $r = h^2$ and for $\Delta x = \Delta t$. We observe the following behavior with respect to h:

$$r = h^{2}: \qquad \frac{\|y - y_{h}\|_{L^{2}(Q_{T})}}{\|y\|_{L^{2}(Q_{T})}} = \mathcal{O}(h^{1.20}), \qquad \frac{\|\partial_{\nu}(y - y_{h})\|_{L^{2}(\Gamma_{T})}}{\|\partial_{\nu}y\|_{L^{2}(\Gamma_{T})}} = \mathcal{O}(h^{0.59}),$$
$$\|\lambda_{h}\|_{L^{2}(Q_{T})} = \mathcal{O}(h^{1.11}), \quad \|Ly_{h}\|_{L^{2}(Q_{T})} = \mathcal{O}(h^{-0.29}).$$

The evolution of the norm $||y - y_h||_{L^2(Q_T)}$ suggests that the unique solution y is correctly reconstructed from the observation. Moreover, in agreement with Remark 1, since $y_{\nu,obs}$ is by construction the restriction to $\{1\} \times (0,T)$ of the normal derivative of a solution of (1), we check, that the sequence λ_h , approximation of λ , vanishes as $h \to 0$. Eventually, in view of the Remark 6, we have $r||Ly_h||_{L^2(Q_T)} = h||Ly_h||_{L^2(Q_T)} \approx ||Ly_h||_{L^2(0,T,H^{-1}(0,1))} \approx \mathcal{O}(h^{1-0.29})$, so that y_h approximates correctly the unique corresponding weak solution of (1).

We also check that the minimization of the functional $J_r^{\star\star}$ introduced in Proposition 2.3 leads exactly to the same result approximation: we recall that the minimization of the functional $J_r^{\star\star}$ corresponds to the resolution of the associated mixed formulation by an iterative Uzawa type method. The minimization is done using a conjugate gradient algorithm (we refer to [13, Section 2.2] for the algorithm). Each iteration amounts to solve a linear system involving the matrix $A_{r,h}$ which is sparse, symmetric and positive definite. The Cholesky method is used. The performance

5 NUMERICAL EXPERIMENTS

of the algorithm depends on the condition number of the operator \mathcal{P}_r : precisely, it is known that (see for instance [15]),

$$\|\lambda^n - \lambda\|_{L^2(Q_T)} \le 2\sqrt{\nu(\mathcal{P}_r)} \left(\frac{\sqrt{\nu(\mathcal{P}_r)} - 1}{\sqrt{\nu(\mathcal{P}_r)} + 1}\right)^n \|\lambda^0 - \lambda\|_{L^2(Q_T)}, \quad \forall n \ge 1$$

where λ minimizes $J_r^{\star\star}$. $\nu(\mathcal{P}_r) = \|\mathcal{P}_r\|_{\mathcal{L}(L^2(Q_T))}\|\mathcal{P}_r^{-1}\|_{\mathcal{L}(L^2(Q_T))}$ denotes the condition number of the operator \mathcal{P}_r . As discussed in [13, Section 4.4], the condition number of \mathcal{P}_r restricted to $\Lambda_h \subset L^2(Q_T)$ (which coincides with the condition number of the matrix $B_h A_{r,h} B_h^T$) behaves asymptotically as $C_r^{-2}h^{-2}$, where C_r is the constant appearing in (54). This quadratic behavior is the typical one for well-posed elliptic problems. Table 2 reports the number of iterations of the algorithm, initialized with $\lambda^0 = 0$ in Q_T . We take $\epsilon = 10^{-10}$ as a stopping threshold for the algorithm (the algorithm is stopped as soon as the norm of the residue g^n given here by Ly^n satisfies $\|g^n\|_{L^2(Q_T)} \leq 10^{-10} \|g^0\|_{L^2(Q_T)}$). We observe that the number of iterates is sub-linear with respect to h, precisely, with respect to the dimension $m_h = card(\{\lambda_h\})$ of the approximated problems. This renders this method very attractive from a numerical point of view.

