Highlights

- Large-scale configuration interaction (CI) including 726 configurations.
- New atomic data for highly ionized ion Ge XX.
- Using the "fine-tuning" process within CIV3.

Abstract

We have performed large-scale configuration interaction (CI) calculations using CIV3 for the lowest (in energy) 155 fine-structure levels of aluminum-like germanium ion. We have calculated the energy levels, lifetimes, oscillator strengths, and transition probabilities for the electric-dipole allowed and intercombination transitions among the levels of ground state $3s^23p(^2P)$ and higher energy levels of states $3s3p^2$, $3s^23d$, $3p^3$, $3s3p3d$, $3p^23d$, $3s3d^2$, $3p3d^2$, $3d^3$, $3s^2(4s, 4p, 4d, 4f)$ of Ge XX in the LSJ coupling scheme. The present results include relativistic effects through the Breit-Pauli operator. In order to keep our calculated energy splittings as close as possible to the experimental and theoretical results compiled by NIST, we attempt to correct the inaccuracies in the CI coefficients in the wavefunctions, which would lead to inaccuracies in transition probabilities, by applying a "fine-tuning" technique. Fine-tuning of the *ab initio* energies was done through adjusting, by a small amount, some diagonal elements of the Hamiltonian matrix. Comparisons are made with other available experimental and theoretical results and the accuracy of the present results is assessed.

1. Introduction

The spectra of Al-like ions with $Z > 30$ have received a great deal of attention both experimentally and theoretically. In previous experimental works, which mainly make use of high-energy lasers or tokamak discharges, the spectra of some Al-like ions in plasmas have been measured, though for the heavier ions like germanium, selenium, molybdenum and silver only the spectra from the transitions of $3s3p^2$ and $3s^23d$ configurations have been identified by Hinnov *et al* [1] and by Sugar *et al* [2] for copper through molybdenum. Transitions in Ge XX between the $3s^23p$, $3s3p^2$, $3s^23d$, $3p^3$ and $3s3p3d$ configurations were identified in the extreme-ultraviolet spectra emitted from linear plasmas, produced using line-focused laser beams [3].

Large-scale theoretical studies of Al-like ions have been performed using different methods: systematic studies of oscillator strengths for fine-structure transitions in the aluminum isoelectronic sequence [4]; relativistic many-body calculations of electric-dipole lifetimes, transitions rates and oscillator strengths for $n = 3$ states in Al-like ions [5].

Critical data compilations based on available theoretical and experimental sources are given in National Institute of Standards and Technology (NIST), Atomic Spectra Database (ASD) [6].

In this work, we have chosen to use Hibbert's program CIV3 to calculate energy levels and oscillator strengths. In a wide range of previous calculations it has demonstrated its ability to obtain results more accurate than those produced by many other programs, especially when strong mixing occurs.

The present study will include extensive calculations and give results for allowed and intercombination electric-dipole transitions within the $n = 4$ complex of states in Ge XX ion by including configuration-interaction and valence correlation effects via configuration interaction.

2. Theoretical method

The wavefunctions describing the atomic states included in these calculations were obtained using configuration interaction code CIV3 of Hibbert [7, 8]. The CI wavefunctions are represented as

$$\Psi(J) = \sum_{j=1}^M a_{ij} \phi_j(\alpha_j L_j S_j J), \quad (1)$$

where (ϕ_j) denotes a set of single-configuration wavefunctions, (α_j) defines the coupling of the angular momenta of the electrons, and the orbital (L_j) and the spin (S_j) angular momenta are coupled to give the total angular momentum (J). The mixing coefficients (a_{ij}) are obtained by diagonalizing the Breit-Pauli Hamiltonian with respect to the basis (ϕ_j) .