Table 3 reports the results for r = 1. We get a slightly better estimate for the norm $||Ly_h||_{L^2(Q_T)}$ but slightly worst estimate for the norm $||y - y_h||_{L^2(Q_T)}$. On the other hand, since r acts as an augmentation parameter, the convergence of the conjugate gradient algorithm is faster. We also check in view of Remark 6 (specifically, (45) and (54)) that the convergence of λ_h toward zero is much lower for r = 1 than for $r = h^2$:

$$r = 1: \qquad \frac{\|y - y_h\|_{L^2(Q_T)}}{\|y\|_{L^2(Q_T)}} = \mathcal{O}(h^{1.02}), \qquad \frac{\|\partial_\nu (y - y_h)\|_{L^2(\Gamma_T)}}{\|\partial_\nu y\|_{L^2(\Gamma_T)}} = \mathcal{O}(h^{0.16}), \\ \|\lambda_h\|_{L^2(Q_T)} = \mathcal{O}(h^{0.17}), \qquad \|Ly_h\|_{L^2(Q_T)} = \mathcal{O}(h^{0.27}).$$

We now discuss the results obtained with the reduced HCT finite element on regular but nonuniform triangulations of the rectangle $\Omega \times (0, T)$. Precisely, we consider 5 levels of meshes of Q_T

described in Table 4. For each of these meshes, we compute h as the maximum of the diameters of the triangles composing the triangulation. The coarsest of this meshes is displayed in Figure 2.

Table 5 collects the numerical results on the reconstruction of the solution y from the observation $y_{\nu,obs}$ obtained with again $r = h^2$. We observe a slightly super linear convergence for the variable y_h and λ_h :

$$\frac{\|y - y_h\|_{L^2(Q_T)}}{\|y\|_{L^2(Q_T)}} = \mathcal{O}(h^{1.22}), \qquad \|\lambda_h\|_{L^2(Q_T)} = \mathcal{O}(h^{1.04}).$$

Table 5: Example **EX1** - HCT element - $r = h^2$ - T = 2.

Figure 3 depicts the exact solution y computed by (71) and its approximation y_h (computed with the mesh $\ddagger 3$). Figure 4 represents the relative error $||y - y_h||_{L^2(Q_T)}/||y||_{L^2(Q_T)}$ reported also in Table 5. Tables 5, 6 and 7 also report the value of the condition number κ_h of the matrix $A_{r,h}$. In both situations, as it is usual for elliptic problems, κ_h behaves quadratically with respect to h^{-1} .

We also emphasize that this variational method which requires a finite element discretization of the time-space Q_T is particularly well-adapted to mesh optimization. Still for the example **EX1**, Figure 5 depicts a sequence of four meshes of $Q_T = (0, 1) \times (0, T)$: the sequence is initialized

Figure 3: Example **EX1**. Exact solution y and approximated solution y_h on the mesh $\ddagger 3$.

Figure 4: Example **EX1** -T = 2 - Relative error $||y - y_h||_{L^2(Q_T)}/||y||_{L^2(Q_T)}$ w.r.t. h for the BFS element with $r = h^2$ (+) and r = 1 (*), the HCT element with $r = h^2$ (\Box) and r = 1 (\circ)

with the coarsest mesh described in Table 4 which is locally refined near boundary Γ_T (where the observation $y_{\nu,obs}$ is localized) and near $\Omega \times \{0\}$ (for a better representation of the initial data). The three other meshes are successively obtained by local refinement based on the norm of the gradient of y_h on each triangle of \mathcal{T}_h . As expected, the refinement is concentrated around the lines of singularity of y_h traveling in Q_T , generated by the singularity of the initial position y_0 . Some information concerning these meshes and the approximation errors obtained where this mesh adaptation strategy is employed are reported in Table 6.