The Hamiltonian used in this work consists of the non-relativistic electrostatic terms plus the one-body mass correction, Darwin term, and spin-orbit, spin-other-orbit, and spin-spin operators of the Breit-Pauli Hamiltonian. The inclusion of the mass correction and Darwin terms shift the energy of a configuration as a whole, while the spin-orbit, spin-other-orbit and spin-spin terms give rise to the fine-structure splitting. The general configuration-interaction code CIV3 uses orthonormal orbitals. Their radial functions $P_{nl}(r)$ are expressed as superposition of normalized Slater-type Orbitals (STOs) of the form

$$P_{nl}(r) = \sum_{j=1}^k C_{jnl} \chi_{jnl}(r), \quad (2)$$

where C_{jnl} are the Clementi-type coefficients and

$$\chi_{jnl}(r) = \frac{(2\xi_{jnl})^{l_{jnl} + \frac{1}{2}}}{[(2l_{jnl})!]^{\frac{1}{2}}} r^{l_{jnl}} \exp(-\xi_{jnl} r) \quad (3)$$

with the integer

$$I_{jnl} \geq l+1$$

The parameters C_{jnl} and ξ_{jnl} are determined variationally while the parameters I_{jnl} are normally kept fixed in any optimization process. The STOs are chosen to satisfy the orthonormality condition

$$\int_0^{\infty} P_{nl}(r)P_{n'l}(r) dr = \delta_{nn'} ; \quad l+1 < n' \leq n \quad (4)$$

In this calculations we used the 14 orthonormal one-electron orbitals: 1s, 2s, 2p, 3s, 3p, 3d, 4s, 4p, 4d, 4f, 5s, 5p, 5d, and 5f.

The optimized parameters of the radial functions are recorded and the method of optimizing the radial functions is given. All the optimizations were undertaken in LS coupling, that is, without the inclusion of the Breit-Pauli effects. In our calculation the 1s, 2s, 2p, 3s and 3p radial functions are taken as the Hartree-Fock orbitals of the ground state $1s^2 2s^2 2p^6 3s^2 3p^2 ({}^2P^o)$ of the Ge XX ion given by Clementi and Roetti [9], whereas for the other basis radial functions 3d, 4s, 4p, 4d and 4f we initially took $k = n - l$ in Eq. (1), so that the coefficients C_{jnl} are uniquely specified by the orthogonality condition on P_{nl} .

However, to increase the flexibility of the form of these radial functions, we then took $k > n - l$ in Eq. (1), thus adding extra basis functions into the $n = 4$ orbital's and also 3d.

Finally, we optimized 5s, 5p, 5d and 5f on different sets of configurations in order to improve the representation of valence correlation in various states.

The configurations included in the CI calculations for each parity are shown. The key of configurations used in our CIV3 calculation are displayed in Table *.

3. Results and discussion

The energy levels and lifetimes for 155 fine structure levels of Al-like germanium have been tabulated in Table ** and arranged in ascending order of energy. Our calculated fine-structure excitation energies relative to the ground level are compared with the compiled values of the National Institute of Standard and Technology (NIST) [6], as far as is possible. The mixing among some of the relativistic levels is very strong. Our *ab initio* calculation, 'Present (a)', is in good agreement with the experimental and theoretical results compiled by NIST, except for the levels $3s3p^2 ({}^2P_{1/2}, {}^2S_{1/2})$, for which our calculated positions of these two levels to be reversed compared with those of NIST. This was previously noted by Gupta and Msezane [10] when comparing the *ab initio* MCHF levels of Froese Fisher et al. [11] with NIST. The wave functions for the levels $3s3p^2 ({}^2P_{1/2})$ and $3s3p^2 ({}^2S_{1/2})$ exhibit very strong configuration mixing (55% and 42%), and in a simple *ab initio* calculation it is difficult to represent that mixing sufficiently accurately.

An *ab initio* CI calculation is necessarily approximate, and even with such a relative extensive set of CSFs our theoretical energies will not, in general, be obtained to the same level of accuracy as could be achieved experimentally. Thus, prior to undertaking the calculation of the Breit-Pauli oscillator strengths, we make further small modifications where by certain diagonal matrix elements are adjusted so that the theoretical energy differences coincide with the relevant experimental values. These corrections to the calculated energy levels result in improvements to the CI mixing coefficients a_{ij} , and therefore to the *ab initio* oscillator strengths. This so-called fine-tuning process has been described and justified by Hibbert [12]. In a way, these adjustments correct the *ab initio* approach for the neglected core-valence correlation [13].