Figure 5: Example **EX1** - reduced HCT finite element: Iterative refinement of the triangular mesh over Q_T with respect to the variable y_h

We end this section with some numerical results for the stabilized mixed formulation (55). The main difference is that the multiplier λ is now approximated in a richer space (see (57)) leading to larger linear systems. Table 7 considers the case of the example **EX1** with T = 2 and $\alpha = 1/2$. In order to compare with the formulation (36), we take again $r = h^2$. We observe the convergence w.r.t. h and obtain similar rates and constants to the ones in Table 5: in particular, we have

$$\frac{\|y - y_h\|_{L^2(Q_T)}}{\|y\|_{L^2(Q_T)}} = \mathcal{O}(h^{1.21}), \qquad \|\lambda_h\|_{L^2(Q_T)} = \mathcal{O}(h^{1.04}).$$

Finally, we also check - in contrast with the mixed formulation (6) - that the positive parameter r does not affect the numerical results.

5.2 Reconstruction of the solution - Two dimensional case (N = 2)

In this section we illustrate the method introduced in Section 2 on a two-dimensional example. The procedure is similar but a bit more involved on a computational point of view, since Q_T is

h	7.62×10^{-2}	3.81×10^{-2}	1.91×10^{-2}	9.53×10^{-3}	4.77×10^{-3}
$\frac{\ y - y_h\ _{L^2(Q_T)}}{\ y\ _{L^2(Q_T)}}$	4.1×10^{-2}	1.55×10^{-2}	6.88×10^{-3}	3.03×10^{-3}	1.39×10^{-3}
$\ \lambda_h\ _{L^2(Q_T)}$	$6.96 imes 10^{-3}$	$3.67 imes 10^{-3}$	$1.71 imes 10^{-3}$	8.42×10^{-4}	3.98×10^{-4}

Table 7: Example **EX1** - HCT element - $r = h^2$ - T = 2 - Stabilized mixed formulation (55).

now a subset of \mathbb{R}^3 . We take again c := 1 in Ω and d := 0 in Q_T .

In order to approximate the mixed-formulation (6), we consider a mesh \mathcal{T}_h of the domain $Q_T = \Omega \times (0,T)$ formed by triangular prisms. This mesh is obtained by extrapolating along the time axis a triangulation of the spatial domain Ω . For all the simulations considered in this section, Ω is the so called Bunimovich's stadium (see [7]) and T = 3. Figure 6-Left displays the domain Ω and the part Γ of the boundary on which the observation is available for $t \in (0,T)$ while Figure 6-right displays an example of mesh of domain Q_T .

Figure 6: Bunimovich's stadium and the subset Γ of $\partial\Omega$ on which the observation is available (Left). Example of mesh of the domain Q_T (Right).

Let Z_h be the finite dimensional space defined as follows

$$Z_{h} = \left\{ \begin{array}{c} \varphi_{h} = \psi(x_{1}, x_{2})\theta(t) \in C^{1}(Q_{T}) \\ \varphi_{h} = 0 \text{ on } \Sigma_{T} \end{array} \middle| \begin{array}{c} \psi|_{K_{x_{1}x_{2}}} \in \mathbb{P}(K_{xy}), \theta|_{K_{t}} \in \mathbb{Q}(K_{t}) \\ \text{for every } K = K_{x_{1}x_{2}} \times K_{t} \in \mathcal{T}_{h}. \end{array} \right\},$$
(72)

 $\mathbb{P}(K_{x_1x_2})$ is the space of functions corresponding to the reduced *Hsieh-Clough-Tocher* (HCT) C^1 element recalled in Section 4.1.1; $\mathbb{Q}(K_t)$ is a space of degree three polynomials on the interval K_t of the form $[t_j, t_{j+1}]$ defined uniquely by their value and the value of their first derivative at the point t_j and t_{j+1} . In other words, Y_h is the finite element space obtained as a tensorial product between the reduced HCT finite element and the cubic Hermite finite element. We check that on each element $K = K_{x_1x_2} \times K_t$, the function φ_h is determined uniquely in term of the values of $\Sigma_K := \{\varphi(a_i), \varphi_{x_1}(a_i), \varphi_{x_2}(a_i), \varphi_t(a_i), \varphi_{x_1,t}(a_i), \varphi_{x_2,t}(a_i), i = 1, \cdots, 6\}$ at the six nodes a_i of K. Therefore, dim $\Sigma_K = 36$.

We consider meshes formed by triangular prisms of the domain $Q_T = \Omega \times (0, T)$. An example of such a mesh associated to the domain Q_T is displayed in Figure 6 right. This mesh is composed by 10 261 nodes distributed in 18 060 prismatic elements (this mesh corresponds to the mesh number 2 described in Table 8).

5 NUMERICAL EXPERIMENTS

Mesh number	1	2	3
Number of elements	1 860	18 060	$158 \ 280$
Number of nodes	$1 \ 216$	$10\ 261$	84 241
Δx	1.82×10^{-1}	8.2×10^{-2}	3.95×10^{-2}
Δt (Height of elements)	0.2	0.1	0.05
h	2.7×10^{-1}	1.29×10^{-1}	$6.37 imes 10^{-2}$

We consider three levels of meshes of the domain Q_T formed by the number of prisms and containing the number of nodes reported in Table 8.

Table 8: Characteristics of the three meshes associated with Q_T .

Comparing to the one dimensional situation described in Section 5.1, the eigenfunctions and eigenvectors of the Dirichlet Laplace operator defined on Ω are not explicitly available. Consequently, from a given set of initial data, we define as the "exact" solution and note \bar{y} the solution obtained numerically with a very fine discretization, from which we can extract an observation on Γ_T . Precisely, we solve the hyperbolic equation (1) using a standard time-marching method: we employ a *HCT* finite elements method in space coupled with a Newmark unconditionally stable scheme for the time discretization.

Here, we solve the hyperbolic equation on the spatial mesh which was extrapolated in time in order to obtain the mesh number 3 of Q_T . This two-dimensional mesh contains 1 381 nodes and 2 638 triangles and corresponds to the value $\Delta x \approx 3.95 \times 10^{-2}$. As for the time discretization, we use the value $\Delta t = 10^{-2}$. We denote \overline{y} the solution obtained in this way for the initial data $(y_0, y_1) \in H_0^1(\Omega) \times L^2(\Omega)$ given by

$$(\mathbf{EX2}) \qquad \begin{cases} -\Delta y_0 = 10, & \text{in } \Omega\\ y_0 = 0, & \text{on } \partial\Omega, \end{cases} \qquad y_1 = 0 \quad \text{in } \Omega.$$
(73)

From \overline{y} , we then generate the observation $y_{\nu,obs}$ as the restriction of $\partial_{\nu}\overline{y}$ on Γ_T . The geometry used here allows to compute easily the normal derivative of \overline{y} on the boundary. Finally, from this observation we reconstruct y_h as the solution of the mixed formulation (28) on each of the three meshes described in Table 8. For this simulations we take the augmentation parameter $r = h^3$. Table 9 displays some norms of y_h and λ_h obtained for the three meshes and illustrates again the convergence of the method.

Mesh number	1	2	3
$\frac{\ \overline{y} - y_h\ _{L^2(Q_T)}}{\ \overline{y}\ _{L^2(Q_T)}}$	3.75×10^{-2}	1.53×10^{-2}	1.39×10^{-2}
$\ Ly_h\ _{L^2(Q_T)}$	2.07	1.39	1.09
$\ \lambda_h\ _{L^2(Q_T)}$	$9.3 imes 10^{-6}$	4.89×10^{-6}	$4.57 imes 10^{-6}$

Table 9: Initial data (y_0, y_1) given by (73).

Figure 7-Left displays the initial position y_0 of (73) while Figure 7-Right displays the initial position $y_h(\cdot, 0)$ corresponding to restriction at time t = 0 of the solution y_h of the inverse problem. Figures correspond to the mesh number 2.. The errors between these two functions are given in the last row of Table 9.

Figure 7: Initial data y_0 given by (73) (Left). Reconstructed initial data $y_h(\cdot, 0)$ (Right).