In general, our adjusted theoretical energies, 'Present (b)', are also listed in Table ** and are in excellent agreement with the NIST data. We included in column 4 of Table ** the leading percentage composition of the various levels (corresponding to Present (b)). The first number of each entry in this column represents the leading percentage of the

level corresponding to the level number under the first column, followed by a set of numbers of the form $X(Y)$. These mean that the next leading percentage is $X\%$ of the level number Y in the first column and so on. As can be seen from the column 4 of Table **, the mixing among several fine-structure levels is very strong, with most of the strongly mixed levels belonging to the $3p^23d$ configurations. No experimental or other theoretical results are available for these levels.

The last column in Table ** represents the radiative lifetime of an excited state which is related to the radiative transition probabilities A_{ji} through

$$\tau_j = \left(\sum_i A_{ji} \right)^{-1} \quad (5)$$

where the sum over i is over all accessible final states and $\Delta E = (E_j - E_i)$, is the transition energy. Eq. (5) gives us a means of comparing theory (transition probabilities) with experiment (lifetimes), but in drawing conclusions from such a comparison, it is important to realize that the experimental lifetimes are not measured directly [14]. Estimation of the accuracy of our results has been done by comparing them with data available from other calculations [5], see Table A.

Table A: Lifetimes (in ns) of some exited levels in Ge XX in comparison with theoretical calculations of Safronova et al. [5]

In Table *** we have tabulated our calculated wavelengths (λ) in Å, oscillator strengths in length form (f_l) and velocity form (f_v), and transition probabilities in length form (A_l) for all allowed dipole transitions among the 155 LS levels of aluminum-like germanium ion. In calculating these parameters we used our adjusted theoretical energy splitting, corresponding to the Present (b) in Table **. The keys of the lower and upper levels involved in a transition are given in Table *. The value f_l/f_v gives an indication of calculation precision, a good agreement between the length and velocity values of the oscillator strengths indicates to some extent the accuracy of the wavefunctions used in our CIV3 calculation. The magnitudes of the oscillator strengths for most intercombination transitions are smaller by several orders of magnitude than those for allowed transitions, and there is a significant difference between the f_l and f_v values for several of these transitions.

In Table B, to assess our results for oscillator strengths for selected transitions, we have compared the present calculations of (f_l) with theoretical results which available since 1986 until now. Huang [15] who used the multiconfiguration Dirac-Fock method (MCDF) to calculate oscillator strengths for transition [$3s^2(^1S)3p^2P_J - 3s^2(^1S)3d^2D_J'$] with $J = 1/2, 3/2$ and $J' = 3/2, 5/2$. Lavin et al. [4] used relativistic quantum defect orbital (RQDO) method, without explicit account for polarization effects.

For oscillator strengths a few calculations within the $n = 3$ complex of states have been performed by Safronova et al. [5], relativistic many-body perturbation theory (MBPT), while we have performed these calculations up to $n = 4$ without including core-valence correlation effects.

Since we lack any experimental measurements of oscillator strengths and any compiled data by NIST the comparison will be limited only to the energy levels.

Table B: Comparison of present oscillator strengths with theoretical calculations of Safronova et al. [5] (MBPT), Lavin et al. [4](RQDO), and Huang[15](MCDF)for some transitions of Ge XX

4. Summary and conclusion

In summary, we have presented our calculated energy splittings of 155 fine-structure levels as well as oscillator strengths and transition probabilities for 3540 transitions among the fine-structure levels of the terms belonging to the ($1s^22s^22p^6$) $3s^23p$, $3s3p^2$, $3s^23d$, $3p^3$, $3s3p3d$, $3p^23d$, $3s3d^2$, $3p3d^2$, $3d^3$, $3s^24s$, $3s^24p$, $3s^24d$, and $3s^24f$ configurations of GeXX. In this calculation, we have used an extensive set of CI wavefunctions and included valence-correlation effects in the excitation up to the 5f orbital. Our calculated excitation energies are in excellent agreement with the values from the NIST Atomic Spectra Database. Our new predicted levels, for which no experimental or theoretical data is available, can guide experimentalists in identifying strongly mixed fine-structure levels [16]. Finally, we believe that the present results are the most extensive and definitive to date and should be useful in astrophysical applications and technical plasma modeling.