5.3 Reconstruction of the solution and the source $\mu \in H^{-1}(\Omega)$ - One dimensional case N = 1

We now consider the reconstruction of both the state and the source from a partial observation, as discussed in Section 3. In order to construct explicit solution, we first recall that the solution of (1) with zero initial condition can be expanded as follows :

$$\begin{cases} y(x,t) = \sum_{p>0} b_p(t)\sin(p\pi x) \\ b_p(t) := \frac{1}{p\pi} \int_0^t \sin(p\pi(t-s))f_p(s)ds, \quad f_p(s) := 2\sigma(s) \int_\Omega \sin(p\pi x)\mu(x)dx. \end{cases}$$

In the following examples, we take $\sigma(t) = 1 + t$ defined on [0, T], T = 2 and $\Gamma_T = \{1\} \times (0, T)$.

We now report the resolution of the discrete mixed formulation (61). We first consider a rather smooth case, with $\mu \in H^1(\Omega)$ given by

(**EX3**)
$$\mu(x) = \frac{x}{\theta} \mathbf{1}_{[0,\theta]}(x) + \frac{(1-x)}{1-\theta} \mathbf{1}_{[\theta,1]}(x), \quad \theta = 1/3.$$

Table 10 reports the main norms with respect to h. Concerning the augmentation parameter r, we use $r = h^4$ which leads to slightly better approximation of the function μ than $r = h^2$. We check the convergence of the approximations (y_h, μ_h) as h tends to 0. In particular, we get

$$\frac{\|y - y_h\|_{L^2(Q_T)}}{\|y\|_{L^2(Q_T)}} = \mathcal{O}(h^{1.9}), \qquad \frac{\|\mu - \mu_h\|_{H^{-1}(\Omega)}}{\|\mu\|_{H^{-1}(\Omega)}} = \mathcal{O}(h^{1.4}).$$

For instance, for $h = 8.83 \times 10^{-3}$ (precisely, $\Delta x = \Delta t = 1/160$) leading to a linear system with 258 566 unknowns, we get a relative error for μ_h of the order of 10^{-4} . This allows a very good reconstruction of the corresponding solution y. Figure 8-Left depicts the function μ and its corresponding approximation μ_h . Figure 8-Right depicts along Ω the function $(-\Delta)^{-1}(\mu - \mu_h)/\|(-\Delta)^{-1}\mu\|_{H_0^1(\Omega)}$ of magnitude 10^{-5} . Here, Δ denotes the Dirichlet Laplacian.

Remarkably, the approach also provides good reconstruction of the solution y when the observation $y_{\nu,obs}$ is obtained from less regular μ function. We consider the following rather stiff examples, respectively in $L^2(\Omega)$ and $H^{-1}(\Omega)$:

$$\begin{aligned} (\mathbf{EX4}) & \mu(x) = \mathbf{1}_{[a,b]}(x) \in L^2(0,1), \qquad a = 0.2, b = 0.5 \\ (\mathbf{EX5}) & \mu(x) = 1/\sqrt{x} \in H^{-1}(0,1). \end{aligned}$$

The corresponding normal derivatives $y_x(1, \cdot)$ in $H^1(0, T; L^2(\partial \Omega))$ (see [27]) and in $L^2(0, T)$ respectively, are depicted on Figure 9.

h	7.07×10^{-2}	3.53×10^{-2}	1.72×10^{-2}	8.83×10^{-3}	7.07×10^{-3}
$\frac{\ y - y_h\ _{L^2(Q_T)}}{\ y\ _{L^2(Q_T)}}$	1.72×10^{-3}	5.06×10^{-4}	1.28×10^{-4}	3.45×10^{-4}	2.14×10^{-5}
$\frac{\ \mu - \mu_h\ _{H^{-1}(\Omega)}}{\ \mu\ _{H^{-1}(\Omega)}}$	$5.9 imes 10^{-3}$	1.63×10^{-3}	8.3×10^{-4}	3.79×10^{-4}	1.68×10^{-4}
$\frac{\left\ \partial_{\nu}(y-y_{h})\right\ _{L^{2}(\Gamma_{T})}^{(n)}}{\left\ \partial_{\nu}y\right\ _{L^{2}(\Gamma_{T})}}$	$6.5 imes 10^{-4}$	2.03×10^{-4}	$5.17 imes 10^{-5}$	1.38×10^{-5}	8.89×10^{-6}
$\ \lambda_h\ _{L^2(Q_T)}$	7.44×10^{-2}	5.26×10^{-2}	3.68×10^{-2}	2.63×10^{-2}	2.35×10^{-2}

Table 10: Example **EX3** - BFS element - $r = h^4$ - T = 2.

Figure 8: **EX3** -Left: Function μ (full line) and its approximation μ_h (dotted line) along Ω ; Right: $\frac{(-\Delta)^{-1}(\mu-\mu_h)}{\|(-\Delta)^{-1}\mu\|_{H^1_0(\Omega)}}$ along Ω .

Table 11 reports some norms with respect to h for the example **(EX4)**. We observe the convergence as $h \to 0$ with as expected a lower rate : precisely, we compute

$$\frac{\|y - y_h\|_{L^2(Q_T)}}{\|y\|_{L^2(Q_T)}} = \mathcal{O}(h^{1.37}), \qquad \frac{\|\mu - \mu_h\|_{H^{-1}(\Omega)}}{\|\mu\|_{H^{-1}(\Omega)}} = \mathcal{O}(h^{0.95}).$$

For $h = 8.83 \times 10^{-3}$, Figure 11 depicts the functions μ and μ_h leading to a relative error equal to 2.16×10^{-2} . The approximation μ_h oscillates around μ and suggests that the convergence (in agreement with Theorem 3.1) may not hold pointwise but in a weaker (average) sense. Again, this weak convergence of the source term is enough to reconstruct with robustness the solution y. The function $-\Delta^{-1}(\mu - \mu_h)/|| - \Delta^{-1}\mu||_{H_0^1(\Omega)}$ of magnitude 10^{-3} suggests the efficiency of the method to reconstruct the spatial term μ of the source f.

h	7.07×10^{-2}	3.53×10^{-2}	1.72×10^{-2}	8.83×10^{-3}	7.07×10^{-3}
$\frac{\ y - y_h\ _{L^2(Q_T)}}{\ y\ _{L^2(Q_T)}}$	$4.72 imes 10^{-3}$	2.34×10^{-3}	5.58×10^{-4}	2.96×10^{-4}	2.18×10^{-4}
$\frac{\ \mu - \mu_h\ _{H^{-1}(\Omega)}}{\ \mu\ _{H^{-1}(\Omega)}}$	1.53×10^{-1}	7.88×10^{-2}	2.5×10^{-2}	2.16×10^{-2}	1.76×10^{-2}
$\frac{\left\ \partial_{\nu}(y-y_{h})\right\ _{L^{2}(\Gamma_{T})}}{\left\ \partial_{\nu}y\right\ _{L^{2}(\Gamma_{T})}}$	$2.76 imes 10^{-3}$	1.08×10^{-3}	3.57×10^{-4}	$1.4 imes 10^{-4}$	$1.01 imes 10^{-4}$
$\ \lambda_h\ _{L^2(Q_T)}$	$6.81 imes 10^{-2}$	5.07×10^{-2}	3.4×10^{-2}	2.56×10^{-2}	2.31×10^{-2}

Table 11: Example **EX4** - BFS element - $r = h^4$ - T = 2.

Similar remarks can be made for the example **EX5**: we refer to Table 12 and Figure 11.

Figure 9: Normal derivative $\partial_{\nu} y|_{q_T} = y_x(1,t)$ on (0,T) associated to $\mu(x) = 1_{(0.2,0.5)}(x)$ (left) and $\mu(x) = 1/\sqrt{x}$ (right).

Figure 10: **EX4** -Left: Function μ (blue) and its approximation μ_h (red) along Ω ; Right: $\frac{(-\Delta)^{-1}(\mu-\mu_h)}{\|(-\Delta)^{-1}\mu\|_{H^{1}_{\Omega}(\Omega)}}$ in Ω .

6 Concluding remarks and perspectives

The mixed formulations we have introduced here in order to address inverse problems for hyperbolic equations seems original. These formulations are nothing else than the Euler systems associated to least-squares type functionals and depend on both the state to be reconstruct and a Lagrange multiplier. This Lagrange multiplier is introduced to take into account the state constraint Ly - f =0 and turns out to be the controlled solution of a hyperbolic equation with the source term $(\partial_{\nu}y$ $y_{\nu,obs}) 1_{\Gamma_T}$. This approach, recently used in a controllability context in [13], leads to a variational problem defined over time-space functional Hilbert spaces, without distinction between the time and the space variable. The main ingredients are, first a unique continuation type property for the hyperbolic equation (assuming some geometric conditions on the measurement zone) allowing to prove the well-posedness of the mixed formulation, and second, a (strong) generalized observability inequality, allowing to quantify the global reconstruction of the solution.

At the practical level, the discrete mixed time-space formulation is solved in a systematic way in the framework of the finite element theory. The approximation is conformal allowing to obtain

h	7.07×10^{-2}	3.53×10^{-2}	1.72×10^{-2}	8.83×10^{-3}	7.07×10^{-3}
$\frac{\ y - y_h\ _{L^2(Q_T)}}{\ y\ _{L^2(Q_T)}}$	1.82×10^{-2}	7.74×10^{-2}	3.18×10^{-3}	1.87×10^{-3}	1.17×10^{-3}
$\frac{\ \mu - \mu_h\ _{H^{-1}(\Omega)}}{\ \mu\ _{H^{-1}(\Omega)}}$	31.44	11.27	3.96	1.42	1.02
$\frac{\left\ \partial_{\nu}(y-y_{h})\right\ _{L^{2}(\Gamma_{T})}^{(\alpha)}}{\left\ \partial_{\nu}y\right\ _{L^{2}(\Gamma_{T})}}$	$2.49 imes 10^{-1}$	2.88×10^{-1}	1.01×10^{-1}	5.68×10^{-2}	4.72×10^{-2}
$\ \lambda_h\ _{L^2(Q_T)}$	2.99×10^{-1}	2.35×10^{-1}	1.91×10^{-1}	1.62×10^{-1}	1.52×10^{-1}

Table 12: Example **EX5** - BFS element - $r = h^4$ - T = 2.

Figure 11: **EX5** -Left: Function μ (blue) and its approximation μ_h (red) along Ω ; Right: $\frac{(-\Delta)^{-1}(\mu-\mu_h)}{\|(-\Delta)^{-1}\mu\|_{H^1_{\Omega}(\Omega)}}$ along Ω .

the strong convergence of the approximation as the discretization parameters tends to zero. In particular, we emphasize that there is no need, contrarily to the classical approach, to prove some uniform discrete observability inequality: we simply use the observability inequality on the finite dimensional discrete space. The resolution amounts to solve a sparse symmetric linear system : the corresponding matrix can be preconditioned if necessary, and may be computed once for all as it does not depend on the observation $y_{\nu,obs}$. Eventually, the space-time discretization of the domain allows an adaptation of the mesh so as to reduce the computational cost and capture the main features of the solutions. Similarly, this space-time formulation is very appropriate to the non-cylindrical situation.

In agreement with the theoretical convergence, the numerical experiments reported here display a very good behavior and robustness of the approach: the reconstructed approximate solution converges strongly to the solution of the hyperbolic equation associated to the available observation. Remark that from the continuous dependence of the solution with respect to the observation, the method is robust with respect to the possible noise on the data.

Eventually, since the mixed formulations rely essentially on a generalized observability inequality, it may be employed to any other observable systems for which such property is available : we mention notably the parabolic case usually badly conditioned – in view of regularization property – and for which direct and robust methods are certainly very advantageous. This is in contrast with the Luenberger approach (mentioned in the introduction) which assume the reversibility in time of the equation We also mention that this kind of approach may be used to reconstruct potential and coefficient.
